Noah, seminal figure in the history of wine according to the BIBLE. See also ORIGINS OF VINICULTURE.

Noah is also the name of a relatively undistinguished AMERICAN HYBRID. It is particularly hardy and was once widely grown in France and Eastern Europe. See HONDARRABI.

noble rot, also known as *pourriture noble* in French, *Edelfaüle* in German, *muffa* in Italian, and sometimes simply as botrytis, is the benevolent form of BOTRYTIS BUNCH ROT, in which the *Botrytis cinerea* fungus attacks ripe, undamaged white wine grapes and, given the right weather, can result in extremely sweet grapes which may look disgusting but have undergone such a complex transformation that they are capable of producing probably the world's finest, and certainly the longest-living, sweet wines. Indeed, the defining factor of a great VINTAGE for sweet white wine in areas specializing in its production is the incidence of noble rot. The malevolent form, which

results if the grapes are damaged or unripe or if conditions are unfavourable, is known as GREY ROT.

Ideal conditions for the development of noble rot are a TEMPERATE climate in which the humidity associated with early morning mists that favour the development of the fungus is followed by warm, sunny autumn afternoons in which the grapes are dried, the progress of the fungus is restrained, and the development of secondary undesirable fungi and bacteria is impeded. In cloudy conditions in which the humidity is unchecked, the fungus may spread so rapidly that the grape skins split and the grapes succumb to grey rot. If, however, the weather is unremittingly hot and dry, then the fungus will not develop at all, and the grapes will simply accumulate sugar rather than undergoing the chemical transformations associated with noble rot, so the result is less complex SWEET WINE.

In favourable conditions, the botrytis fungus *Botrytis cinerea* spreads unpredictably from grape to grape and bunch to bunch in different parts of the vineyard, penetrating the skins of whole, ripe grapes with filaments which leave minute brown spots on the skin but leave the skin impenetrable by other, harmful microorganisms. The grapes turn golden, then pink or purple, and then, when they are in a severely dehydrated state, they turn brown, shrivel to a sort of moist raisin, and may seem to be covered with a fine grey powder that looks like ash (to which the word *cinerea* refers). It can take anywhere between five and 15 days to reach this stage, known in French as *pourri rôti*, literally 'roasted rot'. It is almost incredible that such unappetizing-looking grapes can produce such sublime wine, and there have been many instances in which nobly rotten grapes have been discarded, or at least unrecognized, in wine regions unfamiliar with the phenomenon.

These visible changes are an outward sign of the extraordinary changes that occur inside the grape. More than half of the grape's water content is lost due either directly to the action of the fungus or to loss by evaporation as the skins eventually deteriorate. Meanwhile, *Botrytis cinerea* consumes both the SUGAR IN GRAPES and, especially, ACIDS, so that the overall effect is to increase the sugar concentration,

or MUST WEIGHT, considerably in an ever-decreasing quantity of juice. The fungus typically reduces a grape's sugar content by one-third or more but reduces the TOTAL ACIDITY by approximately 70%; TARTARIC ACID is generally degraded more than the usually less important MALIC ACID. In BOTRYTIZED wines, most of any balancing acidity is more often due to the concentration of acidity in the shrivelled but non-botrytized berries that are harvested, and then fermented, at the same time.

While it metabolizes these sugars and acids, the fungus forms a wide range of chemical compounds in the grape juice, including GLYCEROL (quite apart from that formed by alcoholic fermentation), ACETIC ACID, gluconic acid, various ENZYMES especially LACCASE and PECTINASE, and the yeast-inhibiting glycoprotein dubbed 'botryticine', which limits yeast growth and increases the production of acetic acid and glycerol during fermentation. The PHENOLICS in the grape skins are also broken down by the fungus so that the TANNIN content of the juice is significantly reduced. In sum, botrytized grape juice is very different from regular grape juice, and not just because of its intense levels of sugar. Masuda et al. identified SOTOLON as a contributor to the aroma of botrytized wines. Blanco-Ulate et al. at DAVIS described for the first time that botrytis infections, during noble rot, act as a developmental trigger in white-skinned berries and promote the biosynthesis in the berry of key botrytized wine flavour and aroma compounds, including the accumulation of ANTHOCYANINS that are normally produced only in red-skinned berries. It is unusual for all grapes on a vine, or even on a single bunch, to be affected in exactly the same way, to exactly the same effect, and at exactly the same speed, which is why the HARVEST of a botrytis-affected vineyard can necessitate several passages, or *tries* (see TRI), during which individual bunches, or parts of them, are picked at optimum infection level, and grapes affected by grey rot may have to be eliminated.

Weather conditions other than alternating early mists and warm afternoons can result in a satisfactory noble-rot infection. In cold, wet weather, noble rot may form at a reasonable rate on fully ripe grapes

and grey rot be kept at bay. Wind can help to dehydrate the grapes and concentrate the sugars.

See SAUTERNES for details of common weather patterns there. See BOTRYTIZED wines for details of where and how they are made, as well as their history.

noble varieties, vague term once used specifically in some regions to refer to what are considered their finest varieties, for example Riesling, Gewurztraminer, Pinot Gris, and Muscat Blanc à Petits Grains in ALSACE, or Sercial, Boal, Verdelho, and Malvasia on MADEIRA. The term has bcome increasingly irrelevant and patronizing given the re-evaluation and rising popularity of lesser-known INDIGENOUS VARIETIES. 'Traditional' might be more congruent in the 21st century.

Nobling is a 1940 CROSS of SILVANER × GUTEDEL (Chasselas) that has declined in importance even in Baden, where all its 47 ha/116 acres grew in 2020. Wines are relatively neutral.

node, the part of a plant's stem at which a leaf is attached. In the grapevine, this zone is swollen and bears the leaf winter BUD and

LATERAL SHOOT. TENDRILS or INFLORESCENCES are also borne at nodes on the side opposite to the bud. B.G.C.

Noir, French for 'black' and therefore a common suffix for dark-berried vine varieties.

Noirien is the most common eco-geogroup of related VINE VARIETIES, those found primarily in north-eastern France that are related to or closely associated with Pinot Noir: notably Pinot Gris, Pinot Blanc, Auxerrois, Chardonnay, Melon, and Gamay Noir.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

NoLo, or NOLO, a newly popular term for a category of wines with no alcohol (less than 0.5%; see DE-ALCOHOLIZED WINE) or low alcohol (below 1.2%; see LOW-ALCOHOL WINE). They have become more popular thanks to improved quality and increasingly health-conscious (and abstemious) lifestyles.

non-alcoholic wine is a term sometimes used for wine with an ALCOHOLIC STRENGTH of less than 0.5%. For more details, see DE-ALCOHOLIZED WINE.

non-vintage, often abbreviated to NV, a blended wine, particularly champagne or sparkling wine, which may contain the produce of several different VINTAGES, although in champagne-making practice it is usually substantially based on the most recent vintage, to which some additional ingredients from older years, often called 'reserve wines', may be added.

Some mass-market wines are sold without a vintage year and are in practice a blend made throughout the year, so that the first blend

of the winter season, typically, may contain a mixture of wine from both the new and last year's vintages.

normalized difference vegetation index (NDVI) is the most widely used indicator of plant biomass in agriculture. In viticulture, NDVI provides a relative measure of the size and density of the CANOPY and therefore correlates with VIGOUR. It is calculated from measures of reflected light at wavebands corresponding to red and infrared light. See also REMOTE SENSING and PLANT CELL DENSITY.

R.G.V.B.

Hall, A., et al., 'Optical remote sensing applications in viticulture: a review', *Australian Journal of Grape and Wine Research*, 8/1 (2002), 36–47.

North Carolina , a state on the east coast of the United States with nearly 200 wineries, 931 ha/2,300 acres of wine grapes, and a diversity of wine styles. In 2022 it ranked eighth in the US for wine production (tying with PENNSYLVANIA)—down from number one in 1840, before PROHIBITION effectively destroyed the industry. It remains home to the oldest cultivated grapevine in the US, the Mothervine, which has been producing muscadine grapes since at least the 16th century. (See MUSCADINIA.) This hearty INDIGENOUS VARIETY thrives in the south-central and eastern portions of the state, where the climate is humid subtropical. Moving west and into the Blue Ridge Mountains, temperatures become cooler, with greater DIURNAL TEMPERATURE RANGE and cool breezes. HYBRIDS such as CHAMBOURCIN, CHARDONEL, SEYVAL BLANC, TRAMINETTE, and VIDAL as well as VITIS VINIFERA varieties including Cabernet Sauvignon, Cabernet Franc, Chardonnay, Merlot, and Viognier dominate; there are also pockets of indigenous VITIS LABRUSCA and *Vitis aestivalis* varieties such as CONCORD, NIAGARA, and NORTON (a *vinifera-aestivalis* cross). The state's five AVAs are concentrated in its western end, with Yadkin and its subregion Swan Creek the largest at 162 ha/400 acres of vines. Haw River Valley is the most easterly AVA, between Greensboro and

Raleigh. Two AVAs extend into neighbouring states: Appalachian High Country crosses into Tennessee and VIRGINIA, and Upper Hiwassee Highlands is shared with Georgia. State law specifies that wines labelled North Carolina must contain at least 75% grapes grown within the state; to take an AVA name, at least 85% of the grapes must come from that AVA. B.Y.-I.

www.ncwine.org

North Coast , general CALIFORNIA umbrella region and AVA implying north of San Francisco although it also extends north-east from San Francisco into a portion of Solano County. It includes all vineyards in LAKE, MARIN, MENDOCINO, NAPA, and SONOMA counties. The name appears on some relatively prestigious wines assembled from, especially, Napa and Sonoma and also on some pretty ordinary blends. It is also commonly seen on sparkling-wine labels.

North East Victoria Zone, in the Australian state of VICTORIA, incorporating the wine regions of Alpine Valleys, Beechworth, Glenrowan, King Valley, and Rutherglen.

Northern Rivers Zone, large area on the northern coastal plain of NEW SOUTH WALES in Australia with one GEOGRAPHICAL INDICATION, HASTINGS RIVER.

Northern Slopes Zone, and its GEOGRAPHICAL INDICATION New England Australia is immediately south of Queensland's GRANITE BELT, on the western (inland) side of the Great Dividing Range. While the zone is officially in the state of NEW SOUTH WALES, many Granite Belt producers source grapes from its 77 ha/190 acres of vines which

grow in similar conditions, the soils becoming less GRANITIC moving southwards. A.C.

Northland , or Te Tai Tokerau in Māori, is the birthplace of NEW ZEALAND wine. The GEOGRAPHICAL INDICATION (GI), at the very northern tip of the country, has a humid, sunny, warm climate that could be classified as subtropical. From around 70 ha/173 acres of vines in 2021 come rich, tropical expressions of Chardonnay as well as Syrah and Pinot Gris. S.P.-T.

North Macedonia , known since 2019 as the Republic of North Macedonia, is a country in the south-central Balkans, bordered by BULGARIA, SERBIA, KOSOVO, ALBANIA, and GREECE. Archaeological evidence of winemaking goes back to at least the 13th century BCE. The geographical and historical region of Macedonia covers a much larger area, including parts of Greece and south-western Bulgaria. At one time, under the rule of Philip II (359 BCE) and then his son Alexander the Great (323 BCE), it was the most powerful state in the world. By 146 BCE it had become a Roman province, when it was an important grape-growing region. As in much of Balkans, Macedonia came under Ottoman rule for five centuries until 1913. The region was then partitioned between Bulgaria, Greece, and Serbia. After the Second World War, the territory became part of YUGOSLAVIA. It underwent peaceful secession in 1991 and became the Former Yugoslav Republic of Macedonia until disputes over the Greek region of Macedonia were resolved. The country became a candidate for EU membership in 2005, but progress remained stalled in 2022 due to Bulgarian disputes over language.

North Macedonia lies between latitudes 40 and 43° N. It is landlocked and geographically defined by a central valley formed by the Vardar River, while mountains border the country, with 34 peaks over 2,000 m/6,562 ft. There are 53 lakes including the UNESCO-listed Lake Ohrid, believed to be one of the oldest lakes in the world. The country is seismically active, and the climate is transitional from

MEDITERRANEAN to CONTINENTAL. Hot, dry summers with 270 sunny days are typical, and annual rainfall ranges from less than 500 mm/20 in in the centre to 1,700 mm/70 in in the mountains, making it the driest region in the Balkans, so IRRIGATION is usual. The grape-growing regions are sufficiently hot that ACIDIFICATION but not ENRICHMENT is allowed.

Wine is the second most important agricultural export in North Macedonia, and vineyards cover 10% of arable land. In the 1980s the region accounted for as much as two-thirds of YUGOSLAVIA's wine production, reaching a peak of 1.8 million hl/47.5 million gal in the early 1990s. By 2020 wine production had fallen to 744,120 hl/16.4 million gal, the smallest harvest for at least a decade.

Today's industry claims 28,213 ha/69,716 acres planted to wine grapes in 2020, with 28 varieties. There were 120 wineries by 2021, though only nine with production capacity over 50,000 hl, including the first winery of the modern era, the Tikveš winery, founded in 1885 and now fully private. There are 16 wine districts within three wine regions: Pcinja-Osogovo in the east, Pelagonija-Polog in the west, and the most important Central or Vardar River Valley region, which accounts for 87% of the country's wine grapes. Within it, the Tikveš district is most important, with 43% of the country's vineyards in 2020.

The domestic market for wine remains small, and exports are important at 666,983 hl in 2020. The last few years have seen the industry depend heavily on cheap exports of BULK WINE, especially to Germany, and while this remains notable, producers are working hard to improve quality and shift towards more premium bottled wines. There have been significant investments in updating wineries, and several wineries have recruited foreign CONSULTANTS to modernize winemaking. Another developing trend is identification of better vineyard sites, especially at ELEVATION to mitigate the warm climate. Unusually, it is the larger wineries that are arguably driving quality improvements, including conducting considerable viticultural and winemaking research.

Red-wine varieties predominate, making up 60% of the harvest. Vranec (the usual spelling of VRANAC here), which arrived in 1950s from MONTENEGRO but really suits the warm North Macedonian growing conditions, dominates. The offspring of Kratošija and Duljenga, another Montenegrin grape, Vranec is regarded as the country's flagship variety: it has higher ANTHOCYANIN levels than Cabernet Sauvignon and produces deeply coloured wines, typically over 14% alcohol yet with good acidity (around 6.5 g/l) and relatively low PH, so the resulting wines can be balanced and age well. Other important varieties include SMEDEREVKA, Merlot, Cabernet Sauvignon, Kratošija (the local name for ZINFANDEL), Riesling, Chardonnay, Pinot Noir, RKATSITELI, and PROKUPAC. Stanušina is the only genuinely INDIGENOUS VARIETY so far identified, making light reds and rosé. There are currently three quality categories: regional wines or wines with GEOGRAPHICAL INDICATION (WGI); wines with controlled origin (WCO); and wines with controlled and guaranteed origin (WCGO). C.G.

www.winesofmacedonia.mk

North West Victoria Zone comprises the high-yielding, irrigated vineyards of the Murray Darling and Swan Hill regions falling on the VICTORIA side of the Murray river in Australia.

North Yuba , California wine region and AVA. See SIERRA FOOTHILLS.

Norton, arguably the only variety of AMERICAN VINE SPECIES origin making a premium-quality wine. Little known and little grown outside the eastern and midwestern UNITED STATES, Norton is undoubtedly underrated because of entrenched bias against non-VITIS VINIFERA varieties. In Arkansas and MISSOURI, it was the mainstay of an extremely important wine industry. Leon D. Adams calls Norton 'the

best of all native American red-wine grapes' and praises it for its wines' lack of FOXY character.

The origin of this dark-skinned variety is uncertain, but it takes its name from Dr D. Norton of Richmond, Virginia, a pioneer grape-grower. Recent DNA PROFILING has shown that it is a HYBRID which has both *Vitis aestivalis* and *Vitis vinifera* (see VITIS) in its pedigree. It is also known as Cynthiana in Missouri, Arkansas, and Virginia.

Norton is tolerant of BUNCH ROTS and other fungal diseases such as BLACK ROT, ANTHRACNOSE, DOWNY MILDEW, and POWDERY MILDEW, and its roots are tolerant of PHYLLOXERA. The vine is vigorous and requires a long growing season. The grapes are acidic, but the wine is indistinguishable by taste from wine made from *vinifera* grapes. Grapes are very dark coloured and full-flavoured, and Norton reliably produces healthy fruit in places with high summer rainfall even without SPRAYING. Chrysalis of Virginia is the Norton specialist.

Adams, L. D., *The Wines of America* (1985).

Norway is the easternmost country of the Scandinavian peninsula, sharing a long border with SWEDEN and shorter borders with FINLAND and RUSSIA in the north. Wine grapes have been grown here since the 1970s, mainly by hobbyists in the early days. Thanks to CLIMATE CHANGE, which has seen Norwegian winters become considerably milder and shorter, and to the development of hardy and DISEASE-RESISTANT VARIETIES at the University of Minnesota and at GEISENHEIM UNIVERSITY, the country had by 2021 well over 100 members in the Norwegian Grape Growers Association (Foreningen Norske Druedyrkere), 15 of them certified wine producers licensed to sell wine through the Norwegian Wine Monopoly.

With its extensive coastline on the Atlantic Ocean and the Barents Sea, Norway has a mostly MARITIME CLIMATE, with mild lowland temperatures on the coast. Temperatures are colder inland but still milder than other areas in the world on such northerly latitudes (60° N, the same as Alaska) due to the warming influence of the Gulf

Stream. Most vineyards are small (1–2 ha, with about 4,000 grapevines per ha) and located in southern and western Norway, although there are some as far north as the Sognefjord (61.1° N), where Slinde Vingard is based.

Though the growing season is short, long SUNLIGHT hours during the summer help greatly in achieving ripeness. In western Norway, the steep slopes of the fjords ensure heat accumulation and good DRAINAGE. Water availability is not an issue, with regular rainfall during the growing season and usually abundant snowfall in winter. The average annual temperature is about 8 °C/46 °F, ranging from 1 °C in February to 16 °C in July. The main viticultural challenge is FROST in spring and autumn.

White wine grapes account for 60% of plantings, dominated by SOLARIS, which ripens consistently and can be used for both still and sparkling wine. Among red wine grapes, RONDO dominates. An increasing number of Norwegian grape-growers are planting VITIS VINIFERA, including Riesling and Pinot Noir. D.Co.

nose, the most sensitive form of TASTING equipment so far encountered, the sense of TASTE being so inextricably linked with the sense of smell. When the nose is blocked, whether by a cold or by mechanical means, and the taster has to rely on their PALATE, the ability to taste either food or drink is seriously impaired—so much so that cold sufferers have to resort to decongestants if the need for their tasting skills is serious.

'Nose' is also used as a synonym for the smell, AROMA, or BOUQUET of a wine, as in wines having 'a nose of raspberries', 'a raspberry nose', or even 'raspberries on the nose'.

Nosiola, the only remaining white grape variety indigenous to TRENTINO in northern Italy. It is grown principally on the hills around the village of Pressano, where it produces dry wines, and in the Valle dei Laghi to the west of Trento, where it is used to produce Vino

Santo (see VIN SANTO). Interest in the variety has been revived in recent years as several producers, notably Foradori, have demonstrated that it can, when made with care, produce whites of real interest, including SKIN-FERMENTED examples. DNA PROFILING at SAN MICHELE ALL'ADIGE revealed a surprising parent–offspring relationship with the Swiss RÈZE.

notch grafting, a method of GRAFTING vines that resembles CLEFT GRAFTING. It differs in that the cut trunk is not split across; instead the SCION pieces are cut to fit a V-shaped notch made on either side of the trunk to a length of about 3 cm/1 in. The scion pieces are often tacked into place. Notch grafts are not as secure as cleft grafts. A related method is the bark graft done later in spring when the bark lifts freely, but again the union is sometimes weak. B.G.C.

no-till, the increasingly common practice of minimizing soil disturbance between the rows and under the vines. See TILLAGE and ORGANIC VITICULTURE.

nouveau, French for 'new', and a specific style of wine designed to be drunk only weeks rather than months or years after the HARVEST. The most famous and successful nouveau is BEAUJOLAIS Nouveau, which, at its peak in 1988, accounted for more than 800,000 hl/21 million gal, or 60% of all Beaujolais produced. The Beaujolais producers themselves are keen to point out that their Nouveaux are not simply *un phénomène 'marketing'* but that they owe their origins to the 19th century, when the year's wine would complete its FERMENTATION in cask while en route to nearby Lyons, where the new wine provided a direct link with village life in the Beaujolais hills. The phenomenon originated in a group of villages just west of Villefranche whose wines seemed to mature earliest. After the constraints of the Second World War, the Beaujolais producers were gradually allowed to release an increasing proportion of new wine.

The original term was PRIMEUR, meaning 'young produce', and from 1951 the Beaujolais producers were allowed to release their primeurs from 15 December. These young, refreshing wines enjoyed great success in the bistros of Paris in the 1950s and 1960s, and by the end of the 1960s the phrase *Le Beaujolais Nouveau est arrivé* had been coined. In the 1970s, the phenomenon spread outside France, thanks to energetic work on the part of producers such as Georges Duboeuf and his agents around the world, as well as Alexis LICHINE in the United States. By the end of 1974, Beaujolais Nouveau had reached Great Britain to such an extent that the first Beaujolais Nouveau race (of bottles of purple ink to London) had been run. Eventually the Nouveau was flown, with inexplicable haste and brouhaha, to markets around the world, the craze reaching Australia in 1982 and Japan and Italy in 1985. Initially the release date was fixed at 15 November, but it was eventually changed to the third Thursday in November, for the convenience of the wine trade and the media, who for much of the late 1970s and 1980s were apparently fascinated by this event.

The immense commercial success of Beaujolais Nouveau inevitably spawned other (much less successful) Nouveaux—infant wines from other regions of France, notably Gamays made in TOURAINE and the ARDÈCHE, a range of wines made in the LANGUEDOC and ROUSSILLON, MUSCADET and many VINS DE PAYS, particularly Côtes de Gascogne.

Italy has produced a range of similar wines, described as novello, and Austria's HEURIGE could be said to be a version of the phenomenon. A few southern-hemisphere producers have tried to sell their own early releases as 'Nouveau' because they carry the same year on the label and are available many months before the appearance of Beaujolais Nouveau.

Winemaking techniques have to be adapted to produce wines that are ready to drink so early. The majority of Nouveau wines are red, and many of them are produced, like Beaujolais, by CARBONIC MACERATION or SEMI-CARBONIC MACERATION, which yields particularly fruity, soft, aromatic red wines suitable for drinking young and slightly cool, typically involving a fermentation of only about four days, and

fairly brutal STABILIZATION. Those winemakers who do not or cannot practise any form of carbonic maceration may ferment the grapes traditionally but at lower temperatures than usual (in the low 20s °C/*c*.70 °F) and allow only the briefest of MACERATIONS. White grapes, for which carbonic maceration is not suitable, are generally fermented very cool, at 15–20 °C, and boiled candy aromas typically result.

The great attraction of Nouveau wines for producers is that they produce a financial return so quickly. As one taster remarked, their characteristic aroma is the scent of cash flow. Their appeal for the wine drinker is that they are a refreshing and stimulating reminder of the passing of the seasons, a sort of liquid HARVEST TRADITION. Nouveau wines do not deteriorate in bottle substantially more rapidly than non-Nouveau wines, but their lifespan is inevitably shorter.

Nouvelle, vigorous, productive South African mid 20th century CROSS of CROUCHEN and TREBBIANO Toscano which became popular from the mid 1990s for its ability to add obvious METHOXYPYRAZINE aromas to Cape Sauvignon Blanc. By 2020 plantings had reached 411 ha/1,016 acres.

Nova Scotia is essentially a peninsula in eastern CANADA surrounded by the Atlantic Ocean, the Bay of Fundy, and the Northumberland Strait. The CONTINENTAL CLIMATE, with obvious MARITIME influences, and relatively short growing season determine the grape varieties that can ripen here: plantings, which totalled 607/ ha/1,500 acres in 2021, include local speciality L'ACADIE as well as Chardonnay and Pinot Noir (for sparkling wine), Riesling, VIDAL, SEYVAL BLANC, and MARÉCHAL FOCH. The province has seven wine regions, with the Annapolis Valley having the greatest concentration of wineries and vineyards. There is one appellation, Tidal Bay, applicable to white wines made from a specified range of varieties, with L'Acadie, Seyval, Vidal, and/or Geisenheim 318 making up its

majority, and a maximum permitted alcohol of 11%. The province is increasingly known for TRADITIONAL METHOD sparkling wine and crisp aromatic whites, with several of the 20 wineries also producing FRUIT WINES. J.D.

www.winesofnovascotia.ca

novello, Italian for 'new' or 'young', and a name applied to Italy's NOUVEAU wine.

nuclear magnetic resonance, NMR, is a relatively modern analytical technique which is being increasingly used in many sectors of the food industry. It came to prominence in the wine industry in the 1980s thanks to Professor Gérard Martin of Nantes University.

It was hoped that this method would evolve to help solve some of the wine industry's major analytical challenges, for example identification of origin and grape variety (i.e. AUTHENTICATION). The process compares the test samples against an established, verified database, but the establishment of this database is an enormous challenge when all the variables in the world of wine are considered (different grape varieties, blends, possibly vintage, clonal variation, and more). Work is still being undertaken to try to compile such databases, but it is a long and difficult process, and an NMR machine is very expensive.

While the technique has so far proved disappointing as a means of assessing authenticity, it is a useful tool to detect CHAPTALIZATION. The ETHANOL molecule contains six hydrogen atoms, which occupy three distinct sites, and NMR can distinguish between these sites. Deuterium, which is the stable, natural isotope of hydrogen, is distributed differently within the ethanol molecule according to the source of the sugar from which the ethanol is derived. NMR can therefore differentiate between wines which have been enriched with

cane sugar, beet sugar or GRAPE CONCENTRATE, particularly if the concentrate is produced in a region that is different from the wine's place of origin since the ratio of hydrogen to deuterium varies slightly according to latitude. G.T.

Nuits, Côte de, named after the principal town of Nuits-St-Georges, is the northern half of the escarpment of the CÔTE D'OR, producing the greatest red wines of Burgundy, from the Pinot Noir grape, and very occasional white wines. The principal villages, from north to south, are GEVREY-CHAMBERTIN, MOREY-ST-DENIS, CHAMBOLLE-MUSIGNY, VOUGEOT, VOSNE-ROMANÉE, Flagey-ÉCHEZEAUX, and NUITS-ST-GEORGES. See also MARSANNAY and FIXIN. The soils on the lower part of the slope tend to be much more fertile than the main parent rock because more immature soil has been incorporated. Wines from Fixin, Brochon, Prémeaux, Comblanchien, and Corgoloin may be sold as Côte de Nuits-Villages. These are usually but not exclusively red wines.

See also BEAUNE, CÔTE DE, and the map under BURGUNDY.

J.T.C.M.

Nuits-St-Georges, small market town in Burgundy giving its name to the Côte de Nuits, the northern half of the CÔTE D'OR. Nuits-St-Georges has remained fully independent of BEAUNE to the south and Dijon to the north, with numerous NÉGOCIANTS making their headquarters here. The town also boasts its own charity auction, the Hospices de Nuits, held in March, at which time the wines can be more easily judged than those of the HOSPICES DE BEAUNE in November.

The appellation Nuits-St-Georges can be divided into three parts. North of Nuits, abutting Vosne, the wines combine elegance with a rich, heady quality. The heartiest wines, deepest in colour and most tannic, come from the heartland just south of the town, while furthest south, in the commune of Prémeaux, the wines are a little lighter and should not be over-extracted.

Whereas the Intendant Bouchu noted in 1666 a preference for Nuits, 'where the wine is excellent', over Prémeaux, 'where the wine is of good quality', the king of Saxony specifically ordered in 1780 'the wine of Prémeaux, the colour of the stained glass windows of La Sainte Chapelle'.

Nuits boasts 41 PREMIER CRU vineyards but no GRANDS CRUS, perhaps because the town's leading vigneron, Henri Gouges, was too modest when the CLASSIFICATIONS were agreed in the 1930s. However, a dossier has been prepared to promote the eponymous Les St-Georges vineyard, first singled out for its quality as early as the 11th century. Also particularly fine in the southern Nuits-St-Georges sector are Les Cailles and Les Vaucrains, both adjacent to Les St-Georges, while Les Murgers and Les Boudots on the Vosne-Romanée side and Clos St Marc, Clos des Forêts, and Clos de la Maréchale in Prémeaux have good reputations.

Some white wine is also made from the Chardonnay grape, as in the Clos l'Arlot, and from the Pinot Blanc grape in Domaine Gouges' premier cru Les Perrières. The premier cru Les Terres Blanches is clearly better suited to white wine.

Top producers include Henri Gouges, Robert Chevillon, Domaine de l'Arlot, Thibault Liger-Belair, Patrice Rion, and many growers in neighbouring VOSNE-ROMANÉE.

See also CÔTE D'OR and BURGUNDY map. J.T.C.M.

numbers and wine, a combination that has assumed increasing importance as WINEMAKING has become more scientific and as consumers, faced with a bewildering choice of wines, seek easily appreciated assessments of wine quality such as SCORES. As recently as the 1970s, winemakers had only the vaguest grasp of their wines' vital statistics; and the only numbers of significance to most wine drinkers were those of VINTAGE, PRICE, and, among more sophisticated connoisseurs of bordeaux, the numerical rankings associated with wine CLASSIFICATION.

Numbers are increasingly used for identification, however. Australian wine producers such as PENFOLDS have for decades exhibited a penchant for incorporating BIN numbers into the names of their wines. Individual CLONES of various VINE VARIETIES can be so numerous that they are usually identified by individual numbers, as are CASKS and individual BARRELS in some larger wineries. Some top German wines are identified by barrel (*Fass*) numbers and/or AP NUMBERS.

As the growing of grapes and the making of wine becomes more scientific, numbers as measurements play a key role, as they do in all scientific thinking (see in particular SCORING vineyards).

Consumers, as well as producers, have an interest in measurements taken at all stages of wine production, particularly RESIDUAL SUGAR, and the ALCOHOLIC STRENGTH which appears on most wine labels, even though they cannot be used on their own as a measure of how a wine will taste. J.R.

The meaning of scores

Using a numerical score to denote a wine's quality offers the apparent appeal of brevity, objectivity, and precision. Scores provide an immensely convenient shorthand for the taster, being quick to record and simple to share. They transcend language barriers and are universally understood. With up to 100 values available (if one uses the standard 100-point scale, beginning at 50 but allowing the use of 'plus'), very fine discriminations can be recorded with absolute clarity.

However, while the convenience of wine scoring is not in doubt, such objectivity and precision are somewhat illusory. This is because, despite appearances, scores do not measure an inherent property of wine against an independent scale. They are, rather, rankings of preference, which relate the perceived quality of several wines solely to one another. Although all scoring systems operate on a universal principle—that higher numbers denote higher quality—the choice of which specific numbers to ascribe to a given set of wines is completely arbitrary.

This is a quite separate issue to whether the 5-, 20- or 100-point scale is preferable, as well as to the more fundamental debate concerning objectivity and SUBJECTIVITY in assessing wine quality itself. Even if all the world's tasters were in complete agreement over the quality of every wine and elected to use the same scale, their scores would in all likelihood significantly differ. Nothing other than whim governs where the qualitative boundary between two adjacent scores should lie.

It follows from this that we cannot assume different tasters mean the same thing by identical scores. They might choose a different score to represent an 'average' wine and then distribute their marks either side according to a different method. The same is true for publications: 18 out of 20 in a specialist fine-wine journal does not necessarily refer to the same quality level as the same score in a more mainstream magazine.

An isolated score, therefore, carries no meaning. It can only be understood relative to the taster's overall mark distribution, possibly

modulated by the context in which it is published. Furthermore, the averaged scores awarded by a tasting panel cannot be compared with scores awarded by a different panel, since the way each taster allocates points will vary.

The arbitrariness of point allocation undermines the precision as well as the objectivity of scoring. It is very tempting to start subdividing points, since rarely do two wines appear to be identical in quality, and so in the course of a large tasting, awarding quarter-points or plusses and minuses can feel like the honest thing to do. Although of some private value, the wider utility of this practice is doubtful. Tasters are not like machines that can be calibrated before each use; they cannot know for certain that what they mean today by 16 points is not what they meant by 15.5 points last month. The more finely subdivided the points become, the less sure it is that the boundaries between them are in the same place each time. The impression of precision is misleading and, beyond a certain point, conveys no extra information to the reader.

Numbers fully deserve their place in the world of wine, but they deserve also to be understood within the context of their fairly severe limitations. See also wine SCORING and WINE WRITING. A. H.

Nuragus, ancient white Sardinian grape variety grown on 1,008 ha/2,491 acres in 2015, principally to produce the unremarkable varietal Nuragus di Cagliari on the island of SARDINIA.

nursery in viticultural terms is either a place set aside for nurturing young vines or a name for a PROPAGATION and/or a GRAFTING establishment. Open-ground vine nurseries are where CUTTINGS are planted to develop roots and become ROOTLINGS. Cuttings are taken in

winter, stored in a cold room, then CALLUSED by burying them in moist sand, often on heated beds, until young roots form at the base (after six to eight weeks). In spring they are planted in rows in the nursery, where the first-year shoots develop. Nursery soils need to be deep, friable, and well drained, free of pathogens and with a good water supply. In the following winter or spring, they are lifted, shoots and roots are trimmed, and the vines planted out in the vineyard. For GRAFTED VINES, the products of BENCH GRAFTING are callused in a humid room before planting in a nursery. B.G.C.

nursery budding and nursery grafting, methods for the PROPAGATION of GRAFTED VINES that complement BENCH GRAFTING, used in warm climates where the work can be done in the field. Great flexibility is possible in the type of SCION wood used and in the timing of grafting. Inserted scions are tied tightly with budding tape and, after the inserted bud has started to grow, the ROOTSTOCK foliage is shortened back and later removed. B.G.C.

nutrients. All living things, including vines and yeasts, need NITROGEN, PHOSPHORUS, and POTASSIUM, along with CARBON, hydrogen, OXYGEN, and other MINERALS as nutrients. Lack of nutrients in MUST can lead to STUCK FERMENTATION. For more details of nutrition of the vine, see VINE NUTRITION.

NV. See NON-VINTAGE.

NYSAES, New York State Agricultural Experiment Station in Geneva, renamed CORNELL Agritech in 2018.

oak is the main wood used by coopers to make BARRELS, large wooden VATS, and other types of vessels designed for FERMENTATION and ageing of wine. It is also used to make BARREL ALTERNATIVES. It is hard, watertight, easy to machine, and easy to bend to form STAVES. It can be treated with heat or flames (see BARREL MAKING) and has been shown to complement and enhance many types of wine. Thanks to its extractable tannin and aromatic compounds, oak adds TANNINS, flavour, and aromatic COMPLEXITY to wine. The tannin compounds in the wood and its oxygen permeability contribute to STABILIZATION and CLARIFICATION (see BARREL AGEING).

Oak belongs to the genus QUERCUS, which is extremely widespread throughout the northern hemisphere and comprises approximately 400–500 species. Like other species of forest trees, oaks provide important environmental services such as carbon sequestration, regulating the water cycle, preserving biodiversity, and soil protection, as well as economic services in addition to those related to wine (e.g. carpentry, cabinet-making, veneer).

Botanically speaking, the genus *Quercus* is somewhat ambiguous because there is a main *Quercus* genus and a subgenus with the same name. The subgenus is divided into sections, including *Quercus* (white oaks) and *Lobatae* (red oaks). It is the white oaks that are used in winemaking because they are watertight, unlike red oaks. The species of most interest to coopers are sessile oak (*Quercus petraea*) and pedunculate oak (*Quercus robur*) found mainly in Europe and *Quercus alba* or American white oak.

European oak resources

According to the graph on page 520, which is based on the forest statistics reported by the United Nations Economic Commission for Europe (UNECE) for each European country having a growing stock of over 25 million cubic metres, France is the leading country in Europe, followed by Ukraine and Germany. However, these raw data require a more in-depth analysis because the counting method and the species taken into account can vary from one country to the next. The data for countries with MEDITERRANEAN CLIMATES include high volumes of Mediterranean oaks such as *Quercus ilex* and *Quercus suber* (see CORKS).

Not all growing stock is available wood for the cooperage sector, which is interested only in those stands containing sessile oak and pedunculate oak. These two fairly similar species are capable of growing in a wide range of soils and climatic conditions. Sessile oak, which covers an area extending from northern Spain to Armenia, prefers regions with an Atlantic climate and is less tolerant of more extreme CONTINENTAL conditions. Pedunculate oak, which stretches over a larger area from northern Portugal to the west of the Ural Mountains in Russia, is more tolerant of the more extreme continental conditions. For the most part, the ranges of the two species overlap. They commonly coexist in forests and can even hybridize.

However, the requirements of these two species differ slightly. Pedunculate oak prefers fairly rich, well-watered soils that facilitate its growth, resulting in larger rings and therefore wider GRAIN. Sessile oak is more tolerant of dry conditions and poorer soils. Its Latin name, *petraea*, means it is the oak that grows on rocks. Therefore, sessile oaks tend to have more moderate annual growth rings and thus a finer grain than pedunculate oaks.

Pedunculate oak is a colonizer and grows more readily in open areas. Sessile oak is a 'social' tree and tolerates closed stands and competition between trees. It gradually colonizes forests consisting of pedunculate oaks, which it completely replaces after a few centuries.

Where both species are found, pedunculate oak is widespread over a large part of its distribution area whereas sessile oak is concentrated in specific regions. Two main areas supply wood for a large part of the cooperage industry in Europe. The first of these stretches from the centre of France to southern Belgium and the west-central part of Germany, with particularly high density in France in the Centre-Val de Loire and Burgundy. According to the French National Forest Service, these regions constitute the world's largest production area for fine-grain oak, as reported by Jarret. This is where the most renowned forests such as Tronçais in the Allier region or Jupille in the Sarthe region are found. The forests in these regions are naturally regenerated, using seeds from the oldest trees to maintain the existing genetic pool.

The second area, which is much more continental, extends from eastern Czechia to Slovakia, Romania, and northern Hungary, with high-intensity zones in northern Hungary, in Slovakia, and in the lower region of the Carpathian Mountains in Romania, as described by Eaton et al.

Oak resources in North America

American white oak is the other species commonly used to make barrels. White oak has a high level of genetic variability and is found in a wide variety of habitats. White oak easily hybridizes with other species of the genus *Quercus* such as swamp oak (*Quercus bicolor*) and bur oak (*Quercus macrocarpa*). As these are sometimes difficult to distinguish, they are typically grouped together under the generic term 'white oak' or 'selected white oak', comprising similar species but dominated by *Quercus alba*.

White oak is found in the eastern United States, from south-western Maine to northern Florida and extending to the Canadian border, although some trees are found in Quebec and Ontario. It extends westward to south-western Minnesota and south to south-western Iowa, eastern Kansas, eastern Oklahoma, and eastern Texas. The best growing conditions are found on the eastern slopes of the Appalachians, in the Ohio Valley, and in the central Mississippi Valley.

The total growing stock is 1,011 million cubic metres. As shown on the graph on page 521, the largest volumes are found in Missouri, Virginia, Tennessee, Arkansas, and Kentucky (USDA Forest Inventory and Analysis, 2020).

White oak is the dominant species in a wide variety of forest habitats and sites. It is found on poor soils, on both glaciated and non-glaciated soils derived from many parent materials, and on SANDY plains, GRAVELLY ridges, rich uplands, coves, and well-drained LOAMY soils. Growth is good on all but the driest, shallowest soils. However, forests need to be managed so that the white oaks are not naturally replaced by other species.

Other oak species

Coopers occasionally use other oak species such as *Quercus mongolica*, commonly called Mongolian oak in Japan, and Pubescent oak, *Quercus pubescens*, which is sometimes used in Italy. The latter, which is a Mediterranean oak, is of particular interest because it is a species more resistant to WATER STRESS. With CLIMATE CHANGE, this species may prove valuable if the current sessile and pedunculate oak forests shrink.

Oak wood

The anatomy of different oaks has implications for BARREL MAKING. A trunk can be thought of as a bundle of tubes or vessels and parenchyma cells running parallel to the trunk with groups of fibres called medullary rays running radially from the outside towards the centre of the trunk. When looking at the end of a stave or cross-section, annual rings can be seen, revealing two types of wood: early wood or spring wood (see GRAIN). The growing conditions of the tree will directly affect the ring width, which is the criterion that coopers have traditionally used to select their wood. Barrels made with tight-grained staves, which come from slow-growing trees, are known to be more aromatic and less tannic than those made with wide-grained staves, originating from slower-growing trees.

The watertightness of oak wood comes mainly from the vessels and the medullary rays. These vessels are like tubes a few hundred microns in diameter. In oak species that are suitable for barrel making, the vessels are filled by a thin layer of cellular membranes, called tyloses, formed when sapwood matures to heartwood. These tiny bags or balloons transform these open tubes into filled tubes, where water cannot circulate. This property gives the wood its longitudinal watertightness. European oaks have a medium rate of tyloses, so that when coopers make a stave they must be careful to follow the grain. Usually, the first step in a stave mill is to split the wood with a wedge, to strictly follow the longitudinal fibres and avoid cutting the vessels. White oak (*Quercus alba*) has a very high rate of tyloses, so it is not necessary to be particularly careful when following the fibres. The wood can be sawn without any risk of leakage. Red oak (*Quercus rubra*) cannot be used in cooperage because it has no tyloses in the vessels and the wood is porous.

On the surface of the barrel, the medullary rays provide watertightness. Liquid cannot go through these structures and has to go around the medullary rays to go through the stave. The liquid progression is stopped quickly when the capillary pressure exceeds the hydrostatic pressure of the liquid in the barrel.

Like other wood, oak is hygroscopic (i.e. it takes up moisture from the surrounding environment). Moisture exchanges between wood and air depend on the relative humidity and temperature of the air and the amount of water in the wood. This has a major influence on the wood's properties and performance. Oak may swell or shrink depending on the moisture content of the wood. It remains stable when the moisture content exceeds its saturation point (31% in mass content of water), but below this value the wood changes dimensions: it swells as it gains moisture and shrinks as it loses moisture. This property is a key factor to be taken into account when making a barrel. It explains why overly dry barrels can leak between the staves but become watertight once the moisture content has increased and the wood swells. Swelling and shrinkage also affect oxygen intake and wood extraction during BARREL AGEING because the moisture content of the barrel is always in balance with the relative humidity and temperature of the cellar.

Lastly, oak wood is rich in TANNINS and aromatic compounds. Tannins are the main reason why oak wood is durable, but the contact between these compounds and wine in a barrel improves the wine by stabilizing its colour, increasing its aromatic complexity, and reducing its ASTRINGENCY (see BARREL AGEING).

While some winemakers have started to use less oak or larger oak or older oak in order to decrease the oak influence in their wines, it is still of great significance to wine quality and style.

R.T. du C.

oak ageing, the process of ageing a wine in contact with OAK. This typically involves BARREL AGEING, ageing the wine in a relatively small oak container, although the phrase may also be used for CASK AGEING in a larger oak container and can even be used for wines exposed to the influence of OAK CHIPS or INNER STAVES. Wines thus treated may be described as oak-aged, oak-matured, or oaked. (Oaky is a tasting term usually applied to wines too heavily influenced by OAK FLAVOUR, which smell and taste more of wood than of the fruit and may be aggressively tannic and dry.) See also BARREL ALTERNATIVES.

oak chips, useful if ersatz winemaking tool, an inexpensive alternative to top-quality BARREL AGEING which imparts OAK FLAVOUR

and aroma and which may improve MOUTHFEEL and colour stability, though the resultant wine may be less complex and have poorer AGEING potential.

Oak chips vary considerably both in the provenance of the OAK (from subtle Cher to harsher American oak) and in the size of the chip (from pencil shavings to the more common cashew nut size). Oak chips, just like BARRELS, are also subjected to different degrees of TOAST. The quality of the oak, the method and duration of seasoning, and the degree and duration of toast are far more significant than the shape of the chip or shaving.

Oak chips are used either instead of barrel maturation or to supplement the oak flavour imparted by a used barrel. The average dose of chips is about 1 g/l, or 5 lb per 1,000 gal, typically added at the start of fermentation. Chips offer considerable savings over new cooperage: a sufficient quantity of American oak chips to impart some degree of oak flavour could cost less than one-twentieth of the cost of a new American oak barrel (and an even smaller fraction of the cost of a new French barrel). They are most effective when added during FERMENTATION, when presumably a combination of heat and enzymatic activity combine to generate the most favourable flavour EXTRACTION. Such wines sometimes have such an overpoweringly oaky flavour that they must be blended with unoaked wine. In addition to cost savings, chips have other advantages over barrels: less oak is needed because of the greater surface area in contact with the wine, there is less oak wastage compared with producing barrel staves, the toast is more even, and they take up far less space in the winery.

Research by Wilkinson et al. has shown that the oak character imparted by the chips may intensify after the chips have been removed. This is because the formation of certain oak lactones (see OAK FLAVOUR) takes longer than the period during which the chips are in contact with the wine.

It is possible to buy oak chips impregnated with LACTIC ACID BACTERIA immobilized at the stage immediately prior to exponential

growth so that they can be used to encourage MALOLACTIC CONVERSION, but these are not widely used because of the additional costs involved.

Many wine producers are coy about admitting to using oak chips, although, unlike OAK ESSENCE, oak chips may be used perfectly legally in many wine regions. A wine description which mentions 'oak maturation' or 'oak influence' without actually mentioning any form of COOPERAGE is a good clue that chips have been used.

The oak shavings which can result from BARREL RENEWAL may similarly be used, and larger oak cubes in a perforated bag are sometimes put into older barrels to impart oak flavour.

See also BARREL INSERTS and INNER STAVES. G.T. & J.E.H.

Wilkinson, K. L., et al., 'Rates of formation of *cis*- and *trans*-oak lactone from 3-methyl-4-hydroxyoctanoic acid', *Journal of Agricultural and Food Chemistry*, 52 (2004), 4213–18.

oak essences, or oak extract, are illegal in most wine-producting countries, but some companies are finding creative ways around the regulations. They are an inexpensive means of imparting OAK FLAVOUR and improving wine stability (see STABILIZATION), at least in the short term.

Various powders and liquids are marketed based on extractions from different woods. In some cases, specific TANNINS are targeted and extracted so as to add structure as well as flavour to a wine (see OENOLOGICAL TANNINS).

Doses of powdered oak extracts can vary between 5 and 20 g/hl, but powders are more difficult to use than liquids because of potential problems with CLARIFICATION. The usual dose of a liquid extract is about 0.01% and, since most liquids are based on ETHANOL or brandy, they can be extremely difficult to detect analytically. However, their ability to sustain a wine through bottle AGEING is questionable. G.T.

oak flavour. The wood in which a wine is fermented and/or aged has a profound and often complex effect on its characteristics and flavour (see WOOD INFLUENCE). Certain substances present in wood may also be directly extracted and absorbed into the wine, however. Those extractable substances identified in OAK, the most commonly used wood, are listed below. The flavours of oak-aged wines are the result of compounds extracted from the oak, those derived from the toasting of the wood (see TOAST), and their interaction with compounds in the wine.

Lactones Commonly known as whisky lactones or oak lactones, these compounds, responsible for what is generally called the aroma of oak, or 'oakiness', are derived from LIPIDS in the oak.

Pure lactones, which can easily overpower a wine's inherent AROMA, smell at moderate concentrations of coconut and spice but at lower concentrations can also contribute vanilla sweetness; at higher levels they can smell of green coconut or even vegetal, resinous or mushroom-like. Species and origin of oak affect the concentration, with considerable variation among trees in the same forest, and seasoning and toasting can also develop lactones from precursors in the wood. Higher concentrations are found in American oak. The specific compounds are the cis and trans isomers of *β*-methyl-*γ*-octalactone. The former is reported to be more aromatic than the latter.

Doussot, F., et al., 'Extractives content in cooperage oak wood during natural seasoning and toasting; influence of tree species, geographic location, and single-tree effects', *Journal of Agricultural and Food Chemistry*, 50 (2002), 5955–61.

Phenolic aldehydes VANILLIN, a product of lignin degradation, is the best-known member of this group. Toasting increases the level of these (although they decrease at high toast levels). BARREL FERMENTATION reduces their level because yeast metabolism reduces, for example, aromatic vanillin to odourless vanillic alcohol.

Spillman, P. J., et al., 'Accumulation of vanillin during barrel-aging of white, red, and model wines', *Journal of Agricultural and Food Chemistry*, 45/7 (1997), 2584–9.

Volatile phenols These too are the product of lignin degradation, but some of them (eugenol, for example) are also found in untoasted wood. They impart a spice-like roasted character, ranging from clove to smokiness. The main volatile phenol associated with wood is eugenol (clove-like). Others include guaiacol and 4-methylguaiacol (smoky, charred aromas), which may increase at higher levels of toasting, and 4-vinylguaiacol (reminiscent of carnations).

Carbohydrate degradation products This is a large and complex group that includes furfurals, which are produced from toasting wood sugars. Maltol and cyclotene are also produced from the toasting process and have caramel-like flavours.

Tannins and other non-volatile compounds TANNINS and other PHENOLICS act as a reservoir to balance the oxidative/reductive reactions of the wine, protecting it from OXIDATION and lessening the chance of unpleasant sulfur-related reductive aromas (see REDUCTION). Hydrolysable tannins derived from oak lignin are known as ellagitannins. Their concentration decreases with heavy toasting.

Marchal has shown that quercotriterpenosides (QTT), a family of wood compounds, are responsible for increasing sweetness, roundness, and volume in barrel-aged wines. Lignans and coumarines are natural wood compounds involved in bitterness.

Marchal, A., et al., 'Identification of new natural sweet compounds in wine using centrifugal partition chromatography–gustatometry and Fourier transform mass spectrometry', *Analytical Chemistry*, 83/24 (2011), 9629–37.

Compounds arising from wine–oak interaction It is worth noting that wine in the barrel is biologically active. The YEASTS that effect the FERMENTATION of sugars to alcohol also transform some of these directly extracted oak compounds into other compounds with flavours different from the original. The furfurals, for instance, are derived from hemicellulose and are transformed by the yeasts into compounds which have a range of flavours from smoky to coffee. For example, Blanchard has shown that during BARREL FERMENTATION of white wines, furfurylrthiol (FFT) is formed by yeast from the furfural released by toasted staves. Furfural levels increase with the duration of the toasting. Floch has suggested that vanillin could be transformed into vanillylthiol, reminiscent of cloves. Some other compounds such as pyrroles arising from toasting could be converted in odorant thiopyrroles (hazelnut flavours) during fermentation.

Those who cannot afford to extract their oak flavour from new BARRELS may use OAK CHIPS, BARREL INSERTS, INNER STAVES, or even OAK ESSENCE. Although the contribution made by oak barrels cannot be directly compared with that of BARREL ALTERNATIVES, some winemakers believe that the use of chips and inserts gives them better control over the type and amount of oak flavour extracted. Used carefully and in combination with MICRO-OXYGENATION, these products have allowed some wineries to achieve flavour effects in tank that are quite similar to those promoted by barrel ageing, for a fraction of the cost. oak influence. See WOOD INFLUENCE.

oak root rot, vine disease. See ARMILLARIA ROOT ROT.

Oakville , important source of top-quality NAPA Valley Cabernet.

Obeideh, hardy, vigorous, workmanlike INDIGENOUS VARIETY of LEBANON, high in sugar, low in ACIDITY, used extensively in the making of arak (local spirit), sacramental wines, Chateau Musar's white blend, and now also VARIETAL wines. Obeideh—variously spelt Obaideh, Obeidah, Obeidi, etc.—was once believed to be a strain of Chardonnay, but DNA PROFILING has shown it to be a truly local variety.

M.R.K. & J.V.

Óbidos , DOC in LISBOA in western Portugal with a relatively cool Atlantic climate, known particularly for SPARKLING WINES.

ochratoxin A (OTA) is a mycotoxin (i.e. a toxin produced in very small quantities by certain moulds) found in a range of food and beverages such as cereals, beer, coffee, cocoa, and wine. It is closely related to fungal contamination of damaged grapes in the vineyard, most notably but not exclusively by *Aspergillus carbonarius*. (See also BUNCH ROTS and SOUR ROT.)

EU regulations were tightened in 2005, and the limit is currently 2 µg/l for wine and grape juice. The concentration of OTA may be higher in warmer climates but is typically reduced by up to 80% during winemaking, as described by Gil-Serna and colleagues.

Gil-Serna, J., et al., 'Wine contamination with ochratoxins: a review', *Beverages*, 4/1 (2018).

Oechsle, scale of measuring grape sugars, and therefore grape RIPENESS, based on the DENSITY of grape juice. Grape juice with a

specific gravity of 1.075 is said to be 75 °Oechsle. This is the system used in Germany, and it has its origins in a system of weighing grape MUST developed first by the Württemberg scientist J. J. Reuss and much refined in the 1830s by the Pforzheim physicist Ferdinand Oechsle (see GERMAN HISTORY).

Like other scales used elsewhere (see BAUMÉ and BRIX), it can be measured with a suitably calibrated REFRACTOMETER or HYDROMETER. A similar scale, devised at KLOSTERNEUBURG, is used in Austria.

Each scale of sugar measurement relates to the others. For example, a grape juice of 14.7 °Brix has a specific gravity of 1.06 and an Oechsle value of (1.06 − 1.0) × 1000 = 60. According to published scales, these relationships are not strict ones (as illustrated in Hamilton and Coombe).

For more details, see MUST WEIGHT. B.G.C.

Hamilton, R. P., and Coombe, B. G., 'Harvesting of winegrapes', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

œil-de-perdrix, French for 'partridge's eye', used as a name and TASTING TERM for pale pink wines made from Pinot Noir, especially in the Neuchâtel canton of SWITZERLAND.

Oeillade Noire, very old, now rare PROVENÇAL dark-skinned grape variety. Oeillade Blanche is a synonym for the unrelated PICARDAN.

oenocyanin, a TANNIN product extracted from the skins of black grapes, comprising a mixture of PIGMENTED TANNINS, some ANTHOCYANINS, and other PHENOLICS. Marketed as a food colourant, oenocyanin is a valuable source of natural pigments available from POMACE. Even though it is a tannin derived from grapes and therefore is of a composition more similar to the natural tannins of wine than many OENOLOGICAL TANNINS, regulations in most countries forbid the

use of oenocyanin in RED WINEMAKING because it is classed as a colouring agent. P.J.W.

oenological tannins, or commercial tannins, are products made by extraction of tannin from oak, chestnut, or birch woods and other suitable plant sources, including grape seeds. These have long been used (and are approved ADDITIVES in many winemaking regulations) with the aim of improving the AGEING characteristics, TEXTURE, depth of colour, and colour stability of red wines and also to inhibit LACCASE activity from *Botrytis cinerea* on red grapes. However, they are most useful for CLARIFICATION.

Versari, A., 'Oenological tannins: a review', *Australian Journal of Grape and Wine Research*, 19/1 (2013), 1–10.

oenologist, or, in the United States and South Africa, enologist, one who practises OENOLOGY. CONSULTANT oenologists are likely to concentrate on the activities traditionally considered WINEMAKING but increasingly concern themselves with what happens in the vineyard as well as in the cellar. In general usage, an oenologist is either a scientifically qualified employee or a roving consultant, as opposed to a fully employed practitioner who may or may not have scientific training, the WINEMAKER. In California, certain winemakers are so adept and so modish that their input alone can be enough to double or treble PRICES and transform a wine into a CALIFORNIA CULT wine. Helen Turley was the first. Most famous among them are Philippe Melka and Andy Erickson; others include Heidi Peterson Barrett, Thomas Rivers Brown, Celia Welch, Aaron Pott, Julien Fayard, Graeme MacDonald, and Benoit Touquette.

See also FLYING WINEMAKER.

oenology, or enology, the knowledge or study of wine, derived from the Greek *oinos* meaning 'wine'. The term is similar in several

other languages: *oenologie* (French), *Önologie* (German), *enología* (Spanish), *enologia* (Italian, Portuguese).

Oenology has been used as a synonym for WINEMAKING, as distinct from VITICULTURE, which is concerned with vines. There is a general tendency towards including the study of viticulture as well as wine production in the term, however, as more people accept that wine is made to a great extent in the vineyard. See also OENOLOGIST.

Oenotria, name given to southern Italy when Greek colonists first arrived in the 8th century BCE or soon after. The Greeks may have found the indigenous inhabitants already producing wine and using STAKES to support the vines, and it is possible that they adopted a word meaning 'stake' (*oinotron*) as a name for the inhabitants. But this word is very rare—a different word (*kharax*) is used in most dialects of classical Greek—so it may be that Oenotria was the name already used by the local population and that the similarity between it and the word meaning 'stake' is purely coincidental.

N.G.W. & H.M.W.

Offida, a DOCG for white and red wines located between the Adriatic coast and the town of Ascoli Piceno in Italy's MARCHE region.

Ohio , US state with approximately 600 ha/1,500 vineyard acres in 2021 and over 360 wineries, is the site of North America's first successful commercial wine venture.

Success as a Cincinnati lawyer and land speculator freed Nicholas Longworth after 1828 to concentrate on horticultural passions. He studied the winegrowing attempts of his predecessors and contemporaries, including the efforts of fellow Swiss settlers brought over by Jean Jacques Dufour at Vevay, Indiana, 75 sinuous miles/121 km downstream along the Ohio River. Having achieved promising results on steep riverside slopes already in the early 1820s, Longworth embarked on an ambitious programme underwriting plantings by tenant farmers (mostly German emigrants) and betting

on CATAWBA, a chance AMERICAN HYBRID. Through ambitious promotion, taste for the resulting white wines—dry, high acid, and low alcohol (Longworth disdained CHAPTALIZATION)—grew beyond Cincinnati's German speakers.

An accidental refermentation in the early 1840s convinced Longworth to divert most of his production into sparkling Catawba, which garnered a national following. Cincinnati Catawba drew favourable comparisons at London's Great Exposition of 1851 to Rhenish HOCK, and Longfellow penned a poem, 'In Praise of Catawba Wine'. As 'The Queen City of the West' grew to become the sixth largest in the US, its vine surface nearly tripled to 1,214 ha/3,000 acres between 1846 and 1850. But from the early 1850s, POWDERY MILDEW and BLACK ROT began taking a terrible toll during frequently humid growing seasons, and in the 1860s grape sources for what remained of Longworth's operation moved to Ohio's far north, while his two JURA-born winemakers left for New York's FINGER LAKES.

Vineyards established in the late 1840s on Lake Erie's Bass and Kelley's islands, 16 km/10 miles offshore from Sandusky, Ohio, and 40 miles south of Detroit, MICHIGAN, were soon flourishing with Catawba vines brought from Cincinnati, lake breezes keeping powdery mildew and rot at bay. By 1890, although NEW YORK had long since overtaken Ohio in production, vineyards extended the length of Lake Erie's Ohio shore and—as would continue to be the case, on a much-reduced scale, after PROHIBITION—were responsible for the majority of Ohio wine, most of that from Catawba or from the small share of CONCORD grapes that was not destined for juice and jelly.

By 1960 there were only 47 Ohio wineries (down from 149 in 1940). A late 20th century surge saw that number triple, and by 2021 it had more than doubled again, with five AVAs, four of which are active: Isle St. George, Grand River Valley, Lake Erie (shared with New York and Pennsylvania), and Ohio River Valley (shared with Indiana and Kentucky). Wine-bearing acreage includes both FRENCH HYBRIDS (VIDAL and TRAMINETTE prominent among them) and VITIS

VINIFERA (led by Riesling, Chardonnay, Pinot Gris, and Cabernet Franc). Catawba retains a 4% share. D.S.

oïdium, much-used French name for POWDERY MILDEW, although Anglophones tend to omit the diaeresis.

OIV stands for Organisation Internationale de la Vigne et du Vin, the intergovernmental body which represents the interests of vine-growers, and the wine, RAISIN, TABLE GRAPE, and grape-spirit industries of its members, comprising 49 different countries. Most of the major wine-producing and wine-consuming countries are members, although the US, China, and Canada are notable exceptions. Long based in Paris, in 2022 it moved to Dijon.

The OIV was originally formed in 1924 as the Office International du Vin by an agreement between France, Greece, Hungary, Italy, Luxembourg, Portugal, Spain, and Tunisia. Created and based in Europe, its membership expanded after the Second World War to include non-European wine-exporting countries such as Argentina (1953), Australia (1978), the US (1984–2001), and New Zealand (1994). In response to concerns voiced by non-European wine-producing countries, a review of OIV operations was undertaken, and a new international treaty creating the OIV in its present-day form was signed in 2001.

The OIV undertakes a range of activities to promote research, education, and co-operation, provide data and information, and contribute to harmonization within the wine and vine sector, particularly through its recommendations, which influence the regulations of many countries and particularly those of the EU. The OIV publishes a number of important compilations, including the International Code of Oenological Practices, the International Oenological Codex, the Compendium of International Methods of Analysis of Wine and Musts, and the International Standard for Labelling of Wines. Its statistical work forms the basis for much of the available global data on wine. J.P.H.B.

www.oiv.org

Olasz Rizling, or Olaszrizling, is the most common name in HUNGARY for the white grape variety known in Austria as WELSCHRIESLING (under which more details appear), planted on 3,417 ha/8,444 acres in 2021, although it was introduced less than a century ago. The Olaszrizling produced around Lake Balaton, Somló, and Eger is particularly prized; in general, the warmer climate imbues Hungarian versions of this variety with more weight than their counterparts in Austria. It is planted in virtually every wine region and made in a wide range of styles.

old vines are reputed to produce grapes which make better-quality wine. The phenomenon is largely anecdotal with few scientific studies having been undertaken (but see VINE AGE). The term is used increasingly on labels as a sign of both quality and scarcity as very old vineyards are rare and often low-yielding. Groups have been established to support and protect old vines globally through marketing and to acknowledge old-vine wines as a distinct category. BOLLINGER was one of the first producers to use the French term *vieilles vignes*, for the produce of UNGRAFTED VINES in one walled vineyard. It is common to see 'old vines' on labels from all parts of the wine world, as well as *vinhas velhas* (Portuguese), *alte Reben* (German), *vecchie vigne* (Italian), and *viñas viejas* (Spanish). Some regions such as the Barossa in Australia are home to very old ungrafted vines that have escaped PHYLLOXERA, some producing continually for well over 150 years.

There are few effective controls on the use of the term, however, and little agreement about exactly how many years it is before a vine can be deemed 'old', although the Barossa Old Vine Charter and South Africa's Old Vine Project have chosen 35 years as the baseline,

whereas California's HISTORIC VINEYARD SOCIETY has set the bar at 50 years. D.P.G.

old wine. See AGEING and MATURITY.

Old World, term typically used to refer to Europe and the rest of the Mediterranean basin such as the Near East and North Africa. It is used solely in contrast to the New World. However, the historical and geographical distinction is becoming less useful as more and more wine producers travel freely between Old and New Worlds, exchanging ideas and techniques, and as the terms are used as much to describe attitudes, practices, and wine styles as to pinpoint place of origin. For more details of what has characterized the different approaches associated with these widely used but problematic labels, see NEW WORLD. In this book they are used as shorthand, not as precise categories.

olfactory bulb, the most sensitive part of our personal TASTING equipment, at the top of the NOSE.

Olifants River, chiefly BULK WINE-producing region in SOUTH AFRICA among mountains and along the Atlantic western seaboard. Most growers have supplied large local CO-OPERATIVES with wine for DISTILLATION, but an increasing proportion is exported as wine. Vredendal, South Africa's biggest single winery and part of Namaqua, vinifies more than 95,000 tonnes of grapes annually. But there are pockets of vines with serious potential, particularly in Lutzville Valley district and the tiny Bamboes Bay ward.

oloroso, Spanish word with two related meanings in the sherry-making process. Without its initial capital, *oloroso* refers to a strong, rich type of wine that is the counterpoint to the lighter *fino* (see SHERRY). Oloroso with an initial capital refers to one of several commercial styles of sherry. The purest Oloroso is a dry, dark, nutty wine that is essentially bottled *oloroso* and is often labelled Dry Oloroso. Outside of JEREZ, the term 'Oloroso' used to be applied to any commercial sweet, dark blend of basic sherry plus colouring and sweetening wine, but it now must be labelled as Cream or Medium, depending on its sugar content. Oloroso may have an alcoholic strength of 18–22%. See SHERRY for more details.

Oltrepò Pavese, LOMBARDY's most sizeable viticultural area, administratively part of PIEMONTE from 1741 to 1859, extends across the hills of a series of communes in the province of Pavia south of the Po river where the land begins to rise towards the Ligurian Apennines (the name means 'beyond the Po, in the Pavia region'). In 2020, vineyards totalled 13,500 ha/33,359 acres, of which 11,192 ha were registered for DOC wines.

Oltrepò Pavese is also the name of an extensive umbrella DOC encompassing six DOCs and one DOCG for TRADITIONAL METHOD

sparkling wines. With 4,000 ha/9,884 acres, CROATINA (confusingly called Bonarda, the name of a quite different, generally inferior grape variety here) is the region's most planted grape variety. However, at more than 3,000 ha, Oltrepò Pavese has the largest area of Pinot Noir in the whole of Italy and at least 150 years of history closely aligned with sparkling-wine production. Carlo Giorgi Vistarino of the eponymous and still existing estate planted the variety in 1865 and began to produce a sparkling wine modelled on champagne a few years later. The region's historic role has been to furnish base wine to the large SPUMANTE houses of Piemonte, which have long relied on this neighbouring zone in Lombardy for varieties not cultivated in their own region, but an increasingly lucrative international market, in combination with deep-pocketed outside investors, has spurred producers on to aim for higher quality. Wines produced in the DOCG, established in 2007, must be made with a minimum of 70% Pinot Noir, with Chardonnay, Pinot Grigio, and/or Pinot Bianco, and age for at least 15 months on the LEES (24 months for VINTAGE-dated wines). Some of the best examples are produced from north-facing vineyards. Cruasé is the collective BRAND name for traditional-method sparkling Pinot Noir rosé, a style in which the region has begun to excel and which faces little competition from other regions.

The majority of the rest of Oltrepò production remains not particularly interesting. Significant amounts of BULK WINE have always been sold in nearby Milan, encouraging abundant production at extremely low prices. CO-OPERATIVES have also tended to reward quantity over quality. Oltrepò Rosso, a blend of BARBERA and Croatina, can yield interesting wines. More interesting are the red wines of the revived Buttafuoco DOC, based on Barbera, Croatina, and UVA RARA grown on CALCAREOUS clay and not unlike those of the LANGHE. The best can easily age a decade or more. The even smaller DOC Sangue di Giuda (blood of Giove) produces red blends using the same varieties.

In a publication dated 1884, the Pavia Chamber of Commerce listed a host of INDIGENOUS VARIETIES, including Moradella, Pissadella,

Ughetta di Canneto, Rossara, Barbisino, Pignolo, Besgano, Uva d'Oro, and Sgorbera. The region should seize the opportunity to capitalize on them before they completely disappear. W.S.

Omar Khayyám (d. 1132 CE) was a Persian poet, made famous in the English-speaking world by Edward Fitzgerald's translation (and adaptation) of the *Rubáiyát* ('Quatrains') in 1859 (2nd edn, 1868). In his own life, he was known as a philosopher and a scientist, and he was remembered for a long time, both in the Middle East and Europe, as one of the greatest mathematicians of medieval times. His quatrains would scarcely have been deemed original in his own society (see ARAB POETS). In a time of strict orthodoxy, this genre of occasional verse, which was popular in PERSIA in the 11th and 12th centuries, was the best medium for expressing dangerous personal doubts to a close circle of friends.

Omar Khayyám's own quatrains are the outpourings of a non-conformist intellectual who was opposed to religious fanaticism; they range from a pious outlook to the extremes of scepticism. Wine is an important theme in this poetry. Given the ISLAMIC prohibition against wine, many of the *rubáiyát* may seem heretical; however, the defiant anti-Islamic stance of Bacchism in the 8th and 9th centuries had by the 12th century been transformed in significance by Sufism (Islamic mysticism). Some commentators have, therefore, viewed the *rubáiyát* as a mystical genre, with wine forming part of a sensitive allegory. More recently it has been accepted that wine merely serves to express religious scepticism and provides solace from existential anguish; Omar Khayyám sought to drown the world's sorrows in wine and thus rejected 'the hope of a diviner drink' offered by Islam. Khayyám's was a humanist protest that scorned sectarianism and intolerance: 'If I'm drunk on forbidden wine, so I am! | And if I'm a pagan or idolater, so I am! | Every sect has its own suspicions of me, | I myself am just what I am…To be free from belief and unbelief is my religion.'

Although Persian wine poetry was largely influenced by Arabic poetry, the range of Bacchic expression in the *Rubáiyát* is far more

limited than what we find in the detailed, sometimes exuberant, descriptions of wine among the earlier Arab poets.

Avery, P., and Heath-Stubbs, J. (trans.), *The Ruba ʿiyat of Omar Khayyam* (1979).

Ondarrabi. See HONDARRABI BELTZA.

Ondenc was once an important vine variety in GAILLAC and all over SOUTH WEST FRANCE but has fallen from favour because it yields poorly and is prone to ROT. During the 19th century it must have been taken to Australia, where it was identified, under the name Irvine's White at Great Western in Victoria, by visiting French AMPELOGRAPHER Paul Truel in 1976. Since then it has all but disappeared from Australian vineyards too.

Ontario produces the majority of CANADA's wine, with more than 180 wineries in 2021 and 7,002 ha/17,300 acres of vines, the majority of which is VITIS VINIFERA. The diverse ethnic ancestry of Ontario's grape-growers is reflected in a range of more than 50 vine varieties, with a primary focus on Chardonnay, Riesling, Pinot Noir, and Cabernet Franc. Gamay also excels, with early plantings dating back to the 1970s. Other varieties include Vidal Blanc, Pinot Gris, Sauvignon Blanc, and Gewurztraminer for whites, along with Merlot, Baco Noir, and Cabernet Sauvignon for reds. Ontario is also the home to the Cool Climate Oenology and Viticulture Institute at BROCK UNIVERSITY.

This COOL-CLIMATE growing region has a CONTINENTAL CLIMATE that is subject to extremes of hot, often humid summers with occasional DROUGHT, as well as winters in which temperatures can fall below −20 °C/−4 °F. However, the degree days (see CLIMATE CLASSIFICATION) during the growing season for the Niagara Peninsula (1500 C°) are

greater than for Beaune, France (1315 C°), and Hawke's Bay, New Zealand (1200 C°). Long days and cool nights slow down fruit maturation while retaining ACIDITY.

Ontario has three GEOGRAPHICAL INDICATIONS (GIs) all concentrated in the southern part of the province at latitudes 41–44° N and within influence of two of the Great Lakes, Ontario and Erie, which temper the winter cold and the heat of summer (see LAKE EFFECT).

The Niagara Peninsula, Canada's largest wine region (5,989 ha/14,800 acres), has a unique MESOCLIMATE created by its position between Lake Ontario and the Niagara Escarpment, a steep, dolomite-topped ridge that runs from NEW YORK through southern Canada to Wisconsin (dolomitic LIMESTONE is rich in magnesium). This ridge moderates air flow by acting as a passive barrier against continental winds while capturing warm lake air. The resulting extended growing season allows for LATE HARVEST wines, including ICEWINE. Sparkling wines are also made by more than 100 wineries.

Within the Peninsula, there are two regional appellations—Niagara Escarpment and Niagara-on-the-Lake—and ten subappellations. The vineyards of the Niagara Escarpment face mainly north, the well-drained slopes of CLAY, SILT, and CALCAREOUS clay-LOAM soils sheltered by the escarpment and fed by numerous streams and tributaries. The region is further broken down into the lakeside subappellations Lincoln Lakeshore and Creek Shores and the benchland subappellations Beamsville Bench, Twenty Mile Bench, and Short Hills Bench (see BENCH). On top of the escarpment, Vinemount Ridge has deep clay soils and the Peninsula's only south-facing slopes.

Further east, along the Niagara River, are the vineyards of Niagara-on-the-Lake and its subappellations Niagara Lakeshore, Niagara River, Four Mile Creek, and St David's Bench. Compared with those of Niagara Escarpment, temperatures are slightly warmer throughout the growing season and the TOPOGRAPHY is flatter, with long, gentle slopes and generous sunlight exposure. Red-SHALE soils with high silt and clay content are moderate- to well-drained.

Lake Erie North Shore (576 ha/1,400 acres) in south-western Ontario has the province's longest growing season and the highest number of degree days but also the risk of WINTER FREEZE. It comprises a narrow band along Lake Erie's north shore planted mainly to *vinifera* vines. It also includes the South Islands subappellation, applied to a group of nine islands 20 km/12.4 miles offshore, which was previously the distinct Pelee Island appellation.

Prince Edward County, a two-and-a-half-hour drive east of Toronto, is Ontario's smallest GI, with 263 ha/650 acres of vines and over 40 wineries in 2021. A peninsula on Lake Ontario's north shore, the region averages 5 °C/9 °F cooler than Niagara, with short, warm summers and winters cold enough to require WINTER PROTECTION for the vines. Many of the vineyards are situated on stony soils on limestone bedrock, resulting in naturally low yields. Chardonnay and Pinot Noir wines excel here.

Ontario also has several emerging regions, such as Norfolk County, to the north-east of the Lake Erie North Shore appellation. There are growing communities of wineries in the outskirts and to the north and west of Toronto near Georgian Bay and Lake Huron, as well as in the eastern part of the province near Ottawa, Canada's capital.

Wines carrying a viticultural designation must be made exclusively from *vinifera* grapes—except Icewine, which can also be made from VIDAL. The fruit of VITIS LABRUSCA vines, still grown in Ontario, is used primarily for juice and some inexpensive non-VQA sparkling wine.

In 2017 Ontario became the second wine-growing region in the world (after South Africa) to introduce regulations for SKIN-FERMENTED white wines. In order to use the label 'skin fermented white wine', the winery must declare its intent by November of that harvest year, and 100% of the grapes used must be macerated and fermented on the skins for a minimum of ten days. The wine may be still or sparkling.

opening the bottle is an important and potentially difficult operation for bottles sealed with a cork. A wide range of CORKSCREWS is available for opening bottles of still wine. See CLOSURES for details of alternatives to CORK, most of which are much easier to remove and need no special equipment.

If the cork proves too recalcitrant for a corkscrew, the cork should simply be pushed in, if possible, and the wine poured out of the bottle, perhaps into a jug, while the cork is held down with a long, thin instrument. See PORT TONGS for one way of opening bottles with very old corks.

But before the cork can be extracted, any FOIL or wax seal has to be broached. A knife blade or FOIL CUTTER is the simplest way to cut a foil neatly, just below the lip of the bottle, which should be wiped of any residue from the foil, especially if it is an old one and contains LEAD. Some of the increasingly popular wax seals are more difficult to penetrate and call for a sharp knife, or foil cutter, and tolerance of a certain amount of mess. If the wax is soft enough, the corkscrew can simply be inserted through it.

Opening a bottle of SPARKLING WINE is potentially extremely hazardous, as the pressure inside the bottle can expel a cork so fast that it can inflict grave injury. The bottle should be held at 45 degrees (to maximize the wine's surface area) with the cork pointing in the least dangerous direction (and certainly not at anyone, nor at anything precious or fragile). The wire MUZZLE should be untwisted and discarded. While holding the cork in the bottle, usually with the top of the thumb, the bottle should then be very gently rotated off the cork with one hand while the cork is held in place with the other. The cork should be allowed to escape the bottleneck very slowly and the wine poured from the 45-degree angle, perhaps with a thumb in the punt (see BOTTLES). The racing-driver technique of giving

champagne a good shake and prising off the cork with two thumbs is about as dangerous as motor racing.

See SERVING WINE for the timing of opening a bottle.

Opimian wine is the wine of the consular year of Lucius Opimius, 121 BCE. It owes its fame to the conjunction of an exceptionally hot summer and a momentous historical event, the assassination of C. Gracchus, which temporarily ended the movement for social reform.

Writing in 46 BCE, Cicero states that the Opimian vintage is already too old to drink (*Brutus* 287), and PLINY the Elder describes it as 'reduced to a kind of bitter honey' but still recognizably wine and exorbitantly expensive (*Natural History* 14. 55–7). Petronius (*Satyricon* 36) and MARTIAL (*Epigrams* 1. 26, 3. 82, 10. 49, etc.) treat Opimian as a literary commonplace rather than a real wine: drinking Opimian in large quantities is what the *nouveaux riches* do to flaunt their wealth, but this is satire, not fact.

To have lasted this long, the wines were almost certainly DRIED-GRAPE WINES. H.M.W.

Oporto, Portugal's second city and the commercial centre, known in Portuguese as Porto, which gave its name to Vinho do Porto, better known as PORT wine. Grapes grown in the arid conditions up river of Oporto in the DOURO Valley would be crushed and vinified before being shipped to port shippers' LODGES on the south side of the River Douro in VILA NOVA DE GAIA. Oporto has long had a substantial population of British merchants, whose meeting place, the FACTORY HOUSE, survives to this day.

The PORTUGIESER red grape is sometimes known as Oporto in Romania.

optical sorting. See GRAPE SORTING.

Optima, also called Optima 113, is a 1970 GERMAN CROSS, bred from a cross of SILVANER × RIESLING and MÜLLER-THURGAU. It buds late but ripens very early indeed, sometimes more than ten days before Müller-Thurgau, and can notch up impressive ripeness readings, even if the wines themselves are flabby and undistinguished. Germany's plantings of Optima reached a peak of 420 ha/1,037 acres in 1990 but had declined, unlamented, to 21 ha by 2020. Its offspring ORION has been more successful.

options game, BLIND TASTING game which in practice allows novice tasters almost as great a chance of winning as professionals. Developed by Australian Len EVANS, it requires an informed quiz-master who presents players with a series of increasingly precise options for the identity of the wine. A typical series of options might be: 'Australia, California or Bordeaux?', 'left or right bank?', 'St-Estèphe, Pauillac, St-Julien or Margaux?', '20th or 21st century?', 'first or fifth growth?', 'Latour, Lafite or Mouton?'. Players remain in the game only by choosing the correct successive options.

Orange, coolest of the Central Ranges regions of NEW SOUTH WALES, around the town of Orange. With a CONTINENTAL CLIMATE and ELEVATIONS of 600–1,000 m/1,969?3,281 ft resulting in wide DIURNAL TEMPERATURE RANGE, the region is best known for crisp Chardonnay and also excels with Sauvignon Blanc, Shiraz, and Cabernet Sauvignon. TRADITIONAL METHOD sparkling wines are a speciality. Pinot Noir and Riesling show great promise. A.R.P.

Orange Muscat, also known as Muscat Fleur d'Oranger, white grape variety with MUSCAT characteristics that is a CROSS between CHASSELAS and MUSCAT BLANC À PETITS GRAINS. California plantings of 'Muscat Orange' comprised 316 acres/781 ha in 2020, with a little in Oregon and Australia. There are very limited plantings of this variety

in TRENTINO, under the name Moscato Fior d'Arancio, but confusingly the Veneto wine of the same name is made from MOSCATO Giallo.

orange wine, distinctive, dry and tannic white-grape wine style with links to the contemporary NATURAL WINE movement but inspired by antiquity. Known as *vino naranja* in Spanish, *vino bianco macerato* (sometimes *vino orange*) in Italian, *Orangewein* or *maischvergoren* in German. As in RED WINEMAKING, orange wines are made by fermenting the juice of ripe grapes with their skins and pips, occasionally with the stems, usually for between a week and a year, but with white grapes. The prolonged MACERATION of the skins results in wines darker than conventional whites, in the yellow/amber/gold/orange/pink spectrum depending on variety, ripeness, duration of maceration, EXTRACTION methods, and vessel type (CLAY vessels are increasingly popular but not essential). Stylistic differences within the genre are also influenced by, for example, a preference for aromatic varieties or the decision not to clarify the wine (see CLARIFICATION). TANNIN levels are higher than in conventional white wine, which can be useful in gastronomy and for natural-wine adherents who bottle with low to no additions of SULFUR DIOXIDE. The genre was reintroduced west of the Caucasus for high-quality dry wine by neighbours Stanko Radikon and Josko Gravner of Oslavia in FRIULI, the latter having bottled only orange and red wine since 1997, although he prefers the term 'amber' to 'orange'. However, traditional TOKAJI Aszu wines, white PORT, and many wines of GEORGIA were always macerated. The name was coined in 2004 by UK wine merchant David Harvey, then based on ETNA and tasting such wines. Most are currently officially labelled as white wine and often referred to as SKIN-FERMENTED whites, although some jurisdictions—Hungary and Ontario, for example—now include a definition of orange wine in their wine regulations. In 2020 the OIV adopted 'white wine with maceration' into the International Code of Oenological Practices. J.E.H. & D.A.H.

Orbois. See MENU PINEAU.

order of wines to be served. This can affect how individual wines taste quite considerably. The general convention is a wise one for maximizing pleasure: dry before sweet, ordinary before fine, and, generally, young before old.

A sweet wine can make dry wines taste acidic and unpleasant if they are tasted afterwards, so it makes sense to serve wines in an increasingly sweet sequence (which matches the usual sequence of foods during a meal, although serving the sweet course before cheese can upset things).

Old wines are generally more complex than callow young ones (see COMPLEXITY), and so it generally flatters all wines if the oldest in the sequence are served last. This is not infallible, however. Many young wines are so overwhelmingly robust in comparison to a delicate old wine that they overpower it, and increasing levels of average ALCOHOLIC STRENGTH with each vintage also provides an argument in favour of tasting from (weaker) old to (more powerful) young. For this reason, many tasters approach large tastings of PORT, especially vintage port, from the oldest to the youngest wine. Some wine producers, particularly but not exclusively in newer wine regions, also prefer to show their wines in chronological order of progress, and possibily prowess, from old to young. And those planning particularly generous meals may find that the nuances of the oldest, finest wine they serve last may be lost on some palates already soaked in too many younger wines.

Similar considerations apply to serving wines in an upward sequence of quality.

Oregon , one of the United States known by wine lovers for its PINOTS and with a burgeoning reputation for Chardonnay. Oregon lies between CALIFORNIA and WASHINGTON State; while its southern growing regions can claim climatic kinship with the warm, dry growing regions of these two neighbours, it is the wines from the cooler, wetter,

north-west corner of Oregon upon which the state has built its reputation for quality. While Oregonian viticulture can be traced back five generations, the growth of its wine industry has been a more discreet affair than that of California. Inhabited in large part by Californian wine refugees, and historically underfunded, the Oregon wine industry has cultivated an image of rustic charm and natural simplicity. While wineries producing hundreds of thousands of cases do exist, more than 70% of Oregon wineries produce fewer than 5,000 cases a year.

History

VITIS VINIFERA vine varieties arrived in the region in the late 19th century. A census of 1860—a year after statehood was granted—revealed Oregon's wine production was some 2,600 gal/98 hl. Twenty years later, Jackson County alone was producing 15,000 gal and a post-PROHIBITION boom saw 28 wineries making a million gal by 1938, even if much of that was FRUIT WINE. Little progress was made in the next 25 years as California dominated the market.

Oregon's modern era dates from 1961, when HillCrest Vineyard was established near Roseburg (in what is now Umpqua Valley AVA) by Richard Sommer, a refugee from the University of California at DAVIS, where he had been advised that *vinifera* grapes could not be grown in Oregon. Nevertheless, he planted Pinot Noir and other *vinifera* varieties. But it is David Lett of the Eyrie Vineyard who is referred to as 'Papa Pinot', having first planted Pinot Noir in the Willamette Valley in 1965. He was followed by UC Davis classmate Charles Cour, as well as such names as Erath, Ponzi, Sokol Blosser, and Adelsheim, among others. Most pioneers had done time in California before heading north.

Lett brought Oregon into the spotlight in 1979 when his 1975 Eyrie Vineyard Pinot Noir was placed second in a French-sponsored tasting comparing top French wines with their NEW WORLD emulators. Beaune merchant Robert DROUHIN staged a follow-up which served only to confirm the result. Drouhin eloquently endorsed it by purchasing land and building a winery within a stone's throw of Lett's vineyards. Following this, outside interest began to increase.

Between 2000 and 2020, vineyard area in Oregon more than tripled, reaching 15,998 ha/39,531 acres, with more than 900 wineries in production. In vineyard and volume terms, Oregon remains significantly smaller than Washington to its immediate north, but it has achieved a good deal more publicity.

Geography and climate

While almost all Washington State vines are planted in the rain shadow and semi-desert east of the Cascade Mountains, most Oregon vines lie west of the Cascades and are exposed to airflow from the Pacific Ocean through gaps in the Coastal Range. This provides the state with milder winters and cooler summers than Washington.

Southern Oregon has much in common with the warm, arid parts of northern California. In contrast, northern Oregon is notoriously wet and cool, although CLIMATE CHANGE has somewhat adjusted this image: between 2013 and 2020, only 2013 and 2019 featured cool, wet harvests. Since 2012 DROUGHT and WATER STRESS have become more common, with timing of FLOWERING and HARVEST inching ever earlier and warm, dry summers in the middle. The year 2020 was particularly jarring, with a dry summer leading to the worst WILDFIRES in the state's history. Many producers struggled to decide whether to harvest after days of heavy smoke.

Vineyard ELEVATIONS are commonly 110–330 m/250–750 ft, and soils vary by area. The most-referenced soil series in northern Oregon are Jory and Nekia (colluvium with VOLCANIC origins), Willakenzie and Bellpine (marine sedimentary), and Laurelwood (a type of windblown LOESS). These make up a small percentage of a diverse range of soil series throughout the state that are well mapped by the National Resources Conservation Service.

The state boasts 22 AVAs, with the WILLAMETTE VALLEY, the largest AVA by acreage and volume, receiving the most publicity. However, the fastest rate of growth of land under vine is in the Southern Oregon AVA, which stretches south of Eugene to the California border and encompasses the Umpqua Valley AVA (including the AVAs Red Hills Douglas County and Elkton) and Rogue Valley AVA (including Applegate Valley AVA). These southern AVAs are the warmest in Oregon and receive up to 40% less precipitation than the Willamette

Valley, with the southernmost region, Rogue Valley, the highest in temperature and elevation in the state.

In the north of Oregon, shared with Washington, are the Columbia Gorge AVA and Columbia Valley AVA (including Walla Walla Valley AVA). Within the Walla Walla AVA, entirely on the Oregon side, lies the Rocks District of Milton-Freewater, known for BASALT cobblestones. In eastern Oregon is Snake River AVA, shared with IDAHO. Its distinctly CONTINENTAL CLIMATE and high elevations (762–914 m/2,500–3,000 ft) with large DIURNAL TEMPERATURE RANGE are attracting attention from young winemakers looking for new frontiers.

Viticulture

When David Lett planted Pinot Noir in the Willamette Valley in 1965, he planted the Wädenswil CLONE on its own roots. Charles Coury and Dick Erath followed with the Pommard clone; they too planted UNGRAFTED VINES. As recently as the early 1990s, most vines were planted on their own roots, leaving them prey to PHYLLOXERA. By the mid 1990s, GRAFTING had become popular, and Dijon clones, known for their ability to ripen early in Oregon's MARGINAL CLIMATE, had been grafted on to phylloxera-resistant ROOTSTOCKS. Producers continue to debate the merits of Dijon, Wädenswil, Pommard, and MASS SELECTION. This is due, in large part, to the array of morphological differences present in Pinot Noir. Other varieties do not see the same debate, although, with a rise in the popularity of Oregon Chardonnay there have been debates over whether Wente or Dijon is the better clone for the area (see HERITAGE CLONES).

Oregon wineries tend towards SUSTAINABLE VITICULTURE. In 2021, 5.5% of Oregon's vineyards were certified for ORGANIC VITICULTURE. Although the state produces only 1% of US wine, it claims 574 ha/1,419 acres or 31.7% of BIODYNAMIC-certified vineyard acreage in the US. LIVE certification (a monitored Low Input Viticulture and Enology programme) is popular as well. DRY-FARMING, once a given, is becoming more challenging with climate change, but a large percentage of vineyards are still dry-farmed. The Deep Roots Coalition in Willamette Valley is working to continue this.

The economies of scale necessary for the production of cheap wine are not a feature of the Oregon wine industry, which is therefore motivated by a need for quality rather than quantity. Crop YIELDS tend to be small, often intentionally in an effort to produce superior, concentrated wines. Vines are mostly CANE PRUNED rather than CORDON-trained and SPUR-pruned, thus demanding more time, care, and skill from the grower. High disease pressure and a tendency

towards ORGANIC VITICULTURE means more regular SULFUR spraying and increased LABOUR.

Vine varieties

Pinot Noir accounts for 59% of Oregon's vineyard hectarage and commands a higher average price per ton than any other grape. PINOT GRIS (first planted outside of Europe by David Lett of Eyrie Vineyards) has achieved popularity in a dry style showing more flesh than Pinot Grigio in Italy and more acidity than Alsace versions. CHARDONNAY has been represented since the 1960s but grew in importance after the introduction of Dijon clones in the mid 1990s. If Oregon can be said to have a Chardonnay style, it is taut and fresh while carrying a modest amount of new OAK. RIESLING is commercially viable but declining in plantings, while VIOGNIER plantings have increased in recent years, particularly in southern Oregon.

Among red wine grapes other than Pinot Noir, the Bordeaux varieties MERLOT, CABERNET SAUVIGNON, CABERNET FRANC, and MALBEC are popular in southern Oregon and the Columbia River area. SYRAH and TEMPRANILLO (first produced as a VARIETAL wine in the Americas by Abacela) are also planted sporadically throughout the state, with a heavier concentration in the south. The Willamette Valley has a penchant for GAMAY, with the local Portland market celebrating both fruity NOUVEAU styles as well as more serious examples.

State of the industry

A typical Oregon winery is relatively small, with an annual production of 2,500–20,000 cases. Many use grapes bought from specialist growers in addition to own-grown fruit. ACIDIFICATION is necessary only in the hottest or wettest vintages; and although CHAPTALIZATION is allowed, wines with a natural ALCOHOLIC STRENGTH of at least 12% are easily achieved.

Oregon has the strictest labelling laws in the country, requiring producers who label their wines with the name of an AVA to use 95% fruit from that AVA (compared with the TTB requirement of 85%); wines labelled as Pinot Noir must contain 90% Pinot Noir (rather than the federal standard of 75%, which also applies to other Oregon varieties).

While Oregon's prices generally start well above both Washington and California's bottom tier, they do not reach the ridiculous heights of California's upper echelons. During the American recession following 11 September 2001, many wineries added a lower-priced Pinot Noir to their line-up. Independent NÉGOCIANTS have blossomed, with producers such as A to Z and Union Wine Company cleverly buying over-supplied BULK WINES and blending them into well-priced bargains. The turn of the century also saw the introduction of CO-OPERATIVE and CUSTOM-CRUSH FACILITIES such as The Carlton Winemaker's Studio and 12th & Maple Wine Co. In addition, many wineries rent out space in their own cellars for winemakers to produce their own labels. This has been a godsend for talented winemakers looking to launch a label without outside investment or hefty loans. S.C.-J.

organic matter, or soil organic matter (SOM), the CARBON-containing matter formed in SOIL as plant, animal, and microbial residues decompose. Carbon comprises 50–58% of SOM.

Normally most organic matter occurs in the top 10–20 cm/4–8 in of the soil, with some deeper as a result of deeply penetrating ROOTS and its redistribution by EARTHWORMS and other burrowing animals. On undisturbed soils, much of the store of readily available SOIL NUTRIENTS is associated with the surface layer and its organic matter, having been extracted from the SUBSOIL over millennia and deposited at the surface in plant litter and the excreta of grazing animals. This applies especially to the less soluble nutrients such as PHOSPHORUS and the mineral nutrients (except BORON), which do not appreciably leach down the profile except in very sandy soils. (See VINE NUTRITION.)

Fresh organic matter reflects the composition of the plant and animal materials from which it was formed. As decomposition proceeds, however, the easily decomposable compounds are assimilated by microorganisms with the release of carbon dioxide and the constituent mineral nutrients. Many of these are retained by the microorganisms, but some will be released (mineralized) to become available to plants. The end point of decomposition is a largely inert organic material called stabilized organic matter or, more colloquially, humus. Although humus has a carbon-to-nitrogen ratio between 10 and 15, which is favourable for NITROGEN mineralization, the production of mineral nitrogen is slow because of the inert nature of humus. Humus helps to give the soil a desirable crumb structure and friability (see SOIL STRUCTURE), which improves the soil's water-holding

capacity. Because of its negatively charged surfaces, humus adds to a soil's CATION EXCHANGE CAPACITY.

The total result in undisturbed soils (see NO-TILL) is a constant recycling of nutrients and their steady availability to plants. In well-managed viticulture, the aim is first to build up the amount of soil organic matter and associated MINERAL nutrients, then to maintain them at a level high enough to ensure SOIL HEALTH and a steady supply of nutrients to meet the needs of the vines. On initially infertile soils, this may necessitate a substantial use of FERTILIZERS or, in the case of ORGANIC VITICULTURE and BIODYNAMIC VITICULTURE, the use of plant materials and animal manures. It is also possible to achieve a build-up of soil organic matter through planting COVER CROPS, especially grass species, in the inter-rows. At all stages, the increase in, or maintenance of, soil organic matter demands that TILLAGE, if any, be kept to a minimum.

Viticulture for high-quality winemaking requires that soil organic matter content and fertility be just high enough to ensure a suitable BALANCE between fruiting and moderate vegetative growth. Fertile soils with high organic matter contents can cause excessive vegetative VIGOUR and poor CANOPY MICROCLIMATES. R.E.W.

White, R. E., *Understanding Vineyard Soils* (2nd edn, 2015).

organic viticulture, a system of grape-growing broadly defined as shunning industrially synthesized compounds such as FERTILIZERS, FUNGICIDES, HERBICIDES, and PESTICIDES, as well as anything that has been GENETICALLY MODIFIED. Organic viticulture is a prerequisite for the production of ORGANIC WINE. It contrasts with 'conventional', sometimes even called 'industrialized' or 'chemical' viticulture, in two main ways: by stressing management techniques such as CANOPY MANAGEMENT which seek to prevent rather than cure pests and diseases; and by using naturally occurring substances. The key organic management strategy for perennial crops such as vines, for which no crop rotation is possible, involves stimulating and

maintaining healthy populations of a diverse range of soil microorganisms.

The primary route to achieving this in organic vineyards is through the application of organic fertilizer in the form of COMPOST. Unlike soluble fertilizer, this improves the structure and biological properties of the soil, rather than directly feeding the vine itself, and allows the slow release of MINERAL nutrients, by encouraging what in organic-speak is called a 'soil food web' of living organisms such as EARTHWORMS, beneficial bacteria, protozoa, and fungi (see SOIL BIOTA). Synthetic soluble fertilizers provide nutrients but do not promote the intrinsic life in the soil. The principle of feeding the soil and not the plant also means that foliar feed fertilizers—those applied to the leaves of the vine—are prohibited under organic norms.

Growers who switch from conventional to organic soil and FERTILITY management claim that vine shoots need much less frequent TRIMMING as vine VIGOUR is reduced. This makes yields less erratic (organic growers claim to get lower annual YIELDS, but more regular yields overall compared with their conventional counterparts) and reduces the risk of attack by FUNGAL DISEASES. However, the second and especially third years of the three-year conversion period from conventional to organic (or biodynamic) management are critical. This period can produce uneconomically low yields and unsustainably high disease pressure, two not unrelated conditions arising because vines have been unable to begin accessing slow-release nutrients from the soil, its reserves of quick-release soluble fertilizers having been all but exhausted by then.

Therefore to make conversion to organics a success, would-be organic growers must adopt a prevention-rather-than-cure approach by putting in place mechanisms first to create and then to protect both the soil humus and soil microbiology without which vines and soil nutrients would be unable to interact.

This usually means a combination of compost and COVER CROPS. Compost creates the preconditions for soil humification, being rich both in microbiology and in the basic building block of life, CARBON

(organic winegrowers aim for finished compost with a carbon–nitrogen or C/N ratio of 15:1). Cover crops then protect this microbiologically rich resource from SOIL EROSION and nutrient leeching.

Humus-rich, cover-cropped soils are more likely to hold vital water and nutrients than impoverished ones, and to promote the growth of MYCORRHIZAL fungi on vine roots, organisms which allow vine roots to penetrate deeper into the soil and facilitate the uptake of micronutrients (see VINE NUTRITION), both of which are said by some to make wines taste more TERROIR-specific and thus more complex.

A small but increasing number of organic and biodynamic winegrowers (see BIODYNAMIC VITICULTURE) have moved to minimal or NO-TILL systems by which inter-rows are almost permanently covered by perennial sward (see COVER CROP). Such minimal tillage preserves topsoil structure; it also means that the vineyard becomes a beneficial carbon-sink rather than the cause of the release of carbon and dust into the atmosphere, both of which may contribute to CLIMATE CHANGE and, in the case of dust, encourage certain vine MITES. Perennial swards can also provide MULCH to prevent weed growth directly under the vines if the inter-row vegetation is cut using the so-called 'mow and throw' technique, in which the mowings are left on the ground.

For disease prevention, organic growers are reliant on naturally occurring substances. For instance, elemental SULFUR and the salt copper sulfate (see BORDEAUX MIXTURE) are used to control POWDERY MILDEW and DOWNY MILDEW respectively. Both these treatments and others commonly used in organic vineyards (e.g. soap, plant oils and teas, seaweed, and powders based on BENTONITE, silicates, milk, and wild herbs) are contact or barrier sprays which, unlike chemically produced systemic sprays, do not enter either the vine's sap or the grape pulp and so are less likely to produce RESIDUES in the wine. Organic growers, especially those in damp, humid climates, are often criticized for relying too heavily on copper-based treatments, leading to COPPER toxicity in the soil. Organic growers argue that copper

residues are more easily mobilized where organic management fosters increased levels of soil microbiology, and that organic norms significantly restrict the amount of copper used compared with the amount allowed in conventional vineyards. EU regulations for organic viticulture permit up to 28 kg/ha averaged over a seven-year period, compared with the 30 kg over a five-year period allowed in conventional viticulture. Furthermore, these restrictions have either encouraged organic growers, especially those in marginal European climates, to switch from VITIS VINIFERA to DISEASE-RESISTANT interspecific CROSSES; or have inspired organic growers in both northern and southern hemispheres to find genuinely SUSTAINABLE alternatives to copper and sulfur for mildew control. The most notable of these is aerated compost tea, a low-tech, low-cost, rain-fast way of colonizing vines with beneficial aerobic bacteria, fungi, and other microorganisms that inhibit, consume, or outcompete disease-bearing pathogens. Another increasingly relevant example of this type of approach is the application of strains of the *Trichoderma* fungus to either vine trunks or pruning wounds to protect vines from ESCA. See also BIOLOGICALS.

Other aspects of the organic prophylactic approach to farming in general, and to GREY ROT in particular, include employing canopy management techniques to open up the canopy and reduce the risk of rot. This can result in higher LABOUR costs compared with those of conventional farming. Organic growers who pass these costs on in the price of the wine argue that, from a holistic standpoint, organic viticulture eliminates costs to the wider community such as cleaning up by local authorities of groundwater polluted by anti-rot sprays—an ongoing, sensitive issue. Organic growers also argue that this predisposition towards manual labour provides employment opportunities in communities suffering rural depopulation due in part to increased MECHANIZATION; and that this may account for why organic vineyards in France are now more likely than their non-organic counterparts to be picked by hand, rather than by machine, and to be estate-bottled.

History

The origins of the organic agriculture movement are late 20th century European. Like its predecessors the Enlightenment, the Romantic movement, and Darwinism, organics can be seen as attempting to redefine people's relationship to their natural surroundings. By the end of the 1920s, when the green movement was closely intertwined with reactionary cultural and political phenomena such as National Socialism in Germany and Guild Socialism in Britain, organics had declared itself as opposing the industrialization of agriculture for both social and environmental reasons. Its main target was the mineral 'NPK' FERTILIZER devised in 1836 by Justus von Liebig and mass produced from 1913 using the Haber-Bosch process. These fertilizers transformed the agricultural landscape and economic and social structures. However, two World Wars, austerity, rural depopulation, rapidly rising metropolitan populations, and the ease with which NITROGEN production was switched post-1945 from making munitions to fertilizer meant the infant organic movement provided only a fringe argument against the inexorable industrialization of agriculture. And whereas industrial food conglomerates found GLOBALIZATION both necessary and desirable, organic activists struggled to form international bonds and hence risked accusations of parochialism. The formation in 1972 of the International Federation of Organic Agriculture Movements (IFOAM) to oversee the setting of the majority of the world's organic standards and the certification bodies has helped change this perception.

Nevertheless, although the first organic vineyards were established after the Second World War, it took until the late 1980s for wines produced from organically grown grapes to begin to shake off a reputation for earnest amateurism, inconsistency, and poor value. Critics argue that organic wine's now steadily increasing market share, which began to grow in Europe in the early 1990s, was mainly due to EU subsidies, initially to help growers survive the three-year organic conversion process but now provided to stimulate rural development and optimize the vineyard ECOSYSTEM. However, its

advocates see the main selling point for organics in wine as reinforcing the key notion of TERROIR. This 'working with rather than against nature' handily chimed with increased public unease at the effects of industrialized farming on our food rather than in our wine, notably in the UK, where the food scandals of the mid 1990s and early 2000s involving BSE and foot-and-mouth disease provoked widespread public debate. Concern about the perceived threat that GENETIC MODIFICATION might have on food and wine also stimulated greater interest in the alternatives.

More particularly, though, growers themselves began adopting organics in greater numbers because they felt it would preserve and enhance their main equity, terroir, while giving the wines an organoleptic and marketing edge. More effective vineyard machinery for the control of weeds and disease, improved communication regarding which organic techniques work best, and consumer demand have also contributed to the steady growth in organic viticulture worldwide.

Conford, P., *The Origins of the Organic Movement* (2001).

Organic certification and terminology

To be described as 'organic', a vineyard and/or its wine (see ORGANIC WINE) must have third-party certification, usually from a non-governmental organization or 'certifier' accredited by a ministry of agriculture or its equivalent and to criteria which are ISO 17065 compliant. This verifies that the certifier's standards conform to organic global baselines set by IFOAM (see above). Organic certification is granted after a three-year conversion period as wine grapes are a perennial crop (conversion takes two years for annuals such as cereals or carrots). Certification aims to protect both bona fide organic producers and consumers of organic products from anti-competitive activity or fraudulent claims. Certifiers can advise vineyard owners as to why their vineyard does not meet their standards but cannot provide advice on which organic sprays might be best in any particular situation. Agreements in 2012 between the US, Canada, and the EU mean that organic production and labelling finally enjoy a strong degree of transnational if not yet global equivalence (previously an organic French vineyard exporting to the US needed both EU and American certification documents). Winegrowers who impose on themselves stricter standards than those of the organic baseline may join private organic associations such as France's Nature et Progrès or Germany's Ecovin. These bodies require, for example, wider buffer zones between conventional and organic plots, allow fewer FINING agents, and require lower levels of free and total SULFUR DIOXIDE than those permitted for organic wine.

Organic viticulture worldwide

In 1999, 0.5–0.75% of the world vineyard was certified organic or biodynamic or in conversion, the majority of which comprised small, heritage organic estates prioritizing local rather than international markets. As more blue-chip estates in France, notably in the Loire, Alsace, and Burgundy, began converting to organics and biodynamics in the 1990s, conventional wine's potentially negative impact locally and on the wider environment started to be questioned. In California, organic/biodynamic pioneer Jimmy Fetzer's creation of a Mediterranean-style vine garden melding winegrowing with vegetables, olives, fruit, and both fluffy and feathered livestock helped redefine organic wine as a colourfully positive lifestyle choice, finally providing the movement with sex appeal to go with its gravitas.

Organic viticulture's share of the global vineyard (mostly but not exclusively grown for wine) went from under 2% to 6.1% between 2007 and 2018, of which 87% was in Europe. France's organic vineyard area (including the area under conversion) increased fourfold between 2007 and 2018 to 94,000 ha/232,279 acres. Austria's position as one of the world's winegrowing nations with the highest proportion of organic vineyards (15.3% in 2021) is due in large part to its pre-emptive investment in educating potential consumers about organics, thereby creating a ready market for organic food and wine. South Africa's organic vineyard area has been increasing significantly, more than tripling between 2016 and 2017 and growing by 63% in 2018. In 2015 organic vineyards accounted for 3% of global wine production, and the biggest producer of organic wine in 2018 was Italy. According to Agence Bio, global consumption of organic still wines exceeded 5 million hl/132 million gal in 2017, having increased by nearly 50% since 2012, representing 2.75% of global wine consumption, with Germany enjoying almost one-quarter of that total.

OIV Focus, *The World Organic Vineyard* (2021).

organic wine, wine made from grapes produced by ORGANIC VITICULTURE and processed (fermented) according to standards for organic winemaking, which, despite increasing harmonization, still vary from country to country, notably regarding the use of SULFUR DIOXIDE. Until 2011 wine produced or sold in the EU from organic grapes had to be labelled 'wine from organically grown grapes'. However, in 2012 new EU rules created the term 'organic wine', referring to that made from organic grapes, giving preference 'to the use of ADDITIVES and PROCESSING AIDS derived from organically farmed raw materials' if they are available, and with restrictions on some oenological practices, including lower maximum levels for added sulfur dioxide: around 15–30% lower than for conventional wines, depending on wine colour, sweetness, and style (for example 100 g/l for red wines and 150 g/l for dry white and rosé wines).

In the US, in contrast, the term 'organic wine', as defined in the National Organic Program (NOP), refers to wine made from organic grapes but with no added sulfites, while 'made with organic grapes' applies to similarly grown wines containing up to 100 mg/l of added sulfites. In Canada, an 'organic wine' must conform to the requirments of the Canadian Organic Regime, for both grape-growing and winemaking: grapes must be certified organic, additives are regulated, and the level of SO_2 depends on the amount of RESIDUAL SUGAR (RS) in the wine (e.g. up to 30 mg/l free SO_2 for wines with less than 50 g/l RS). In both the US and Canada, any other agricultural ingredients that go into organic wine—yeast or yeast nutrients, for example—must be organic if they are available. Paradoxically, all European wines from organic grapes sold in the US must be labelled 'made with organic grapes' rather than 'organic wine', even if they contain no added sulfites because EU rules permit

sulfite addition in wines labelled as 'organic wine'. Canada and the EU, however, recognize each other's organic production rules.

Organic winemaking standards worldwide generally permit most other winemaking treatments, including, for example, adding DIAMMONIUM PHOSPHATE as a yeast nutrient (not permitted under the more restrictive NOP) and REVERSE OSMOSIS, because these have also been allowed for organic food (several such processes are pending review in the EU but are allowed because of 'lack of viable alternatives'). Although PVPP and potassium ferrocyanide (see BLUE FINING) are universally proscribed FINING agents for organic wine, most other fining agents are allowed, so that wines labelled in some way as organic may be unsuitable for vegetarians and vegans. (It is a common misconception that organic also equals vegetarian- or vegan-friendly.) Energy-intensive treatments (such as CONCENTRATION, THERMOVINIFICATION, and PASTEURIZATION) are allowed by general organic standards, although members of organic wine producer groups such as Nature et Progrès in France voluntarily agree to shun them. Where possible, naturally derived additives, agents, and aids such as sugar for CHAPTALIZATION, yeast hulls to feed ferments, and egg whites for FINING should be from organic sources. Grape spirit used in organic fortified wines must have been distilled from certified organic grapes/marc/wine.

Organic wines made in the EU must carry the EU organic logo (stars in the shape of a leaf) and the code number of their certifying body. M.W.

Regulation (EU) 203/2012 of the European Parliament and of the Council.

USDA, *Organic 101: Organic Wine* (2017).

origins of viniculture. The beginning of viniculture, encompassing both VITICULTURE and WINEMAKING, cannot have begun

where our species, *Homo sapiens sapiens*, originated in sub-Saharan Africa. While our ancestors might have exploited other high-sugar fruits (e.g. fig and marula) for fermented beverages, the wild Eurasian grapevine (*Vitis vinifera sylvestris*; see WILD VINES) did not grow there. Only when humans came 'out of Africa', 60,000–100,000 years ago, did they encounter the grape. This occurrence, so auspicious for the future cultural and technological history of humanity, probably took place in the area of modern Lebanon, the southernmost point where wild vines grow in the Near East today and probably for the last 100,000 years.

No archaeological evidence of this initial encounter nor of the first wine exists for the Palaeolithic period. Containers which could be chemically analysed have not survived since they were made of perishable materials such as leather or wood. Yet the centrality of FERMENTATION to life on Earth as well as the physiological propensities (sensory, dietary, and mind-altering) of most animals for consuming alcohol imply that humans would soon have discovered how to make wine from wild grapes.

Grapevines that festooned the forests of coastal and mountainous Lebanon would probably have captivated our ancestors, and the colourful fruit, even if it were sour, would almost certainly have been gathered up for food and made into the 'first wine', whether accidentally or by applying traditional African methods. We might imagine the following, according to the 'Palaeolithic Hypothesis' or 'Drunken Monkey Hypothesis': fruit was piled into a primitive container, juice was exuded from grapes near the bottom of the container under the weight of fruit above and, depending on its ripeness, fermentation of this liquid (the ideal, nutritious medium) would be initiated by YEAST on the skins of some of the grapes in a warm climate in several days. Reaching the bottom of the container, our ancestors would have been amazed by the aromatic and mildly intoxicating beverage that was produced. More intentional squeezings and tastings might well have ensued. You had to drink it quickly, since methods for preserving wine were likely poorly developed.

It is also possible that observation led to the discovery of LAYERING, in which some vine woody parts, including STEMS and CANES, would have formed roots when growing along the ground. Once the new vine had sprung up, it might have been trained to grow up a nearby tree or even an artificial support.

A detailed knowledge of PRUNING and VINE TRAINING would have come later, at least by *c.*3000 BCE. By severing a rooted vine part from the parent plant, it could have been transplanted. Controlling the vine's height and shape would have enabled easier care and harvesting. Whoever did this was the world's first vine-grower, and this would have been the world's first vineyard.

For larger-scale, more organized viniculture, we must cast a wider net than the Levant, to include the vast upland region of the eastern Taurus, Caucasus, and Zagros Mountains of north-western Iran. These areas comprise a sort of world centre of the Eurasian grapevine, where its greatest genetic diversity is found and where a wine culture consolidated itself in the Neolithic period, *c.*9500–5000 BCE.

Oldest grape wines

To date, the earliest chemically attested instance of grapes being used in a fermented beverage is at the Neolithic site of Jiahu in the Yellow River in the central plains of ancient China during the seventh millennium BCE. Yet the probable native wild grape was only one of several other fermentable ingredients in this mixed beverage. (With upwards of 30 native wild vine species, China accounts for more than half of the vine species in the world, some of which produce berries containing as much as 19% sugar by weight. No evidence, however, has yet been found to show that any of these species were ever domesticated until recent times.)

For an alcoholic beverage fermented solely from the Eurasian grape, the earliest chemical evidence for grape wine comes from early Neolithic villages of the Shulaveri-Shomutepe culture in present-day Georgia in the South Caucasus region, *c.*6,000–5,800 BCE. This finding is based on the presence of TARTARIC ACID, which is found in large amounts in the Middle East only in grapes, and other scientific evidence (archaeological, archaeobotanical, climatic, etc.).

Previously, the earliest known wine came from another early Neolithic village in the northern Zagros Mountains of Iran: Hajji Firuz Tepe, *c.*5400–5000 BCE. Six jars in a kitchen of an average household would originally have held some 55 l (15 gal) of wine. The intended product was most likely wine and not vinegar or another grape product, because clay stoppers were used to plug the narrow mouths of the jars and a tree resin, probably terebinth with antioxidant properties, was added to the wine as a preservative. Hajji Firuz was among the first year-round settlements based on newly domesticated plants and animals of the Neolithic period. The Eurasian VITIS VINIFERA grapevine might well have been one of those domesticates. The invention of pottery around 6000 BCE gave impetus to the process, since special vessels for preparing, storing, and serving wine could now be made.

The large amount of wine for a single household implies that the Eurasian grape had already been domesticated at Hajji Firuz. In contrast to the wild dioecious plant (with separate male and female vines), the domesticated vine is hermaphroditic (with male stamen and female pistil on flowers of the same plant). It produces much more fruit, since it is not dependent on insects or wind for pollination.

For the vine to have been domesticated, either the sub-macroscopic sexual organs of a hermaphrodite need to be observed (quite unlikely since hermaphrodites comprise only about 6% of the wild population) or, more probably, the would-be Neolithic viniculturalist noted that some vines yielded more fruit than others and proceeded to CLONE them by layering. Transplantation by CUTTINGS, roots, or buds was eventually discovered. Plants could also be selected for special characteristics (e.g. juicier and tastier fruit, different sizes and colour, fewer seeds, etc.) and moved to another place. Cloning could not have been done with the seeds of a desirable plant because they are genetically different to the parent plant. The magnitude of the accomplishment in domesticating *vinifera* vines can be appreciated by considering that of the many other grape species around the world, no evidence yet exists that any of them were domesticated by ancient humans. That distinction belongs solely to the Eurasian grapevine, which produces 99% of the world's wine today.

The Noah Hypothesis

But how early and where was the Eurasian grapevine domesticated? Was it in the South Caucasus or in the northern Zagros Mountains—both areas where the wild vine still grows today—or elsewhere in the Near East? Recent DNA PROFILING of modern wild grape and domesticated VINE VARIETIES in Europe and the Near East (including Türkiye, Armenia, and Georgia but not yet Lebanon or Iran) points to a single Near Eastern domestication event (the so-called NOAH Hypothesis). Specifically, a very close relationship has been shown between wild and domesticated vines from eastern Türkiye and Georgia and important western European cultivars, including Pinot Noir, Nebbiolo, Syrah, and Chasselas. Since the European *Vitis vinifera sylvestris* was far removed from these cultivars, it cannot fully account for their origin.

As the domesticated grapevine was transplanted southwards to Egypt and Shiraz (see PERSIA) and westwards across the Mediterranean and the continent, there was introgression with wild vines in those areas such as Greece, Italy, France, and Spain to yield many more Middle Eastern and European varieties. At a later time, when the grapevine was better understood, independent domestication events may have taken place where the wild grapevine grew—in Spain, for example.

The Noah Hypothesis is plausible for other reasons. Exploitation of wild grapes had been going on since the Natufian period (*c.*11,000–10,000 BCE), as evidenced by the finding of pips at numerous sites along the middle Euphrates in Syria. Several hundred kilometres upstream in the Taurus Mountains of Türkiye, Çayönü on the upper Tigris has yielded wild grape seeds dating back to around 9000 BCE, and many other sites in the region have yielded similar evidence ranging in date as recently as the late Chalcolithic period, *c.*3500 BCE.

To date, only wild Eurasian grape pips, which are generally shorter and broader than their domesticated counterparts (although Pinot is an exception), are reported from the Neolithic sites of the Shulaveri-

Shomutepe culture. Once DNA PROFILING methods for extracting and testing ancient grapes have been developed, the wild/domesticated gene can be used to verify the equivocal botanical criteria.

Shulaveris-Gora and nearby Neolithic sites are also notable for having some of the earliest Near Eastern pottery decorated with motifs which may well be grape clusters and vines; these may have served as fermentation and drinking vessels. Chemical analyses were under way in early 2014. Since the later archaeology and history of Georgia was dominated by a wine culture intertwining almost every aspect of life—from everyday meals to special celebrations, religious rites, and the economy as a whole—it may be reasonably hypothesized that the newfound horticultural and technological advances of the Neolithic period laid the basis for what followed and for what continues today.

Recent explorations in the eastern Taurus Mountains are revealing equally extraordinary developments in the Neolithic period there, going back to 9500 BCE. At Göbekli Tepe and Nevali Çori, not far from Çayönü, 'sanctuaries' of three-dimensional monoliths with vivid, realistic portrayals of carved animals, humans, and symbolic motifs were constructed. Pottery had not yet made its appearance, but stone goblets and bowls were made of the highly absorbent clay mineral chlorite, found at many other sites along the upper Tigris extending into Syria. Celebratory scenes are again depicted, possibly fuelled by a fermented beverage. Wine again appears to be a distinct possibility, according to ongoing chemical analyses of copious amounts of ancient organic compounds extracted from the vessels using solvents. But wheat/barley beer cannot be ruled out, since einkorn wheat, one of the Neolithic founder plants, has been traced by DNA to the south-eastern Taurus. A more complex fermented beverage of wine, beer, honey, and other botanicals, underlining the experimental prowess of our Neolithic ancestors, is also possible.

Another startling discovery was announced in 2011 from a cave at Areni in Armenia. In this mountainous area, humans constructed plaster floors for grape PRESSES designed to run the grape juice into underground jars, which constitute the earliest *karas* (in Armenian) or

QVEVRI (in Georgian). Grape seeds in the vicinity suggested that the contents of the vessels were wine, and chemical analysis confirmed this. A contemporaneous cemetery within the cave suggests that the wine was used in burial services for the ancestors. This finding bridges the gap from winemaking during the Neolithic period to the recent discovery of a probable wine cellar at Tel Kabri in the Galilee, *c.*1700 BCE, and the enormous Urartian wine cellars of *c.*800–600 BCE, some 2,500 years later. The large-scale production at Areni points to a long gestation period after pottery was invented and large jars for fermentation were developed. But if Areni comes at the end of a long development, we are still left with the question, according to the Noah Hypothesis: where was *Vitis vinifera* first domesticated and wine first made?

Recent DNA analyses of modern wild and domesticated grapevines even suggest that the plant was already domesticated in the Levant as early as *c.*9000 BCE, immediately following the Ice Age during the early Neolithic period. One might question this hypothesis, however, given that Lebanon, as well as large areas of the Middle East, is not represented in the study. It is also doubtful that early Holocene hunter-gatherers would have had the necessary horticultural expertise to transplant and nurture a grapevine until it bore fruit after some 5?7 years. Utilizing, even cultivating, wild grapes for food and drink is one thing, but actually domesticating the Eurasian grapevine is much more difficult. Moreover, dating solely by genetic criteria is problematic. Corroborative archaeological, archaeobotanical, and/or chemical evidence is needed to sustain this hypothesis.

Levantine influence spreads south and west

We do know that viniculture ultimately radiated out from the mountainous Near East to other areas on the western and eastern arms of the Fertile Crescent. It had reached CANAAN by *c.*3500 BCE, to judge from grape seeds, wood, and even whole dried grapes (raisins) recovered from sites in the Jordan Valley. In MESOPOTAMIA, transplantation of the vine and winemaking followed the spine of the Zagros Mountains and had arrived in Shiraz in south-western Iran by at least 2500 BCE.

The southern Levantine industry had matured to such a degree that the tomb of Scorpion I (*c.*3150 BCE), one of the first rulers of a united Egypt, at Abydos was stocked with 4,500 l of wine imported from southern Canaan. The wine was laced with terebinth tree resin, to which fresh fruit (grapes and figs) and various Levantine herbs such as thyme and savory had been added. The grapes might also have been added as raisins. It was essentially a medicinal powerhouse, and the well-documented Egyptian pharmacopoeia of later times clearly drew inspiration, as well as the botanicals themselves, from the Canaanite world. Only the best beverage could serve to usher a pharaoh into the afterlife.

Once the kings and upper classes had been enticed by wine, the next logical step was to transfer viniculture to Egypt itself, so as to tailor the wines to individual tastes and exercise more control. Beginning around 3000 BCE, the Egyptian pharaohs financed the establishment of a royal wine industry in the Nile Delta.

The new Egyptian industry was striking in its level of sophistication from the outset. Of course, the Canaanite specialists had many millennia of tradition behind them when they brought grapevines to the Nile Delta. Even the Egyptian hieroglyph meaning ‘grape’, ‘vineyard’ or ‘wine’ is a telling piece of evidence of viticultural expertise. As the earliest written character referring to the domesticated grapevine and wine from anywhere in the world, the hieroglyph graphically depicts a well-trained vine growing up on to a trellis of vertical poles, forked at their upper ends to hold the vine.

The plant is rooted in a container, probably for ease of watering. In short, the best practices of modern vineyard management, including a drip irrigation system, were on display at the inception of the ancient Egyptian industry.

The Canaanite winemakers also had to be creative. Levantine vineyards, generally in hilly terrain with good drainage for winter rains, had a very different TERROIR than the flat, alluvial Nile Delta, where blistering summer heat and much less precipitation meant that crops, especially water-sensitive grapes, had to be irrigated. A trellising system minimized direct exposure of the grapes to intense sunlight. Fortunately the alluvial deposits of the delta, washed down from the upper Nile during the annual flooding, had produced well-drained and fertile soils.

Wine, which was specifically referred to by where it came from in the delta (the ancient equivalent of today's vineyard-specific wines), had achieved canonical status as an essential funerary offering by Dynasty 6, around 2200 BCE. In time, nearly every major religious festival, including the all-important *heb-sed* to guarantee the continued welfare of the pharaoh and the fruitfulness of the land, called for wine offerings and prolific drinking, often lasting for weeks.

With winemaking success in Egypt behind them, the Canaanites ventured further throughout the Mediterranean on their Byblos ships (the telling Egyptian term for a sea-going vessel) made of Cedar of Lebanon. They applied a similar formula wherever they went: import wine and other luxury goods, entice the rulers with wine culture by presenting them with speciality wine sets, and then wait until they were asked to help establish native industries, including viniculture, by transplanting the domesticated Eurasian grapevine.

According to the biomolecular and archaeobotanical evidence, one of the first stops in the island-hopping jaunts of the Canaanites across the Mediterranean was CRETE. Nearly 1,000 kilometres from the port city states of Lebanon and southern Syria, this large island lies on the threshold of the larger Greek world. Although modern scholars are understandably sceptical about the often-contradictory and fantastic tales of classical writers, a recurring theme in many

accounts has the Greek wine god DIONYSUS voyaging from PHOENICIA to Crete as a daring seafarer. One beautifully painted drinking-cup (*kylix*) made by the master potter Exekias in the 6th century BCE shows the god single-handedly manning a small sailing boat, its mast festooned with a luxuriant grapevine. Apparently, having been attacked by pirates, Dionysus fought back by miraculously growing the vine and dousing his attackers with wine; they were transformed into frolicking dolphins, who are seen circling around the boat. Could this tale be inspired by an actual voyage that carried the domesticated grapevine to Crete aboard a Byblos ship?

The earliest wine so far identified on Crete was from the late third millennium BCE farming community of Myrtos-Phournou Koryphe, along the southern coast. Numerous large jars (*pithoi*) holding about 90 l were recovered from storerooms and kitchens of ordinary houses throughout the site. The pottery was locally produced, as was presumably the wine. Grape seeds, stems, and skins in some jars suggested fermentation on the lees, minimal filtration, and/or adding fresh grapes for flavour.

Numerous circular vats, often called 'bathtubs', were also found at Myrtos. Such finds, also well attested in ancient Egypt, are most often associated with industrial winemaking. The bathtubs, fitted with spouts for draining the grape juice into large jars, were ideal for FOOT TREADING. As one worker tired, the next would step into the vat and take over. Large-scale production was also marked by a massive funnel, the stock-in-trade of the Near Eastern winemaker, and impressions of grape leaves on the pottery pointed to vineyards in the vicinity.

Much like the royal winemaking industry in Egypt, the Myrtos enterprise appears to have sprung out of nowhere. Did the impetus to make wine at Myrtos come from elsewhere in Greece, or was it brought to this island by the Canaanites? The latter position is better supported. Myrtos lay at the terminus of a well-travelled maritime route for ships coming from Egypt and the Levant, and the distinctly Near Eastern character of its winemaking industry suggests influence from this quarter. The Canaanites were looking to spread their wine

culture, and they saw an opportunity in Greece to work with the local Cretan people to advance their interests.

Greek winemaking's debt to the Canaanites, as well as to their Egyptian trading partners, is also reflected in the later signs for 'grape', 'vineyard', and 'wine' in the earliest Greek scripts, including Cretan Hieroglyphic and Linear A. The characters are unquestionably derived from the Egyptian hieroglyph, which shows a well-trained vine growing on a horizontal trellis.

It is also possible that winemaking penetrated Greece from the north, especially from Macedonia, where masses of grape skins and seeds, probably from pressings, have been recovered from Dikili Tash dating to the late fifth millennium BCE, or perhaps came from western Anatolia via the Aegean Islands, where domesticated grape remains and leaf impressions on pottery have been found. A notable finding of domesticated grape pips inside a *pithos* was made at Aghios Kosmas in Attica. The large jar had a hole near its base, just like the Myrtos vessels. This is *prima facie* evidence that winemaking, perhaps along the same scale as that at Myrtos, was known on the mainland at about the same time.

The Canaanites, who became the Phoenicians of the Iron Age, did not stop at Crete. They sailed on to CARTHAGE in Tunisia and other parts of the western Mediterranean. The founders of Carthage, probably in the late 9th century BCE, entered a territory only sparsely occupied by Berber pastoral nomads, who offered little resistance. Unlike more populous regions of the Mediterranean, it allowed the Phoenicians to play the role of true colonialists by forgoing trade agreements and building a settlement completely to their specifications. As Carthage grew in the following centuries, it became the capital of the Punic empire and the breadbasket of the Roman Empire. Its ships plied the waters from Carthage through the Tyrrhenian Sea to the port of ROME at Ostia. Long lines of AMPHORAE spread out on the sea floor at a depth of as much as l,000 m, representing the cargo lost by foundering ships, mark the approximately 600-km/373-mile route, notably at Skerki Bank about 80 km north-west of SICILY.

Wine was naturally the beverage of choice in Carthage. One of the first AGRICULTURAL TREATISES on viniculture and other forms of agriculture was composed by a 3rd–2nd-century BCE Carthaginian named Mago, who is quoted extensively in later Roman writings (VARRO, COLUMELLA, and PLINY the Elder). Presumably he drew on Phoenician traditions dating from the founding of the colony. To date, however, pips from the 4th century BCE are the earliest excavated evidence for the domesticated grape at Carthage.

Although the wild vine grows in Tunisia, special precautions had to be taken to assure survival of the domesticated grapevine in such a hot climate. Mago advised on how to aerate the soil and plant vineyards (e.g. on north slopes to take advantage of rainfall coming from the Mediterranean) to compensate for the low rainfall. His recipe for raisin-wine involved picking the grapes at peak ripeness, rejecting damaged berries, drying the grapes on reed platforms in the sun for several days (taking care to cover them at night, so that they were not dampened by the dew), resaturating the raisins with fresh juice, and then treading the grapes. A second batch was prepared in the same way, and then the two lots were combined and fermented for about a month, finally being strained into vessels with leather covers. The end result must have been a delicious, luscious elixir, also referred to in the earlier Anatolian texts of HOMER and HESIOD, much like a Tuscan VIN SANTO or Moscato di PANTELLERIA.

The huge Phoenician and Carthaginian shipments of wine, along with other luxury items, conveyed a new, wine-based way of life which gradually permeated the societies, religions, and economies of those they came in contact with. In the wake of the Phoenicians, native fermented beverages, including beers, and mixed fermented beverages of all kinds (‘grogs’) were marginalized, modified, and displaced.

Wine culture invades Greece, then Italy, then France

Greece, which became a pre-eminent wine culture, was won over from its native 'Greek grog', made from Pramnian wine, honey, and barley, topped with cheese—the so-called *kykeon* of the Homeric epics. Even after the Greeks had become seafaring merchants in their own right and had begun vying with Phoenicia for control of the Mediterranean, their lasting debt to eastern Mediterranean wine culture was demonstrated by their adoption of the Phoenician alphabet, which became the basis of our modern Western and Arabic scripts. The earliest archaic Greek inscription was incised on a wine jug (*oinochoe*) in the 8th century BCE and reads: 'Whoever of all dancers performs most nimbly will win this *oinochoe* as prize.' Later in the same century, a Rhodian wine cup (*kotyle*) from the tomb of a young boy at Pithekoussai, an early Greek colony established on the island of ISCHIA in the Bay of Naples, states in elegant dactylic hexameter poetry, the language of the Homeric epics, that 'Nestor's cup was good to drink from, but anyone who drinks from this cup will soon be struck with desire for fair-crowned Aphrodite.' The Dionysiac interweaving of wine, women, and dance, inspired by Canaanite and Phoenician wine culture, is striking.

During the early first millennium BCE, the Phoenicians ventured ever further into the western Mediterranean, where they founded more bases and colonies along the north coast of Africa, on strategic islands (MALTA, CORSICA, Motya in western SICILY, Lipari, Ibiza, etc.), and along the Spanish coast, even out into the Atlantic at Huelva, near Cádiz.

Greek traders followed suit, establishing colonies on many of the same islands (e.g. eastern Sicily and Corsica), southern Italy (OENOTRIA), northern Africa (e.g. Cyrene), and at Massalia (modern Marseilles) in southern Mediterranean France.

Numerous Iron Age shipwrecks, loaded with amphorae and wine-related paraphernalia, have been located and excavated along the Italian and French coasts. The Phoenician and Greek impact

throughout the Mediterranean was so pronounced that one can say that it was mediated by wine culture itself.

The 8th century BCE saw the climax of Phoenician influence on the hearts, minds, and palates of native Mediterranean peoples. The ETRUSCANS of central Italy along the Tyrrhenian Sea illustrates the phenomenon and how it spread. They probably first came in contact with the Phoenicians before the Greeks arrived on their shores, as shown by their 'Orientalizing' industries, which closely reflected Phoenician style, technology, and iconography in metals, pottery, ivory, and glass. Their amphora was modelled after the Phoenician amphora, and where a similarity of form exists, it was likely because it served a similar function: primarily to hold grape wine, which soon began to be supplied by a nascent local industry.

As in other parts of Europe, the Etruscans already had a tradition of making a mixed fermented beverage before the Phoenicians had an impact on their culture. According to the available evidence, this 'grog' probably combined honey, barley, and wheat, even pomegranates, hazelnuts, herbs such as rosemary and thyme, tree resins, wild grapes, and so on. The Phoenician traders lured them into a wine culture by presenting them with cauldrons, kraters (see CRATER), and other drinking vessels. The Etruscans probably first adapted the vessels to their native customs and mixed beverages, similarly to the CELTS further north. After they had adopted the wine culture, they made their own wine vessels in pottery and precious metals, including Phoenician-type gilded drinking bowls.

In turn, the Etruscans became the principal conveyors of wine culture to coastal Mediterranean France by *c.*625–600 BCE. It is not surprising that the GAULS or Celts there should have become equally entranced by the cultural and economic possibilities for wine and began to substitute it for their native beverages.

The Gauls might have had a general knowledge of the Eurasian vine, which grew wild along the northern Mediterranean shore, but any successful exploitation of the domesticated vine to make wine would have required much more horticultural knowledge and technological proficiency, probably provided by the Etruscans. The

domesticated grapevine needed to be transplanted and tended. Specialized equipment was needed to transform it into wine, which was preserved by a tree resin additive to stoppered vessels.

Plantings of the domesticated Eurasian grapevine in France were probably transported on Etruscan ships. A Punic shipwreck off the coast of Mallorca at El Sec, dated to the 4th century BCE, illustrates how this might have been accomplished: grapevines were embedded in soil in the ship's cool hull; this would have enabled them to travel safely enough to be replanted.

This supposition has now been corroborated by archaeological, chemical, and botanical findings at the heavily Etruscan-influenced site of Lattes (ancient Lattara), near Montpellier, where numerous Etruscan wine amphorae were imported in the 6th century BCE and stored in harbour storehouses. As analyses have shown, the wine was resinated with pine and laced with botanicals (rosemary, thyme, and/or basil). A century later, local winemaking had begun at the site, as shown by the finding of masses of grape seeds, pedicels, and even fruit (grape skins), commonly associated with treading activity, and what is so far the earliest wine press yet discovered in France.

The Etruscan role in the process was further revealed by a shipwreck (Grand Ribaud F), found just off Hyères east of Marseilles and dated *c.*515–475 BCE. Its hold was filled with grapevines and some 700 to 800 amphorae. All the Etruscan amphorae on board this ship had been carefully stoppered with cork (among the earliest evidence for this technology, and also attested at Lattara) and stacked at least five layers deep in the hull. Significantly, they are of the same pottery type as, and are contemporaneous with, the Etruscan amphorae at Lattara. The ship's final destination may have been Lattara.

The wine culture of Mediterranean France spread inland after the Roman conquest up the Rhône and Rhine rivers to the rest of Europe, where, centuries later, monasteries such as the Cistercian Abbey of Vougeot in Burgundy refined French viniculture so that it became a model for the world. It needs to be stressed, however, that France owes a debt of gratitude to earlier Levantine viniculture.

Orion, complex, OPTIMA × VILLARD Blanc HYBRID bred at Geilweilerhof in Germany in 1964. This partially DISEASE-RESISTANT VARIETY produces crisp, aromatic white wine, notably in Europe's northernmost wine

regions, including England and Denmark. More recent selections such as Calardis Blanc are showing even greater promise. See JULIUS-KÜHN INSTITUT.

Orléans , AOC created in 2006 for wines produced around the city of Orléans where the river Loire turns west. Burgundian influence is evident in the choice of grape varieties, principally Chardonnay and Pinot Meunier. At one time this was an important wine region, but the development of the RAILWAYS changed all that, and today fewer than 100 ha/250 acres of vineyards remain. Only 80 km/50 miles south of Paris, the region's light, pale, fragrant wines have many devotees in the French capital. Orléans-Cléry is an even smaller AOC zone south-west of the city on the left bank of the Loire for Cabernet Franc-based reds.

Ormeasco, local name for DOLCETTO on the north-western coast of Italy. For more details, see LIGURIA.

Ortega, a CROSS of MÜLLER-THURGAU and SIEGERREBE that was once popular as an OECHSLE booster in German wines, especially with the blenders of Rheinhessen. It produces extremely full-flavoured wines that often lack ACIDITY but can reach high MUST WEIGHTS, if not quite as high as the equally early-ripening but dwindling OPTIMA. VARIETAL wines are made, but a little goes a long way, and the vine is susceptible to COULURE and ROT. Germany's total plantings dropped from around 1,200 ha/2,960 acres in the late 1980s to 395 ha in 2020. The variety is also planted to a very limited extent in England, British Columbia, and Sweden.

Ortrugo, white grape grown on 709 ha/1,752 acres in the hills around Piacenza in Emilia, often blended with MALVASIA. Ortrugo dei

Colli Piacentini is the DOC for white and sparkling wines made from this grape variety (minimum 90%) in EMILIA-ROMAGNA.

Orvieto , white wine produced near the medieval hill city of the same name, an important artistic centre during the late Middle Ages and Renaissance, is one of Italy's historically renowned white wines and by far the most important DOC in UMBRIA. Within the extensive DOC, partially shared with neighbouring LAZIO, is a historic CLASSICO zone. The vines are grown on TUFA, and wines come in dry (*secco*), medium dry (*abboccato*), medium sweet (*amabile*), LATE HARVEST (*vendemmia tardiva*), and BOTRYTIZED (*muffa nobile*) sweet versions, though the sweet wines are increasingly rare. Owing to the proximity of Lakes Corbara and Bolsano, as well as frequent autumn fogs, Orvieto is one of the very few places in Italy regularly affected by NOBLE ROT. The wine is a blend of Procanico, a local name for TREBBIANO Toscano, and the much more characterful GRECHETTO, VERDELLO, MALVASIA Bianca, and tart DRUPEGGIO. Although Orvieto's reputation was harmed by over-produced wines based on Procanico, today the production rules require a higher proportion of Grechetto than Procanico, and several producers have begun to bottle VARIETAL Grechetto, usefully demonstrating the grape's potential. While yields of up to 11 tonnes/ha are allowed, the actual average yield hovers around a much more reasonable 60 hl/ha, indicating a trend towards quality. Notably, completely dry Orvieto, without any RESIDUAL SUGAR, is rare, a concession to a supposed market taste.

Faced with declining sales and low prices for Orvieto, in 1998 the local CONSORZIO created a red wine DOC Orvietano Rosso based on ALEATICO, Cabernet Sauvignon, and Merlot, as well as MONTEPULCIANO, SANGIOVESE, CILIEGIOLO, and Pinot Noir, blended or as single varieties. Although considerable investments as early as the late 1970s were made in the region, notably by the likes of ANTINORI with its Castello della Sala estate, and a regular influx of consultant OENOLOGISTS, the focus tended to be on INTERNATIONAL VARIETIES and BARRIQUES. More

distinctive expressions are expected as local varieties are re-evaluated, but progress has been exceedingly slow. W.S.

Oseleta, revived red wine grape speciality of VALPOLICELLA, Italy.

Osey, variously spelt Oseye and Osaye, FORTIFIED WINE from PORTUGAL drunk in England in the 15th century, thought likely to have originated from vineyards near Lisbon, the name being an English corruption of the locality of Azóia north-west of Lisbon. See also CARCAVELOS and SETÚBAL. R.J.M.

Mayson, R., *The Wines of Portugal* (2020).

osmosis. See CONCENTRATION and REVERSE OSMOSIS.

OTR. See OXYGEN TRANSMISSION RATE.

Ottavianello, Puglian name for the French red grape variety CINSAUT.

ouillage, French word meaning both ULLAGE and TOPPING UP. The term ouillé is used in the JURA to differentiate white wines made this way from those that are aged OXIDATIVELY or under FILM-FORMING YEASTS.

ovary, the ovule-containing part of the pistil of a FLOWER which, in the grapevine, develops into the grape berry. After FLOWERING, the ovary becomes a berry and the ovules become seeds (see GRAPE).

B.G.C.

overcropping, a vine condition which delays grape RIPENING and therefore reduces wine quality. It is associated with low LEAF TO FRUIT RATIOS. Overcropping can be due to PRUNING to many buds with some fruitful varieties or to a loss of leaf area as a result of INSECT PESTS or FUNGAL DISEASES. If climatic conditions are limiting for PHOTOSYNTHESIS, as with low temperatures or very limited SUNLIGHT, then vines may be considered overcropped. The grapes of overcropped vines are typically lower in sugar, colour, and flavour and have an increased PH. Wines made from such fruit are typically described as thin or dilute. Overcropping can be overcome by CROP THINNING.

The term 'overcropping' is also used emotively in arguments against high vineyard yields. Provided that the vine is in BALANCE and good health, even high yields can be properly ripened with good weather and good vineyard management. See also YIELD. R.E.S.

overripeness, a usually undesirable stage in grape maturity whereby grapes start to shrivel (see BERRY SHRIVEL) and acid levels fall to a dangerously low level. Grapes at this stage are sometimes described as exhibiting 'dead fruit' flavours. It may well be the result of extended HANG TIME, once fashionable in CALIFORNIA, for example.

o.w.c. stands for 'original wooden case' and is frequently used as a description in the sale of FINE WINE. See CASE.

own-rooted vine. See UNGRAFTED VINE.

oxidation, the opposite of REDUCTION, is the chemical reaction in which a chemical compound loses electrons. Although controlled and moderate oxidation can be beneficial and is essential for some wine styles (see below), the term usually refers to a wine FAULT resulting

from excessive exposure to OXYGEN (as opposed to AERATION, which is deliberate, controlled exposure to oxygen). Wines spoiled by oxidation are said to be oxidized. See also OXIDATIVE WINEMAKING.

Oxidation is a threat as soon as the grape is crushed, which is why high-quality grapes are transported to the winery as fast as possible in shallow containers and why field pressing stations sited as close as possible to the vineyard are increasingly common. When the grape is crushed, unless special precautions are taken to exclude oxygen it immediately starts to react with the liberated juice compounds. The most obvious change is the browning of the juice resulting from the oxidation of PHENOLICS catalysed by an ENZYME (polyphenol oxidase) present in grapes and thus referred to as 'enzymatic oxidation' or 'enzymatic browning'. The presence on the grapes of moulds associated with ROT introduces additional oxidative enzymes (LACCASES) which accelerate reactions with oxygen, especially those involved with browning. Small amounts of SULFUR DIOXIDE (5 g/hl) are therefore usually added to the must to inactivate enzymes and counter the oxidation of phenolics. See PROTECTIVE JUICE HANDLING for the techniques involved in minimizing the risk of oxidation.

Some winemakers, however, deliberately encourage a certain amount of pre-fermentation oxidation of grape varieties such as Chardonnay in order to develop a range of flavours other than those associated with primary fruit AROMA. Sometimes known as hyperoxidation, this also enhances enzymatic oxidation of phenolics and their conversion to insoluble polymers, which are then removed by CLARIFICATION treatments. As a result, the wine contains lower amounts of phenolic compounds that may generate brown pigments and haze through non-enzymatic oxidation reactions (see below) and is thus more stable. This technique is usually reserved for non-aromatic grape varieties. See WHITE WINEMAKING for more details.

The last step of FERMENTATION, the REDUCTION of ACETALDEHYDE to ETHANOL, is coupled with the oxidation of the co-enzyme NADH, as shown in this equation:

$$CH_3CHO + NADH + H^+ \rightarrow$$
$$CH_3CH_2OH + NAD^+$$

Note that no new oxygen is involved in this reaction and that the essence of the reduction is the transfer of electrons from the co-enzyme to the acetaldehyde. Most oxidation–reduction reactions involved in growing grapes and making wine are of this type.

In wine itself, however, exposure to oxygen in the presence of an organism such as ACETOBACTER could result in a reversal of the above reaction, with alcohol being oxidized to acetaldehyde. The NADH produced by oxidizing alcohol is, in turn, oxidized by oxygen from the air. When this happens, the wine loses its fresh, fruity aroma and becomes vapid and flat-smelling. Further exposure to oxygen converts the acetaldehyde to ACETIC ACID, the acidic component of wine VINEGAR, the winemaker's *bête noire*.

Oxygen reacts with the phenolics in both white and red wines through complex chemical oxidation processes that may also promote oxidation of ETHANOL to ACETALDEHYDE. In whites, the COLOUR changes from light yellow to amber and ultimately brown, and at this last stage the quality of a TABLE WINE is usually seriously impaired. In reds, with their greater complement of phenolics (ANTHOCYANINS, TANNINS, and PIGMENTED TANNINS), the colour change is much less apparent, and a red wine can accommodate, and indeed benefit from, considerably greater exposure to oxygen than a white wine. While the natural formation of stable pigmented tannins in a red wine is a process requiring oxidation, other products of the reaction of the wine's phenolics with oxygen bring about highly desirable changes in the sensory properties of the wine. An appropriate level of oxygen exposure is usually accomplished through PUMPING OVER, RACK AND RETURN, RACKING, TOPPING UP, and the usual transfer operations imposed on a red wine. BARREL AGEING also involves regular exposure of the wine to small amounts of oxygen. This has inspired the development of technologies such as MICRO-OXYGENATION and the use

of CLOSURES with controlled OXYGEN TRANSFER RATES to control oxygen exposure during ÉLEVAGE and bottle AGEING.

To produce table wines attractive in aroma and colour, and certainly those designed to be drunk young, the winemaker generally restricts the exposure of MUST and wine to oxygen as much as is technically feasible (see PROTECTIVE WINEMAKING for more details).

Some wines, however, such as *oloroso* SHERRY, tawny PORT, MADEIRA, and some traditional white RIOJA, owe their character to deliberate exposure to oxygen. And those who make wines of all sorts are constantly experimenting with various aspects of controlled oxidation, often motivated by the role played by oxygen in AGEING. See WHITE WINEMAKING and RED WINEMAKING.

The term MADERIZATION is sometimes used interchangeably with 'oxidation', although it should theoretically also involve excessive exposure to heat.

See also OXYGEN. V.C.

oxidative winemaking contrasts with PROTECTIVE WINEMAKING and REDUCTIVE WINEMAKING in that the winemaker deliberately exposes the wine to oxygen at various stages in the winemaking process in order to encourage certain reactions and achieve a particular style of wine—*oloroso* SHERRY being an extreme example. See also OXYGEN, AERATION, BARREL AGEING, MICRO-OXYGENATION, and OXIDATION.

oxygen, colourless, odourless, tasteless gas that makes up nearly 21% of the atmosphere. It is essential to all animal life forms and for many other living systems. Unlike NITROGEN, which makes up a much higher proportion of air and is inert, oxygen is highly reactive, being essential for aerobic RESPIRATION in plants, animals, and soils. Oxygen interacts with grape juice, MUST, and wine in good ways (see AERATION) and bad ways (see OXIDATION).

Handling juice

It is important to minimize the amount of oxygen dissolved in the must, especially when it comes to white wine grapes, in order to avoid the oxidation of aromas and PHENOLIC compounds. (See OXIDATION for a very different approach.)

Making wine

Early on in the fermentation (typically on the second day), a small amount of oxygen is required for the multiplication of the YEAST. At this stage, there is no risk of oxidation because the CARBON DIOXIDE given off by the nascent wine prevents exposure to oxygen. However, when fermentation ceases, the wine must be protected from oxygen if it is to remain wine. Early winemakers learnt that, with very few exceptions, wines had to be kept in full containers at all times lest they change into VINEGAR.

Modern winemakers have equipment which allows most steps in making wine to exclude oxygen. One of the most effective has been the STAINLESS STEEL tank. If the tank is not completely full, the ULLAGE space can be filled with INERT GAS to exclude oxygen. Wooden vats, casks, and barrels are not sufficiently impervious for this blanketing technique. Some tanks have lids that can be raised or lowered depending on the volume of liquid in the tank. The oxidation of wine can also be minimized by additions of SULFUR DIOXIDE, which is also used to inhibit microbial activity. ASCORBIC ACID has also been employed to a certain extent as an antioxidant, but it must be used in conjunction with sulfur dioxide (see ERYTHORBIC ACID too). REFRIGERATION of wine in storage slows all reactions, including oxidation, but it has the danger that oxygen solubility increases at low temperatures. For white wines, the aim of PROTECTIVE WINEMAKING is to minimize oxidation, although see WHITE WINEMAKING for alternative approaches.

Oxygen plays a positive role during RED WINEMAKING, when the small doses of oxygen which the wine receives during the inevitable operations of filling, RACKING, and TOPPING UP deepen and stabilize COLOUR, soften and intensify flavour, and assist natural STABILIZATION and CLARIFICATION by encouraging the precipitation of the less stable PHENOLICS.

Bottling

Oxygen management throughout the winemaking process, during FINING, FILTRATION, and BOTTLING, and in relation to wine-bottle CLOSURES (see OXYGEN TRANSMISSION RATE and TOTAL PACKAGE OXYGEN) plays a key role in a wine's AGEING ability, which is why it is currently the subject of increasingly sophisticated research around the world. Academics and producers of SYNTHETIC CLOSURES and AGGLOMERATE CORKS have invested in international research projects that look at all aspects of wine–oxygen interaction and how this highly significant aspect of winemaking may be controlled.

See also OXIDATION, AERATION, MICRO-OXYGENATION, and SERVING WINE. P.J.W. & V.L.

Goode, J., *Wine Science: The Application of Science in Wine* (3rd edn, 2021).

oxygen transmission rate (OTR) is a key property of wine PACKAGING and most commonly discussed with regard to wine-bottle CLOSURES because the interaction between wine and OXYGEN is critical to the way a wine changes post-bottling (see AGEING). Some used to think that CORKS and alternative closures provided an airtight seal that allowed no oxygen into the bottle, except when the closure had failed. But packaging technology companies can measure typical OTR rates for CORKS of about 1 mg/year or lower. While first-generation synthetic corks had OTRs that were too high, resulting in wines that showed signs of oxidation after a fairly short period of time, most manufactured closures, such as synthetic corks or AGGLOMERATE CORKS, now have published OTRs similar to those of CORKS or, particularly in the case of tin-lined SCREWCAPS, much lower. Recent research, much of it funded by closure producers such as Nomacorc, has focused on the effects of different OTRs on wine development, and manufacturers are now able to offer products with engineered levels

of OTR in order to give winemakers control over how their wine will develop post-bottling. The trajectory of bottle ageing is affected by OTR and storage temperature, with 'normal' ageing typically defined by the history of BOTTLES sealed with corks and kept in traditional CELLARS.

See also TOTAL PACKAGE OXYGEN. A.L.W.

ozone is a form of OXYGEN having three instead of the usual two oxygen atoms per molecule. It is formed in the upper atmosphere by the action of ULTRAVIOLET RADIATION on normal oxygen; by being opaque to further incoming ultraviolet radiation, it happily prevents most of the potentially very damaging ultraviolet wavelengths from reaching the Earth's surface.

Some synthetic molecules such as the chlorofluorocarbons, once widely used in REFRIGERATION, can, if released into the atmosphere, add to the effects of natural gases from volcanoes and so on to destroy ozone. This happens only at very low temperatures, such as occur over the poles in winter, but is nevertheless a matter of concern.

Some ozone is also released into the lower atmosphere as an industrial pollutant and can cause a recognizable 'stippling' of vine leaves close to industrialized areas. Its significance to viticulture has been studied in California and New York State, but the economic effects remain uncertain.

In a winemaking context, ozone has been advocated as a sanitizing agent for the maintenance of HYGIENE in a winery and for use, for example, on stainless-steel tanks, bottling equipment, and BARRELS, although it is not effective in killing microflora (e.g. BRETTANOMYCES) in material such as OAK because it does not penetrate the oak surface. Ozone is sometimes used in cork manufacture as a preventive measure to retard microbial growth, though, again, its effectiveness is uncertain.

It has also been suggested that fumigating grapes with ozone may reduce the effect of SMOKE TAINT, but this is as yet unproven.

P

Paarl , inland wine district in SOUTH AFRICA home to an increasing number of well-known estates. It reaches north into TULBAGH and WELLINGTON and east towards FRANSCHHOEK, all separate areas of origin. The biggest cellars are KWV's, and the most important branded wine producer is Nederburg, with 21 labels. Much of Paarl's fruit is blended with grapes from districts such as STELLENBOSCH and Wellington to be sold under the more generic regional origin COASTAL REGION.

Pacherenc du Vic-Bilh, defiantly GASCON name for an AOC in the MADIRAN region of SOUTH WEST FRANCE devoted to characterful white wines. Made mainly from a mixture of local grape varieties COURBU, PETIT COURBU, GROS MANSENG, and PETIT MANSENG, sometimes with ARRUFIAC, the deep yellow wine can be either dry or more probably sweet, and the general character is not dissimilar from that of JURANÇON. Some 300 ha/750 acres are dedicated to this keenly priced wine, for which the grapes destined for sweet versions may be picked as late as December. These, made from PASSERILLÉ and not BOTRYTIZED grapes, can last ten years or so in bottle. P.S.

Perry, D. M., *Madiran and Pacherenc du Vic-Bilh* (2014).

Pacific Northwest , region in the far north-west of the United States encompassing the states of WASHINGTON, OREGON, and IDAHO.

packaging of wine most often involves BOTTLING, but alternative options are proliferating. BOTTLES are still by far the most popular form of wine packaging, not least because GLASS is inert and tasteless so, unlike other packaging materials, has no effect on the wine even over decades. It does have the disadvantages of being very fragile and relatively heavy, as well as using up considerable natural resources during manufacture, TRANSPORT, and recycling. See BOXES, CANS, CARTONS, KEGS, PAPER BOTTLES, PLASTIC BOTTLES, and POUCHES, all of which are made from other materials. See also SUSTAINABILITY and CARBON FOOTPRINT OF WINE.

Padthaway , a significant, moderately cool, primarily grape-growing (rather than winemaking) region in the LIMESTONE COAST ZONE in the south-east of SOUTH AUSTRALIA. While all the mainstream varieties are grown, and while grape quality is, as elsewhere, sensitive to yield, Shiraz is a regional speciality and can produce high-quality, long-lived wine.

Pagadebit, occasionally Pagadebito or Pagadebiti, is used as a synonym for several different Italian varieties, most notably BOMBINO BIANCO in Puglia. The name refers to the vine's reliable yields which, in theory, should allow growers to pay their debts.

pago, Spanish term for a vineyard, used particularly in JEREZ and CASTILLA Y LEÓN. See also VINO DE PAGO.

Païen, Valais name for SAVAGNIN BLANC.

pairing food and wine. See FOOD-AND-WINE MATCHING.

País , Chilean name for the historic grape variety also known as CRIOLLA CHICA, MISSION, and Listán Prieto. It is most common in Maule and Bío-Bío in southern CHILE and is mainly grown in old, DRY-FARMED plots by elderly farmers, often as FIELD BLENDS. Accurate numbers are elusive, but Chile's official vineyard report for 2020 records 10,443 ha/25,805 acres in total. The variety used to be scorned, but producers throughout Chile have begun making small-volume wines that have also inspired winemakers in California and Spain to reconsider the variety.

Pakistan . According to OIV statistics, the total area of vines in this Asian ISLAMIC republic grew from 3,000 ha/7,400 acres in the late 1980s to 17,534 ha in 2020. They are dedicated to the production of TABLE GRAPES and RAISINS, but VITIS VINIFERA wine may occasionally be made from WILD VINES growing in the high valleys along the Silk Road, where one of the richest resources of ancient, genetically varied plant material may still be found.

Palacios family, a network of talented winemakers in northern Spain. José Palacios Remondo founded Palacios Remondo in Alfaro, RIOJA Oriental, in 1945. He had nine children, of whom four are or were connected with wine: Antonio the second-born, Chelo (Consuelo, a girl) the third, Álvaro the seventh, and Rafa (Rafael) the youngest. Álvaro left in 1989 to play a major part in establishing modern PRIORAT, his most famous wine L'Ermita setting new records for price. Rafa also left to focus on white wine and from 2004 did for VALDEORRAS what his brother had done for Priorat. One of Chelo's sons, Ricardo Perez Palacios, has run Descendientes de J. Palacios in BIERZO since 1999 in conjunction with his uncle Álvaro, who has also taken over and revived Palacios Remondo in Rioja.

palaeoethnobotany and the archaeology of wine. The study of the botanical remains of grapes and wine residues found in

archaeological excavations is something of a detective story in which small pieces of evidence are put together to build up a picture of the development of humankind's use and, later, domestication of grapes.

The botanical evidence consists of the remains of vine LEAVES, BERRIES, STEMS, and SEEDS (see GRAPE); sometimes even the roots, or the hollows left by them, may subsist too. Their recovery is the result of painstaking examination of archaeological deposits. Usually the finds of grape remains form a very small proportion of the total botanical material recovered, the bulk of which is usually the seeds of annual crops such as cereals, pulses, and oilseeds.

The most common remains of grapes found are grape pips, and they usually subsist because they have become charred at the time of deposition. Once converted to charcoal, they will subsist in recognizable form for many thousands of years buried in the ground. On other archaeological sites they may be preserved in damp or wet soils in a waterlogged condition. Elsewhere, where there is a high concentration of calcium in the groundwater, they may become mineralized or semi-fossilized. Sometimes stray pips were incorporated in handmade clay pots, and when the pots are fired they burn out, leaving a small hole the exact size and shape of the pip.

Occasionally, complete fruits survive in charred form, as when grapes were thrown on to a funeral pyre as part of the ritual (e.g. at Salamis and Athens). Exceptionally, finds of skins of fruits (possibly remains of pressings) survive, for example at early Minoan Myrtos, Crete (see ancient GREECE).

Finds of burnt fruit stalks (PEDICELS) are exceptional but can be taken to indicate the presence of domesticated vines (the stems of bunches of WILD VINES are very strong and robust and do not come away with the fruit in the way that those of cultivated vines do). They have been recovered from the Greek prehistoric sites of Sitagroi and Myrtos.

The Greek prehistoric potters of the early Bronze Age developed the habit of standing their pots on upturned vine leaves to dry in the sun before firing. This resulted in the veins on the underside of these

leaves being finely impressed and then baked on the bases of these pots. In some places—the Cyclades, for example—these are the only evidence that grapes were present on these islands at that time. Vine leaves were also used on clay sealings of Bronze Age pots, such as at Menelaion near Sparta. If vine leaves were being used in these ways by the Bronze Age Greeks, they may also have been used for cooking, as they are in Greece today.

The critical question in examining all this palaeoethnobotanical material is how can one tell whether it is derived from wild or cultivated sources. Apart from the fruit stalks, just discussed, it is the size and shape of the pips which give us the clue: the pips of wild grapes are spherical, with a short stalk or beak and a small, round chalazal scar on one side, and two divergent grooves on the other side of the pip. The pips of cultivated grapes are usually larger and pear-shaped. The stalk is usually longer, the chalazal scar larger and often oval in outline, and the grooves on the back of the pip parallel to each other. These features can be seen on the archaeological material, however it is preserved.

The domestication of grapes seems to have first taken place around 6000 BCE in the region between the Black and Caspian seas. The domesticated grapevine provides fresh fruit, raisins, wine, vinegar, grape juice, and a light salad oil obtained by crushing the pips. The most significant product, however, was wine, which was greatly valued. (See ORIGINS OF VINICULTURE for details of a recent study proposing an earlier date for domestication of the grapevine in the Levant.)

Finds of wild grape pips in archaeological contexts go back to the earliest palaeolithic sites in Europe, for example at Terra Amata in the south of France (*c.*350,000 BCE), where the fruits appear to have been eaten. There are a number of sites from the mesolithic period (12th–9th millennium BCE) with finds of wild grape seeds: from Belma Abeurader, France, to Grotte del Uzzo in Sicily, the Frangthi Cave in southern Greece, Çayönü in Türkiye, Tell Abu Heureya in Syria, and Jericho in Jordan. The earliest finds of pips from domesticated grapes come from the neolithic site of Shulaveris-Gora in Georgian

Transcaucasia, dated *c.*6000 BCE. From this site too comes a residue of resinated wine in a pot: the earliest find of wine to date. Another site which has yielded traces of neolithic wine is Hajji Firuz Tepe in northern Iran. Here a kitchen was excavated dating to 5400–5000 BCE. In it were six jars set into the floor with their lids nearby. Chemical analysis has shown that they contained wine resinated with resin from the terebinth tree. It is not clear whether this wine was made from wild or cultivated grapes (wild grapes still grow close to the site today). If all these jars had contained wine they would have held around 50 litres, suggesting large-scale wine production at a very early date.

The excavations at the Areni 1 cave complex in ARMENIA have yielded remains of a wine-pressing structure dating to *c.*4000 BCE. It consists of a shallow clay tub, 1 metre wide, with raised edges and a sloping base leading down to the mouth of a large jar. Desiccated grapes, pomace, grape seeds, and grape skins still attached to their pedicels have been found in close proximity to it. Biochemical analyses of the contents of associated pots revealed the presence of malvidin, the pigment responsible for red wine. It is thought that wine pressing here was associated not with regular consumption or feasting but with rituals surrounding the burial of the dead. Remains of both primary and secondary depositions of dismembered and complete human skeletons were found in the inner spaces in the caves.

It is not essential that vines were domesticated before WINEMAKING was invented. What appears to be necessary is having a suitable container in which to store the wine during and after the FERMENTATION process. All the ingredients—the sweet, juicy fruit, and airborne YEAST—are available for wild fruits. Thus, it is possible that the finds from palaeolithic sites (Old Stone Age) in the Mediterranean region of wild grape pips could indicate that winemaking had begun using leather bags even before the beginnings of agriculture.

The finds of grape remains such as pips, stalks, and skins in circumstances suggesting wine production are rare. The finds from House 1 at Dikili Tash in northern Greece of 2,460 grape pips, which

have been directly dated to 4,460–4,000 BCE, together with more than 300 empty, pressed grape skins, strongly suggest that they represent winemaking residues. The measurements of the pips suggest that they were morphologically grapes from WILD VINES or from plants in the process of domestication. Another exceptional find comes from Kurban Huyuk in eastern Türkiye, where masses of grape pips and stem and vine fragments were found together with cakes of pressed fruits in a pit dating to the mid to late third millennium BCE. In prehistoric GREECE, they occur associated with spouted vessels on the early Bronze Age sites of Áyios Kosmas, Attica, and Myrtos in Crete. Remains of wine presses also occur occasionally, as at Minoan Vathypetro in Crete, and there are a great number of drinking vessels made from exotic materials from Bronze Age sites suggesting that drinking wine was a special activity.

Analysis of residues found in the bottom of pottery containers has been undertaken by Patrick McGovern of MASCA in the University Museum, Philadelphia, using infrared, liquid chromatography and other chemical techniques to identify traces of tartaric acid, calcium tartrate and terebinth resin indicating the residues of wine. The actual residues in the bases of *pithoi* (see PITHARI) of wine have not been found very often (partly because the analysis of residues found in pottery vessels is still comparatively new in archaeology). Apart from identifying the earliest finds of wine residues, detailed above, these analyses have also given evidence of the earliest trade in wine. This dates back to 3500 BCE at Godin Tepe, IRAN, where a reddish deposit turned out to be formed from TARTRATE crystals (similar to those which form on the bottom of wine corks today). Godin Tepe lies on a well-documented trade route through the Zagros Mountains to lowland Mesopotamia. Even stronger evidence of trade comes from the earliest finds of wine residues in Egypt from the royal tomb of Scorpion I at Abydos dating to 3100 BCE. Here three rooms in the tomb formed a kind of wine cellar filled high with about 700 amphorae arranged in three or four layers, one on top of another. They were stoppered with clay sealings bearing fine seal impressions. Deposits of crusty yellow residues inside the amphorae turned out to

be of a resinated wine. In addition, 47 of them contained grape pips, and several had raisins, stalks, skins, pips, and dried pulp intact. Eleven of the jars also contained the remains of sliced sycamore figs which had been strung together and suspended in the wine. Analysis of the clays from which the amphorae were made indicated that they probably came from various regions in the southern Levant. Viticulture was firmly established in the delta region of Egypt and in some of the western oases by the Sixth Dynasty (*c.*2323 BCE). Processes of winemaking are shown in paintings and engravings on the walls of tombs from the Old Kingdom onwards, for example in the tomb chapels at Beni Hasan, especially nos. 15 and 17.

Recent finds in the CANAANITE palace at Tel Kabri in northern Israel, dating to 1700 BCE, have revealed a wine cellar holding the remains of 40 jars that are 91 cm/3 ft tall. Chemical analysis of the residues of their contents, by Andrew Koh of Brandeis University, revealed traces of TARTARIC ACID, as well as flavourings of honey, mint, cinnamon bark, juniper berries, and resins used as preservatives. Of the 40 vessels, 38 contained wine residues all with the same constituents, the equivalent of 3,000 modern bottles of wine. The contents are consistent with winemaking recipes from the ancient texts found at the palace at Mari on the Euphrates in modern SYRIA.

One of the most romantic finds of labelled wine jars must be that from Tutankhamun's tomb. They were sealed with clay and their contents were reduced to dried residues. The 26 wine jars have labels indicating the location of the vineyard, the year of the vintage (the majority belonging to the years 1345 BCE, 1344 BCE, and 1340 BCE), the ownership of the vineyard, and the name of the chief vintner. Most of them came from the western delta, one from the eastern delta, and one from the El Kharga oasis. Two of the vintners had Syrian names; four of the jars were labelled 'sweet wine'.

Analyses have also shown that sometimes wine was mixed with other alcoholic beverages. It appears that this was the case in Minoan Crete, where a number of residue analyses have shown that wine was mixed with barley beer and honey to form what McGovern has called 'Greek grog'. This was also the case in the finds from

Midas' tomb at Gordion in Türkiye (*c.*700 BCE), where the funeral feast consisted of a tasty lamb and lentil stew washed down with an intoxicating beverage made from mixing wine, barley beer, and honey mead.

Other early residues of wine are known from 7th century BCE Cyprus and from the contents of AMPHORAE in a Roman shipwreck off the southern coast of France, near Marseilles. There is a Roman glass BOTTLE containing what is claimed to be Roman wine in the museum in Speyer, Germany.

From apparently insignificant remains of grape pips, stalks, pulp, and leaves, and from analyses of dried-up residues in the bottom of pots, found by chance to subsist in sediments on archaeological sites and extracted with painstaking care, it is possible to begin to understand the ORIGINS OF VINICULTURE and its development.

Ancient biomolecules

In 2003, scientists at the Botanical Garden of Geneva, Switzerland, were able to analyse for the first time by DNA PROFILING a tiny amount of DNA from waterlogged and charred grape pips recovered from archaeological sites in France (Iron Age and Greek period, 5th century BCE) and Hungary (Roman times, 2nd to 4th centuries CE). These remains could not be matched to any modern cultivar, but they could be assigned to their most likely geographic origin. More recently, ancient DNA (aDNA) studies have been able to assign archaeological specimens from pre-Roman to medieval times to groups of modern Western European varieties in the Italian peninsula, on Sardinia, and in Armenia. Future studies could help elucidate domestication events, genetic introgression from local wild populations, and the origins and histories of varietal lineages. J.V.

palate, frequently misspelt term used when describing TASTING as a process and an ability. It is generally used to describe the combined human tasting faculties in the mouth (and, sometimes, NOSE). The impact of a wine on the mouth may be divided chronologically, and somewhat loosely, into its impact on the front, middle, and back palate. The word may also be used more generally as in describing a good taster as 'having a fine palate'. A pallet of wine is dozens of CASES. Some may describe a BOUQUET as being composed of a palette of FLAVOURS.

Palatinate, originally territory under the jurisdiction of a local authority with sovereign powers, the term came to be used for that part of Germany which today includes both Rheinhessen and the PFALZ wine regions. It is also an alternative English name for the German wine region the Pfalz. See also GERMAN HISTORY.

Palestine , region on the Mediterranean with a viticultural history dating back at least to the third millennium BCE, when CANAANITE winemakers furnished their Egyptian rulers with wine. Winemaking continued, flourishing at times, through eras ruled by Philistines, Hebrews, Assyrians, Babylonians, Greeks, Romans, Byzantines, Arabs, Franks, Ottomans, and others, to the present. Sweet wines from the hinterlands of Gaza and Askalon were prized in Europe through Byzantine times, and, during the Crusades, Palestine was a major source of wines for the merchants of GENOA.

Wine production continued through the ISLAMIC period, albeit in limited ways. Palestinian Christians have always made wine domestically, and MONKS AND MONASTERIES have also played a role, as at Cremisan, founded in 1885 and now Palestine's oldest winery.

Contemporary Palestinian wine culture, however, is fraught with challenges, as the land of Palestine is synonymous with the area internationally recognized as the state of ISRAEL and includes the West Bank, a territory currently largely under Israeli rule, and Gaza, internally governed by Hamas, a prohibitionist Islamist government.

Grapes remain a major agricultural crop in Palestine, second only to olives: according to OIV estimates, in 2020, the country's vineyards extended over 3,423 ha/8,458 acres, which include vineyards producing TABLE GRAPES, RAISINS, and products such as grape molasses that are important to the cuisine. A portion of the harvest is also distilled into arak, the national spirit, for local consumption and for export. There is no CONTROLLED APPELLATION system in Palestine, though wine made by Palestinians in the West Bank is labelled with that place name. In Gaza, the government compels winegrowers to work underground, so their wines remain unlabelled. The term 'Palestinian wine' is also sometimes used to describe wine made by self-identified Palestinians within Israel from land that has been in their families from before the founding of the state. The latter includes the hills west of Jerusalem, near the town of Ramleh, and the upper Galilee, by the border with LEBANON, east of Acre. However, as these areas are located within the 1949 armistice lines that serve as Israel's international consensus borders, the wines are labelled 'Made in Israel'. In 2022, there were six Palestinian wineries in the West Bank and another five self-identifying Palestinian winegrowers working within Israel.

Close to 85% of Palestinian vineyards today are in the West Bank, between Bethlehem and Hebron, where the warm MEDITERRANEAN CLIMATE is moderated in parts by ELEVATIONS that reach up to 1,000 m/3,280 ft. Throughout much of the country, well-draining, iron-rich TERRA ROSSA soil dominates, with patches of CLAY and LIMESTONE, especially around Bir Zeit and Beit Jala in the West Bank. Rainfall averages 454 mm/18 in a year. IRRIGATION is used when needed, though DRY-FARMED vineyards are common in parts of the West Bank that experience cooler evening temperatures and HUMIDITY.

Grape-growing in Gaza is largely confined to the lower-elevation (maximum 100 m/330 ft) coastal Gaza Strip, where soils are largely SANDY and CALCAREOUS and the climate is hot and dry, with rainfall averaging just 225 mm/9 in a year in the south, 400 mm in the north, concentrated in the winter months. Irrigation is used when possible, though water SALINITY is a problem.

According to research by Fadi Batarseh (then at the University of Udine, Italy, now winemaker at Cremisan), there are 21 INDIGENOUS VARIETIES in the Holy Land, with up to eight suitable for winemaking. These include the white wine varieties Daabouki/Dabouki (also called Zaini/Zeini), Jandali, and Hamdani (also called Marawe/Marawi); reds include Baladi Asmar, Baluti, Beituni/Bituni, and Shayukhi/Sheukhi. Once mostly subsumed into blends for local consumption or for Christian pilgrims visiting holy sites, these varieties are gaining more attention, though INTERNATIONAL VARIETIES remain more common.

The greatest challenge for Palestinian winegrowers is the Israeli-occupation regime in the West Bank, where they contend with frequent checkpoints, road closures, and work stoppages imposed by the Israeli army; vandalism, land confiscation, and water diversion by colonists; and the rapidly expanding Israeli separation wall which cuts off direct access to many vineyards. Nonetheless, the desire to assert Palestinian identity through indigenous products combined with greater international interest in local wines has sparked the growth of a modern Palestinian wine industry, its wines exported all over the world. J.A.R.

Palette, miniature AOC of just 43 ha/106 acres in PROVENCE in the hills east of Aix-en-Provence. The appellation is relatively old, created in 1948 in recognition of a distinctive LIMESTONE outcrop on the north-facing bank of the river Arc. A single property, Ch Simone, produces most of the wine and for many years was responsible for the most serious wine of the appellation. For seven generations, Ch Simone has been in the Rougier family, who continue to respect the traditional winemaking techniques, involving very OLD VINES,

prolonged FERMENTATION, and BARREL MATURATION using very little new wood. FIELD BLENDS of southern vine varieties make extremely dense, long-lived reds, full-bodied rosés, and characterful white wines which belie modern white-winemaking philosophy. The INDIGENOUS VARIETIES permitted are even more numerous than those allowed in CHÂTEAUNEUF-DU-PAPE. E.A.G.

Palhete is a historic Portuguese term for a light-coloured red wine made from a combination of red and white grapes. Following a niche revival of the style, from 2017 the term can only be used to label red wines obtained from the partial MACERATION of red grapes or the maceration of both red and a maximum of 15% white grapes. In the ALENTEJO, light-coloured blends of red and white grapes (very often from TALHA) are traditionally called *petroleiro*. S.A.

Woolf, S. J., and Opaz, R., *Foot Trodden: Portugal and the Wines That Time Forgot* (2021).

pálido, Spanish wine term with more than one meaning: in CONDADO DE HUELVA and RUEDA, it refers to a dry, FORTIFIED wine aged under FLOR in oak for at least three years; in Rueda it must be made from PALOMINO FINO and/or VERDEJO. In MÁLAGA, it describes a sweet, FORTIFIED WINE made from PEDRO XIMÉNEZ and MOSCATEL without the addition of ARROPE. F.C.

Palladius (4th century CE). Next to nothing is known about the life of this agrarian writer of ancient ROME. He is the author of a treatise called, like Varro's earlier work, *De re rustica*, in 15 books. The first book is a general introduction to farming; the last two comprise a guide to veterinary medicine and an account of GRAFTING. The remaining 12 books deal with the tasks to be carried out throughout the agricultural year, one book for each month; Palladius has more to say about the vine than about any other crop. What he says,

however, is sound but not original: he relies heavily on earlier authors, especially COLUMELLA (and, to a lesser extent, PLINY and VARRO). Unlike CATO, Varro, and Columella, he was well known in the Middle Ages and in the early Renaissance: he is quoted by Albertus Magnus, Vincent of Beauvais, and PETRUS DE CRESCENTIIS; and an anonymous Middle English translation of his work, connected with Humfrey, duke of Gloucester, survives. There is no direct evidence for his influence on medieval English wine producers, however. H.M.W.

Pallagrello Nero, red wine grape planted on 107 ha/264 acres of CAMPANIA in 2015. Unrelated to the even rarer Pallagrello Bianco.

Palmela , DOP on the Setúbal peninsula in southern Portugal. See PENÍNSULA DE SETÚBAL.

palmento, ancient winemaking facility or wine cellar typical of ETNA in Sicily. Especially popular during the 19th century, *palmenti* (plural) were built on the slopes of the volcano to take advantage of gravitational flow to process large quantities of grapes. Palmenti are the direct descendants of the *palmenti rupestri* (*rupestre* means 'what is carved out of rock'), ancient outdoor winemaking facilities cut out of the rock by early Greek settlers on Etna. Many of Etna's monumental palmenti are no longer in use since the EU outlawed them due to alleged health concerns with their sand or dirt floors, which aid in maintaining perfect HUMIDITY levels but cannot be cleaned. Some have been restored, with concrete floors added, in the belief that they are very much part of the TERROIR. W.S.

Palo Cortado, a traditional style of sherry often described as mysterious but in fact simply explained by the fact that nature is

greyscale rather than black and white. This is a wine that was originally pre-selected to become a *fino* or *amontillado,* aged under a protective veil of FLOR yeast, as opposed to *olorosos*, which are typically aged in OXIDATIVE fashion from the start. Yet some examples of these more delicate wines do not fully develop the protective veil and end up ageing in an *oloroso* way. As a result, such wines have an intermediate style—the elegance of the Fino/Amontillado with the concentration and body of the Oloroso. This is a rare category of sherry, yet some of the greatest dry sherries are Palos Cortados. For more details, see SHERRY. V. de la S. & J.B.

Palombina, synonym for PIEDIROSSO.

Palomino Fino, white grape variety most closely associated with the making of SHERRY around JEREZ in southern Spain that is generally declining in importance. It is almost certainly of Andalucian origin, supposedly named after one of King Alfonso X's knights, and was introduced to the CANARY ISLANDS, where it is known as Listán Blanco. It is often referred to as simply Palomino.

The vine is relatively susceptible to DOWNY MILDEW and ANTHRACNOSE and responds best in warm, dry soils. Its loose, generous bunches of large grapes make it suitable for TABLE GRAPES as well as wine. Its YIELD is relatively high and regular, about 80 hl/ha (4.5 tons/acre) without IRRIGATION, and the wine produced is, typically, low in both ACIDITY (as low as 3.5 g/l expressed in tartaric acid) and fermentable SUGARS. This suits most sherry producers, who pick Palomino grapes at about 19 °Brix (see MUST WEIGHT) and find Palomino must's tendency to OXIDIZE no inconvenience. However, a handful of Jerez and Canary Island producers have started turning low-yielding, OLD VINE Palomino/Listán Blanco into exciting, complex, unfortified whites.

Spain's official 2020 statistics distinguished between the Canary Islands' 1,580 ha/3,904 acres of Listán Blanco de Canarias, 2,095

ha/5,177 acres of Palomino Fino, and 11,651 ha/28,790 acres of plain Palomino, but according to DNA PROFILING they are genetically identical. The only mainland Spanish regions with sizeable plantings of Palomino other than Andalucía are GALICIA and CASTILLA Y LEÓN, where productive Palomino was planted after PHYLLOXERA but is being replaced by INDIGENOUS VARIETIES. The great majority is in sherry country around Jerez, but as sales of sherry have declined so has the total area of Palomino.

Outside sherry country, in France, for example, it is often known as Listán, or Listán de Jerez, and sometimes just Jerez. In Portugal it is known as Malvasia Rei, planted on 1,394 ha/3,445 acres in 2020, mainly in the north of the country and in Lisboa, where it makes generally bland table wine. However, on the island of Porto Santo, small PARCELS of old vines, under the name Listrão and typically used for local fortified wines, are showing great potential for unfortified wines. CYPRUS imported the Palomino vine because of its dependence on producing inexpensive copies of sherry, but very little remains.

The country with the most Palomino planted outside Europe was at one stage South Africa. Formerly known as Fransdruif in Afrikaans and White French in English, the variety has been losing ground fast. However, its decline is being arrested thanks to the burgeoning interest in fruit from older vineyards as a component in some of the Cape's more avant-garde blends.

California's acreage of the variety, once misidentified as Golden Chasselas, has always been very limited, almost all in the SAN JOAQUIN VALLEY. In Australia, total plantings have shrivelled as dramatically as production of sherry-like wines. New Zealand once also grew a surprising amount of Palomino considering its hardly ideal climate, but the vines have been replaced with more suitable varieties. Argentina has limited planting of the variety but PEDRO GIMÉNEZ predominates.

Pamid, BULGARIA's most widely planted and least interesting INDIGENOUS VARIETY producing rather thin, early-maturing red wines

with few distinguishing marks other than a certain sweetness from 1,058 ha/2,614 acres of vines. It does not play a major role in bottles bound for export. It is planted more extensively, on 2,653 ha/6,556 acres in 2021, as Roşioară, in Romania.

Pampanuto, also known as Pampanino, synonym for the Puglian white grape variety VERDECA.

Pannobile, a name derived from the Pannonian Plain, refers to a group founded in 1994 of (now) nine growers in Austria's NEUSIEDLERSEE region, all near the north-eastern edge of the eponymous lake, and to a single prestige blended red each of them offers (from some combination of ZWEIGELT, BLAUFRÄNKISCH, and ST-LAURENT grapes) as well as, in some cases, a white (from some combination of CHARDONNAY, PINOT GRIS, PINOT BLANC, and NEUBURGER).

D.S.

Pansa Blanca, synonym for the Catalan white grape variety XARELLO.

Pantelleria, VOLCANIC island at the extreme southern limit of Italy and closer in fact to Cape Bon in TUNISIA than to the southern coast of SICILY, to which it belongs administratively. Moscato di Pantelleria is one of Italy's finest dessert wines, made from ZIBIBBO (MUSCAT OF ALEXANDRIA). The wine has enjoyed a certain reputation since the 1880s, when the MARSALA house of Rallo began to market it. The viticulture of the island is unusual: vines are GOBELET-trained but buried in a hole (called a *conca* by local growers) and vineyards surrounded by stone walls built from volcanic rock to prevent dehydration by the hot scirocco WINDS that sweep across the island.

Moscato di Pantelleria comes in two versions. The first is the regular Moscato, with at least 11% alcohol and 68 g/l of RESIDUAL SUGAR, although many of the better producers raisin the grapes for

10–12 days to achieve higher levels of total alcohol and residual sugar (see DRIED-GRAPE WINES). The second version, Passito di Pantelleria, is lusher and richer, a true dessert style, with at least 14% alcohol and 100 g/l residual sugar, although many now seek a more decadently sweet style, sun-drying the grapes for up to 30 days and arriving at close to 140 g/l residual sugar. This search for power can come at a cost: the Moscato perfumes tend to be destroyed by the high level of VOLATILE ACIDITY that may result from prolonged sun-drying.

Both the Moscato and the Passito can come with the suffix 'liquoroso', indicating the addition of ETHANOL, which arrests the alcoholic fermentation, leaving a substantial amount of unfermented sugar in the wine. They may be additionally labelled Vino Dolce Naturale, the Italian equivalent of VIN DOUX NATUREL, but these rarely achieve the complexity of the unfortified versions. Changes in the production rules in the early 2010s created a new category of dry white wines labelled as Pantelleria Bianco as well as sparkling wines. After a period of neglect, the island's wines are experiencing revived popularity and recognition in Italy, with an undeniable increase in overall quality driven mainly by ambitious small-scale producers, notably Marco de Bartoli and BIODYNAMIC avantgardist Salvatore Ferrandes. Donnafugata's Passito di Pantelleria Ben Ryé, combining high quality with economics of scale, is the wine's international ambassador. W.S.

paper bottles, form of PACKAGING developed by a British company in 2020. Sealed with a SCREWCAP, the paper bottle is five times lighter than a lightweight 345-g glass bottle and has a CARBON FOOTPRINT four times lower than that bottle. The outer framework is made from two layers of recycled paper formed around a plastic inner pouch that

uses nearly 70% less plastic than a PLASTIC BOTTLE. The bottle's OXYGEN TRANSMISSION RATE means that the wine should remain in good condition for up to a year after bottling, making it suitable for all but the small percentage of wines intended for bottle AGEING.

British company Frugalpac pioneered these incredibly light PAPER BOTTLES in 2020. Even with a plastic pouch inside, they have a much lower CARBON FOOTPRINT than lightweight glass BOTTLES and offer a large surface area for BRANDING. © Frugalpac Ltd

Paraguay in SOUTH AMERICA has only a small wine presence due to the tropical conditions. The once-robust vineyards of Colonia Independencia, a colony settled by German winegrowers from BADEN in 1919, had dwindled to less than 200 ha/500 acres by 2021, but there was excitement around a new estate, Bodega Giacometti, 40 ha/99 acres in the Infante Rivarola zone, 700 km/435 miles from Asunción near the Bolivian border. Its first own-grown wines were anticipated to be released in 2023 as sadly their initial plantings were destroyed by ANTS. E.M.G.

Goldstein, E., *Wines of South America* (2014).

parcel, a defined plot or block of vines, often within a larger vineyard. A parcel, unlike a CLIMAT, typically has one owner. See also SÉLECTION PARCELLAIRE.

Pardillo, once known as Pardilla, is a vine variety planted on 1,418 ha/3,504 acres of LA MANCHA, in Spain, where it makes sturdy whites.

Pardina, light-skinned grape producing rather ordinary wines in EXTREMADURA shown by DNA PROFILING in 2005 to be the same as CAYETANA BLANCA.

Parellada, highly regarded white grape variety originally Aragonese but now grown almost exclusively in CATALUÑA, especially around San Sadurni d'Anoia on just under 9,014 ha/22,274 acres in 2020, where it is widely used, with MACABEO and XARELLO, for the production of

CAVA. It is the least planted of these three varieties in PENEDÈS, the region most closely associated with these Spanish sparkling wines. Parellada can produce aromatic, high-quality wine when grown in relatively poor soil and in cooler conditions. It buds early and ripens late. Occasionally made as a VARIETAL still wine.

Paris , capital of FRANCE, once the centre of a thriving wine region and still one of the few capital cities in which vineyards of any size may be found (see also VIENNA). Its several suburban vineyards include 2,000 vines on the slopes of Montmartre, originally densely planted in 1933, whose meagre produce is auctioned for charity. Even smaller plantings (170–400 vines) can be found in various parks across the city. In 2004, 470 vines were planted in the garden of an *hôtel particulier* next to the Bois de Boulogne and now produce a sparkling wine sold onsite for €60 per bottle.

Beyond the inner city, the surrounding Île-de-France region was home to 30,000–45,000 ha/74,132–111,197 acres of vines at the end of the 18th century (more than in Burgundy today). In 2020 it achieved IGP status. Recent plantings include a collaboration in 2021 involving Guillaume d'Angerville of Domaine Marquis d'Angerville and the chef Yannick Alléno, in Conflans-Ste-Honorine. E.L.

History

Wine was grown around Paris in the 4th century, and its fame as a winegrowing area dates from long after the Roman Empire. Clovis, king of the Franks 481–511, made Paris the capital of his kingdom, and from the 8th century onwards Frisian, Saxon, and English merchants sailed up the river Seine to Paris to buy wine. Under the Merovingians and the Carolingians, Paris was an important centre of trade, and much of the wine sold there would have been produced locally.

A document from the beginning of the 9th century shows that viticulture was a major part of the local economy. The Roll of Irminon, named after the abbot of St-Germain-des-Prés who instigated this survey of his monastery's lands, is the only document of its kind dating back to the time of CHARLEMAGNE. Vineyards at Rambouillet, Dreux, Fontainebleau, Sceaux, and Versailles were cultivated not only by monks but also by laymen, and it is clear from the amounts produced that there must have been a surplus to sell on the open market. Documents from the Abbey of St-Denis, near Paris, show that St-Germain-des-Prés was not unique in this respect. In the 9th century, St-Denis had vineyards in the abbey precincts and possessed winegrowing estates in the Île-de-France, as the Paris basin was known; many smaller monasteries in the area also produced wine for sale (see MONKS AND MONASTERIES).

In the 10th century, Paris was well established as a centre of the wine trade. The main trade route was down the Seine to Rouen and thence overseas. In the late 10th century, merchants from England, Ireland, Flanders, and Picardy visited Rouen, and later Henry II of England gave Rouen the monopoly of transporting wine to England. Later, from the 13th century onwards, the trade route from Paris was down the Seine or up the Oise to Compiègne, where the wine would be loaded on to carts and driven to Flanders. By then the merchants of Paris had managed to acquire for themselves privileges similar to those of their Gascon counterparts (see BORDEAUX). In an edict of 1190, Philip Augustus, king of France, declared that only the

merchants of Paris, who were themselves usually wine producers as well (see CLIMATE CHANGE for details of the warmer MACROCLIMATE prevailing then), had the right to sell wine in Paris. They were able to prevent the sale of any wine they wished, thus regulating the import of wines and controlling the quality of the wines sold as 'vins de France'. The wines of AUXERRE, CHABLIS, and Tonnerre had to pass through Paris before they were permitted to be transported further, and wines from other regions were not to be offered for sale before the 'vins de France' had all been sold. The wines of the LOIRE were also put on the market in Paris.

The 'vins de France' included not only the wines of Paris up to Vernon in Normandy but also those of CHAMPAGNE (Reims, Épernay, Châlons-sur-Marne): this usage continued among wine producers until just after the French Revolution. The Capetian kings of France, who reigned 987–1498, were particularly fond of the wines of Paris, but some of what they drank must have been from Champagne, since no distinction was made. In those days the region grew more than it could drink. Some of it was sold to the neighbouring areas of Normandy, Picardy, and Artois; the principal foreign export markets in the Middle Ages were England and Flanders. The 'vins de France' were highly esteemed both at home and abroad: in 1200 they fetched higher prices in London than the wines of ANJOU. H.M.W.

Parker, Robert M., Jr (1947–), extremely influential American wine critic whose most obvious contribution to the LITERATURE OF WINE has been the concept of applying NUMBERS to wine. His scores, followed slavishly by some COLLECTORS and even more by INVESTORS, had a demonstrable effect on individual wine PRICES, especially in the 1990s and the early years of the 21st century.

Robert Parker was born in farming country near Baltimore and both trained and worked as a lawyer there. He discovered wine at the age of 20 on his first trip to France. By the mid 1970s, at the height of active consumerism, Parker became frustrated by the lack of truly independent and reliable wine criticism and began to think about launching his own consumer's guide to wine buying.

The first, complimentary, issue of his bi-monthly newsletter the *Wine Advocate* appeared in 1978, and by 1984 he felt confident enough of its success to retire from the legal profession and concentrate on the punishing schedule of tastings and travel on which it was based. By then he had made a name for himself with his enthusiastic, and unusually detailed, endorsement of the 1982 vintage in Bordeaux, and subscriptions grew rapidly alongside the American market for wine FUTURES. By 1998, when a French-language edition was launched, the *Wine Advocate* had more than 45,000 subscribers, mainly in the United States but in more than 35 other countries. There were no advertisements but hundreds of TASTING NOTES and assessments of individual, usually fine, wines. His judgements had a huge effect, not just on market demand and the commercial future of some producers but on wine styles, since he was perceived as favouring concentrated wines relatively high in alcohol, and such wines would be described as Parkerized. His power at one stage was so great that it encouraged producers around the world to adapt the style of their wines regardless of their own personal tastes.

Parker's was by no means the first American consumer wine newsletter, but it was the first to use scores—effectively between 85 and 100 for individual wines—quite so obviously. This system was easily and delightedly grasped by Americans familiar with high-school grades, even though Parker himself urged caution, asking readers to use the numerical ratings 'only to enhance and complement the thorough tasting notes, which are my primary means of communicating my judgments to you'. Wine salespeople were less circumspect and used Parker's ratings mercilessly, while the notion of SCORING wine at all came under attack from some other wine

authorities, notably Hugh JOHNSON, whose view is that wines themselves vary with time and conditions of tasting and that wine tasting is an intrinsically subjective process. Parker's own view, stated on the cover of every issue of the *Advocate*, was that 'wine is no different from any consumer product. There are specific standards of quality that full-time wine professionals recognize.'

Parker's diligence in recording the impressions of his hard-worked palate provided the ingredients for several lengthy books, including *Wine Buyer's Guides*, essentially *Advocate* compendia. *Bordeaux* first appeared in 1985 and enjoyed considerable success in the United States, in Britain in 1987, and in France in 1989. The fourth edition appeared in 2003. *The Wines of the Rhône Valley and Provence*, which appeared in 1987 and was updated ten years later, reflected Parker's other great passion (he was instrumental in establishing the reputation and ambitious pricing policy of GUIGAL of Côte Rôtie, for example). *Burgundy* (1990), with its complex mosaic of appellations, producers, and vintages, and much subtler wines, succumbed less easily to being 'Parkerized'. Burgundian négociant François Faiveley's 1994 lawsuit was the first of several, subsequent ones involving past associates. By the late 1990s Parker was no longer working alone, and by 2012, when the *Wine Advocate* and associated website were sold to a Singapore former wine merchant for a reported $15 million, he had a substantial, fluctuating team of fellow tasters. Subsequently, in a two-stage deal, the business was sold to Michelin. Parker contributed his last tasting note in 2016 and officially retired in 2019.

Parker was a fervent, if critical, admirer of French wines. He was the first non-Frenchman to write a wine column for *L'Express* magazine and was made a particularly emotional Chevalier de l'Ordre du Mérite National in 1992. The Légion d'Honneur followed in 1999.

The sale, and the emergence of a new, post-Parker generation of American wine enthusiasts with different tastes and idols, resulted in a decline in the *Wine Advocate*'s influence.

Parraleta, interesting, fragrant red wine grape rescued from extinction in Spain's SOMONTANO region. It is also grown on Corsica and in Portugal under several aliases including Tinta Caiada.

partially de-alcoholized wine, an EU category for wine that has undergone alcohol reduction but retains a minimum of 0.5% alcohol by volume and does not exceed the legal minimum actual alcoholic strength before de-alcoholization for that category of wine (for still TABLE WINES, 8.5% in the cooler northern regions and 9% in the south). Unlike de-alcoholized wine, partially de-alcoholized wine may be labelled as a PDO or PGI, if permitted by the appellation concerned. Most other countries do not have a formal definition and may use looser terminology such as 'lighter alcohol', 'low alcohol' or 'reduced alcohol'. J.P.H.B.

partial rootzone drying, or PRD, Australian IRRIGATION technique designed to control vine VIGOUR and maintain wine quality with minimum interference to YIELD. PRD was developed by scientists Dry and Loveys from the University of ADELAIDE and CSIRO, after observation of basic vine physiology in response to WATER STRESS. Initially using vines with divided root systems, they discovered that when only a portion of a vine's root system was drying, TRANSPIRATION was reduced and shoot growth was slowed as a consequence of the production of the hormone ABSCISIC ACID by drying roots.

Field experiments with Cabernet Sauvignon showed that it was possible to control shoot vigour and reduce the amount of water needed while maintaining yield and quality. This was achieved with two DRIP IRRIGATION lines per row, used alternately for irrigation while the other part of the root system was drying. The results from these studies have been used to interpret some of the known beneficial effects of water stress, especially for red-wine quality. Commercial

adoption in vineyards has been limited, but research on grapevines and other crops has clearly shown that PRD can generate a unique physiological response that is distinct from what happens with conventional irrigation, including REGULATED DEFICIT IRRIGATION.

Iland, P., et al., *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

Pascale di Cagliari, Sardinian dark grape speciality, posssibly a natural progeny of Gibi (or Hebén) and MONASTRELL from Spain, according to DNA PROFILING.

Paso Robles , very large California wine region and AVA on the inland side of the coastal mountains in SAN LUIS OBISPO County.

An isolated inland plain of gently rolling hills, where the headwaters of the Salinas river congregate, Paso Robles first drew attention for its rich deposits of mercury ore. Mining operations grew quickly during the GOLD RUSH, attracting settlers such as Andrew York, who in 1882 set down the region's first vines of ZINFANDEL and established what would become York Mountain Winery. Despite some early plantings, including notably the Dusi Vineyard's Zinfandel in 1925, Paso remained a sleepy, rural wine region until the 1970s when significant plantings of Cabernet Sauvignon and Chardonnay were shown to be successful. Gary Eberle planted the state's first post-PROHIBITION acres of Syrah in Paso Robles in 1975. The 247,000-ha/612,000-acre region was established as an AVA in 1983 and divided into 11 sub-AVAs in 2014, largely on the basis of climatological and soil differences. Across Paso Robles the climate varies from relatively cool in its westernmost AVAs to quite warm (Region IV in the eastern highlands according to Winkler's CLIMATE CLASSIFICATION scale). Soils in the western reaches can be quite CALCAREOUS, while alluvial LOESS and even LOAM can be found in the eastern hills. The region's sub-AVAs include the cooler districts of El Pomar, Adelaida, Willow Creek, Santa Margarita Ranch, and

Templeton Gap; the warmer alluvial soils of the Creston, Estrella, San Juan Creek, and San Miguel districts; and the hot, windy hillsides of the Paso Robles Highlands and Geneseo districts.

Since its confirmation as an AVA, newcomers in an expanding roster of local wineries have embraced a wide array of grape varieties, with an emphasis on red BORDEAUX and RHÔNE varieties in addition to ZINFANDEL. Chardonnay still makes up 5% of the region's 16,187 ha/40,000 acres of vines, though it has been gradually losing ground to the more successful GRENACHE BLANC, MARSANNE, and ROUSSANNE, thanks in no small measure to the winery and vine nursery of Tablas Creek, a 1987 joint venture between the Perrin family of Ch de Beaucastel in CHÂTEAUNEUF-DU-PAPE and their American importer Robert Haas. This partnership firmly anchored Paso Robles specifically, and the Central Coast more broadly, as the epicentre of the RHÔNE RANGER movement in California. A.Y.

passerillé, French word for a grape that has dried, shrivelled, or raisined on the vine in a process known as passerillage, concentrating the SUGAR IN GRAPES—an alternative to wines whose sugars have been concentrated by BOTRYTIS. See also CUT CANE.

Passerina, white variety from Italy's Adriatic coast making a wide range of wine styles on 933 ha/2,305 acres of vines in 2015.

Passetoutgrains. See BOURGOGNE PASSETOUTGRAINS.

passing the port. One of the wine trade's most cherished traditions is the rule that PORT, particularly a decanter of vintage port, must be passed round a table from the right hand of diners to the left. No single satisfactory explanation has ever been advanced.

Howkins, B., *Real Men Drink Port…and Ladies Do Too!* (2011).

passito, Italian term for DRIED-GRAPE WINE.

Pasteur, Louis (1822–95), scientific genius and gifted scholar, has left a body of work which impinges on physics, chemistry, microbiology, agronomy, and medicine. On the centenary of his birth in 1922, the Institut Pasteur in Paris published a monograph on his principal discoveries listed under the following headings:

1847: Molecular dissymmetry
1857: Fermentations
1862: Supposedly spontaneous generations
1863: Study of wines
1865: Silkworm diseases
1871: Study of beers
1877: Virus diseases
1880: Viral vaccines
1885: Rabies protection

Pasteur's original work on what were supposedly spontaneous generations, or transformations, led him to interpret the process of alcoholic FERMENTATION and to demonstrate that this, far from being spontaneous, was the result of intervention by living cells, YEAST, using sugar for their own nutrition and transforming it into ALCOHOL and CARBON DIOXIDE. 'What causes it? I admit that I have no idea' (*Œuvres de Pasteur*, ii. 77). With something approaching genius, Pasteur understood the phenomenon without being able to provide a precise explanation; contemporary biochemistry was able to explain

in detail the different stages of the chemical fermentation mechanism only in the first half of the 20th century.

During his career as a scientist, Pasteur must have devoted only three or four years to the study of wine. Yet in this time he achieved as much as a good specialist researcher would have been delighted to achieve in an entire lifetime. Not only did he apply his theories to fermentation and ensure the mastery of the basics of vinification and conservation of wines, but he also perfected the art of adding TARTARIC ACID, demonstrated the presence of SUCCINIC ACID and GLYCEROL, and made valuable suggestions about the role of OXYGEN in wine AGEING.

But it was above all in the field of microbiological diseases of wine that Pasteur's work has been most valued. One of the early problems assigned to Pasteur was to explain and prevent the vinegar spoilage of red wines shipped in barrel from Burgundy to Britain, as well as to try to explain some of the many FAULTS in French wine which had become apparent at the time. He identified the following transformations in various wine constituents:

mannitic acid: degradation of sugars
tourne: degradation of tartaric acid
bitterness: degradation of glycerol
graisse: production of a polysaccharide

From his discovery of the various microorganisms which caused different wine maladies, such as the ACETOBACTER which turn wine into vinegar, came the whole science of bacteriology. He suggested that the application of heat (now called PASTEURIZATION) would destroy these microorganisms and prevent microbial development, with beneficial effects on the quality of wine. The demonstration of the existence of these BACTERIAL DISEASES was extremely fruitful for the science of OENOLOGY; it resulted in the progressive reduction in VOLATILE ACIDS in wine, which was an important factor in raising quality. Pasteur's research work on wine, and beer, also gave rise to

his remarkable studies on the cause and prevention of infectious diseases in humans and animals.

From a drop of faulty wine, characterized by the presence of microorganisms which could be seen with the aid of a microscope and by faults which could be tasted, Pasteur could contaminate a perfectly healthy wine. In 1866 he expressed his thoughts thus: 'When one observes beer and wine experiencing fundamental changes because these liquids have given asylum to microscopic organisms which were introduced invisibly and fortuitously to them, where they since proliferated, how could one not be obsessed by the thought that similar things can and must sometimes happen to humans and animals?'

Whatever the undoubted merits of Pasteur's work, to which we owe the basis of wine microbiology, with all its practical consequences for vinification and wine conservation, it should be noted that he did not understand the positive role that LACTIC ACID BACTERIA could have in degrading MALIC ACID. Because of this it was particularly difficult to grasp the principles of MALOLACTIC CONVERSION, which, in 1930, Jean RIBÉREAU-GAYON elucidated as a bacterial transformation which could be of great benefit to a wide range of wines. It was not until the 1970s that the rest of the wine world was convinced.

For Pasteur, 'yeast make wine, bacteria destroy it'. Pasteur truly created the science of winemaking; if today oenology is a discipline in so many universities throughout the world, it is to Pasteur that we owe this achievement. P.R.-G.

pasteurization, process of heating foods, including wines, to a temperature high enough to kill all microorganisms such as YEAST and BACTERIA. It is named after Louis PASTEUR, the French scientist who discovered that microorganisms were alive and the cause of much wine spoilage.

Heat sterilization techniques have improved greatly since the early versions of pasteurization, which often resulted in burnt or cooked

flavours in wines treated, particularly those that had not been subjected to complete CLARIFICATION. Wines are pasteurized by rapid heating to about 85 °C/185 °F for one minute, followed by quick cooling and a return to the storage tank or bottling line. Keeping the wine longer, for up to three days, at about 50 °C/122 °F is used to coagulate heat-unstable proteins and to speed ageing in low-quality red dessert wines. Flash pasteurization may also be effected by heating to temperatures as high as 95 °C for a few seconds, followed by rapid cooling. Some wine is hot bottled (at about 55 °C) and allowed to cool slowly; for utmost effectiveness, closed bottles of wine are occasionally heated to about 55 °C and cooled to room temperature under a water spray. These techniques are relatively brutal, however, and are used only on ordinary wines which have no potential for improvement after bottle AGEING. See also KOSHER wine.

Pauillac , small port and communal appellation in the MÉDOC district of BORDEAUX which has the unparalleled distinction of boasting three of the five FIRST GROWTHS ranked in Bordeaux's most famous CLASSIFICATION—Chx LAFITE, LATOUR, and MOUTON ROTHSCHILD—as well as a bevy of other CLASSED GROWTHS rivalling them (and each other) with increasing insistence. For all the importance of its wines, Pauillac gives the impression of being the only settlement in the Haut-Médoc to have an existence independent of wine—an impression reinforced by its size and nearby industrial installations.

This, however, is Cabernet Sauvignon country *par excellence*, and while there is considerable variation between different properties' TERROIRS and winemaking policies and capabilities, certain expressions recur in Pauillac tasting notes: cassis (blackcurrant), cedar, and cigar box (the last two sometimes a reflection of the top-

quality French oak COOPERAGE which the selling prices of Pauillac permit). A high proportion of the Médoc's most concentrated wines are produced here.

About 1,200 ha/3,000 acres of vines produce this famous appellation in an almost continuous strip between Pauillac's boundary with ST-JULIEN to the south and ST-ESTÈPHE to the north, separated from the waters of the Gironde estuary by only a few hundred metres of *palus* too marshy for serious viticulture (although very suitable for grazing Pauillac's famous *agneaux présalés*, salt-marsh lamb). This strip of vines, 3 km/2 miles wide and more than 6 km long, dedicated to the production of the world's most famously long-lived red wine, is divided into two by the small river Gaët, whose banks are also unsuitable for vines. As elsewhere in the Médoc, the layers of GRAVEL here provide the key to wine quality, offering excellent DRAINAGE, aided by the almost imperceptibly undulating topography and a series of *jalles* or streams running water off the gravelly plateau and into the Gironde.

The stars of the northern sector of Pauillac are the two ROTHSCHILD properties Chx Lafite and Mouton Rothschild, whose plots of vineyard are intermingled on the plateau of Le Pouyalet, reaching the considerable (for the Médoc) elevation of 30 m/100 ft at its highest point. Clustered around them are their satellite properties, whose wines benefit from the first-class winemaking ability of their owners. Ch Duhart-Milon is Lafite's fourth growth, made in the town of Pauillac. The fifth growths Ch Clerc-Milon and Ch d'Armailhac (the latter called Ch Mouton Baron Philippe and then Ch Mouton Baronne Philippe between 1956 and 1989) are made, to an often very high standard, close to Mouton itself. Other classed growths on this plateau just a stream away from St-Estèphe are the fifth growths Pédesclaux and Chx Pontet-Canet, the latter of which has attracted attention as a result of its espousal of BIODYNAMIC VITICULTURE.

Throughout the 1970s, much was made of the inter-Rothschild rivalry in the northern half of Pauillac, but it was resolved by the next generation. In the mid 1980s and early 1990s, the extreme south of the appellation around the village of St-Lambert was a battleground

for wine supremacy, between first growth Ch Latour and, particularly, its near neighbours the two Pichons. All three of these have made considerable investments in their vineyards, *chais*, and more cosmetic aspects of their property, and the Pichons have demonstrated that, just like first growth Latour, they are capable of making sublime wine at the St-Julien end of Pauillac. The Pichon-Longueville estate was originally one, but had already been divided into a smaller 'Baron' portion and a larger Comtesse de Lalande portion by the time the 1855 classification ranked them in the bottom half of the second growths (a very much lower position than they merit today). Pichon-Baron has been lavishly renovated by AXA Millésimes, while ROEDERER, owners of Pichon Lalande, later did the same across the road.

In the hinterland of this southern extreme of Pauillac are neighbouring fifth growths Chx Batailley and Haut-Batailley, whose wines can challenge those of fifth growth Ch Grand-Puy-Lacoste to the immediate north, which can offer some of Pauillac's best value. A dozen of the 18 fifth growths are in Pauillac, and none has been more successful than the Cazes family's flamboyantly styled Ch Lynch-Bages (the name betraying the original Irish connection), whose standing and fame suggest a considerably higher ranking. The biodynamically certified Ch Haut-Bages-Libéral, between Chx Latour and Lynch-Bages, can be great value.

Two of Pauillac's most distinctive products do not feature in the 1855 classification. Les Forts de Latour, the SECOND WINE of Ch Latour, is regularly one of its most successful wines, while the noted co-operative at Pauillac sells some of its dwindling production under the name La Rose Pauillac. Penning-Rowsell, E., *The Wines of Bordeaux* (6th edn, 1989).

Paulée, La. Originally a HARVEST TRADITION, the term was appropriated for a huge BYOB extended lunch in MEURSAULT on the Monday after the annual HOSPICES DE BEAUNE sale and is now used for

a series of bibulous events in the United States at which considerable predations are made in COLLECTORS' stocks of TROPHY WINES.

Pays d'Oc, the largest of the six regional IGPs in France, encompasses 120,000 ha/296,526 acres across four *departéments* in the Languedoc and Roussillon, from Gard in the east to the Pyrénées-Orientales in the west (plus a small part of the Lozère *département* north of Gard). Pays d'Oc wines make up around 15% of French wine production, the vast majority being VARIETAL wines made from any of the 58 allowed varieties but particularly Merlot, Cabernet Sauvignon, and Chardonnay. The vast region contains a great many MESOCLIMATES, as demonstrated by the diverse AOCs within it, but generally sunny, dry weather and frequent WINDS allow the region to produce more ORGANIC WINE by volume than anywhere else in France. In 2019, in an effort to combat CLIMATE CHANGE and further reduce the need for AGROCHEMICALS, the region introduced five DISEASE-RESISTANT varieties to the mix: Cabernet Blanc, Cabernet Cortis, Muscaris, Soreli, and Souvignier Gris, which can constitute up to 15% of a blend. More than half the region's production is in red wines; 25% is white; and the rest is rosé (mainly from Grenache, Cinsaut, and Syrah). Sparkling and sweet wines are also made.

PCA, or 2,3,4,5,6-pentachloroanisole. See TECA.

PCD. See PLANT CELL DENSITY.

PCR, abbreviation for polymerase chain reaction, a laboratory method based on DNA analysis used to detect vine pathogens. This technique has helped in determining strains of VIRUS, for example, and the INSECTS responsible for their spread.

Golino, D., et al., 'Laboratory testing for grapevine diseases', in L. J. Bettiga (ed.), *Grape Pest Management* (3rd edn, 2013), 61–8.

PDO, abbreviation for Protected Designation of Origin, a superior EU wine category created as part of the 2008 wine reforms. It encompasses all of the EU's CONTROLLED APPELLATION systems such as France's AOC, Spain's DO/DOCA, Italy's DOC/DOCG, and Portugal's DOC. Translations of PDO (such as AOP in France, DOP in Spain, Italy, and Portugal) are now seen on wine labels. In 2020 PDO wines represented 46% of EU production, although the proportion of PDO wine produced—as well as the quality—can vary dramatically among member states. PDOs enjoy special privileges in the EU wine system, including protection against misuse as well as the right to use TRADITIONAL TERMS and the special EU PDO symbol on the label. Non-EU countries are, in theory, able to register their own GEOGRAPHICAL INDICATIONS (GIs) as PDOs in Europe, but in most cases mutual protection of GIs is agreed with the EU through bilateral wine or free-trade agreements.

The PDO category is regarded as a higher order of geographical designation than the PGI. The quality and characteristics of a PDO are required to be 'essentially or exclusively due to a particular geographical environment with its inherent natural and human factors'—a higher threshold than for the PGI category. The grapes must also be grown entirely in the delimited area. Until recently they had to be sourced exclusively from VITIS, VINIFERA grape varieties, but this has been relaxed to make way for DISEASE-RESISTANT VARIETIES. PDOs generally have more stringent controls than PGIs, covering matters such as maximum yield, vineyard-management techniques, permitted varieties, harvesting, and winemaking. J.P.H.B.

www://ec.europa.eu/info/food-farming-fisheries/food-safety-and-quality/certification/quality-labels/geographical-indications-register

pearls or pearl glands, small, spherical nodules that develop on the surface of vine stems, PETIOLES, and the underside of leaves along the

large veins. They form under warm humid conditions, such as in a glasshouse, and when the vine's growth is exuberant. They are a multicellular outgrowth of the epidermis, even to the extent of an occasional STOMA, but collapse to a rusty colour and disappear when the humidity drops. B.G.C.

Pécharmant, AOC for red wines (400 ha/1,000 acres) within the BERGERAC district in SOUTH WEST FRANCE. The grape varieties are as for Bergerac (Cabernets Franc and Sauvignon with Merlot and sometimes a generous dose of Malbec); their distinctiveness is due to the soil, which contains a good amount of IRON and MANGANESE. The wines are some of Périgord's longest-lived reds, but few escape the region. The best-known producer is Ch de Tiregand, presided over by members of the St-Exupéry family. P.S.

Pecorino, vine speciality of the MARCHE and ABRUZZO on Italy's east coast that has made a VARIETAL comeback because of its firm, dry, minerally white wine that compares well with the local Trebbiano. Total area planted grew from 87 ha in 2000 to 1,628 ha/4,023 acres by 2015. Also a Calabrian synonym for GRECO BIANCO.

pectinase, an ENZYME used to break up grape PECTINS and thus speed up SETTLING. It is also used to promote juice and flavour extraction during SKIN CONTACT.

pectins, carbohydrate polymers made up of galacturonic acid units which have the important function of 'gumming' plant cells together. The group is diverse and includes pectic acid, hemicelluloses, and gums; the associated sugars are galactose, mannose, and arabinose. The pectin content of grapes increases steadily throughout ripening, reaching levels of about 1 g/l. Pectin is an important contributor to COLLOIDS. For the importance of pectin hydrolysing enzymes to winemaking, see ENZYMES. B.G.C.

Pedernã, MINHO synonym for ARINTO.

pedicel, the stalk of an individual flower which, on a bunch of grapes, becomes the short stem bearing each berry. Its length varies with vine variety, from 5 to 15 mm (0.2–0.5 in), and its diameter varies with variety and BERRY SIZE. After FLOWERING, pedicels are liable to develop a separation layer at their base causing the unfertilized flower to drop; the remainder adhere and can develop into berries (as in FRUIT SET). When berries of certain vine varieties ripen, the pedicels may develop a corky abscission at their top, at the junction with the berry. If this does not happen, then pulling off the berry tears the skin and leaves behind a chunk of pulp on the end of the pedicel that is called the BRUSH. B.G.C.

pedogenic limestone. See LIMESTONE.

Pedro Giménez, declining but still quite important white grape variety in ARGENTINA, where, along with the coarse and declining CRIOLLA GRANDE and CEREZA, it is one of the vines underpinning the country's substantial production of everyday wine for domestic consumption. Most of its 9,587 ha/23,690 acres in 2020 were in Mendoza, but it is also found in Chile's PISCO region. It is a spontaneous LISTÁN Prieto (Criolla Chica) × MUSCAT OF ALEXANDRIA (Moscatel) cross and not related to PEDRO XIMÉNEZ.

Pedro Ximénez, white grape variety traditionally associated with ANDALUCÍA in southern Spain, found especially in MONTILLA-MORILES, where it accounts for around 95% of all plantings, and also in CASTILLA-LA MANCHA. By 2020 there were 7,865 ha/19,435 acres of the variety in Spain. Producers in JEREZ and MÁLAGA routinely import the dark, super-sticky wines made from Pedro Ximénez grown in Montilla-Moriles to sweeten blends. Many SHERRY producers sell varietal PX, as

it is often called, under their own labels. Traditionally dried in the sun, the thin-skinned grapes are generally lower in acid and alcohol than the sherry grape PALOMINO FINO, which is more productive and less disease-prone than Pedro Ximénez. It is grown as Perrum on about 250 ha/717 acres of Portugal's ALENTEJO.

In Australia, Pedro Ximénez, often breezily called Pedro, was once quite widely grown but its total area had fallen to 15 ha/37 acres by 2022. It has been known to shine, most particularly in BOTRYTIZED form to produce the rich, deep golden McWilliam's Pedro Sauterne (*sic*) made in the last century in IRRIGATED vineyards near Griffith in NEW SOUTH WALES. Most of Chile's Pedro Jiménez (*sic*) is used for PISCO production, but a VARIETAL dry white is made in the Elqui Valley.

peduncle. See STEM.

Peel, warm coastal region just to the south of Perth in WESTERN AUSTRALIA with CHENIN BLANC and SHIRAZ its best wines.

pé franco , Portuguese for UNGRAFTED.

Pelaverga, pale, rare red grape of Piemonte making slightly fizzy, strawberry-flavoured wines. The even rarer and more admired Pelaverga Piccolo is a distinct variety.

Peloursin, obscure red grape variety found in Isère in France's Rhône-Alpes region and known mainly as a parent of PETITE SIRAH.

Pemberton , cool inland region of WESTERN AUSTRALIA with 466 ha/1,152 acres of vines in 2020 and strength in CHARDONNAY.

Penedès in Catalan, Penedés in Spanish, is the largest and most important denominated wine zone in CATALUÑA in north-east Spain (see map under SPAIN), producing an innovative range of wines from 24,259 ha/59,945 acres of vineyard in 2021. With its proximity to Barcelona, Penedès has always had a ready outlet for its wines. In the 19th century, it was one of the first regions in Spain to begin mass production, and France, stricken by PHYLLOXERA, became an important market. Phylloxera reached Penedès in 1887, by which time José Raventós had laid the foundations of Cordoníu and the CAVA industry. Vineyards that had once produced strong, semi-FORTIFIED reds were uprooted in favour of white grapes for sparkling wine. Cava has subsequently developed a separate nationally organized DOP.

Penedès underwent a second radical transformation in the 1960s and 1970s largely because of Miguel Torres Carbó and his son Miguel A. Torres (see FAMILIA TORRES), wine (and brandy) producers in the heart of the region at Vilafranca del Penedès. They were among the first in Spain to install TEMPERATURE CONTROL and STAINLESS STEEL tanks. Miguel Torres Jr, who studied OENOLOGY in France, also imported and experimented with such revolutionary vine varieties as Cabernet Sauvignon, Chardonnay, Sauvignon Blanc, Merlot, Pinot Noir, Riesling, and Gewürztraminer, which were planted alongside and blended with INDIGENOUS VARIETIES. Other growers followed in the Torres family footsteps, and Penedès was in the 1980s one of the most dynamic and varied wine regions in Spain. By the late 1990s, however, the region was failing to confirm the high hopes placed in its red wines, which were increasingly overshadowed by those of PRIORAT.

The Penedès DOP allows almost any style of wine or grape variety. The region rises from the Mediterranean like a series of steps and divides into three distinct zones, with ten subzones. Penedès Maritím sits between the sea and the coastal hills, its vineyards planted in LIMESTONE soils at ELEVATIONS of 250 m/825 ft. The warmest part of the region, it traditionally grew MALVASÍA and Moscatel de Alejandría (MUSCAT OF ALEXANDRIA) grapes for sweet FORTIFIED wines, but today still, dry XARELLO and Malvasía de Sitges are more representative

wines. Penedès Superior is inland, climbing into the mountains, at 500–800 m (1,640–2,625 ft) in elevation. This is the region's coolest area where some of the best white grapes are grown. The native PARELLADA is its most important variety, but Riesling, Muscat of Alexandria, Gewürztraminer, and Chardonnay are also successful, and Xarello is increasingly positioned as the most TERROIR-expressive wine in the region, with producers bottling high-end 100% VARIETAL examples.

In between is Penedès Central, a plain at 500 m/1,640 ft in elevation. This is the most productive part of the region providing much of the base wine for the sparkling wine industry at Sant Sadurní d'Anoia (see CAVA). MACABEO, Xarello, and PARELLADA are grown for Cava and sparkling wines, together with Chardonnay and red varieties such as TEMPRANILLO (often called here by its Catalan name Ull de Llebre) and Cabernet Sauvignon.

The increased interest in SPARKLING WINE in this century led to the creation of Clàssic Penedès in 2014. Reserved for DOP Penedès sparkling wines made from organically grown grapes (see ORGANIC VITICULTURE), produced using the TRADITIONAL METHOD, and aged at least 15 months before release, the category has drawn some prominent names such as Albet I Noya, AT Roca, and Loxarel away from the DOP Cava. Producers using the MÉTHODE ANCESTRALE can use just DOP Penedès.

In 2021, Vi de Mas classification was introduced in order to highlight top parcels with history and track records for exceptional wines. Vi de Mas wines can come only from officially recognized farm estates (MAS) that predate the phylloxera outbreak of 1900; the parcels themselves must be wholly controlled by the estate, at least ten years old, and organically farmed. Gran Vi de Mas come from vineyards at least 25 years old and have attracted international attention for quality wines for at least a decade. The first five Vi de Mas wines were certified in 2022, with more expected to come.

Penfolds, makers of Australia's most famous fine wine Penfolds Grange, since 2014 the jewel in TREASURY WINE ESTATES' crown. Penfolds was founded in 1844 at Magill, SOUTH AUSTRALIA, by Dr Christopher Rawson Penfold and his wife Mary. For more than 100 years, Penfolds, in common with most Australian wineries, concentrated on producing FORTIFIED wines and brandy, much of which was exported to the UK. In 1950, Max Schubert, then chief winemaker, visited Europe, primarily to observe the making of SHERRY in Spain, but detoured on the way home to visit Bordeaux, where he was taken in hand by important NÉGOCIANT Christian Cruse. This inspired him to adopt an entirely new approach to fermentation techniques and the use of new oak, the aim being simultaneously to protect the varietal flavour of Shiraz while adding a level of complexity previously unknown in Australia. Schubert's ambition was to create a red that would rival the finest wines of Bordeaux for both quality and the potential to improve with age for up to 50 years. This he achieved with Penfolds Grange, known as Penfolds Grange Hermitage until EU authorities objected to this misappropriation of a French place name. The first vintage of Grange, named after Dr Penfold's cottage in Magill, was 1951; all early vintages were made from Shiraz grapes grown at Magill and Morphett Vale, Adelaide, and the wine was BARREL AGED in new American oak for 12 months. So intense did the first vintages seem that they were rejected as maverick 'dry port'. In 1957 Schubert was ordered to cease production of Grange; instead he took the operation underground, emerging three years later when maturing vintages began to fulfil their promise. The best vintages of Grange improve for up to 30 years and beyond, and the wine became the first NEW WORLD wine to become an internationally acknowledged collectible (see TROPHY WINES). Fruit from Kalimna in the Barossa Valley was introduced in 1961, boosted by grapes from the Clare and Koonunga Hill vineyards. Small amounts of Cabernet Sauvignon are included in most vintages

of Grange, and the wood-ageing period has been lengthened to 18–20 months. The wine is not released until five years after the vintage.

A string of award-winning red wines from Penfolds followed, many identified by BIN numbers which originated in the winery stock-keeping system. Of particular note is Bin 707 Cabernet Sauvignon. In 1998 Penfolds released the first vintage of its super-premium Yattarna Chardonnay, now recognized as one of Australia's finest. A stream of 'Special Bin' luxury reds followed in the early 2000s, not least the 2008 Bin 620 Cabernet/Shiraz, priced in line with first-growth bordeaux, and 2010 Bin 170 Kalimna Shiraz, which is even more expensive. If PRICES are a guide, Penfolds had truly arrived on the luxury catwalk by the early 21st century. Penfolds became so famous in CHINA that it was paid the compliment of COUNTERFEITING, with Treasury dreaming up ever more expensive formats of the BRAND. See also RECORKING. J.H. & H.H.

Caillard, A., *The Rewards of Patience* (8th edn, 2020).

Hooke, H., *Max Schubert, Winemaker* (1994).

Penicillium, one of a group of FUNGI commonly found on rotten grapes. See BUNCH ROTS.

Península de Setúbal, VINHO REGIONAL in southern Portugal (called Terras do Sado until 2009) encompassing the SETÚBAL Peninsula between the Tagus and Sado estuaries and, to the south, the Troia Peninsula and a 60-km/37-mile stretch of the Alentejo Litoral (see PORTUGAL map). The warm MARITIME CLIMATE is particularly well suited to winemaking. In the 19th century, the north-facing slopes around the village of Azeitão were planted with several Moscatel (MUSCAT) varieties for sweet, FORTIFIED Setúbal, but, since this wine's decline in popularity, other varieties have largely taken their place.

Production is heavily concentrated in the hands of one of Portugal's best CO-OPERATIVES, Cooperativa Agrícola de Santo Isidro de Pegões, and three companies—José Maria da Fonseca, Bacalhôa Vinhos de Portugal (previously known as J. P. Vinhos), and Ermelinda Freitas—who have modernized the region's winemaking and vineyards. Accordingly, the Península de Setúbal now produces a wide range of wines, from well-established brands such as Periquita to single-estate wines such as Quinta da Bacalhôa.

Within the region is the Palmela DOC, which has two distinct TERROIRS: the LIMESTONE hills of the Serra da Arrabida, and the SANDY soils of the plain which extends eastwards from the fortress town of Palmela. Here, the widely planted, traditional CASTELÃO grape (which must represent at least two-thirds of any DOC red) can produce distinctive, full-bodied wines which develop savouriness and depth with bottle AGEING. Where the rules are more relaxed, Castelão (here nicknamed Periquita) has become less important, especially where Cabernet Sauvignon, Merlot, and Syrah (and for whites, Chardonnay) have been grown so successfully on the limestone Arrabida Hills. Vine varieties from northern Portugal have taken hold here, too, including TOURIGA FRANCA, TOURIGA NACIONAL, and, for whites, ALVARINHO, VERDELHO, and ENCRUZADO, which augment local varieties ARINTO and FERNÃO PIRES. To the south (on the Troia Peninsula and in the Alentejo Litoral area) several ambitious estates were established in the early 21st century. The grapes of the ALENTEJO have been most popular, especially ALICANTE BOUSCHET, Aragones (TEMPRANILLO), and TRINCADEIRA—although one producer has made a name for itself with SANGIOVESE. Another is ageing wines under the ocean (see UNDERWATER AGEING). White and red wines here tend to be full-bodied; those benefiting from pronounced Atlantic influence can retain impressive acidity. S.A.

Mayson, R. J., *The Wines of Portugal* (2020).

Peninsulas, The. This wine zone and GEOGRAPHICAL INDICATION on the western edge of SOUTH AUSTRALIA takes in the Southern Eyre Peninsula and the Yorke Peninsula on either side of the Spencer Gulf.

Penning-Rowsell, Edmund (1913–2002), English wine writer with a scholarly interest in the history and wines of BORDEAUX in particular. Educated at Marlborough College and a lifelong socialist, he was a journalist on the *Morning Post* from 1930 until 1935, when he began a career of almost 30 years as a book publisher. He was introduced to the pleasures of wine when his wife's employer at the BBC gave her as a leaving present (only unmarried females were then regarded as suitable employees) some non-vintage MOULIN-À-VENT. Correspondence and eventual friendship with Bristol wine merchant Ronald Avery was another formative influence.

The traditional but non-profit-making ethos of the co-operative buying group the WINE SOCIETY suited him perfectly, and he joined the Society soon after his marriage in 1937. He served as its chairman from 1964 until 1987, a record length of time.

In 1949 he reviewed wine books for the *Times Literary Supplement* and in 1954 wrote his first wine article for the magazine *Country Life*. After 1964, soon after his publishing career came to an end, he became wine correspondent of the *Financial Times*, scrupulously refusing to mention the Wine Society during his chairmanship. His wine primer *Red, White and Rosé* was published in 1967, and a second edition appeared in 1973, but his great gift to the LITERATURE OF WINE is *The Wines of Bordeaux*, which was first published in 1969 and whose sixth edition appeared 20 years later.

Until his sight failed him, he meticulously recorded the facts of his remarkable cellar in a series of cellar books in his characteristic green ink. This unique archive included details of every purchase, every souvenir from his annual round of visits to the wine regions (continued into his ninth decade), and impressions of every bottle sampled.

A perennial figure in Bordeaux at vintage time and at the HOSPICES DE BEAUNE auction, Penning-Rowsell was made a Chevalier de l'Ordre du Mérite Agricole in 1971 and a Chevalier de l'Ordre du Mérite National in 1981.

Loftus, S., 'Purple prose: the wine writers', in *Anatomy of the Wine Trade* (1985).

Pennsylvania , state in the north-east United States ranking sixth nationwide in number of wineries and eighth (tied with NORTH CAROLINA) in volume of wine produced. The state's winemaking history dates to 1683, when William Penn, founder of the colony of Pennsylvania, planted a vineyard with VITIS VINIFERA varieties brought from Bordeaux. They quickly died, but the attempt spurred others, both English hoping to recreate CLARET and Germans homesick for RHENISH wine. Success came in the 1780s with Pierre Legaux, a French immigrant who, with the backing of shareholders including Alexander Hamilton and Aaron Burr, established a commercial winery and nursery with what he believed to be *vinifera* but turned out to be Alexander, a spontaneous *vinifera* × VITIS LABRUSCA hybrid thought to have originated from Penn's original plantings. While Legaux's business ultimately failed, vines from his nursery led to winegrowing ventures all over the east coast and the Midwest.

In 1870 Pennsylvania's industry reached its peak, at 440,971 l/97,000 gal of wine a year. A subsequent shift to growing CONCORD, used mainly for juice and jam, soon followed by PROHIBITION, decimated the industry.

Post-Prohibition, rebound was hampered by the state's Liquor Control Board, which tightly controls the production and distribution of all liquor within the state. It was not until 1968 with the establishment of the Limited Winery License that winemakers were allowed to sell a limited amount of wine directly to customers. From 11 wineries in 1976, there were more than 370 in 2022, with 5,665 ha/14,000 acres of vines.

Concord continues to dominate plantings, grown extensively in the north-western end of the state, in the Lake Erie AVA, shared with NEW YORK and OHIO. More important to the fine-wine industry are the AVAs in the south-east. Lehigh Valley, on a LIMESTONE basin along the east side of the Lehigh river, has well-drained SHALE and limestone soils and a moderate climate supportive of *vinifera* varieties such as RIESLING and CABERNET FRANC, although the local speciality is CHAMBOURCIN. Lancaster, to the south-west, is a continuation of that limestone basin, with richer soils and warmer temperatures.

Winemaking challenges across the state include FROST, humidity, FUNGAL DISEASES, and pests such as the SPOTTED LANTERNFLY and Spotted Wing DROSOPHILA. PennState College of Agricultural Sciences runs a robust research centre focused especially on east-coast vine-growing, including evaluation of disease-resistant and cold-hardy varieties and sustainable winegrowing.

Pinney, T., *A History of Wine in America: From the Beginnings to Prohibition* (1989).

pennsylvaniawine.com

pepper, a tasting term for two very different aromas commonly found in red wines. Bell peppers, or green peppers, is used characteristically in the US for the aroma of underripe CABERNET SAUVIGNON. A freshly sliced green pepper or capsicum liberates the chemical compound 2-isobutyl-3-methoxypyrazine (see METHOXYPYRAZINES), a vegetable-like or HERBACEOUS aroma to which many tasters have a very low threshold (see FLAVOUR COMPOUNDS).

Young wines made from the SYRAH grape, on the other hand, particularly if it does not reach full maturity, can smell of black peppercorns, while GRÜNER VELTLINER sometimes smells of white peppercorns. See ROTUNDONE.

Per'e Palummo. See PIEDIROSSO.

pergola, a form of overhead VINE TRAINING. Where the CANOPY is horizontal, the pergola can alternatively be called TENDONE. Pergola trellises can be either one- or two-armed, depending on whether the vines are trained on one or both sides of the row. If the trellis is joined overhead, it is called a closed pergola.

The pergola is widely used in northern Italy, where the canopies vary but are often inclined rather than horizontal (in Trentino, for example, the slope is 20–30 degrees). *Maggiorina* is an ancient and rare type of pergola found only in ALTO PIEMONTE, for example in BOCA. In Emilia-Romagna the pergoletta system is used, while the pergoletta Capucci was developed by the eponymous Bologna professor. The pergoletta a Valenzano is very similar to the GENEVA DOUBLE CURTAIN. Where the vines have marked VIGOUR, the bunches which hang below the leafy canopy are in SHADE, with predictable negative effects on wine quality. This century there has been a resurgence of interest in pergola systems. It does intercept most if not all SUNLIGHT and so has a high yield potential in marginal climates. The overhead leaf canopy may be an advantage as temperatures increase with CLIMATE CHANGE, and in AOSTA its value in protecting against HAIL has been noted. R.E.S.

pericarp, the 'fruit wall' forming the bulk of a plant's ovary, consisting of sugary flesh and highly coloured skin attractive to animals, especially BIRDS, with the result that the seeds are spread. In the grape berry, the whole fruit except for the seeds (both the skin and the flesh) constitutes the pericarp. See GRAPE for more details.

Pérignon, Dom (1639–1715), Benedictine monk who has gone down in history as 'the man who invented champagne'. The title is the stuff of fairy-tales: the transition from still to sparkling wine was an evolutionary process rather than a dramatic discovery on the part

of one man. The life of Dom Pérignon was in fact devoted to improving the still wines of CHAMPAGNE, and he deserves his place in the history books for that reason. Father Pierre Pérignon arrived at the Abbey of Hautvillers, north of Épernay, in 1668. His role was that of bursar, and in the 17th century that included being in charge of the cellars. He collected tithes from surrounding villages in the form of grapes and wine, fermenting and blending until he created wines that sold for twice as much as those of the abbey's rivals. Dom Pérignon introduced many practices that survive in the process of modern wine production, among them severe PRUNING, low YIELDS, and careful harvesting. He also experimented to a great extent with the process and was one of the first to BLEND the produce of many different vineyards. Dom Pérignon produced still white wines, favouring black grapes because a second fermentation was less likely. Ironically, he was often thwarted in his endeavours by the refermentation process (see SECOND FERMENTATION), which produced the style of wine that was eventually to prove so popular. His fame as the 'inventor' of champagne probably spread after his death, embellished by Dom Grossard, the last bursar of the abbey, which closed at the time of the French Revolution. More modern champagne producers have jumped on the bandwagon, promoting the idea of a founder figure. Eugene Mercier registered the brand name Dom Pérignon before MOËT & CHANDON acquired it and used it to launch the first champagne marketed as a PRESTIGE CUVÉE, a 1921 vintage launched in 1936.

Periquita, Portuguese word meaning 'parakeet' that is both a name for CASTELÃO in the PENÍNSULA DE SETÚBAL and a branded red wine from José Maria da FONSECA.

perlant, French term for a wine that is only slightly SPARKLING. Perlwein is the German equivalent. See FIZZINESS.

Perle, pink-berried, late-budding, rot-prone GERMAN CROSS of Gewürztraminer and Müller-Thurgau that can still be found in small pockets in Germany, mainly in FRANKEN.

Perlwein, German term for lightly SPARKLING wine, with a pressure inside the bottle of 1–2.5 bar. See FIZZINESS.

Pernand-Vergelesses, village in the Côte de Beaune district of Burgundy's CÔTE D'OR producing red and white wines. The former, made from Pinot Noir, now ripen more successfully than they did in the past. This was never a problem with the finest east-facing vineyard, Ile des Vergelesses, whence Pernand derives its suffix.

The most sought-after wines are the whites on the Pernand side of the hill of Corton (see ALOXE-CORTON). Seventeen of the 58 ha/143 acres entitled to the GRAND CRU appellation Corton-Charlemagne lie within Pernand-Vergelesses. White Pernand wines, made from Chardonnay, have a hard but attractive flinty character which develops well during bottle AGEING. As it ages, BOURGOGNE ALIGOTÉ from this area is said to resemble white Pernand-Vergelesses; and white Pernand to approach the quality of Corton-Charlemagne.

The most famous producer based in Pernand-Vergelesses is Bonneau du Martray, one of the top names in Corton-Charlemagne, while Domaines Dubreuil-Fontaine, Rapet, and Rollin also produce fine ranges of wine.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

peronospora, European name for the very important VINE DISEASE more usually called DOWNY MILDEW.

Perricone, north-west SICILIAN red grape variety whose total area stood at 521 ha/1,287 acres in 2020. Sometimes called by its synonym Pignatello, it has been shown by DNA PROFILING to be an offspring of SANGIOVESE.

Perricoota, riverine region on the northern banks of the Murray river in southern NEW SOUTH WALES.

Perrum. See PEDRO XIMÉNEZ.

Perruno, old, light-skinned Spanish variety from EXTREMADURA and one of the six traditional varieties recently added to those authorized for the production of SHERRY.

Persan, rare but promising SAVOIE red grape which can produce wines worth AGEING. Interest in it is also increasing in neighbouring ISÈRE.

Persia, Near Eastern country officially known as IRAN since 1935, which has known the consumption of wine since ancient times.

Ancient Persia

Much of this area was also known as MESOPOTAMIA in classical times. The earliest chemical evidence for grape wine comes from the Neolithic village of Hajji Firuz Tepe, about 5400–5000 BCE, in the northern Zagros Mountains of north-western Iran. Six jars in a kitchen of an average household would originally have held some 55 l/15 gal of wine, based on the presence of TARTARIC ACID which is found in large amounts in the Middle East only in grapes. The intended product was most likely wine and not vinegar or another grape product, because clay stoppers were used to close the narrow mouths of the jars and a tree resin, probably terebinth with antioxidant properties, was added to the wine as a preservative. Hajji Firuz was among the first year-round settlements based on newly domesticated plants and animals of the Neolithic period. The Eurasian VITIS VINIFERA grapevine might well have been one of those domesticates. The invention of pottery around 6000 BCE gave impetus to the process, since special vessels for preparing, storing, and serving wine could now be made. Similarly, two millennia later, pottery jars, one stored on its side, in rooms at the site of Godin Tepe, further south in the Zagros (dated to about 3500 BCE) in central western Iran, were shown to contain a resinated wine.

More detailed evidence is available from the era of the Achaemenid Dynasty, which ruled ancient Iran from *c.*559 to *c.*331 BCE. Cyrus the Great and Darius extended Persia's power to cover all the lands from the Mediterranean in the west to the river Indus in the east, incorporating the old empires of BABYLONIA and Assyria, which were overwhelmed and extended. Dating from the period just before Persia and Greece became embroiled in the Persian Wars, an enormous archive of documents written on clay tablets in the Elamite language preserves detailed records of the administration of the Achaemenid royal capital Persepolis from 509 to 494 BCE. Here there are records concerning the distribution of large quantities of (grape) wine and *sawur*, another (probably weaker) sort of wine. Sometimes

the wine was stored at, or issued from, the ancient city of SHIRAZ, whose name is now associated with so many wines. Wine was normally released in monthly amounts, although in certain cases the issue was daily. One *marrish* (a measure of 10 quarts) of wine was valued at one shekel.

Such 'rations' often amounted to far more than one person could consume: perhaps they would be better described as salaries. Some were given to important women with households of their own to support: these received 30 quarts per month. King Darius writes in one order that 100 sheep and 500 gal of wine should be issued for the royal princess Artystone, no doubt in order for her to give a lavish banquet at her own court. Persian royal ladies were very independent and maintained their own establishments and dependants.

Generally wine was not given to boy and girl workers (who did, however, receive other rations including sometimes beer), except according to one document where some boys received one-third of a quart daily for 156 days. Otherwise the general allowance was 10 or 20 quarts monthly for men and 10 for women. Some labourers received a good deal less.

Presumably in an effort to increase the working-class population available for large-scale labour, special wine rations were provided under the Achaemenid Dynasty as a reward for women labourers who had just given birth to children: women who bore sons received 10 quarts, and those who bore daughters 5 quarts. The issue was sometimes spread out over the entire subsequent year.

Important caravans of diplomatic visitors accompanied by elite guides travelled from as far afield as Kandahar, India, Sardis, and Egypt. Those due to arrive at the capital Persepolis during the cooler months of the year (November to May), when the king and his entourage were in residence, were issued with travel rations to ease their arduous journey at the various stations at which they put up on the Royal Road. The records indicate that these, naturally, included generous amounts of wine.

On occasions wine was issued, along with grain and beer, for the benefit of the royal horses, perhaps when they were used for long

journeys. The amounts issued varied from half a pint to 10 pints per animal per month. *Sawur* wine was even made available to the king's camels as an occasional concession.

In the 5th century BCE, HERODOTUS noted that the Achaemenids would make important decisions in a drunken state, then confirm these decisions when sober, and vice versa. The Persian empire was finally split up after the death of Alexander the Great in 323 BCE.

Hallock, R. T., *Persepolis Fortification Tablets* (1969).

Shiraz as wine capital

The consumption of wine survived through the Sassanian Period, from the 3rd to the 7th centuries CE, influenced in part by Zoroastrian rite, and continued after the subsequent ISLAMIC conquest of the country.

Shiraz, a city rebuilt 50 km/30 miles from the site of Persepolis by the Arabs in the 8th century and the home town of Hāfiz, Persia's most famous mystic Bacchic poet (see ARAB POETS), had acquired a reputation by the 9th century for producing the finest wines in the Near East.

Thanks principally to the work of Edward Fitzgerald in the 19th century, the medieval polymath and poet OMAR KHAYYÁM has become famous in the west for poetry in which wine plays an important part.

From the diaries of 17th-century English and French travellers and especially the writings of C. J. Wills in the 19th century, we gain a picture of the excellence of some Persian wines. Tavernier (17th century) wrote: 'The wine of Shiraz has by far the greatest foreign as well as native celebrity, being of the quality of an old sherry and constitutes an excellent beverage.' In the same century, Thomas Herbert commented: 'No part of the world has wine better than Shiraz.'

The wine most often described and praised was white, made from thick-skinned, pip-filled grapes grown on terraces round the village of Khoullar, four days' camel ride away from Shiraz (those grown in the immediate vicinity of the city produced watery wine, thanks to excessive IRRIGATION). C. J. Wills describes a 19th-century replication of the traditional Shiraz winemaking process in some detail. The wine, fermented on the skins with regular PUNCHING DOWN, was made either sweet and fruity for long keeping, the stems being removed immediately after fermentation in used jars, or dry and rich in PHENOLICS for drinking in its first year or so. A form of FILTRATION through coarse canvas bags was practised. Wills describes the wine as 'like a light BUCELLAS' when young, to be avoided on account of the

headaches it induces. After five years, however, it attains a 'fine aroma and bouquet' and 'nutty flavour'.

See also DRIED-GRAPE WINES, for the Persians were certainly in the habit of drying their grapes. P.K.

Hugh Johnson paints a fascinating and vivid picture of the export of wine from Shiraz to India by European merchants, in 1677 already in BOTTLES 'wrapped in straw and packed in cases… swaying down to the Gulf Coast on mule back. There is scarcely any earlier instance of the regular use of bottles for shipping wine.' Tavernier notes that the 1666 vintage was so bountiful that the Persian king gave permission to export as much wine to the French, English, Dutch, and Portuguese trading companies as was retained by himself and his court. Wine was measured in 'mans', units of weight rather than volume.

For an outline of modern viticulture, see IRAN.

Perth Hills, picturesque, rapidly growing warm region just east of Perth in WESTERN AUSTRALIA.

Peru , the first country in South America to have encouraged systematic viticulture. Under orders from the famous conquistador Francisco Pizarro, the first Peruvian vineyard was planted in about 1547. VINE VARIETIES were imported from Spain's CANARY ISLANDS, particularly Negra Criolla (see NEGRAMOLL), which is used today chiefly for PISCO. By the 1560s Peru is thought to have had 40,000 ha/99,000

acres under vine, producing so much wine that it was exported to other South American countries and even, according to one document, as far as Spain. One of the several ways by which viticulture spread to Argentina was from Peru, with Nuñez de Prado, a 16th-century Spanish conquistador.

The arrival of PHYLLOXERA in 1888 heralded the start of a serious decline in Peruvian viticulture. Only in the 1970s was progress made on establishing suitable planting material, and there are now NURSERIES at Ica, Chincha, Moquegua, and Tacna, as well as a national wine research centre, Centro de Innovación Tecnológica Vitivinícola (CITEVID).

According to OIV statistics, 48,000 ha/118,611 acres of Peru were planted with vines in 2020, yielding mainly TABLE GRAPES. In 2021 Peru had just over 40 wine producers dedicated to still wine production. The main wine producers are Tacama, with 187 ha/462 acres planted, and Queirolo, with 300 ha dedicated to INTERNATIONAL VARIETIES.

Almost all vines have traditionally been grown in Ica province south of Lima, close to the port of Pisco (which gives its name to the national drink). Winter temperatures in this area are so high (6–16 °C/43–60 °F) that full vine DORMANCY cannot be relied on. Summer temperatures are also high, 16–34 °C/60–93 °F in the hottest month, and rainfall is low. Wells have traditionally supplied IRRIGATION water, but levels are falling as DRIP IRRIGATION is being introduced. Yields may reach 12 tonnes/ha (5 tons/acre), but attempts are being made to upgrade techniques and wine quality.

By 2000, projects were also being developed in cooler areas such as Palpa, 100 km/62 miles south of Ica, where Syrah is promising, and Curahuasi, 125 km west of Cusco, where Apu Winery has vineyards planted in LIMESTONE soils at ELEVATIONS as high as 3,300 m/10,827 ft.

There has also been a rediscovery of traditional historical winemaking in areas such as Moquegua, Tacna, and Arequipa, regions in southern Peru that are home to the country's oldest vines,

many pre-PHYLLOXERA. Producers are revisiting the CRIOLLAS; some, such as Valle de Caravelí in Arequipa, maintain the tradition of winemaking in clay TINAJAS. Moreover, there are diminutive producers, such as Murga in Pisco Valley and Moquillaza in Cañete and Ica, fully dedicated to vinifying Criolla wines. E.M.G.

Goldstein, E., *Wines of South America* (2014).

pervaporation, a combination of permeation and evaporation, is a two-stage membrane technology used for ALCOHOL REDUCTION that depends on dense silicone membranes which at about 30 °C/86 °F are particularly efficient at separating alcohol from water.

Castro-Muñoz, R., 'Pervaporation-based membrane processes for the production of non-alcoholic beverages', *Journal of Food Science and Technology*, 56 (2019), 2333–44.

Pessac-Léognan, important BORDEAUX appellation created in 1987 for red and dry white wines from the most celebrated part of the GRAVES district immediately south of the city. It takes its somewhat cumbersome name from its two vinously most important communes and includes all of the properties named in the 1959 CLASSIFICATION of Graves and many other fine châteaux too. This is Bordeaux's most urban wine area—indeed, the vineyards of its most famous property Ch HAUT-BRION and its neighbour and stablemate Ch La MISSION-HAUT-BRION are today surrounded by suburban development, including the campus of the University of BORDEAUX, on the boundary of the suburbs of Pessac and Talence. It is hardly surprising that Bordeaux's earliest wine estates were developed here, although the wines of Chx Haut-Brion, La Mission-Haut-Brion, and Pape-Clément justify the properties' existence on grounds far more solid than mere geographical convenience. Further from the city, vineyards are carved out of the pine forests which extend south-west into the Landes. In all, about 1,600 ha/3,952 acres of vineyard within Pessac-Léognan

produce red wine, and the total area devoted to white wine grapes hovers around 280 ha/692 acres.

Soils here have particularly good DRAINAGE, being made up of GRAVEL terraces of very different eras. The ENCÉPAGEMENT for red wines is very similar to that of the MÉDOC to the immediate north, being mainly Cabernet Sauvignon grapes with some Merlot and Cabernet Franc, but the wines can be quite different. It is not fanciful to imagine that the best wines of Pessac-Léognan have a distinct aroma that reminds some tasters of minerals, some of smoke, others even of warm bricks. Ch Haut-Brion is the most obvious exponent of this genre. Other current overachievers include Chx Pape-Clément, Smith Haut-Lafitte, and Haut-Bailly, while Chx de Fieuzal and La Louvière can provide some of Bordeaux's better value.

The region also makes some of the most characterful dry white wines in the world from Sauvignons Blanc and Gris, Sémillon, and Muscadelle grapes grown generally on the lighter, sandier parts of the vineyard, and often produced with considerable recourse to BARREL FERMENTATION and BARREL MATURATION. The most admired (Domaine de Chevalier and Chx Haut-Brion Blanc and La Mission-Haut-Brion Blanc) can develop in bottle over decades. J.R. & J.L.

Brook, S., *The Complete Bordeaux* (4th edn, 2022).

Penning-Rowsell, E., *The Wines of Bordeaux* (6th edn, 1989).

pesticides, substances or mixtures of substances applied to vineyards which are used to prevent, destroy, repel, or reduce the harmful effects of FUNGI, BACTERIA, INSECTS, NEMATODES, or other undesirable organisms regarded as VINE PESTS. Pesticides are made up of AGROCHEMICALS and biocontrols (see BIOLOGICALS) and are usually classified according to their principal use as, for example, fungicides, bactericides, insecticides, nematicides, miticides, etc. Many pesticides have more than one mode of action and may be effective against more than one type of pest. For example, SULFUR is both a fungicide and a miticide in vineyards.

Most pesticides consist of an active chemical constituent in a concentrated form that is suitable for use after mixing with a diluent (water or oil). Less often, pesticides are formulated as dusts, granules, or fumigants and require DUSTING rather than SPRAYING. For reasons of worker safety, there is a move away from these latter formulations. Mixtures of active ingredients may be combined in one product for greater efficacy or versatility: two chemicals may be mixed, for example, to produce a DOWNY MILDEW fungicide with both protectant and eradicant properties. For convenience, two or more pesticides may be combined in a spray mixture. However, problems due to chemical incompatibility may arise when different pesticides are mixed.

Pesticides are, to varying degrees, toxic chemicals, and their potentially harmful effects on humans, other animals, and non-target organisms in the environment must be recognized. Since the 1990s, increasing attention has been paid to the safety of vineyard workers and the environment, with chemicals classified according to toxicity and workers taught safe handling practices. Recycling spray machines are increasingly used to minimize drift on to the environment. See also RESIDUES.

The following factors should be taken into consideration when developing strategies for pesticide use in vineyards: use patterns, rates, the potential development of pesticide resistance, and potential effects on non-target organisms. Use patterns may involve routine application schedules or more flexible strategies that rely on pest warning services and/or the monitoring of pest activity, as in INTEGRATED PEST MANAGEMENT. Such flexible strategies are often adopted to minimize pesticide use.

The continuous use of some pesticides may result in a dramatic increase in the proportion of individuals in a pest population that are able to survive exposure to the pesticide. Chemical resistance is the inherited ability of an organism—be it a disease, weed or insect—to survive doses of an agrochemical that would normally control it. An example has been the development of resistance by the BOTRYTIS fungus to the fungicide Benomyl and also to the dicarboximide group

of fungicides. Recognition that increasing the rate or frequency of sprays of some agrochemicals often exacerbates the problem led to the development of resistance management strategies. These include limits to the number of sprays per season of particular agrochemicals, rotation of chemical applications or stipulations that certain chemicals are used only when tank-mixed with other chemicals active against the target pest. These spray programmes have been proven to delay or prevent the development of pest resistance.

pests of vineyards. See VINE PESTS.

Petaluma Gap, low spot within California's coastal mountains at the southern boundary of Sonoma County and northern edge of MARIN County that channels cool ocean air and fog into the region; also an AVA. See SONOMA.

pétillant, French term for a lightly sparkling wine, somewhere between PERLANT and MOUSSEUX.

pétillant naturel, lightly sparkling wine which, unlike most other sparkling wines, is the result of a single fermentation that starts in a tank or other FERMENTATION VESSEL, is then interrupted by chilling, and finishes in the bottle, hence the bubbles. They are often relatively low in alcohol and usually dry even if more traditional styles of wine made by the MÉTHODE ANCESTRALE typically contain some RESIDUAL SUGAR. The style has been enthusiastically embraced by producers of NATURAL WINE, who have coined the term PET-NAT for it. A wide range of very

varied examples of this increasingly popular style are now made all over the world of wine. See also MONTLOUIS.

petiole, the stalk of a plant's leaf which supports the leaf blade or lamina. Petioles are stem tissue and branch from the main stem of the shoot having similar anatomical features. At both ends of the petiole are swellings that alter the position of the leaf blade according to such stimuli as water stress and low light. Samples of petioles taken at FLOWERING are used as a basis for assessing a vine's status in terms of VINE NUTRITION.

The characteristics of petioles vary with vine variety and growing conditions, being longer on vigorous vines. Between varieties, petiole length varies from 5 to 20 cm/2 to 8 in, petiole colour varies from green to red, and petioles themselves may vary from smooth to hairy. These features help in the identification of varieties (see AMPELOGRAPHY). B.G.C.

petit, 'small' in French and therefore often encountered in wine and grape names.

petit château. See PETITS CHÂTEAUX.

Petit Courbu, ancient, rescued white Basque grape variety capable of adding body, aroma, and quality to the wines of BÉARN, IROULÉGUY, JURANÇON, and PACHERENC DU VIC-BILH as well as those of ST-MONT. Known as Hondarrabi Zuri Zerratia in Spain's Basque country (see TXAKOLI).

Distinct from COURBU.

Petite Arvine. See ARVINE.

Petite Sirah, name common in both North and South America, and first mentioned in California wine literature in the early 1880s, for a related group of black grape varieties. DNA PROFILING techniques suggested in the late 1990s that the name had been applied in California vineyards to no fewer than four different vines: mainly DURIF but also true SYRAH of the Rhône, PELOURSIN (an obscure French vine which turned out to be Durif's parent), and even PINOT NOIR.

Petite Sirah is relatively important in a wide range of warm wine regions, especially in California. It is also grown in Australia (see DURIF) and in Chile, and OLD VINES show its potential in Israel. In California, acreage declined until the mid 1990s then began to climb again, reaching 1,781 ha/4,400 acres by 2003 and then more than doubling to 4,842 ha/11,964 acres by 2020, mostly in Sonoma, Paso Robles, Amador, Mendocino, and Napa. Accurate acreage assessment is difficult because so many of the old Italian vineyards were planted with a mixture of different varieties (see FIELD BLEND).

Historically, Petite Sirah was established in California to bring structure and depth to ZINFANDEL field blends. In the 1990s, its potential for dark, well-balanced, sturdy red wine was revealed in VARIETAL wines. Like Cabernet Sauvignon, it has also been essential as a backbone for some everyday red blends, providing both colour and TANNINS, and producers such as Ridge, Freemark Abbey, and Souvrain have shown it ages impressively well. Some winemakers are now also experimenting with lighter-bodied styles as well as rosé. Petite Sirah grows best in well-drained soils, especially in DRY-FARMED vineyards with HEAD-TRAINED vines. California producers started a promotional push for the grape in 2004 called P.S. I Love You. In MEXICO it is championed by L. A. Cetto.

Petit Manseng, top-quality white grape variety originally from SOUTH WEST FRANCE which is the superior form of MANSENG. Petit Manseng, which is much more suitable for sweet wines than its probable progeny GROS MANSENG, has particularly small, thick-skinned

berries which yield very little juice (sometimes less than 15 hl/ha, although up to 40 hl/ha (2.3 tons/acre) is allowed for both JURANÇON and PACHERENC DU VIC-BILH, and even higher for dry wines) but can withstand lingering on the vine until well into autumn, or even December, so that the sugar is concentrated, resulting in shrivelled (i.e. PASSERILLÉ) grapes. The variety is however sensitive to both POWDERY MILDEW and DOWNY MILDEW. By 2019 France's total plantings had grown to 1,484 ha/3,667 acres, although those of Gros Manseng were nearly 4,000 ha. It is known as Iskiriota Zuri Tipia over the border in Spain's Basque country (see TXAKOLI).

The variety, which makes firm, distinctively tangy, often slightly green-hued wines of all SWEETNESS levels, has already been planted to a limited extent in the LANGUEDOC, central Italy, Virginia, California, Georgia, Australia, New Zealand, and Argentina.

Petit Meslier, ancient and almost extinct white variety cultivated in CHAMPAGNE. It used to produce fruity wines, but it has fallen out of favour because of its naturally low yields. DNA PROFILING at DAVIS showed in 2000 that Petit Meslier is a progeny of GOUAIS BLANC and SAVAGNIN. A tiny amount persists in Australia.

Petit Rouge, fine, ancient, dominant, INDIGENOUS VARIETY in the Valle d'AOSTA, making fruity, spicy red wines. Plantings totalled 68 ha/168 acres in 2015.

petits châteaux, a French term meaning literally 'small castles', has a very specific meaning in the BORDEAUX wine region. These thousands of properties are modest both in their extent and in their reputation and price. A CLASSED GROWTH or equivalent is emphatically not a petit château, no matter how few hectares it encompasses, and nor is a CRU BOURGEOIS. The greatest concentration of petits châteaux, invariably family-owned and run, is in the Bordeaux AOC and Côtes

de BORDEAUX appellations, although they are found throughout the region. Some of Bordeaux's best wine value is to be found at the most conscientious petits châteaux.

See also CHÂTEAU.

Petit Verdot is one of BORDEAUX's classic black grape varieties. Plantings may be way below those of Cabernet Sauvignon and Merlot, but it is enjoying a revival, in part as a result of CLIMATE CHANGE, and at some estates is starting to replace Cabernet Franc as an influential blending ingredient, particularly on the LEFT BANK. The vine ripens even later than Cabernet Sauvignon and is equally resistant to ROT, sharing Cabernet Sauvignon's thick skins. When it ripens fully, it yields concentrated, tannic, ageworthy wines rich in colour, sometimes rather spicy, but in a cool year it can add a distinctly raw, underripe note to a blend. Its inconveniently late ripening encouraged many producers to abandon it in the 1960s and 1970s so that total French plantings were just over 300 ha/740 acres in 1988, but by 2019 they had increased to more than 1,615 ha/3,991 acres, 1,235 ha of these in the Gironde.

Its qualities are increasingly recognized elsewhere. It is well suited to warm, dry parts of Spain such as CASTILLA-LA MANCHA, where most of the 2020 total of 2,206 ha/5,451 acres are planted. The pioneer was Marqués de Griñon near Toleda. Italy's total plantings also increased in the first decade of the 21st century but were still only 296 ha/731 acres by 2015, while even Portugal, not usually a great fan of INTERNATIONAL VARIETIES, grew 307 ha/759 acres, mainly for blends in the ALENTEJO, by 2020. Outside Europe, it is proving popular in ISRAEL, particularly in high-end blends. It has performed exceptionally well in VARIETAL form in the irrigated inland regions of AUSTRALIA, where by the mid 2000s plantings totalled more than 1,600 ha—although this had fallen to 1,108 ha by 2022. In California, where the state's total plantings were more than 1,403 ha/3,467 acres by 2020, mainly in NAPA and the SAN JOAQUIN VALLEY, it has so

far been used mainly as an ingredient in MERITAGE blends. WASHINGTON State has much less and also tends to use it in BORDEAUX BLENDS, while a number of VIRGINIA producers make a speciality of varietal versions. It is also planted on Long Island in NEW YORK and in Canada's British Columbia, but it does need a warm summer. It is therefore well suited to both Argentina and Chile, where 650 ha and 904 ha respectively are grown and varietal versions of 'Verdot' (which may include the inferior GROS VERDOT) abound, and to South Africa where total plantings stood at 734 ha in 2020, concentrated in the prime regions of Paarl and Stellenbosch, where Petit Verdot is welcomed as a seasoning for a Bordeaux blend.

pet-nat, name coined by the NATURAL WINE movement for an amorphous group of very varied lightly sparkling wines, occasionally with some RESIDUAL SUGAR. They may well be cloudy if the wines have not been disgorged (see SPARKLING WINEMAKING). See PÉTILLANT NATUREL.

Petri disease, fungal disease found in young vines (generally younger than five years old) caused by several Ascomycete species, including *Cadophora luteo-olivacea*, *Phaeomoniella chlamydospore*, and *Phaeoacremonium* spp., with *Phaeoacremonium minimum* being the most prevalent. Named after Italian plant pathologist Lionello Petri (1875–1946), who discovered it in 1912. Affected vines appear stunted and weak and show greatly reduced tolerance of stress. Internal symptoms are primarily found in the ROOTSTOCK or at the basal end of the trunk in UNGRAFTED VINES and are characterized by dark brown and/or black streaking of the wood. Though spores of *P. chlamydospora* and *P. minimum* are known to infect pruning wounds in mature vineyards, it has been well documented that infections can originate and spread during the PROPAGATION process in NURSERIES. Vines may be asyptomatic until the fungus becomes virulent under stress conditions. Clean propagation planting material and the

avoidance of stress during the first years of vineyard establishment help to minimize the impact of this disease. See also TRUNK DISEASES.

J.R.U.-T.

Gubler W. D., et al., 'Esca, Petri, and grapevine leaf stripe disease', in W. F. Wilcox et al. (eds.), *Compendium of Grape Diseases, Disorders, and Pests* (2nd edn, 2015), 52–7.

Petrus, the most famous wine of POMEROL and today the most expensive in BORDEAUX.

In the heart of the small Pomerol plateau, Petrus was bought in stages from 1922, by Mme Loubat, wife of the owner of the Hôtel–Restaurant Loubat in Libourne. By 1949 it consisted of 6.5 ha/16.8 acres planted with 70% MERLOT vines and 30% CABERNET FRANC. In 1969, 5 ha were purchased from the adjoining Ch Gazin. Although it won a gold medal at the Paris International Exhibition in both 1878 and 1889, and although the London-based WINE SOCIETY listed the 1893, Petrus received little international attention until the remarkable, tiny crop of 1945 and the much more widely distributed 1947. Its exceptional concentration of colour, bouquet, and richness of flavour derives from a pocket of CLAY in the middle of the vineyard and the subsoil which affords exceptionally good DRAINAGE.

However, its fame is largely due to M. Jean-Pierre MOUEIX of the Libourne merchants, who started his business before the Second World War. He took over the sole distribution of Petrus in 1952. After Mme Loubat died in 1961, Jean-Pierre Moueix purchased from her nephew in 1964 50% of the shareholding, which Jean-Pierre's elder son Jean-François Moueix inherited in 1969. The other 50% went to Mme Loubat's niece Mme Lily Lacoste, to be acquired by Jean-François in 2001. His son Jean is now in charge of Petrus. Olivier, son of the distinguished OENOLOGIST Jean-Claude Berrouet, manages the property and is in charge of winemaking. The limited size of the property means that all the grapes can be harvested, at optimum ripeness, in a day and a half if necessary.

FERMENTATION VESSELS are neither wood nor stainless steel, but CONCRETE.

There is no official CLASSIFICATION of Pomerol, but Petrus is unofficially recognized as a PREMIER CRU. It tends to fetch a much higher price than any other red bordeaux (although see LE PIN), and at AUCTION it achieves even higher prices relative to the rest. In 2012, a rather grander building superseded Petrus's modest farmhouse.

Petrus de Crescentiis (1230–1310), Italian author whose writings on wine were much read in the Middle Ages (see LITERATURE OF WINE). Petrus de Crescentiis finished his *Liber ruralium commodorum* ('Book on agriculture') *c.*1304. Only part of this work, Book 4, is concerned with wine. He knows and quotes from the classical writers on agriculture (mainly PLINY, COLUMELLA, and VARRO), but he is no mere slavish follower of his authorities, for he has a great deal to say about medieval WINEMAKING practice and his advice is reliable.

The ancients loved old wine, but Petrus knew that medieval wine was a different matter; if wine was kept in a wooden BARREL instead of an impermeable earthenware AMPHORA, it would not last long. Most medieval wine was drunk within a year of the vintage, but sweet or highly alcoholic wines, as some Mediterranean wines were, kept longer. Petrus divides wines into three categories: new (under a year); old (four years); and between new and old. New wine, he says, has no digestive or diuretic properties but inflates the belly. Old wine is bitter and can be off; unless it is mixed with water, it goes to the head. Two-year-old wine is best. Petrus also points out that TOPPING UP casks of wine is essential in order to stop the wine turning into VINEGAR; alternatively, a layer of olive oil can be floated on the surface of the wine. He also explains how to achieve the RACKING of a wine from one cask into another.

Given the soundness of his advice and the clarity of his prose style, it is not surprising that Petrus's book should have been popular.

It survives in many manuscripts and early printed editions. By the end of the 15th century, it had been translated into German, French, and Italian. H.M.W.

Peynaud, Émile (1912–2004), Bordeaux oenologist whose work had a profound and worldwide impact on winemaking and wine appreciation in the second half of the 20th century. After the Second World War, Peynaud worked with Jean RIBÉREAU-GAYON before joining him at BORDEAUX University's Institut d'Oenologie, while employed by the house of Calvet. It was here, in the late 1940s, that he began to advise numerous BORDEAUX châteaux on their winemaking. Because this CONSULTANCY work was the activity for which he later became best known, it is perhaps easy to forget his achievements as a taster, scientist, and teacher.

Peynaud wanted to understand the detail of the winemaking process, to eliminate its hitherto haphazard nature, and to produce consistently clean-tasting and healthy wines. Many of the practices that now seem unexceptional in winemaking were by no means axiomatic in the 1950s, and they are rooted in changes resulting from his wide-ranging scientific research. Among these were the complete control of MALOLACTIC CONVERSION, as well as the understanding that quality starts in the vineyard with good-quality grapes, that red grapes should be fully ripe when picked, and that dark grapes' skins (containing the PHENOLICS so crucial to red-wine aromas and textures) should be treated more gently with softer CRUSHING, better-controlled fermentation temperatures, shorter MACERATION, and more moderate PRESSING of the skins for the PRESS WINE. Each technique aimed at improving the flavour and texture of the resulting finished wine.

Taste became the arbiter in winemaking decisions, and it underlay his other cardinal principle: selection. Select only healthy grapes when picking, vinify the produce of plots of vines of markedly different age or quality separately, choose only the best vats to be incorporated in the principal wine, and so on. This was the subject of his first book, *Connaissance et travail du vin*.

Peynaud considered that the ability to taste accurately was as essential to good winemaking as a thorough grasp of OENOLOGY. His second book, *Le Goût du vin*, was as comprehensive and lucid on tasting wine as his first book was on making it.

As with his pupil Michel ROLLAND, critics used to complain that his winemaking methods so marked the wines that they were losing their individuality, but mature bottles tended to show genuine distinction and individuality.

Peynaud would have left his mark on the wine world had his gifts been limited to scientist, technician, and possessor of a refined palate; that his influence has been so widespread is due to his additional great gift as a teacher and communicator. M.W.E.S.

Pézenas , small, named CRU in the LANGUEDOC AOC producing red wines mainly from Syrah, Mourvèdre, and Grenache at lower ELEVATIONS than some of the other crus just to its north.

Pfalz, until 1992 known as Rheinpfalz, is the second largest wine region in GERMANY. Its 23,684 ha/58,524 acres of vineyard in 2019 abutt RHEINHESSEN to the north and follow the eastern edge of the Haardt range (a northern extension of ALSACE'S Vosges) for about 80 km/50 miles (see map under GERMANY) along the so-called Deutsche Weinstrasse, or German Wine Route, officially established in 1935 to link 40 villages. Relatively sunny and dry, Pfalz has long been a

mecca for German TOURISTS but has since the 1980s acquired a national and international reputation as an innovative and exciting winegrowing region buoyed by demand for its red and dry white wines and by the proximity of prosperous metropolitan Mannheim, Ludwigshafen, and Karlsruhe. Of the roughly 10,000 vine-growers in the region, over half deliver their grapes to producers' associations, merchants' cellars, or one of more than 15 CO-OPERATIVES, of which a number boast not only high standards but also significant shares of top vineyards. Not to be underestimated is the continuing influence of Müller-Catoir ex-cellarmaster Hans-Günter Schwarz, whose principles of 'minimalism in the cellar, activism in the vines' have been imparted to two generations of vineyard managers and winemakers who today fill dozens of the most important positions throughout the Pfalz. The Pfalz has also proven fertile 21st-century ground for BIODYNAMIC VITICULTURE: several members of the growers' association respekt-Biodyn are Pfälzer, including long-running VDP president Steffen Christmann and VDP-Pfalz chairman Hansjörg Rebholz.

The vineyards to the north of Neustadt, collectively known as the Mittelhaardt, are the best known in the Pfalz, in large part thanks to wine estates with such historic reputations as Bassermann-Jordan, Bürklin-Wolf, and von Buhl. The top sites of the Mittelhaardt villages largely nestle between the western edge of the villages and the lower slopes of the Haardt, on SANDSTONE, VOLCANIC, and CALCAREOUS marl soils. From south to north, they include: Neustadt (Vogelsang), Haardt (Bürgergarten, Mandelring), Gimmeldingen (Mandelgarten), Königsbach (Idig, Ölberg), Ruppertsberg (Nussbien, Gaisböhl, Hoheburg, Reiterpfad), Deidesheim (Paradiesgarten, Leinhöhle, Hohenmorgen, Kieselberg, Mäushöhle, Grainhübel, Kalkofen), Forst (Ungeheuer, Freundstück, Kirchenstück, Jesuitengarten, Pechstein), Wachenheim (Altenburg, Gerümpel, Goldbächel, Rechbächel), Bad Dürkheim (Michelsberg), Ungstein (Herrenberg, Weilberg), and Kallstadt (Saumagen). While vineyards on the hilly western side of the Weinstrasse north of Kallstadt are relatively little known, those of twin villages Zell and Zellertal are undergoing impressive revival.

The low, rolling calcareous and SANDY hills east of the Weinstrasse—notably at Laumersheim (Kirschgarten, Mandelberg), Grosskarlbach (Burgweg), and Freinsheim—have also demonstrated their ability to generate memorable wines. South of Neustadt, the so-called Südliche Weinstrasse long endured a reputation for high yields of indifferent grape varieties, but—thanks above all to the ambitions of local winegrowers and a boom in dry wines from SPÄTBURGUNDER (Pinot Noir), GRAUBURGUNDER (Pinot Gris), WEISSBURGUNDER (Pinot Blanc) as well as RIESLING—this cooler area has become increasingly fashionable. Top villages (and sites), from south to north, include: Ilbesheim (Kalmit), Birkweiler (Kastanienbusch, Mandelberg), Siebeldingen (Im Sonnenschein), Gleisweiler (Hölle), Burrweiler (Schäwer), and Weyher (Michelsberg). The village of Schweigen, 19 km south of Ilbesheim and adjacent to the small Alsace city of Wissembourg, represents an important anomaly: most of the vineyards with which Schweigen developed its serious late 20th century reputation for Pinot Noir lie within France but are farmed by German estates and authorized to produce German wine.

High YIELDS, MECHANICAL HARVESTING, and a reliance on such CROSSES as MÜLLER-THURGAU, KERNER, and MORIO-MUSKAT were long associated with the Pfalz. But Riesling, always dominant in the prestigious towns of the Mittelhaardt, has staged a comeback and now accounts for one-quarter of vine surface. Red-wine vines gained ground rapidly from the 1990s and now account for just over one-third of Pfalz production. Pinot Noir (Spätburgunder), Weissburgunder, and Grauburgunder now collectively represent just over 20% of Pfalz plantings. SCHEUREBE may be statistically relatively insignificant, but, as with RIESLANER, there are impressive examples as well as signs of a revival, though both have been threatened with removal from Germany's list of authorized varieties. TRAMINER, traditionally associated with the Pfalz, has failed in recent decades to mirror its success in neighbouring Alsace, but the best examples, dry and sweet, can still be excellent.

Across the region, most wine produced is now dry (TROCKEN), as befits both climate and demand. This explains why this region has been a leader in advocating the establishment of GROSSES GEWÄCHS, full-bodied, dry wines (principally Riesling) from the best sites. But the second decade of the 21st century has seen a marked revival of interest in Riesling bottled with some RESIDUAL SUGAR, including KABINETT. Pfalz red wines including Spätburgunder today typically exceed 13% alcohol, and BARREL AGEING is common, although there remains a local market for the traditional, light red as well as pink WEISSHERBST from PORTUGIESER (steadily shrinking and just 5.4% in 2019). DORNFELDER plantings increased five-fold between 1990 and 2015 so that it is now Pfalz's second most planted variety though the resulting wines are generally undistinguished. An increasing amount of Pfalz wine is made sparkling (see SEKT). Standards for sparkling Sekt have been set high, not least by the Sektkellerei Schloss Wachenheim, which specializes in TRADITIONAL METHOD renderings of their own and other growers' generally high-quality base wines, especially from Riesling, Weissburgunder, and Spätburgunder.

PGI, abbreviation for Protected Geographical Indication, a wine category created in 2008 as part of the EU wine reform. It encompasses what used to be known as TABLE WINES with a GEOGRAPHICAL INDICATION such as France's VIN DE PAYS, Italy's IGT, Spain's VINO DE LA TIERRA, and Germany's LANDWEIN. In 2020 PGI wines accounted for roughly 20% of total EU wine production. The equivalent abbreviation in many other countries, including France, Spain, Italy, and Portugal, is IGP, although the speed with which the reformed terminology has been adopted varies by country.

The qualifying criteria for a PGI are lower than those for the PDO, or Protected Designation of Origin category. A PGI need only 'possess a specific quality, reputation or other characteristics attributable to [its] geographical origin', in line with the international definition of a geographical indication. A minimum of 85% of the grapes must come from the delimited area, and these may be either VITIS VINIFERA or a CROSS between *vinifera* and other VITIS species. PGIs enjoy special privileges in the EU wine system, including protection against misuse as well as the right to use TRADITIONAL TERMS and the special EU PGI symbol on the label.

Non-EU countries are, in theory, able to register their own geographical indications as PGIs in Europe, although very few choose to go through the registration process because in most cases mutual protection of GIs is agreed with the EU through bilateral wine agreements or free-trade agreements. pH, a scale of measurement of the concentration of the effective, active ACIDITY in a solution and an important statistic, of relevance to how vines grow, how grapes ripen, and how wine tastes, looks, and lasts. Low values of pH indicate high acidity and the tart or sour taste that occurs in lemon juice, for example. Values near 7 are effectively neutral; drinking waters have pH values near 7. Values between 7 and 14 are found in basic or alkaline solutions such as caustic or washing soda. Grape must and wine are acidic, with pHs generally between 3 and 4. pH is the negative logarithm of the hydrogen ion concentration, so a solution with a pH value of 3 has ten times as much hydrogen ion activity as one whose pH is 4.

Soils

Soil pH measures the acidity or alkalinity of a soil. It can be approximately measured in the vineyard using a pH test kit comprising barium sulfate powder and a pH indicator dye, or more accurately in a laboratory in a soil–water suspension or in dilute calcium chloride. Acid soils have a pH less than 7 and alkaline soils a pH greater than 7. Soils formed on acidic parent materials (see SOIL), such as GRANITIC rocks or highly weathered SANDSTONES, generally have acid pH values, whereas those formed on basic parent materials, such as LIMESTONE, BASALT, or dolerite, generally have alkaline pH values. The optimum pH range for grapevines is from 5.5 to 8 (in water) and approximately 0.6–0.8 units lower in calcium chloride solution. Within this range, the possibility of aluminium toxicity (at low pH) or micronutrient deficiency (at high pH) is avoided. However, grapevines are tolerant of soil pH outside this range. There is no evidence of a direct link between soil pH and wine pH. See also SOIL ACIDITY and SOIL ALKALINITY. R.E.W.

White, R. E., *Understanding Vineyard Soils* (2nd edn, 2015).

Grapes

The pH of grapes as well as wines can vary enormously since TEMPERATURE, RAINFALL, SOIL TYPE, viticultural practices, and VINE VARIETIES can all influence the different natural organic acids and minerals of ripe grapes. In general, cool regions produce wines with low pH and hot regions produce wines with high pH. Part of the reason why white wines generally have a lower pH than red wines is that red wines have higher levels of POTASSIUM, which is extracted from the grape skin, where this ion is concentrated, during fermentation. See also GRAPE and ACIDITY.

The pH of grape juice is now well established as a factor affecting wine quality. In particular, high pH values are associated with low acidity, and red wine quality in particular is diminished (see below).

Wines

The pH range of most wines is between 2.9 and 4.2. The perception of acidity or tartness is determined by both the pH and TOTAL ACIDITY. Usually a wine with a higher total acidity will also have a lower pH, but many factors can affect the relationship between the two (soil POTASSIUM, warmth of climate, SHADE during ripening, RIPENESS at harvest, SKIN CONTACT). Wines with a lower pH are less hospitable to harmful BACTERIA, age better, and have a clearer, brighter COLOUR (see below). Wines with higher pH values tend to taste flat, look dull, and be more susceptible to bacterial attack. In the last 20 years, average pH levels have risen considerably as a result of longer HANG TIME and a FASHION for riper wines. While it is possible to manipulate pH values, with grapes and wines it can sometimes be difficult to get both the pH and the total acidity in the desirable range or balance. The pH can be increased or decreased by several methods. (See ACIDIFICATION and DEACIDIFICATION for discussion of the legal and practical aspects of these operations.)

In general terms most YEASTS are tolerant of wine pH, while few bacteria are capable of growing in the strongly acidic environment that wine presents (even fewer with the alcohol levels found in wine).

Keeping wine pH values low is of further importance because the hydrogen ion concentration of the wine influences the effectiveness of SULFUR DIOXIDE. Sulfur dioxide exists in equilibria in multiple forms in wine. It is only the molecular sulfur dioxide form that has antimicrobial effect. The ratio of molecular sulfur dioxide is much higher at low pH; for example, at pH 3, 6% of the sulfur dioxide is in the molecular form, whereas at pH 4, only 0.6% is in that form.

Awareness of pH is also important in winemaking because the PIGMENTED TANNINS that colour red wines exist (like the monomeric ANTHOCYANINS from which they are formed) in several forms of different colours. At low pH values, the high concentration of hydrogen ions forces the pigment molecule into a form with a positive charge and a bright red colour. As pH increases (and

hydrogen ion concentration decreases), the pigment molecules tend more and more to change through dull purple to blue and, ultimately, greyish forms. The net result in the several pigments of red wine is a passage from bright to purplish red and finally to a dull brownish red as pH increases. M.J.T.

phenolic ripeness, or phenological ripeness. See PHYSIOLOGICAL RIPENESS.

phenolics, very large group of highly reactive chemical compounds of which phenol (C_6H_5OH) is the basic building block. These include many natural colour pigments such as the ANTHOCYANINS of fruit and dark-skinned grapes, vegetable TANNINS such as occur in grapes, and many FLAVOUR COMPOUNDS.

The terms polyphenolics or polyphenols are often used as synonyms of phenolics but should be restricted to plant secondary metabolites featuring more than one phenolic ring and derived from specific metabolic pathways, as Quideau et al. explain.

In grapes

These compounds occur in great profusion in grapes. They are particularly rich in stems, seeds, and skins but also occur in juice and pulp. The concentration of phenolics in grape skins increases if the berries are exposed to sunlight, in particular to ULTRAVIOLET RADIATION, because the phenolic compounds act as a natural sunscreen. Phenolic compounds strongly absorb ultraviolet radiation, a fact used in their laboratory analysis. Manipulating fruit exposure in the vineyard is therefore a way to affect the phenolic content of berries and wine made from them. See CANOPY MANAGEMENT.

Many hundreds of compounds belong to the phenolic category, and they can initially be classified as either non-flavonoid or FLAVONOID. The former include compounds derived from cinnamic and benzoic acids (one of the most abundant in grape juice is caftaric acid, the tartrate ESTER of caffeic acid) and stilbenes such as RESVERATROL. Flavonoids encompass CATECHINS and their polymers, called PROANTHOCYANIDINS or condensed tannins, which are an essential part of the taste and flavour of grapes and other fruits, and pigments, including FLAVONOLS and anthocyanins. With a few exceptions, such as the phenolic amino acid tyrosine that is a constituent of proteins, phenolics belong to the general group known as secondary metabolites, meaning that they are not involved in the primary metabolism of the plant. They are highly water-soluble and are secreted into the berry VACUOLE, many as GLYCOSIDES, and some are FLAVOUR PRECURSORS or precursors of off-flavours.

B.G.C. & V.C.

In wines

Phenolic acids (especially cinnamic acids) are the major phenolics in grape pulp and juice and, thus, also in white wines made without SKIN CONTACT. Anthocyanins are localized only in the skins, except in red-fleshed *teinturiers*, so that red winemaking requires a MACERATION phase to extract them into the juice. Flavonols, which are constituents of skins, stems, and leaves, as well as catechins and proanthocyanidins, which are also present in seeds, are simultaneously extracted. Alcohol, produced by FERMENTATION, greatly speeds up this extraction process. Additional phenolics (including gallotannins and ellagitannins as well as flavour compounds such as VANILLIN) may also be present in wine as a result of BARREL AGEING, the use of OAK CHIPS, or the addition of OENOLOGICAL TANNINS. Once extracted into the wine, the hydroxycinnamic acids, anthocyanins, catechins, and tannins are gradually converted to various types of derivatives, including PIGMENTED TANNINS. These reactions are responsible for the colour and taste changes observed during wine AGEING.

Catechins and proanthocyanidin oligomers taste bitter, while larger tannins are responsible for the mouth-puckering ASTRINGENCY in young wines. As the wine ages, tannins and their derivatives form larger and larger particles through aggregation and complexation with other molecules such as PROTEINS and POLYSACCHARIDES. This may result in the development of haze and sediments and other technological problems (e.g. clogging of filtration membranes, adsorption on tank surfaces).

A significant number of flavour precursors as well as FLAVOUR COMPOUNDS also have the phenol structure. Examples of these are vanillin, the key aroma compound of the vanilla bean, and raspberry ketone, the impact compound of raspberries. An ESTER, methyl salicylate, familiar as oil of wintergreen, is also a phenolic compound. These and many others are either grape constituents or are produced as trace components during alcoholic fermentation and by glycoside

HYDROLYSIS during the subsequent processing and ageing phases. See also OAK FLAVOUR for details of the part played by the phenolics in new OAK.

P.J.W. & V.C.

As a tasting term

The word ‘phenolic’ is also sometimes used, imprecisely, as a pejorative tasting term, to describe (usually white) wines which display an excess of phenolics by tasting astringent or bitter.

As health benefit

It is in its high phenolics content that red wine is distinguished from white, and it is thought that it may well be the ANTIOXIDATIVE properties of phenolics which reduce the incidence of heart disease among those who consume moderate amounts of red wine. See HEALTH.

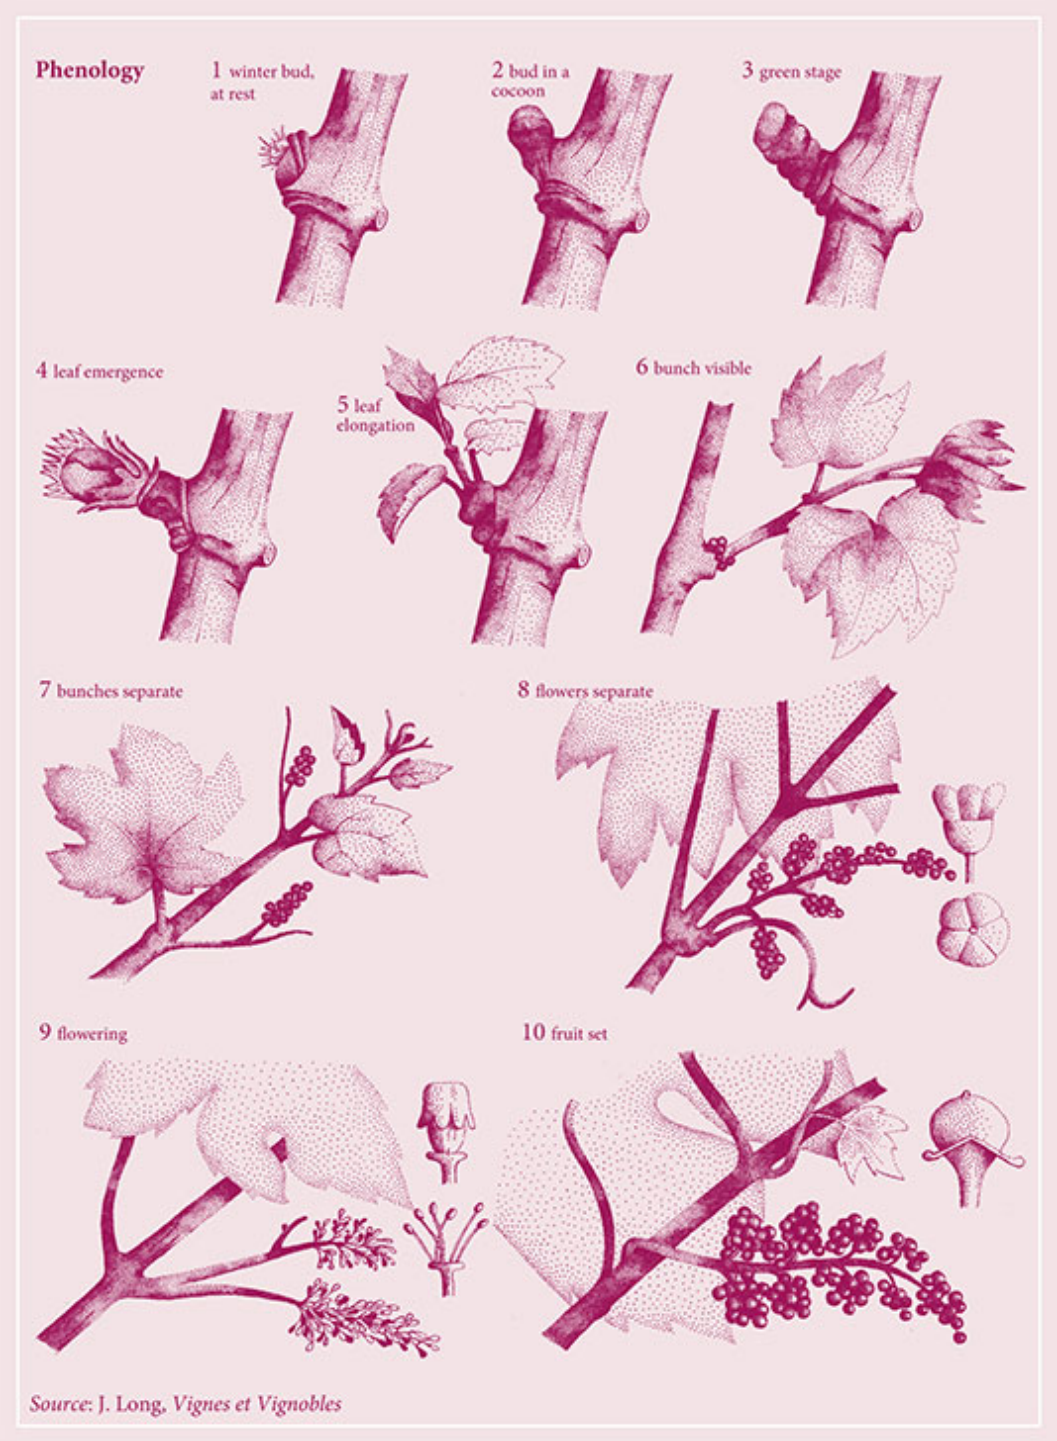
phenology, the study of the sequence of plant development (see diagram). As applied to vines, it records the timing of specific stages such as BUDBREAK, FLOWERING, VERAISON, and LEAF FALL. Such studies indicate the suitability of VINE VARIETIES to certain climatic zones. See VINE GROWTH CYCLE.



pheromones are, in a viticultural context, synthetic products used in the biological control of vineyard INSECT PESTS. They work by causing sexual confusion (see INTEGRATED PEST MANAGEMENT).

philosophy and wine. Wine first played a part in the history of Western philosophy at the SYMPOSIUM of the early Greek philosophers, where it enlivened and encouraged discussion. Later, during the Enlightenment, David Hume recommended drinking wine with friends as a cure for philosophical melancholy, and Immanuel Kant thought wine softened the harsher sides of men's characters and made their company more convivial. In recent times, philosophers have turned their philosophical attention to wine as an object of perception, assessment, and appreciation. Their enquiries have focused on the relationship between wine and our experience of it, including its intoxicating effect on us (see DRUNKENNESS) and the meaning and value it has for us in our lives (see Scruton 2009).

The issue of objectivity

To know the chemical WINE COMPOSITION and its method of VINIFICATION is not yet to know how it tastes. To know this, one must experience the wine itself by TASTING it. But in tasting a wine, are we discovering properties the wine has or just noting our SUBJECTIVE responses to it? And is every response as good as any other? Here we have a key philosophical question: how subjective are tastes and tasting? In one view, the only objective knowledge we can have of wine is that provided by scientific analysis: the chemist describes the way the wine is, the wine critic describes the way it tastes. The former is objective, the latter merely subjective. But are the two unconnected? Winemakers rely on scientific analysis to achieve the flavours they are aiming for, and experienced wine tasters rely on tasting to identify and describe compounds of flavours or aromas that arise from fermentation. For this to be so, wine tasters must draw objective conclusions about a wine from their subjective responses to it, and wine makers must create conditions they hope will produce a certain taste for the consumer. A revised view would be that, while tasting is a subjective experience of individual tasters, *what* we taste, the TANNINS, or ACIDITY in a wine, are objective properties or characteristics of the wine itself.

Nevertheless, many of the qualities we value in wine such as finesse, BALANCE, COMPLEXITY, HARMONY, and LENGTH can only be confirmed by tasting. And some philosophers would argue that these more complex properties depend on us and should be conceived as some kind of relation between the wines and our responses to them. The problem for this view is whether to treat all such responses as equally good. If we differ in opinion about whether a wine is round or balanced, does this mean there is no fact of the matter about who is right? Is it balanced for me but not for you? On such a subjectivist view, matters of taste are neither right nor wrong: the conclusion is that *de gustibus non est disputandum*.

Tastes and tasting

Philosophers who reject this conclusion argue that taste properties, such as a wine's length or balance, *are* objective features of a wine and that, under the right conditions and with the right experience and training as tasters, they are revealed to us in experience. Tasting a wine involves the taster's subjectivity, but verdicts based on those subjective experiences are not mere matters of opinion and so not subjective in that sense. Certain experiences will be more accurate than others, some people will be better tasters then others, and judgements of a wine can be right or wrong. In this objectivist view, *tastes* are in the wine, not in us, and by improving the skills of *tasting* we can come to know them more accurately (see Smith 2007).

What is meant by ‘fine wine’?

A related issue concerns the evaluation of wines and whether there is a clear separation between describing a wine and assessing its QUALITY. Part of this issue is how we should characterize FINE WINE. From the absence of a definition we should not infer there is no category of fine wine, any more than our inability to define ‘chair’ satisfactorily should lead us to conclude that there are no chairs. Criteria for being a fine wine can be given, as when we can say that a fine wine is one whose complex, individual character rewards the interest and attention paid to it and affords the degree of discrimination we exercise in assessing its qualities and characteristics. But is a fine wine a wine that must be appreciated? Or can experienced wine tasters assess the qualities of a wine without enjoying it? The alternative view is that recognizing a wine’s merits depends on the enjoyment, pleasure, or preferences of the individual taster. The dispute here concerns the ultimate nature of wine tasting and wine appreciation. Do we directly perceive the quality of a wine, or do we assess its quality on the basis of what we first perceive? Tasting seems to involve both perception and judgement. But does the perceptual experience of tasting—which relies on the sensations of touch, taste, and smell—already involve a judgement of a wine’s quality? Is such judgement a matter of interpretation, and, if so, does assessment require wine knowledge in order to arrive at a correct verdict?

Some philosophers would claim that one cannot assess a wine’s quality on the basis of perceptual experience alone and that evaluation goes beyond what one finds in a description of its objective characteristics. According to these thinkers, something else is required to arrive at an assessment of a wine’s merits. This may be the pleasure the taster derives from the wine, the valuing of certain characteristics, or the individual preferences of the taster. Is there room in such views for non-subjective judgements of wine quality?

To say that assessments of quality rest on interpretation is to say that one cannot recognize a wine’s quality on the basis of perceptual

experience alone. And yet according to some philosophers, a novice taster can recognize the merits of wine by taste without the expert knowledge of the wine CRITIC. Moreover, expert knowledge may enable one to recognize a wine as an excellent example of its type, but if that style of wine offers one no pleasure, could one, as a wine critic, still judge it to be (or admire it as) a great wine? Many philosophers would think not, but then on what basis does one judge something to be a great wine, and what could separate experienced and novice tasters in evaluating wines? Do experienced tasters really taste more than novices, or do they simply have a better command of the LANGUAGE OF WINE used by professionals to describe what they taste? Could one appreciate the quality of a wine yet be unable to describe it? Is every taster's opinion equally good, and is the claim that some are better able to appreciate a wine merely snobbery? (See Smith 2013.)

A standard of taste?

Here we address a question raised by David Hume about whether there can be a standard of taste. Hume's solution was to rely on the excellence of JUDGES or critics who: showed delicacy of judgement; were free from prejudice; could draw on a wide range of experience for comparisons; paid due attention; and were unclouded by mood. These may be prerequisites for accurate tasting, but on what basis does such an excellent critic appreciate a truly great wine? An answer to this question can be found in Kant's account of aesthetic judgement (which he did not himself extend to wine). To claim that a wine is great is not just to judge for oneself alone but to judge for all. The judgement is made on the basis of pleasure, but this is not a claim about what one finds personally pleasant or agreeable. It is a judgement about the pleasure the wine affords anyone suitably equipped to taste it. There is no such thing as a wine that is great *for me*. In claiming to recognize a great wine, I am claiming something about *the wine itself*, about how it will (and should) strike others. It is thus a universal claim about the delight all can take in it, and others would be mistaken were they not to judge it so. Kant's solution does not solve all problems of the objectivity of taste, however. Disagreements about a wine's qualities are still disagreements among ourselves, not disagreements settled solely by the properties of the wine itself.

A further problem is created when two (or more) experienced, unprejudiced wine critics differ in their opinions regarding the excellence of a wine. Perhaps they agree in their descriptions of the wine's objective characteristics but diverge in evaluating its merits. If they merely point to divergent qualities, one can argue for pluralism about the qualities and flavours of a wine (see Todd 2010). However, if they genuinely conflict in judgement, but neither has overlooked any aspect of the wine's identifiable properties and both agree in the terms they use to describe and classify wines, we may be tempted to conclude neither is right and neither is wrong. However, subjectivism about standards of taste can be resisted in this case by embracing

relativism about matters of taste. According to relativist doctrine, both critics are right: both make true judgements about the wine in question. It is simply that the truth of each judgement is *relative* to a standard of assessment, or set of preferences, not shared by the other. Cultural differences could account for these divergences and there would still be a right answer according to one set of standards or the other. In effect, this is to claim there can be more than one standard of taste and that each critic is right relative to a standard of assessment (see Burnham and Skilleas 2012).

Finally, philosophers have stressed the meaning and value wine has in our lives and our emotional attachment to it, as a celebration of our relationship with our natural surroundings. What a wine expresses is a collaboration between culture and nature that neither entirely controls (see Furrow 2020). The place, culture, and history of a people that falls under the concept of TERROIR are celebrated and acknowledged in drinking a wine that reflects that terroir and the efforts of people to uphold and maintain the traditions with which they transformed soil and vine into grape, grape into wine. The final transformation, according to philosopher Roger Scruton (Smith 2007), occurs when we take wine into ourselves and, through its intoxicating effects, it transforms us and opens us up to one another. phloem, the principal food-conducting tissue of the vine and other vascular plants. Phloem is composed of a mix of CELL types which lie alongside the XYLEM, the water-conducting tissue, and the combination makes up a system of veins or vascular bundles. Despite their proximity, phloem and xylem are entirely different: phloem has thin-walled tubes containing a strongly sugared sap under positive pressure which moves along from areas of strong to weak concentrations, while xylem consists of large, strong-walled tubes through which a dilute mineral solution moves under negative pressure (suction/tension) by forces generated by TRANSPIRATION. During the thickening of woody parts, the CAMBIUM produces cells on the outside that become the new season's phloem; in later years these cells are added to the bark of the vine. Phloem of grapevine wood has the characteristic, unusual among deciduous trees, of reactivation after the next BUDBREAK and can remain functional for three to four years.

The vascular system permeates throughout the plant, but bundles of veins are particularly dense in the LEAF blade, as can be seen by holding it up to the light. This high density facilitates the loading of newly photosynthesized SUCROSE into the phloem tubes for its movement out of the leaf (see TRANSLOCATION). B.G.C.

Phoenicia, ancient mercantile state of the Iron Age (*c.*1200–539 BCE) and the Persian period until the capture of Tyre by Alexander the Great. The Phoenicians were the successors of the CANAANITES ethnically and culturally and so inherited their aptitude for viniculture. Phoenician territory at its widest extent included modern LEBANON and coastal southern SYRIA and northern ISRAEL. Arwad, Byblos, Beirut, Sidon, and Tyre were among the famous city states of Phoenicia. Vines and olives were grown along the coast and in fertile inland

valleys, especially the Beqaá (Bekaa Valley). The Phoenicians were seafaring merchants and colonizers par excellence, spreading the Near Eastern 'wine culture' elsewhere in the Mediterranean. They applied a similar formula wherever they went: import wine and other luxury goods; entice the rulers with the wine culture by presenting them with speciality wine sets; and then wait until they were asked to help in establishing native industries, including viniculture, by transplanting the domesticated Eurasian grapevine. Their greatest colony, CARTHAGE in modern Tunisia, survived until destroyed by the Romans in 146 BCE.

Evidently the Phoenician colonists found in North Africa a fertile region ideal for viticultural development. The Graeco-Roman historian Diodorus Siculus describes the Carthaginian countryside as being (in the 4th century BCE) full of vines, olives, and cattle, especially in the Bagradas Valley and in southern Tunisia. The Carthaginian author Mago left an extensive treatise on agriculture, including instructions on viticulture.

Phoenix, a rot-prone DISEASE-RESISTANT VARIETY, a GERMAN cross of BACCHUS and VILLARD Blanc which produces attractive, herbaceous, elderflower-scented wine in England with a minimum of SPRAYING. Despite its parentage, it produces remarkably VITIS VINIFERA-like wine so has been registered as a *vinifera* variety. Consequently, it may be used in the production of PDO wines in the UK. Very little is grown in Germany.

Phomopsis, may refer to either Phomopsis cane and leaf spot or Phomopsis dieback. Both are caused by the fungus *Diaporthe ampelina*, formerly known as *Phomopsis viticola*, but the symptoms are quite different.

Phomopsis cane and leaf spot, also known as *excoriose* in Europe, occurs in most of the world's viticultural regions, but it is particularly severe in those characterized by a cool and wet spring followed by humid, temperate weather through the growing season. Under these conditions, the disease may cause crop losses of up to 30%. The fungus can infect all green parts of the grapevine, causing black lesions at the base of grape shoots, leaf petioles, and bunch stems; bleached patches on winter canes; the death of affected fruit buds; stunted shoots; small black spots with yellow halos on deformed leaves; and rot on infected berries. Infected wood appears bleached during the dormant season and fruiting structures of the fungi (pycnidia) can be seen embedded in the bark. Although this disease poses the greatest threat in early spring, control measures to protect the fruit may continue into the summer in some regions. Because the fungus colonizes old wood, CANE PRUNING and hand harvesting reduce pressure from this disease. Wine-grape varieties such as Cabernet Sauvignon, Chardonnay, Merlot, and Syrah are less susceptible than some TABLE GRAPES. However, GRENACHE is one of the most susceptible.

Phomopsis dieback is a TRUNK DISEASE that has received less attention than Phomopsis cane and leaf spot. Field studies conducted in California in the mid 2000s found this fungus to be associated with other trunk diseases, especially BOTRYOSPHAERIA DIEBACK. *Diaporthe ampelina* was isolated from perennial cankers in spurs and cordons from grapevines showing a lack of spring growth or reduced shoot growth. Later studies confirmed the presence and severity of *Diaporthe ampelina* as a trunk-disease pathogen causing perennial cankers in Arkansas, Missouri, Texas, and eastern North American vineyards. phosphorus is one of the most important MINERAL elements required for vine growth (see VINE NUTRITION), yet the amounts required are sufficiently small that for most vineyards the natural supply from the soil is enough. There is only about 0.6 kg of phosphorus in a tonne of grapes (1.3 lb per ton). Phosphorus in the vine is an essential component of compounds involved in PHOTOSYNTHESIS and sugar–starch transformations as well as the transfer of energy. Phosphorus deficiency in vines is uncommon and found mostly on soils with a large content of iron and aluminium oxides, as in parts of the Yarra and King valleys in VICTORIA, Australia, and the WILLAMETTE VALLEY, Oregon. Its symptoms are a gradual loss of VIGOUR and, sometimes, some red spots on the leaves.

R.E.S. & R.E.W.

photosynthesis, a biochemical reaction which combines water and atmospheric carbon dioxide using the energy of the sun to form SUGARS in plants, including vines. Important in this process are the green chlorophyll pigments in leaves which capture the sun's energy. Photosynthesis is the essential first step in the winemaking process, as the sugars formed in photosynthesis, along with other chemical products derived from sugar, are transported to grape berries (see SUGAR IN GRAPES) and eventually fermented into ETHANOL to produce wine. (According to the neat laws of nature, humans eventually metabolize wine's ethanol back to carbon dioxide and water; see CARBON DIOXIDE.)

Photosynthesis can be summarized by this chemical equation:

$$6CO_2 + 6H_2O + \text{lightenergy} = C_6H_{12}O_6 + 6O_2$$
$$(\text{carbon dioxide} + \text{water} + \text{sunlight} = \text{sugar} + \text{oxygen})$$

The process of photosynthesis maintains atmospheric supplies of OXYGEN, essential for animal life on Earth. It also takes the carbon dioxide from the atmosphere and is thus increasingly seen as a method of carbon capture by plants in a world becoming concerned with CLIMATE CHANGE. Since these reactions take place inside the leaf, carbon dioxide must be able to diffuse in and oxygen out. This takes place through minute pores called STOMATA on the underside of vine leaves.

The rate of photosynthesis is affected by environmental and plant factors, all of which have an effect on grape RIPENING and hence wine quality. SUNLIGHT, TEMPERATURE, and WATER STRESS are the three most important climatic controls. Photosynthesis is limited by low light levels, as, for example, under overcast conditions or, more commonly, for shaded leaves away from the canopy surface (see CANOPY MICROCLIMATE). Light levels of about 1% of full sunlight are too low for photosynthesis and can occur behind two leaf layers from the canopy surface. Leaves exposed to such very low light levels turn yellow and eventually fall off. Photosynthesis increases almost linearly with light up to about one-third full sunlight; beyond that is said to be light saturated, in that any further increase in sunlight intensity will not increase photosynthesis. So outside leaves on vine canopies are often light saturated in sunny conditions, and some sunlight is effectively wasted.

Photosynthesis is highest with leaf temperatures from about 15–30 °C/59–86 °F, with a slight peak at about 25 °C. Photosynthesis is severely inhibited for temperatures below 15 °C and above 30 °C. During one day in hot DESERT regions, DIURNAL TEMPERATURE RANGE may be so great that vine leaf photosynthesis is inhibited by both low temperatures in the early morning and high temperatures in the afternoon. Low temperatures limit photosynthesis and hence grape ripening in COOL-CLIMATE wine regions such as those of northern Europe. High-quality vintages there are warm, sunny years when photosynthesis is highest.

Dry soil conditions will cause stomata to close, thus interfering with photosynthesis but saving the vine from further desiccation.

Such an effect of water stress on photosynthesis and grape ripening can be seen, especially towards HARVEST, in many of the world's wine regions, typically in MEDITERRANEAN CLIMATES. The vine can, however, tolerate mild water stress with no negative effect on wine quality. Indeed, if it occurs before VERAISON, and SHOOT growth is slowed, quality will probably be enhanced. WIND can also cause stomata to close and interfere with grape ripening, as is common in MONTEREY in California, for example.

As a general rule, photosynthesis is enhanced by sunny conditions and mild temperatures. These conditions are known to give maximal sugar concentration in grapes and, conventionally, the best wine quality. R.E.S.

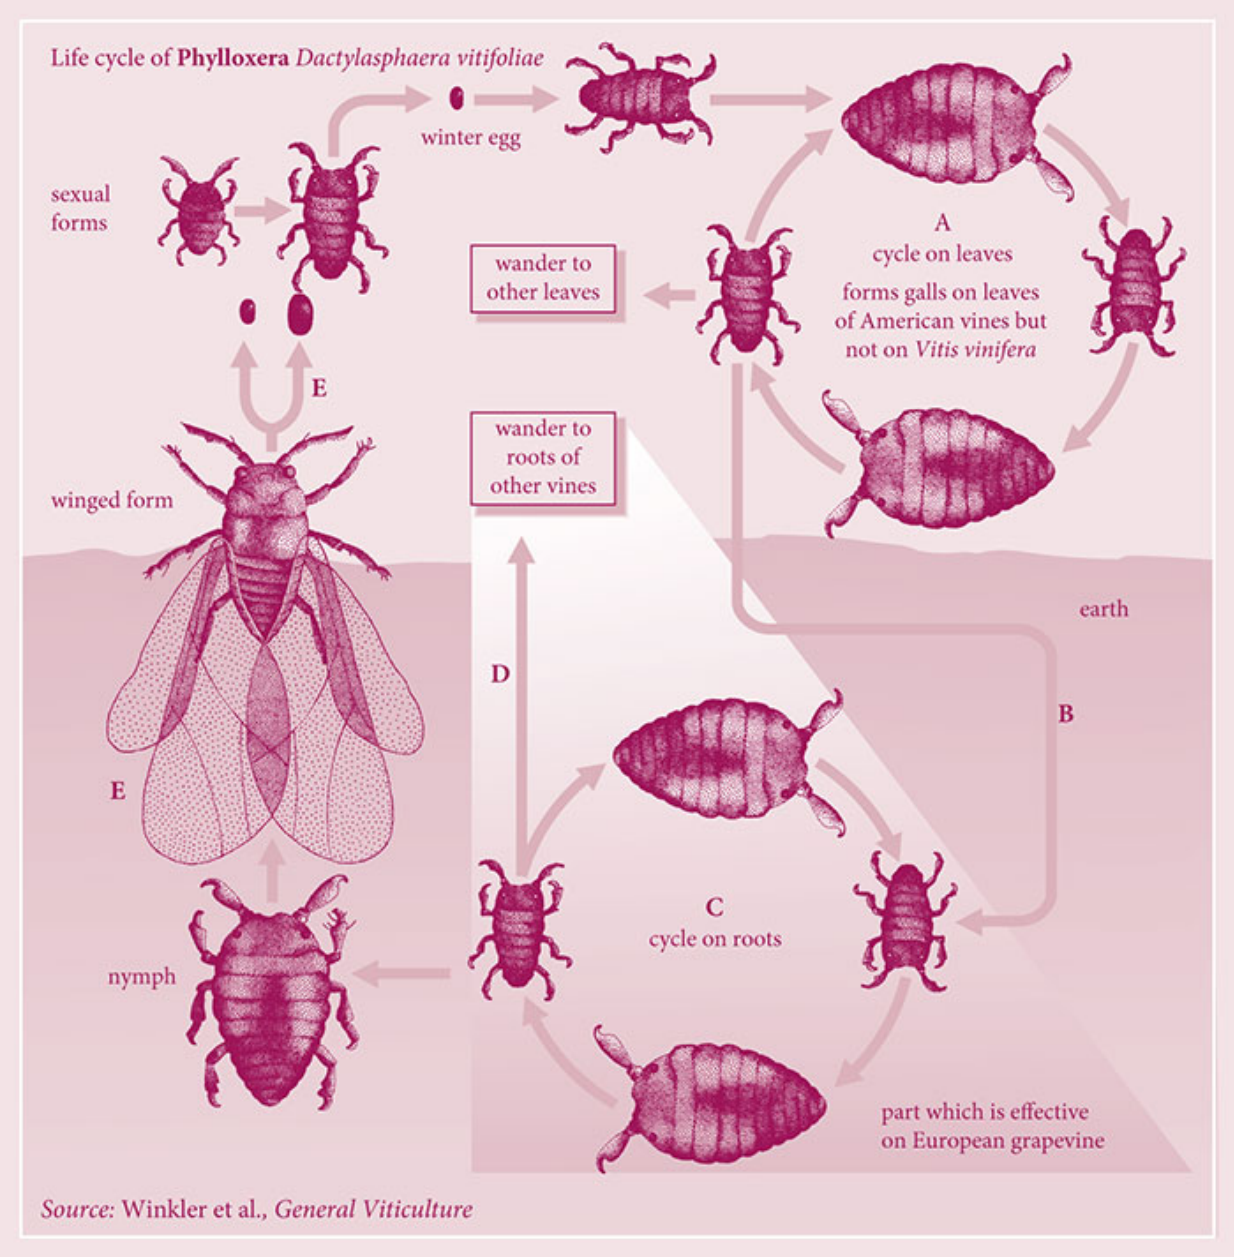
phylloxera. This small, yellow, aphid-like insect, sometimes referred to as the grape root aphid, has probably had a more damaging impact on wine production than any other VINE PEST or any VINE DISEASE. The grape phylloxera attacks only grapevines and kills vines by attacking their roots. For many years after it first invaded Europe there was no known cure. The effects of phylloxera were first noted in France in 1863, just as the country was recovering from another great scourge of 19th-century European viticulture: oidium, or POWDERY MILDEW, which was first noted in 1847. Like powdery mildew and the other FUNGAL DISEASES yet to arrive (DOWNY MILDEW in 1878 and BLACK ROT in 1885), phylloxera was an unwelcome import

from America which devastated European vineyards until appropriate control measures were found. In the history of agriculture, phylloxera rivals the potato blight of Ireland as a plant disease with widespread social effects. In France, for example, almost 2.5 million ha/6.2 million acres of vineyards were destroyed, the pest making no distinction between the vineyards of the most famous châteaux and those of humble peasants. Phylloxera invasion had a major social and economic impact, involving national governments and local committees and requiring international scientific collaboration. For a while the very existence of the French wine industry was threatened. (See BURGUNDY, modern history, for example.)

Phylloxera had many different scientific names between 1855 and 1974, when Louise Russell ended the confusion, proposing *Dactylasphaera vitifoliae* (Fitch) as the correct name for the grape phylloxera, even if the French scientist J.-E. Planchon's *Phylloxera vastatrix* (the devastator) is better known and the origin of the common name phylloxera (grape phylloxera is more accurate, since there is also an oak phylloxera, for example).



Source: Winkler et al., *General Viticulture*

Biology

The female phylloxera is yellow and about 1 mm/0.039 in long. Typically surrounded by masses of eggs, it is barely visible to the naked eye as it feeds on the roots. There are four to seven generations in the summer, each producing females capable of laying more eggs. As the eggs hatch, so-called 'crawlers' move to other roots of the vine, and some climb the trunk and can spread to other vines, or even vineyards, by the action of wind or machinery dislodging them from the foliage. Phylloxera tends to spread in a circle from the original infected vine. Wind-blown crawlers create secondary infections downwind.

It has a complex life cycle, with both sexual and asexual stages and existing in both root-living and leaf-living forms. It causes damage to vines by injecting saliva to produce galls, by feeding on the sap, and by causing root deformities. In humid regions, there is also an associated life cycle whereby the root-hatched nymph produces a winged form which can travel longer distances and lays male and female eggs. The hatching female in turn lays a winter egg which develops into the stem mother or fundatrix, which lays eggs in a leaf gall (these galls typically being produced only on the leaves of AMERICAN VINES). Nymphs hatching from galls can begin new infections as egg-laying females on roots.

The principal agent for the spread of phylloxera is humans. It is most commonly transported from one vineyard to another on soil and roots of ROOTLINGS. It is also easily moved in the soil that sticks to implements and by IRRIGATION water. Research in New Zealand showed that crawlers present in vine foliage lead to secondary spread over considerable distances; they are moved by machines which brush against foliage, such as foliage trimmers and harvesters, and also by wind.

Phylloxera is native to the east coast of the United States, and so native AMERICAN VINE SPECIES have generally evolved with resistance. Studies have shown that the basis of resistance is the development of cork layers beneath the wound made by phylloxera feeding on the

root. This stops the invasion of other microbes (bacteria and especially fungi such as *Fusarium oxysporum*) which eventually rot the root and kill non-resistant vines.

Phylloxera kills vines that do not have this resistance, such as the European VITIS VINIFERA vine species from which most wine is made, by destroying the root system. When first present, the phylloxera numbers build up quickly on roots, galls are formed, and there is initially little apparent root damage. Phylloxera can be diagnosed by the presence on the roots of the bright-yellow females, their eggs, and the characteristic gall symptoms. After a few years, the root rot affects the top growth, shoot growth is stunted, and leaves lose their healthy green colour. Normally a vine dies within several years of the first infection. Vines which are struggling for other reasons are more susceptible to phylloxera and succumb more quickly. Those growing on deep, fertile soil can continue to produce economic crops for many years after phylloxera attack. Phylloxera does not survive well in sandy soil, so vines planted in SAND (such as on the Great Plain of HUNGARY, those planted by Listel on the French Mediterranean coast, or COLARES in Portugal) are immune from attack.

History

Attempts by early European colonists in North America to establish imported *vinifera* vines met with disaster, presumably substantially because of grape phylloxera, to which they had no resistance—although at this time phylloxera had yet to be identified, and other American vine diseases such as PIERCE'S DISEASE in Florida, downy and powdery mildew in all regions, and the very cold winters doubtless played a part in their demise. (See UNITED STATES, history, for more details.)

How did phylloxera come to Europe? In the mid 19th century there was considerable importation of living plants into Europe. This trade was supported by wealthy people who could afford elaborate gardens, greenhouses, and conservatories, encouraged by the Victorians' keen interest in botany. Plants could be imported dormant or kept alive and protected from salt spray by a glass container (the 'Wardian case') built into the ship's deck, like a modern terrarium. In 1865 alone, 460 tons of plants worth 230,000 francs were imported into France, and this trade had grown to 2,000 tons by the 1890s. Jules Planchon, Professor of Pharmacy at MONTPELLIER University, noted that rooted American vines were imported in particularly significant quantities between 1858 and 1862, sent to parts of Europe as far apart as Bordeaux, England, Ireland, Alsace, Germany, and Portugal. No doubt phylloxera was an unsuspected passenger on vine roots at the same time.

The first reporting of phylloxera, like that of the fungal disease powdery mildew, was in England, in 1863, when Professor J. O. Westwood, an entomologist at Oxford University, received insect samples from a greenhouse in the London suburb of Hammersmith. Since the insects were in a leaf gall, the vine species was probably American, and these plants may even have been a source of introduction of the pest to England. In 1863, an unknown vine disease in France was being talked about, with two vineyards in the southern Rhône affected. The first printed report in France was a letter written by a veterinarian in 1867 about a vineyard planted in

1863 at St-Martin-de-Crau (only about 30 km/20 miles north-east of the site of the University of Montpellier's 20th-century phylloxera-free vine collection on the Mediterranean coast, ironically), which developed unhealthy vines in summer 1866, failing to grow the following spring. It is most likely that infection occurred several years beforehand. There were other reports from Narbonne in the Languedoc, from the Gard and Vaucluse *départements* in the southern Rhône in 1867, and from Bordeaux in 1869. (It was usually several years after the initial sighting that the pest's impact had a serious effect; the Médoc, for example, was not commercially compromised until the late 1870s.)

The first of many committees formed to resolve the phylloxera question was a Commission instigated by the Vaucluse Agricultural Society. On 15 July 1868 it began its investigation of affected vineyards in the southern Rhône. One member of the Commission was Jules Planchon, who had good training to work on phylloxera. He had spent a period at Kew Botanical Gardens in England and subsequently became the brother-in-law of J. Lichtenstein, an amateur entomologist. Planchon noticed that dying vines had small yellow insects on their roots and noted the resemblance to *Phylloxera quercus* (the oak phylloxera) living on oak trees. He named the insect believed to be ravaging vineyards *Phylloxera vastatrix*.

The Hérault Commission made its findings public in August 1868, but these caused little interest in any but the local newspapers. There was a marked reluctance to accept that this little yellow insect could be causing such devastation. Other explanations current at the time were OVERCROPPING, winter cold and other bad weather, weakening of the vineyards as a result of continued vegetative reproduction, soil exhaustion, and also God's wrath at contemporary vices. The distinguished entomologist V. Signoret thought phylloxera was an effect, not the cause, and Dr GUYOT thought its presence was due to over-severe PRUNING (the opposite of overcropping)! The debate was ended by the 1869 Commission of the Société des Agriculteurs de France, headed by viticulturist L. Vialla, who gently but firmly debunked all false theories.

Total French wine production fell from a peak of 84.5 million hl/2,200 million gal in 1875 to a mere 23.4 million hl in 1889. But even by June 1873 the French government was sufficiently alarmed by the spread of phylloxera to offer a large prize (300,000 francs) for a remedy, which was to be verified by experimentation carried out by the School of Agriculture at Montpellier. Up to October 1876, 696 suggestions were forwarded to Professors Durand and Jeannenot at Montpellier, and between 1872 and 1876 1,044 treatments were evaluated. Among the deluge of suggestions submitted were those verging on the ridiculous, which included burying a living toad under the vine (to draw the poison) and irrigating the vines with white wine. Entries were received from other countries as diverse as Denmark and Singapore. All of this work, however, produced little benefit, as only two treatments based on the chemical application of various forms of SULFIDE appeared to show much advantage. Surprisingly, carbon bisulfide failed in the evaluation even though it was later used extensively.

Early attempts at commercial control of phylloxera included flooding, which was studied by the Commission in 1873. It was found that flooding in winter for weeks on end controlled the pest, but of course few vineyards were near enough to water supplies or sufficiently flat for this to be a widespread solution (although it is still used in parts of Argentina). Vineyards on sandy soils were noted to be immune, although this offered no control. The insecticidal properties of carbon bisulfide were found in 1854 on grain weevils, and Baron Paul Thénard evaluated it in Bordeaux in 1869. The injection of the liquid carbon bisulfide was to become widespread, so that by 1888 some 68,000 ha/168,000 acres had been treated. The first experiments used too high a dose, severely affecting the vines, but subsequently the practice of injecting it, mixed with water, into the soil, using about 30,000 holes per ha, became common.

By the time of the International Phylloxera Congress at Bordeaux in 1881, two distinct schools of thought had emerged on how the industry might be saved. The chemists considered salvation to lie in carbon bisulfide or related chemicals, or in flooding. In opposition were the ‘Americanists’, who advocated grafting desired varieties on

to American vine species used as ROOTSTOCKS. Gaston Bazille had suggested GRAFTING in 1869, and Leo Laliman of Bordeaux drew early attention to the resistance of these species to phylloxera. Laliman had studied the resistance of American species to powdery mildew in a collection in his vineyards since 1840.

Following successful demonstrations of the ability of American vines to withstand phylloxera, and after the visit of Planchon to America in 1873, where his study was guided by the noted scientist C. V. Riley, state entomologist of Missouri, the use of FIELD GRAFTING began, rising from 2,500 ha/6,178 acres in 1880 to 45,000 ha in 1885. It was Riley who positively identified the unknown French insect as identical to the American one, a critical step in its eventual control; he was one of the first to suggest grafting European varieties to American rootstocks, and his authority and expertise on phylloxera gave weight to the suggestion. Initial American vine imports, cuttings taken from WILD VINES, were from the north-east, growing on acid soils. VITIS LABRUSCA was found to lack phylloxera resistance, but *Vitis aestivalis*, VITIS RUPESTRIS, and VITIS RIPARIA were found to be most effective.

All was not plain sailing, however. Many American species used for rootstocks could not tolerate the CALCAREOUS soils of France (see CHLOROSIS). A second visit to the US by Vialla led to the intervention of Texas nurseryman, breeder, and AMPELOGRAPHER T. V. MUNSON. The two met in 1878, and Munson guided Vialla to species resistant to calcareous soils, *Vitis berlandieri*, *Vitis cordifolia*, and *Vitis cinerea*. Munson was rewarded for his contribution to saving French viticulture by the medal of the French Legion of Honour and a statue in Montpellier.

However, the transition to grafting was not simple. The amount of grafting to be done was almost overwhelming. Rootstock cuttings were planted in the field and in the second year of growth were hand-grafted using SCION buds of the desired variety. There was a concern that the use of these foreign rootstocks (whose own wine is so often reviled for its FOXY flavour) might affect wine quality, and in

Burgundy the importation of American vines was prohibited until 1887, although the clandestine activities of growers anxious to save their vineyards forced its repeal.

Eventually rootstock use became the established method for the control of phylloxera, and this has had a dramatic effect on vine NURSERY operations worldwide. There was a period in the late 19th century, however, when it was thought that breeding HYBRIDS of European with American vine varieties might produce vines with sufficient phylloxera resistance not to need grafting, whose wines were not marked by the undesirable FOXY flavour of some American grapes. The class of varieties so created is loosely termed FRENCH HYBRIDS or DIRECT PRODUCERS. These efforts were generally unsuccessful, however, in that the vines had inadequate phylloxera tolerance and produced lower-quality wine, although they became popular with growers because of their high yields and their tolerance of fungal diseases. While hybrids bred in this period were not destined to remain commercially viable, they did form a useful germplasm pool of disease tolerance for highly successful breeding projects in the latter part of the 19th century (see HYBRIDS). Nevertheless, many of the rootstocks used today (see ROOTSTOCKS for a detailed list) were bred by Europeans in the late 19th and early 20th centuries—although hybrids with *vinifera* as one parent have been generally found to have insufficient tolerance to phylloxera (see below).

Geography

Phylloxera is now widespread around the world, having been found in California (1873), Portugal (1871), Türkiye (1871), Austria (1872), Switzerland (1874), Italy (1875), Australia (1877), Spain (1878), Algeria (1885), South Africa (1885), New Zealand (1885), and Greece (1898). There are few parts of the world free from the pest, although these include parts of Australia (on which a strict QUARANTINE is imposed), parts of China, Chile, Argentina, India, Pakistan, and Afghanistan, and some Mediterranean islands such as Crete, Cyprus, and Rhodes.

There are also small sandy vineyards in otherwise affected wine regions (see BOLLINGER and COLARES) which have never been affected by phylloxera either because of isolation or because of the SOIL TEXTURE.

For much of the late 20th century, phylloxera was not regarded as a serious problem, either because it was not present in a region or because of the availability of a wide range of rootstocks suited to different varieties, soil, and climate conditions along with tolerance to other pests such as NEMATODES. About 85% of all the world's vineyards were estimated in 1990 to be grafted on to rootstocks presumed to be resistant to phylloxera.

Late 20th century outbreaks of phylloxera were noted on ungrafted vines in parts of Greece, England, New Zealand, Australia, and Oregon; most dramatically, they were also found on vines grafted on to the AXR1 rootstock (see ROOTSTOCKS for details) in California where the so-called 'biotype B' strain of phylloxera was identified and blamed for the outbreak.

Phylloxera is known to occur naturally as a number of related strains or biotypes. King and Rilling exchanged phylloxera and vine cuttings between New Zealand and Germany, confirming evidence of the biotype differences between the two countries. Interestingly, the AXR1 rootstock was found not to be affected by phylloxera from New Zealand, but it was affected by German phylloxera. New Zealand

probably obtained phylloxera from California in 1885, which suggests that the biotype of phylloxera originally in California did not affect AXR1. With the introduction of other biotypes, perhaps on rooted vines imported from eastern American states at a time of nursery shortages in California in the early 1980s, the demise of AXR1 began. It was found to offer insufficient phylloxera tolerance, and a significant proportion of grafted vineyards in Napa and Sonoma valleys succumbed to phylloxera leading to extensive replanting in the 1980s and 1990s.

Better molecular testing of phylloxera strains is now available, and they are referred to as genotypes or as clones or races. The term 'biotype' is now used only to describe strains by reference to their interactions with specific rootstocks, for example by studying and classifying the insects' survival and population growth.

No doubt one of the most important effects of the phylloxera invasion of the world's vineyards was the inadvertent spread of VIRUS DISEASES. As grafting became widespread towards the end of the 19th century, virus diseases were also distributed as a common result of grafting, because virus-infected cuttings were used in grafting. A virus originally present only in the rootstock would spread to the fruiting *vinifera* variety after grafting, and vice versa. Rootstocks do not show virus symptoms, and virology in viticulture was not well understood until the 1950s. With known effects on fruit ripening, perhaps it was virus diseases more than grafting which led to the debate as to the relative merits of 'PRE-PHYLLOXERA' and 'post-phylloxera' wines.

Since the 1980s, BENCH GRAFTING has widely replaced field grafting. This, along with poor sanitary conditions in some nurseries growing rootstock MOTHER VINES, has been associated with the widespread appearance of TRUNK DISEASE fungi in grafted vines. R.E.S.

phylogeny, or phylogenesis, is the chronological reconstruction of the evolutionary history of a given group of organisms. Formerly based on morphological comparisons (see VINE MORPHOLOGY), this field has been revolutionized in the last 30 years by phylogenetics, the DNA analyses of various molecular markers found in the nucleus (inherited from both parents) or in the organelles (e.g. the chloroplasts, maternally inherited in grapevines) and usually represented as a phylogenetic tree. See BOTANICAL CLASSIFICATION for the phylogeny of the GRAPEVINE. J.V.

physiological ripeness, or physiological maturity, terms loosely used by some winemakers, especially in CALIFORNIA, to contrast with RIPENESS measured by the typical analytical measures of MUST WEIGHT, ACIDITY, and PH. The terminology is imprecise but typically includes so-called phenolic ripeness, or phenological ripeness, which refers to changes in colour, TANNINS, and flavour that are important to eventual wine quality. See also GRAPE COMPOSITION AND WINE QUALITY.

The idea of physiological ripening arose when winemakers realized that in many (particularly warmer) wine regions, these chemical measures were not sufficient to predict the optimum HARVEST date for wine quality. A common example is the relatively faster rate of sugar increase in warm to hot climates compared with phenolic development, flavour increase, and acid decrease. The resulting wines tend to be high in alcohol but lacking ripe fruit flavours. In red wines, the TANNINS may be astringent and taste unripe. On the other

hand, varietal flavour appears to increase more quickly relative to sugar in cooler climates.

Research into the effects of increased TEMPERATURE on grape composition by Sadras and colleagues in Australia has shown that, in Shiraz and Cabernet Franc, accumulation of ANTHOCYANINS is 'decoupled' from sugar accumulation during ripening. This was due to the delayed onset of anthocyanin accumulation at warmer temperatures. For other recent developments in the prediction of harvest dates, see GRAPE QUALITY ASSESSMENT.

In the late 20th century, there was an increasing tendency to encourage growers to leave grapes longer and longer on the vine. The aim of this prolonged HANG TIME was riper PHENOLICS, especially tannins, but this was often achieved at the cost of excessively high sugar levels. In such circumstances, winemakers may resort to adding WATER to the must, where local regulations allow, or the use of equipment such as the SPINNING CONE to reduce the ALCOHOLIC STRENGTH of the finished wine.

Many wine producers are now trying to find ways to achieve ripeness across all parameters at the same moment as optimal sugar accumulation and acid retention is reached. These include precisely timed IRRIGATION regimes, manipulating crop load, controlling fruit exposure, slowing sugar accumulation by careful reduction of the LEAF TO FRUIT RATIO, and research into YEASTS specifically designed to result in lower alcohol levels. As CLIMATE CHANGE leads to more frequent HARVEST COMPRESSION, there is even greater concern about achieving ripeness across all harvest parameters. J.E.H. & R.E.S.

Sadras, V. O., and Moran, M. A., 'Elevated temperature decouples anthocyanins and sugars in berries of Shiraz and Cabernet Franc', *Australian Journal of Grape and Wine Research*, 18/2 (2012), 115–22.

physiology of the vine. See VINE PHYSIOLOGY.

phytoalexins, anti-microbial compounds produced by plants in response to bacterial or fungal attack. They are not normally present in significant quantities until a plant is invaded by disease. In grapevines, phytoalexins belong to a class of PHENOLICS called stilbenes (see RESVERATROL). G.L.C.

phytoplasma, once known as mycoplasma, small and sometimes microscopic organisms similar to BACTERIA associated with vine diseases of the PHLOEM, transmitted by insects and propagation. The most serious diseases caused, GRAPEVINE YELLOWS, may well continue to have widespread implications for the world's wine industry in the 21st century. The relentless spread of various forms of phytoplasma continues in many European grape-growing regions, France, Germany, Slovenia, and Hungary among others. In recent years, CLIMATE CHANGE has been implicated, as the insect vectors spreading the disease migrate polewards. R.E.S.

Dermastia, M., et al., *Grapevine Yellows Diseases and Their Phytoplasma Agents* (2017).

Piacentini, Colli, diverse DOC zone centred on the hills of Piacenza in Emilia in north-central Italy. See EMILIA-ROMAGNA for more details.

Piave, mainly red wine DOC in the hinterland of Venice in north-east Italy. Like the neighbouring LISON-PRAMAGGIORE, the Piave DOC embraces vineyards in the plain of the Piave river and is demarcated by the pre-alpine Conegliano and Montello hills to the north and the flatlands of the river's Adriatic delta to the south. Even if the vineyard surface in production is only 189 ha/467 acres, the DOC is so extended that it overlaps the DOCGs Conegliano-Valdobbiadene, Asolo, Colli di Conegliano, and Montello, as well as the DOC Lison-Pramaggiore. The wines—mostly VARIETAL reds from Cabernet Franc,

Cabernet Sauvignon, Merlot, and RABOSO, or whites from Chardonnay, Manzoni Bianco (INCROCIO), TAI BIANCO, and VERDUZZO—are, at their best, fruity, fresh, and unpretentiously appealing; with permitted yields of up to 90 hl/ha for Merlot and over 80 hl/ha for Cabernet and Tai Bianco, they seem destined to remain that way. The zone doubles as the DOCG Piave Malanotte, of which so far only 16 ha/40 acres are in production. A potentially much more interesting red, it is made from Raboso, 15–30% of which must be dried, arguably to counteract the variety's tannic, high-acid character. But in the right hands this variety can produce long-lived, complex red wines, even without the dried-grape component. W.S.

Picapoll Blanco, vine variety making crisp white wine in the far north-east of CATALUÑA which is genetically very similar to CLAIRETTE Blanche but is unrelated to PIQUEPOUL.

picardan, a sweet white wine developed in the LANGUEDOC from CLAIRETTE and PICQUEPOUL grapes by the DUTCH WINE TRADE in the late 17th and 18th centuries. Picardan is also the name of one of the most neutral white grape varieties allowed in CHÂTEAUNEUF-DU-PAPE.

Piceno. See ROSSO PICENO.

picking grapes is seemingly romantic but in practice often back-breaking work. For more details, see HARVEST and LABOUR.

Pico, DOC on the island of the same name which is dominated by Portugal's highest mountain, Ponto do Pico, a volcano. Pico has more vines than other islands in the AZORES because its crust of black BASALT is an inhospitable environment for any other crop. Vines are planted in cracks filled with soil from the neighbouring island of Faial and protected from harsh winds and sea spray by volcanic rock walls

(*currais*). In 2004 this unique landscape gained UNESCO World Heritage status, which has spurred investment and innovation in the wine sector. The island tradition is for dry to fully sweet, nutty, honeyed, saltily persistent wines made from overripe and raisined grapes, principally VERDELHO. Its production even exceeded that of MADEIRA during the mid 19th century but has now slowed to a trickle. Contemporary examples are fortified and labelled LICOROSO (with the exception of Czar, the leading exponent, whose wines are labelled 'Not Fortified'). In dry wines, the island's most thrilling are the saline, mineral whites which attained DOC status in 2012. They must comprise a minimum of 85% VERDELHO, ARINTO do Açores, and Terrantez do Pico, varieties said to be Azorean (although Madeira also lays claim to Verdelho). Other dry wines made from a much broader range of white and red grapes (including French and mainland varieties) have enjoyed Vinho Regional Açores status since 2004. Consistent with increased recognition for dry wine, the DOC vineyard area increased from 130 to 712 ha/1,759 acres between 2014 and 2020. S.A.

Volcanic Mount PICO, rising to 2,531 m/7,713 ft on the island of the same name dwarfs the Azores Wine Company's brilliantly camouflaged winery in Bandeiras. The lava-rock walls (currais) that protect these Arinto dos Açores vines from the WIND and sea spray are essential to the survival of these tenacious vineyards. © Azores Wine Company/ Armando Jorge Mota Ribeiro

Ahmed, S., 'Pico, The Azores: Volcanic Wines in the Midst of Waves', *The World of Fine Wine*, 57 (2017) 178–82.

Picolit, also written Piccolit and Piccolito in the past, fashionable and audaciously priced sweet white VARIETAL wine made in the FRIULI region of north-east Italy, one of the more commercially successful of the DRIED-GRAPE WINES. The grape variety derives its name from the small, or *piccolo*, quantity of grapes it produces, thanks to its exceptionally poor pollination rate in the vineyard. The variety probably originates in Rosazzo in the FRIULI COLLI ORIENTALI.

The wine was already famous in the 18th century but was almost extinct when the Perusini family of the Rocca Bernarda of Ipplis worked to identify and then reproduce hardier CLONES with a reduced failure rate.

Some better estates still make the wine much as it was in the past —Fabio Asquini left copious notes on his working methods—with the bunches, harvested late in mid October, left to dry and raisin on mats before pressing. Other producers have opted for a late-harvest style, with the grapes left even longer in the vineyard, picked with higher MUST WEIGHTS, but not raisined after picking. The use of small oak BARREL AGEING is an innovation introduced in the mid 1980s. Although Picolit is generally considered a dessert wine, it is not luscious and is best considered a VINO DA MEDITAZIONE, a wine to be sipped alone in order to appreciate its delicate floral aromas and its light sweetness, which suggests peaches and apricots.

The wine became the object of a cult enthusiasm in Italy in the late 1960s and 1970s, fetching extremely high prices that non-Italian connoisseurs find difficult to understand or justify; the Picolit boom has also resulted in frequent and illegal blending of the wine with the more neutral VERDUZZO, which has stretched the quantities available but has done no service to the wine's reputation. There were just 121 ha/299 acres of the variety in Italy in 2015. A small amount is grown over the border in western Slovenia.

Picpoul de Pinet, one of the France's few VARIETALLY named AOC wines and arguably the Languedoc's greatest commercial success of the 2010s. Made exclusively from Picpoul Blanc—called PIQUEPOUL

outside of the appellation—and awarded its AOC in 2013, the wine comes from about 1,400 ha/3,460 acres of fairly low-lying land between Pézenas and the Bassin de Thau lagoon. A range of hills protects the vines from northern winds, while breezes off the nearby ocean moderate the summer heat. The majority of wines are produced by CO-OPERATIVES and are pale green, crisp, saline, and lemony, although independent producers such as Julie Benau have been working with LEES CONTACT, SKIN CONTACT, and even BARREL AGEING to introduce more texture and complexity. M.S.

Pic-St-Loup, one of the most highly regarded subregions of the LANGUEDOC, elevated to an AOC in 2016. The zone, with mixed but largely CALCAREOUS soils, includes 12 communes around the eponymous and dramatic 658-m/2,159-ft peak north of Montpellier. The CONTINENTAL CLIMATE produces wines with a high degree of freshness, slightly lighter in body than those from many of its AOC Languedoc counterparts and laced with scents of GARRIGUE. Wines are 90% red, the rest rosé, based on Grenache, Mourvèdre, and Syrah, with back-up from Cinsaut and Carignan. The zone's white wines are often labelled either as AOC Languedoc or IGP St-Guilhem-le-Désert. M.S.

pièce, size and shape of barrel conventionally used in Burgundy. See BARREL TYPES for more details.

pied de cuve. French term for a fermentation starter made using ambient rather than cultured YEAST. A small volume of grapes is harvested a few days early, crushed, and allowed to start fermenting, thus building a healthy yeast population. The *pied de cuve* is added to the MUST or juice of the main harvest. Using a *pied de cuve* to start a SPONTANEOUS FERMENTATION reduces the risk of sluggish or STUCK FERMENTATION.

Börlin, M., et al., 'The "pied de cuve" as an alternative way to manage indigenous fermentation: impact on the fermentative process and *Saccharomyces cerevisiae* diversity', *OENO One*, 54/3 (2020).

piede franco, Italian for UNGRAFTED VINE.

Piedirosso, one of CAMPANIA's relatively few red wine grapes, very much in second place after AGLIANICO, grown around Naples and on the islands of ISCHIA and Capri. Also known as Per'e Palummo and Palombina, it can make fresh, fruity reds, but total plantings had declined to 593 ha/1,465 acres by 2015.

Piedmont , Anglicized name for PIEMONTE.

pie franco, Spanish for UNGRAFTED VINE.

Piemonte , qualitatively outstanding and highly distinctive wine region in north-west ITALY whose principal city is Turin (see map under ITALY). This subalpine part (its name means 'at the foot of the mountains') of the former kingdom of Savoy was the driving force behind Italian reunification in the 19th century and led the initial phases of Italy's industrial revolution. Its geographical position both isolated and protected it during the period of Habsburg, Bourbon, and papal domination which marked Italian life 1550–1860, while its proximity, both geographical and cultural, to France (the kingdom's court and nobility were Francophone until well into the 19th century) gave it both an openness to the new ideas of the European enlightenment and relative prosperity—in stark contrast to the poverty of much of the rest of the peninsula. In 2020 total annual wine production averaged over 2.7 million hl/59 million gal, with over 80% DOC or DOCG.

In Piemonte vines are planted at ELEVATIONS of 150–400 m/490–1,150 ft and regularly higher for the Alta Langa DOC sparkling wines, with the best, south-facing sites typically devoted to NEBBIOLO, while the coolest positions are planted with DOLCETTO (or MOSCATO in the zones in which it is grown). BARBERA is widely planted in between. Average summer temperatures and rainfall are very similar to those in Bordeaux. Although there are 21 Nebbiolo-based DOCs or DOCGs, only the world-famous BAROLO and BARBARESCO supply significant amounts of wine. GATTINARA, for example, which is the largest of the Nebbiolo DOCs outside the LANGHE hills, encompassed in 2020 hardly more than 111 ha/274 acres of vineyard. More common is Barbera, planted virtually everywhere in the provinces of ALBA, ASTI, and Alessandria. It was considered Piemonte's workhorse grape until the 1980s, when high-quality and expensive oak-aged Barberas appeared on the market, showing the variety's real potential and radically changing perceptions. While Barbera d'Asti has been a DOCG since 2010, the elevation of its subzone Nizza to DOCG in 2019 is further recognition of Barbera's intrinsic quality. DOLCETTO, almost as ubiquitous as Barbera and similarly considered modest rather than great, delivers most of Piemonte's fruity red wine for early drinking. It ripens even earlier than Barbera and is regularly vinified in less than a week to make sure the fermentation tanks are empty before Barbera and Nebbiolo are harvested.

White grapes, except for the MOSCATO used extensively for various SPUMANTE and FRIZZANTE (most notably ASTI), used to be a virtual afterthought in Piemonte, but the region's production of white wine grew considerably in the late 20th and early 21st centuries. Part of this surge is due to the commercial success of Asti and MOSCATO D'ASTI, but wines based on CORTESE such as GAVI and those from the Colli Tortonesi and Alto Monferrato have become enormously popular since the 1990s. INDIGENOUS VARIETIES such as ARNEIS, a mere curiosity in the early 1980s, is planted on 925 ha/2,286 acres in 2020, producing millions of bottles annually. While the 1980s saw the arrival and a certain acceptance of INTERNATIONAL VARIETIES, they never

established a real foothold here, no doubt due to Piemonte's many high-quality indigenous varieties. While the plantings of Chardonnay and Pinot Noir have helped trigger a budding and promising METODO CLASSICO production under the Alta Langa DOC, other white Piemontese varieties, such as ERBALUCE (dry as well as sweet or sparkling), TIMORASSO, and NASCETTA, now with its own subzone Novello under the LANGHE DOC, are beginning to earn deserved recognition.

Piemonte is the only region in Italy that does not allow the production of IGT wine. Instead, an overarching DOC Piemonte, the size of the entire region, was created, encompassing 59 DOCs and DOCGs. The intention was to brand the region's entire production at the highest quality level in order to obtain greater prestige and success in the international market. But the system failed, because the Piemonte DOC's production rules had to be as flexible as those of an IGT to allow both international varieties and higher YIELDS. This weakened the significance of the DOC system as well as the notion of origin in high-quality wines. While the DOC Piemonte is not widely used, several other regions, notably Sicily and Friuli Venezia Giulia, have followed its example. The only radical refinement of the Piemontese DOC system has been the creation of recognized single-vineyard sites, called *menzione geografica aggiuntiva* (MGA), of which especially Barolo and Barbaresco have taken advantage (see BAROLO for more detail).

For more details of individual wines, see ALBA, ARNEIS, ASTI, BARBARESCO, BARBERA, BAROLO, BRACHETTO, CAREMA, CORTESE, DOLCETTO, ERBALUCE, FAVORITA, FREISA, GATTINARA, GAVI, GRIGNOLINO, LANGHE, MOSCATO, NEBBIOLO, ROERO, RUCHÈ, and SPANNA. W.S.

Pierce's disease, or PD, is one of the vine BACTERIAL DISEASES most feared around the world as it can quickly kill grapevines and a wide range of economically important crops including olives, almonds, and citrus. There is no cure, and it is extremely difficult to control because the bacterium has a wide range of host plants and is spread by insects from several different families.

Along with FLAVESCENCE DORÉE, Pierce's disease is a principal reason for QUARANTINE restrictions on the movement of grape cuttings and other plants between countries. In common with many other economically significant vine diseases, it originates on the American continent and is a principal factor limiting grape-growing in the Gulf Coastal plains of the United States (see TEXAS) and southern CALIFORNIA, but in the last decade it has been found in Europe, first in olive trees but now also in grapevines.

The disease was first described in 1892 in southern California as Anaheim disease, but was later named after the Californian researcher Pierce. By 1906, the disease had destroyed almost all of the more than 16,000 ha/39,500 acres of vines, and there was another epidemic in the 1930s in the Los Angeles basin, which never recovered as a viticultural area. Pierce's disease has continued to cause chronic problems in southern California, in coastal northern California (Napa and Sonoma) in isolated hot spots near riparian vegetation, and in the Central Valley near insect-vector breeding habitats such as pastures and hayfields. The disease is today found across the southern United States and throughout Mexico and Central America. It has also been reported in Venezuela.

The leaves of infected plants develop marginal discoloration that advances to dead tissue. This progressively enlarges until the leaves drop leaving only the PETIOLE attached. The clusters also dehydrate and are left unpicked. Vines die within one to five years after infection, depending on grape variety, vine age, and climate. Originally believed to be a virus, the disease is now known to be caused by a bacterium named *Xylella fastidiosa*. Various strains of the bacterium differ from one another in their ability to multiply within, and cause disease to, certain plant species. For example, grape

strains do not multiply in sweet orange, but orange strains (now in South America) cause disease in grapevines. The disease is spread by insects called sharpshooters (see LEAFHOPPERS), which transmit the bacterium from host plants to the vineyards during feeding. In coastal California, vectors originally fed and reproduced in natural vegetation along streams, and the largest numbers of infected vines were therefore typically within 100 m/330 ft of a vineyard edge. Only the spring infections of vines (April–May) establish chronic Pierce's disease; later infections are removed by pruning or killed by winter temperatures.

However, the introduction of the GLASSY-WINGED SHARPSHOOTER into southern California in the 1980s has led to far more widespread damage. This leafhopper also spreads the bacterium, and, significantly for vineyards, it can fly further and more frequently. Vineyards near Temecula, for example, were destroyed by an outbreak spread by this new insect vector. It has moved northwards in the Central Valley, and vigorous QUARANTINE efforts are protecting vulnerable Napa and Sonoma counties for the moment. Since Pierce's disease exists in these counties but the insect vector is limited, a new insect vector could have major implications.

There are no resistant VITIS VINIFERA varieties, and some such as Chardonnay and Pinot Noir are especially susceptible. Varieties developed from MUSCADINE grapes or other wild grape species native to south-eastern USA and Mexico have natural resistance or tolerance and are the only ones to be grown where the disease is endemic. In California, growers are advised to avoid planting near hotspots or use less susceptible varieties. There is no satisfactory chemical control of the bacterium.

However, the discovery of strong single-gene resistance to *Xylella fastidiosa* in forms of *Vitis arizonica* from Texas and northern Mexico led to the possibility of breeding high-quality PD-resistant wine grapes by classical VINE BREEDING. Genetic mapping of this resistance gene enabled the marker-assisted selection of breeding populations, which—coupled with aggressive growing practices to force grapes into a two-year seed-to-seed cycle—has allowed 97% *vinifera* PD-

resistant selections to be created over about 12 years at the University of California, DAVIS (see DISEASE-RESISTANT VARIETIES).

In 2013 PD was detected on olive trees in Puglia and has spread northwards killing millions of trees. In 2015–17, several subspecies and strains were detected on around 30 different host plants in southern France and Corsica; in 2016 on almonds, grapevines, cherries, and plums in the western Iberian peninsula of Spain, as well as on the Balearic Islands. It has also been found on grapevines in Iran, Türkiye, Taiwan, on Mallorca, and, in 2023, in Portugal. Cold winters appear to limit where the disease occurs in North America and could do the same in northern Europe. The situation in Europe will be worsened by CLIMATE CHANGE, as Godefried et al. report.

www.cdfa.ca.gov/pdcp/research.html

Pierrevert , AOC in the Alpine foothills of northern Provence, regarded by the INAO as an eastern satellite of the southern RHÔNE.

The appellation extends over 300 ha/741 acres east of the LUBERON and includes some of the highest vineyards in France. Wines of all three colours are produced, with rosé the most important. Thanks to the relative harshness of the climate, they are usually marked more by acidity than body. Grenache and Syrah are the dominant grapes. Tourism in the Alpes de Haute-Provence is such that there has been little need to seek export markets.

Pigato, characterful white grape variety producing distinctively flavoured VARIETAL wines in the north-west Italian region of LIGURIA. DNA PROFILING showed that Pigato and VERMENTINO, both long-established in Liguria, and FAVORITA cultivated in Piemonte are all genetically identical.

pigeage, French term for PUNCHING DOWN.

pigmented tannins, also called polymeric pigments, are responsible for the colour of red wines, together with ANTHOCYANINS, which are the phenolic red PIGMENTS of dark-skinned grapes. Pigmented tannins comprise a great diversity of molecular species formed by the reactions of anthocyanins with non-pigmented CATECHINS, PROANTHOCYANIDINS (i.e. condensed tannins from grapes), and ellagitannins (i.e. hydrolysable tannins extracted from barrels or added as components of some OENOLOGICAL TANNINS), under the influence of acids and oxygen. Their formation begins in the course of MACERATION and then progresses throughout the AGEING of a red wine, so that the grape anthocyanins as individual molecular species make only a transitory and ever-diminishing contribution to the colour of a red wine.

Although this process has been known for over thirty years, some of the structures postulated for pigmented tannins have only recently been shown to form in wine, owing to progress in the development of analytical techniques, whereas others have not yet been confirmed.

Besides, several hitherto unsuspected reaction processes and products have been unravelled in the last few years. Formation of pigmented tannins occurs through both direct addition reactions between anthocyanins and tannins and reactions involving fermentation products such as ACETALDEHYDE and pyruvic acid. The nature and amounts of the resulting products depend on the nature and proportions of the phenolics present and the relative kinetics of the various reactions. Physico-chemical parameters such as PH and temperature and the presence of oxygen, of yeast metabolites, and of co-factors, such as metal ions, also affect the type and/or kinetics of the reactions.

Colour changes, from the purple nuance of young wines towards the red-brown tint of mature wine, are classically ascribed to the conversion of anthocyanins to pigmented tannins. However, pigmented tannins cover a wide range of colours, from orange to purple and blue. Besides, anthocyanin reactions also yield lower molecular weight orange pigments which are not pigmented tannins and various kinds of polymeric pigments (e.g. anthocyanin oligomers, pyranoanthocyanin dimers) which are not derived from tannins. Reactions of tannins under OXIDATIVE conditions also lead to brown-orange pigments that do not derive from anthocyanins. Most of these pigments show increased colour stability with respect to hydration and sulfite bleaching compared with anthocyanins, but this property is neither characteristic of nor specific to pigmented tannins. Known pigments account for only a small proportion of wine colour, meaning that most pigmented tannins are of analytically intractable nature, due to their multiplicity and diversity of structure and the transient nature of individual molecular species as they equilibrate among each other.

There is also conjecture about interactions of pigmented tannins with PROTEINS and POLYSACCHARIDES and the influence of such putative interactions on the properties (particularly taste properties—see below) of the pigmented tannins.

Experience has also shown that the formation of pigmented tannins, as well as conferring stability on the colour of a red wine (for

decades, in favourable circumstances), also modulates the ASTRINGENCY of the very high concentration of phenolics of the wine, improving its TEXTURE and other taste properties. The desirable effects of pigmented tannins on mouthfeel are well illustrated by a comparison of the taste properties of a red wine with those of a white wine made, like a red wine, with extensive MACERATION. Such highly tannic white wines (except for the few made deliberately in this way; see ORANGE WINE, QVEVRI, and SKIN-FERMENTED whites for examples) are not just unattractive but crude and coarse on the palate; furthermore, they do not improve with age but remain tannic and undrinkable. In contrast, the pigmented tannins of the red wine make it palatable and soft with good AGEING characteristics, and this despite the fact that their presence increases further the phenolic and tannin polymer content of the red wine relative to that of its macerated white wine counterpart.

Changes in astringency taking place during red-wine ageing are usually attributed to an increase of tannin molecular weight as a result of the formation of co-polymers with anthocyanins since larger polyphenolic species have been claimed to be insoluble and thus non-astringent. However, recent studies have shown that tannin solubility does not decrease with molecular weight and that astringency in fact increases with the tannin size. Besides, tannin reactions in wine do not only yield larger polymers but also lead to lower molecular weight species. The latter reactions may contribute to the decrease of astringency observed during wine ageing. Nevertheless, the taste of pigmented tannins and the effect of incorporating anthocyanin units in a tannin structure on its astringency remain to be investigated.

P.J.W. & V.C.

Fulcrand, H., et al., 'The fate of anthocyanins in wine: are there determining factors?', in A. L. Waterhouse and J. A. Kennedy (eds.), *Red Wine Color: Revealing the Mysteries. ACS Symposium Series 886* (2004), 68–88.

pigments, inclusive name for the compounds which impart colour. Colour results from the presence in these compounds of structures or

functional groups that absorb light of particular wavelengths. Young red wines get their colour from the ANTHOCYANINS and PIGMENTED TANNINS, with the former decreasing in concentration and the latter reciprocally increasing and making the dominant contribution to colour as the wine ages. In contrast to the broad understanding of the pigments (and their chromophores) responsible for red-wine colour, the yellow to amber colours of white wines are less well understood. PHENOLICS present in the white grapes are evidently involved, and some limited OXIDATION of these is assumed to play a role in desirable white-wine colour development. Brown polymers, resulting from excessive oxidation of white-wine CATECHINS, are known to be responsible for the browning of oxidized wines. See AGEING and COLOUR. P.J.W.

Pignatello, synonym for the Sicilian red grape variety PERRICONE.

Pignola Valtellinese, dark-berried vine almost certainly originating in VALTELLINA. DNA PROFILING revealed a parent–offspring relationship with Rossolino Nero, also of Valtellina. It may be related to NEBBIOLO.

Pignoletto, lively, crisp white grape grown in Umbria and in EMILIA-ROMAGNA in northern Italy on an area totalling about 1,172 ha/2,896 acres in 2015. This ancient variety is also known as GRECHETTO Gentile.

Pignolo, promising red grape variety native to the FRIULI region of north-east Italy, probably first cultivated in the hills of Rosazzo in FRIULI COLLI ORIENTALI. Pignolo is a very shy bearer; it was generally ignored by local growers who preferred other, more productive grape varieties until, like SCHIOPPETTINO, it was given a new lease when in

1978 it was authorized for use in the province of Udine. Plantings in Italy had reached 50 ha/124 acres by 2015.

Little, B., *Pignolo* (2016).

Pineau, a word widely used in France as a synonym for the PINOT group of grape varieties. It seems to have been a portmanteau word for any better-quality vine in medieval France (probably a reference to the pine-cone shape of so many bunches of grapes) but is today a word associated primarily with the Loire. It is the first word of a wide range of vine synonyms, sometimes various forms of Pinot but often CHENIN, most notably as Pineau de la Loire.

Pineau d'Aunis, sometimes called Chenin Noir although unrelated to CHENIN BLANC, is a historic Touraine variety making light-red wines once sought by the kings of both France and England, according to Pierre GALET. France's total plantings, 479 ha/1,184 acres in 2019, have remained steady and are concentrated around Tours in the Loire Valley. The variety is one of the many sanctioned for the red and rosé appellations of TOURAINE and ANJOU but is used only to a limited extent, mainly to bring peppery liveliness and fruit to rosés, although in ripe years it can yield a fine red, too, notably in Coteaux du LOIR. See also Coteaux du VENDÔMOIS.

Pineau des Charentes is the VIN DE LIQUEUR of the Cognac region and has enjoyed some *réclame* in France as a strong, sweet APERITIF more likely to be the product of an artisan than of big business. It is made by adding at least year-old cognac straight from cask to must that is just about to ferment, thereby producing what is effectively a mixture of grape juice and brandy. AOC regulations specify that rosé versions must age for at least eight months; reds for 12; and whites for 18, mainly in barrel, though finer examples tend to be aged far longer. Those labelled *vieux* age more than seven years and *extra vieux* more than 12. The final product is bottled at 16–22%

alcohol. The style most often encountered outside France is pale gold, decidedly sweet and spirity, but there are many subtler examples, including soft, fruity rosé styles made from the same grapes as red BORDEAUX. See also FLOC DE GASCOGNE.

Pinenc, local name for the FER Servadou red wine grape variety in MADIRAN.

Pinot is the first word of many a French vine variety name and is thought to refer to the shape of Pinot grape bunches, in the form of a pine (*pin*) cone. Pinot is considered one of the most important and ancient grape varieties, possibly a selection from WILD VINES. The variety may well have existed for as long as two millennia. Although Morillon Noir was the common name for early Pinot, a vine called Pinot was already described in records of Burgundy in the 14th century, and its fortunes were inextricably linked with those of the powerful medieval monasteries of eastern France and Germany (see BURGUNDY and GERMAN HISTORY). So long has Pinot existed that an unusual number of CLONES have emerged, more than 1,000 according to the father of modern vine identification Pierre GALET, of which PINOT BLANC, PINOT GRIS, PINOT MEUNIER, and PINOT NOIR are just some of the better known. CHARDONNAY is still occasionally called Pinot Chardonnay. Galet maintained that Chardonnay was not a member of the Pinot family, but DNA PROFILING analysis in 1999 dropped the bombshell that at least 21 distinct varieties are the progenies of Pinot and the obscure and rather ordinary variety GOUAIS BLANC, including ALIGOTÉ, Aubin Vert, AUXERROIS, Bachet Noir, Beaunoir, CHARDONNAY, Franc Noir de la Haute-Saône, Gamay Blanc Gloriod, GAMAY Noir, Knipperlé, MELON, Peurion, ROMORANTIN, Roublot, and SACY. Furthermore, independent DNA analysis in Austria revealed a parent–offspring relationship between Pinot and SAVAGNIN. Other instances of DNA profiling have shown that Pinot is probably a grandparent of TEROLDEGO, MARZEMINO, LAGREIN, and DUREZA, parent of Syrah. A family

tree in *Wine Grapes*, with Pinot, Gouais Blanc, and Savagnin at the top (and many blanks for unknown relatives), includes 156 Western European vine varieties, most of them well known. So much for Pinot's genetic importance. As for nomenclature, there are no fewer than 30 entries beginning 'Pinot' in the index of *Wine Grapes*, although they are by no means all distinct.

In German, members of the Pinot group frequently have the word 'Burgunder' in their German names (SPÄTBURGUNDER, WEISSBURGUNDER, and GRAUBURGUNDER) in a reference to Pinot's Burgundian homeland. There was a marked increase in the popularity of these grape varieties throughout the 1980s as tastes changed in favour of drier, fuller German wines. Throughout Eastern Europe, Pinots of various sorts have 'burgund' in their name.

Galet, P., *Dictionnaire encyclopédique des cépages* (2nd edn, 2015).

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Pinotage, a hardy and moderately vigorous red grape variety, is SOUTH AFRICA's most notable contribution to the history of the VITIS VINIFERA vine. In 1924 STELLENBOSCH University viticulturist A. I. Perold crossed Pinot Noir and Cinsaut, then commonly called Hermitage in South Africa, hence the contraction Pinotage. It took until 1961 for the name to appear on a label, that of a Lanzerac 1959. The grape has been controversial, particularly in earlier decades, when it frequently made reds with a flamboyantly sweetish paint-like pungency (from ISOAMYL ACETATE) and, often, some degree of bitterness. Greater viticultural and winemaking understanding have made such problems increasingly rare, but local and international detractors remain. Many examples are indeed too powerful and jammy, with the excessiveness of a certain type of ambition taking its toll. Nonetheless, some unquestionably good VARIETAL and blended wines are produced, at all levels, from accessibly fruity rosés and

lighter reds to fine, deep-coloured, rich, seriously oaked examples, although examples made in the 1960s, long before the era of vinification in BARRIQUE, reveal that Pinotage does not depend on the use of wood to acquire longevity and complexity. Most of the best of them come from mature BUSH VINE vineyards with restricted YIELDS, and some have a perfume recalling the grape's parentage. Fairly simple CO-OPERATIVE winery examples from the 1960s and 1970s that have been drinking well (and rather elegantly) in the second decade of this century, as well as the complex maturation of older wines from the likes of Pinotage specialist Kanonkop in STELLENBOSCH, testify to Pinotage's longevity. So-called 'coffee Pinotage', with mocha notes deliberately derived from artful oaking, became a notorious early 21st century success story in South Africa and in some export markets. Pinotage works well in blends, and attempts continue to establish CAPE BLEND as a generic name for reds with a certain (but disputed) percentage of the grape. Since 1994, plantings of Pinotage, along with other major red varieties, have grown substantially, and by 2020 the total area planted, 6,637 ha/16,400 acres, represented around 6% of all South African vine plantings. Pinotage is also grown, to a much more limited extent, in Australia, New Zealand, Brazil, California, Oregon, Washington, Israel, Zimbabwe, and most vine collections.

May, P. F., *Pinotage: Behind the Legends of South Africa's Own Wine* (2009).

Pinot Beurot, ancient Burgundian synonym for PINOT GRIS.

Pinot Bianco, common Italian name for the white PINOT BLANC grape of French origin and much, much more widely grown than the French original in France. Introduced to north-eastern Italy as Weissburgunder well before the mid 19th century when the region was under Austrian rule, it was once very popular there. By 2000, however, it had been decisively overtaken by Chardonnay and Pinot Grigio, and total plantings in 2015 were just 2,337 ha/5,775 acres.

It is grown particularly in TRENTINO-ALTO ADIGE, the VENETO, FRIULI, and LOMBARDY, although, as in ALSACE, Pinot Grigio enjoys higher esteem in these areas. Pinot Bianco is prized in Alto Adige, however, and has produced some of this region's finest white wines. It was first noted in Piemonte in the early 19th century, and until the mid 1980s the name 'Pinot Bianco' was used to describe Pinot Blanc, Chardonnay, or a blend of the two. Even today there are vineyards in which both varieties grow side by side. Italians often vinify Pinot Blanc as a high-acid, slightly SPRITZIG, non-aromatic white for early consumption, but good Pinot Bianco from low-yielding vineyards in Alto Adige, sometimes fermented and aged in oak barrels, indicate that Pinot Bianco could give much better results in Italy if it were treated with more respect. In Lombardy the high acid and low aroma is useful to the SPUMANTE industry, but CLIMATE CHANGE may make this variety less suitable.

Pinot Blanc, French white vine variety, member of the PINOT group and particularly associated with ALSACE, where most of its French 1,159 ha/2,864 acres in 2019 were to be found. It was first observed in Burgundy at the end of the 19th century, a white mutation of PINOT NOIR. Although its base is Burgundian, today it is found all over central Europe.

For many years no distinction was made between Pinot Blanc and CHARDONNAY since the two varieties can look very similar. No Pinot Blanc is notable for its piercing aroma; its perfume arrives in a cloud. Most wines based on Pinot Blanc are also relatively full-bodied, which has undoubtedly helped reinforce the confusion with Chardonnay, not only in Burgundy but also in north-east Italy, where it is known as PINOT BIANCO. Although Chardonnay dominates white burgundy, Pinot Blanc is technically allowed into wines labelled BOURGOGNE Blanc but is no longer grown in any quantity in Burgundy.

Even in Alsace, Pinot Blanc's French stronghold, it is less important in terms of total area planted than Riesling or even the white AUXERROIS with which it is customarily blended in Alsace, to be sold as

'Pinot Blanc'. In LUXEMBOURG, on the other hand, the higher acidity of Pinot Blanc makes it less highly regarded than Auxerrois.

While in Alsace it is regarded as something of a workhorse (and sometimes called Clevner or Klevner), it has been generally held in much higher esteem in German-speaking wine regions, where it is known as WEISSBURGUNDER. Germany has a much greater area planted than France, up to 5,922 ha/14,634 acres by 2020, making it Germany's fifth most planted white-wine CULTIVAR, with vinous personalities ranging from the full, rich, oaked examples of Baden and the Pfalz to relatively delicate, mineral-inflected variations along the Nahe and Mosel, and with quality aspirations ranging from a workaday norm to occasional brilliance. It is popular with growers seeking food-friendly wines that are softer than Riesling and can show local characters.

As Pinot Bianco it is a popular dry white in Italy and is also grown in Switzerland, but it is in AUSTRIA that, as Weissburgunder, the variety reaches some of its greatest must weights. Also the fifth most planted white wine grape on a total of nearly 1,884 ha/4,655 acres in 2021, it is grown in all regions. As a dry white varietal, Weissburgunder is associated with an almond-like scent, medium to high alcohol, and an ability to age, but it has achieved its greatest glory in Austria in ultra-rich, botrytized TROCKENBEERENAUSLESE form, often blended, typically with WELSCHRIESLING (acting out the respective parts of Sémillon and Sauvignon Blanc in Sauternes).

Pinot Blanc is broadly disseminated over eastern Europe. In Slovenia, Croatia, and Serbia, it is widely grown and may be called Beli (White) Pinot. It is also grown in Czechia and Slovakia and is typically used in Hungary to produce full-bodied, rather anodyne dry whites more suitable for export than INDIGENOUS VARIETIES.

Vine-growers outside Europe recognize that Pinot Blanc has lacked Chardonnay's glamour, but in 2020 there were still 132 ha/326 acres of a variety called Pinot Blanc in California, mainly in Monterey, usually treated to BARREL AGEING and the full range of Chardonnay winemaking tricks, to creditable effect. Older vines bearing this name

are almost certainly not Pinot Blanc but the Muscadet grape MELON (now proven to be another member of the extended Pinot group).

Viticulturally, if not necessarily commercially, Pinot Blanc seems particularly well adapted to the Okanagan Valley in British Columbia. Elsewhere in the New World, Pinot Blanc is largely ignored.

Pinot Chardonnay is an old synonym for CHARDONNAY, the classic white grape of Burgundy. It was adopted at a time when Chardonnay was believed to be a white mutation of PINOT NOIR (incorrectly, as it turned out—see PINOT).

Pinot Grigio, during the first decade of the 21st century, took over from Chardonnay as the name of the most popular white wine in the global mass market. It came to signify a vaguely aromatic, dryish, unoaked white. It is also the common Italian name for the French vine variety PINOT GRIS and, as such, is probably the name by which the variety is best known to many wine drinkers. Because of Pinot Grigio's popularity, many producers worldwide choose this name in preference to Pinot Gris. There were about 3,500 ha/8,600 acres of Pinot Grigio vineyard in Italy in 1990 (much less than the area planted with PINOT BIANCO, for example), but so great was demand for Pinot Grigio that its plantings had overtaken those of Pinot Bianco to reach 6,700 ha by 2000 and 18,821 ha/46,507 acres by 2015, almost as much as Chardonnay's 19,769 ha.

The variety is said to have been introduced to Italy via Piemonte in the early 19th century but became a speciality of the north-east. The best and richest wines are produced in FRIULI, with the traditional version called Ramato, SKIN-FERMENTED, resulting in a copper-tinged (*ramato*) wine, while those produced in Alto Adige can be particularly aromatic. But the bulk of Pinot Grigio produced today comes from the VENETO, where large volumes are produced by growers for their local CO-OPERATIVES and then sold to the large bottlers. These Veneto versions tend to be rather neutral and, at their best, inoffensive, the high yields diluting any true Pinot Grigio character. The variety is also

grown widely in LOMBARDY although there is less fastidiousness here about distinguishing it from other hues of PINOT, especially when supplying grapes for the sparkling wine industry. Pinot Grigio is planted as far south as EMILIA-ROMAGNA and as far north as ALTO ADIGE.

Pinot Gris is the widely disseminated, fashionable vine variety (see PINOT GRIGIO) that can produce soft, gently perfumed wines with more substance and colour than most whites, which is what one might expect of a variety that is one of the best-known MUTATIONS of PINOT NOIR. If Pinot Noir berries are purplish blue and the berries of the related PINOT BLANC are greenish yellow, Pinot Gris grapes are anything between greyish blue and brownish pink—sometimes on the same bunch. In the vineyard, this vine can easily be taken for Pinot Noir for the leaves are identical and, especially late in a ripe year, the berries can look remarkably similar. At one time, Pinot Gris habitually grew in among the Pinot Noir of many Burgundian vineyards, adding softness and sometimes acidity to its red wine. Even today, as Pinot Beurot, it is sanctioned as an ingredient in most of Burgundy's red-wine appellations, and the occasional vine can still be found in some of the region's famous red-wine vineyards. It was traditionally prized for its ability to soften Pinot Noir, but older CLONES have a tendency to YIELD very irregularly.

Within France, Alsace is where Pinot Gris (once known as Tokay, see GERMAN HISTORY) is most familiar and where by far the majority of the country's 3,139 ha/7,757 acres of the variety grew in 2019. Here it has been gaining ground and is revered as provider of super-rich, usually dry, wines that can be partnered with food without the distraction of too much aroma. For more on the wines, see ALSACE. There also remain small pockets of the variety in the Loire, where it is often known as Malvoisie (in Coteaux d'ANCENIS, 'Malvoisie' is officially allowed as a suffix to the appellation name). It can produce perfumed, substantial wines in a wide range of different sweetness levels. It is also known as Malvoisie in SAVOIE and the Valais in SWITZERLAND, where its wines are also notably full-bodied and richly

aromatic—rather different from the neutral mouthwash that is typical mass-market PINOT GRIGIO. The variety is also much admired for its weight and relatively low acidity in LUXEMBOURG, where it represents 15% of the vineyard area.

As with Pinot Blanc, much more Pinot Gris is planted in both Germany (see GRAUBURGUNDER) and Italy (see PINOT GRIGIO) than in France.

The variety, like Pinot Blanc, is widely planted not just in AUSTRIA but throughout eastern Europe, particularly in HUNGARY, where in 2021 it was planted on 1,827 ha/5,415 acres and known as Szürkebarát, although varietal versions may often be exported as the more familiar Pinot Gris or even the more marketable Pinot Grigio, a name it often takes on in MOLDOVA too. Many eastern European synonyms are inspired by the word RULÄNDER, the German name for sweeter styles of Pinot Gris, although the Slovenian name Sivi Pinot is more literal. The variety can make fine wines in both eastern and western SLOVENIA.

With the exception of OREGON, where this mutation of its beloved Pinot Noir has long been the state's leading white-wine grape and was planted on more than 2,104 ha/5,200 acres by 2019, Pinot Gris' impact beyond Europe has been more limited but has been increasing thanks to Pinot Grigio's commercial success. In the late 20th century, there was a dramatic increase in plantings in California, mainly Monterey and Napa, and its 2020 total of 6,649 ha/16,431 acres makes it the state's third most planted white wine grape after Chardonnay and French Colombard, just ahead of Sauvignon Blanc. In Washington State it is third most popular after Chardonnay and Riesling, and it is planted in much of the rest of North America. Pinot Gris has been a fixture in the Argentine vinescape since the LURTON brothers introduced it in the early 1990s, but it is not common in Chile. T'Gallant of the Mornington Peninsula was Australia's Pinot Gris pioneer, using both French and Italian names, and the country's total area had reached 4,935 ha/12,195 acres by 2022. It was improved CLONAL SELECTION and increased interest in AROMATICS that precipitated

a renewal of enthusiasm in New Zealand, where Pinot Gris' total 2022 plantings of 2,809 ha/6,941 acres were catching up fast with those of second most planted white wine grape Chardonnay.

Pinot Liébault, unusual and slightly more productive Burgundian selection of PINOT NOIR, first identified in GEVREY by A. Liébault in 1810, according to Galet.

Galet, P., *Dictionnaire encyclopédique des cépages* (2nd edn, 2015).

Pinot Meunier, known as Meunier in France, may be France's tenth most planted black grape variety, but it is rarely encountered on a wine label. Most of Pinot Meunier's more than 12,000 ha/29,650 acres are in the CHAMPAGNE region. It is an early, particularly downy, MUTATION of PINOT NOIR and earns its name (*meunier* is French for 'miller') because the underside of its downy leaves can look as though they have been dusted with flour. In Germany it is known as MÜLLERREBE (miller's grape).

The variety is treasured in Champagne, as it was in the once-extensive vineyards of northern France, because it buds later and ripens earlier than the inconveniently early-budding Pinot Noir and is therefore much less prone to COULURE and more dependably productive. Acid levels are slightly higher, although alcohol levels are by no means necessarily lower than those of Champagne's most planted variety, Pinot Noir. Pinot Meunier is therefore the popular choice for Champagne's growers, especially those in cooler north-facing vineyards, in the damp, frost-prone Vallée de la Marne, and in the cold valleys of the Aisne *département*. In fact, so commercially reliable is Meunier for Champagne's powerful vine-growers that until recently it was Champagne's most popular variety by far, but it has now been overtaken by Pinot Noir. Common wisdom has it that, as an ingredient in the traditional three-variety champagne blend, Meunier contributes youthful fruitiness to complement Pinot Noir's weight and Chardonnay's finesse. Few producers boast of their Pinot Meunier,

however (with the honourable exception of KRUG), although several Champagne growers make a VARIETAL Pinot Meunier, which is generally lower in PIGMENTS than Pinot Noir.

It has largely disappeared elsewhere in northern France, although it is still technically allowed into the rosés and light reds of Côtes de TOUL, wines of MOSELLE, and, in the Loire, TOURAINE, and ORLÉANS.

See MÜLLERREBE for plantings in Germany. It is also grown to a very limited extent in German-speaking Switzerland. Elsewhere, Meunier tends to be grown by those slavishly following the champagne recipe (as in England and California, for example). But curiously, in Australia Pinot Meunier has a longer documented history as a still red varietal wine (at one time called Miller's Burgundy) than Pinot Noir, notably at Great Western (now called GRAMPIANS) in VICTORIA.

Pinot Nero is Italian for PINOT NOIR, which is grown there chiefly for the SPUMANTE industry (see, for example, FRANCIACORTA and TRENTODOC). There was a total of 5,057 ha/12,496 acres in 2015. The great majority is planted in the province of Pavia in LOMBARDY, where it is increasingly important for both still and sparkling wines in OLTREPÒ PAVESE, but a few producers—Hofstätter, Haas, and Gottardi—are making a name for the variety in Alto Adige.

Pinot Noir is the most important and oldest form of PINOT. It is the grape variety wholly responsible for red BURGUNDY and one that suddenly became the height of FASHION, thanks to the 2004 film SIDEWAYS. It gives its name to the NOIRIEN group of grape varieties. Unlike Cabernet Sauvignon, which can be grown in all but the coolest conditions and can be economically viable as an inexpensive but recognizably Cabernet wine, Pinot Noir demands much of both vine-grower and winemaker. It is a tribute to the unparalleled level of physical excitement generated by tasting one of Burgundy's better reds that such a high proportion of the world's most ambitious wine producers want to try their hand with this capricious and extremely

variable vine. Although there is relatively little consistency in its performance in its homeland, Pinot Noir has been transplanted to almost every one of the world's wine regions, except the very hottest, where it can so easily turn from essence to jam.

If Cabernet produces wines to appeal to the head, Pinot's charms are decidedly more sensual and more transparent. The Burgundians themselves refute the allegation that they produce Pinot Noir; they merely use Pinot Noir as the vehicle for communicating local geography, the characteristics of the individual site, the TERROIR on which it was planted. Perhaps the only characteristics that the Pinot Noirs of the world could be said to share would be a certain sweet fruitiness and, in general, lower levels of TANNINS and PIGMENTS than the other 'great' French red varieties Cabernet Sauvignon and Syrah. The wines are decidedly more charming in youth and evolve more rapidly, although the decline of the very best is slow.

No fewer than 50 Pinot Noir CLONES (as opposed to 25 of the much more widely planted Cabernet Sauvignon) are officially recognized within France. According to GALET, the most popular is one of the first generation of virus-free Burgundy clones, 115, followed by the productive Champagne clones 375 and 386. Marsh surveyed top Côte d'Or producers in the early 2000s and found second-generation clone 677 marginally more admired for wine quality than the more widely planted 777 or 828. It is possible to choose a clone of Pinot Noir specially for the quality of its wine, its productivity, its regularity of yield, its resistance to rot, and/or for its likely ripeness (which can vary considerably). A major factor in the lighter colour and extract of so much red burgundy in the 1970s and 1980s was injudicious CLONAL SELECTION, resulting in higher yields but much less character and concentration in the final wine. The most reputable producers of all tend nowadays to have made MASS SELECTIONS from their own vine population. The clone called Pommard is well distributed in the New World, especially in North America, as has been one named after the WÄDENSWIL viticultural station in Switzerland. Often more sought-after now are Burgundian, 'Dijon', or in Australia 'Bernard' clones. In general the most productive clones, which have large-berried

bunches, are described as Pinot Droit for the vines' upright growth, while Pinot Fin, Pinot Tordu, or Pinot Classique grows much less regularly but has smaller berries with thicker skin.

Inasmuch as generalizations about a vine variety with so many different forms are possible, Pinot Noir tends to bud early, making it susceptible to spring FROST and COULURE. Damp, cool soils on low-lying land are therefore best avoided. Yields are theoretically low, although too many Burgundians disproved this with productive clones in the 1970s and early 1980s. The vine is also more prone than most to both DOWNY and POWDERY MILDEW, ROT (its grape skins tend to be thinner than most), and viruses, particularly FANLEAF and LEAFROLL. Indeed it was the prevalence of disease in Burgundian vineyards that precipitated the widespread adoption of clonal selection there in the 1970s.

Pinot Noir generally produces the best-quality wine on CALCAREOUS soils and in relatively cool climates where this early-ripening vine will not rush towards maturity, losing aroma and acidity. In Burgundy, for example, where it is typically cultivated alongside the equally early-ripening Chardonnay, Pinot Noir may ripen after Chardonnay in some years, before it in others. There is general agreement, however, that Pinot Noir is very much more difficult to vinify than Chardonnay, needing constant monitoring and fine-tuning of technique according to the demands of each particular vintage.

Pinot Noir is planted throughout eastern France and has been steadily gaining ground so that by 2018 its total area of French vineyard was 36,727 ha/90,754 acres, up from 28,006 ha in 2008, finally overtaking the area planted with Greater Burgundy's other red vine variety, the GAMAY of Beaujolais.

The extension of the CHAMPAGNE region from the 1980s saw Champagne's area planted with the variety—more than 13,000 ha/32,124 acres in 2010 and little changed over the last decade—overtake that of Burgundy, which recorded 10,978 ha in 2019. Pinot Noir is also the principal red wine grape of ALSACE, JURA, SAVOIE, SANCERRE, MENETOU-SALON, and ST-POURÇAIN—and recent global demand for the variety has encouraged some planting in the

Languedoc, even if few corners are as suitably cool as LIMOUX. Even in the Greater Burgundy region, Pinot Noir is rarely blended with any other variety, except occasionally with Gamay in a BOURGOGNE PASSETOUTGRAINS and, increasingly, to add class to a MÂCON. See under individual appellation names specified for the CÔTE D'OR and Côte CHALONNAISE for more detail on individual wines. Pinot Noir is the favoured black grape variety in northern Burgundy too, where in 2019 there were 1,048 ha for such wines as IRANCY and particularly northern versions of BOURGOGNE. A tiny amount is cultivated even further north-east for the light reds and VIN GRIS of Lorraine such as Côtes de TOUL and the wines of MOSELLE.

The greatest increase in Pinot plantings in Europe has been in Champagne, where it is used, as it is in the production of a wide range of sparkling wines made around the world in champagne's image, as a still, very pale pink ingredient in the base blend of still wines. The grapes are pressed very gently, and any remaining pigments tend to agglomerate with the dead yeast cells during the champenization process. In such a blend, Pinot Noir is prized for its body and longevity—as well it might be, for that small proportion of champagne made exclusively from Pinot Noir is usually memorably substantial. In Champagne, only a tiny quantity of Pinot Noir is used for still red Coteaux CHAMPENOIS and ROSÉ DES RICEYS, but there is growing interest in the former due to CLIMATE CHANGE.

Pinot Noir has become increasingly well made, and desirable, in all areas where German is or was spoken. In ALSACE, where it has been an important vine since the early 16th century (see GERMAN HISTORY), it is effectively the only black-berried vine variety planted, with a total area of 1,874 ha/4,631 acres in 2019. Climate change means Alsace Pinot Noir has been getting darker and the wines much more substantial. The same phenomenon is even more marked in Germany, where the variety, often but not always called Spätburgunder, was the country's second most planted variety in 2020, just ahead of the waning MÜLLER-THURGAU. See SPÄTBURGUNDER for more details.

So popular is the variety in SWITZERLAND that it is the country's most planted, with more than 3,875 ha in 2020, even more than the area planted with Chasselas, although both are in decline. Graubünden has a particularly strong reputation for its sturdy Pinots. In AUSTRIA, Pinot Noir is also sometimes called Blauburgunder but is not nearly as popular as BLAUFRÄNKISCH and ST-LAURENT.

Pinot Noir is spread widely in the vineyards of eastern Europe, where its name is usually some variant on the local word for Burgundian (although Romania's Burgund Mare is Blaufränkisch). Romania had most (2,039 ha), followed by Moldova (1,271 ha), Hungary (1,171 ha), Croatia (988 ha), and Russia (918 ha), and there are also several hundred hectares in Ukraine. Elsewhere in Europe, the finicky nature of the Pinot Noir vine has set a natural limit on its spread. In Iberia, there has been some successful experimentation in SOMONTANO, and substantial plantings for CAVA in Spanish CATALUÑA, where plantings had gone down slightly to 832 ha in 2020. Portugal's limited plantings are mainly in the north. There have been some noble experiments in some cooler Italian wine regions, notably LOMBARDY, where it is used for sparkling-wine production. See more details under PINOT NERO.

It was wine producers in the New World, however, who turned the full heat of their ambitious attentions on Pinot Noir from the late 1980s and early 1990s. Some even relocated their wineries many hundreds of miles in order to be closer to sources of suitably cool-climate Pinot Noir fruit. OREGON's wine reputation has so far rested heavily on its fine, fruity Pinot Noirs, with a state total of 9,531 ha/23,552 acres in 2020, almost 60% of the total vineyard area. This Pacific Northwestern state, with its cool, wet winters, has long been recognized as producing America's answer to red burgundy. However, as summers have become warmer and wines riper, the differences between Oregon Pinot Noirs and those from CALIFORNIA have narrowed, especially in California's cooler regions such as the Sonoma Coast, Carneros, Chalone, the Gavilan Mountains of San Benito, and Central Coast districts most affected by the Pacific. Both states now produce a range of styles from ripe, fruity, and heavily oaked to

leaner earthier examples. California's total acreage remained steady into the 1990s but then took off after the SIDEWAYS effect, so that by 2020 there were 19,378 ha/47,885 acres of Pinot Noir in the state (up from barely 24,000 acres when *Sideways* was made). The variety is also valued as an ingredient in champagne-like sparkling wines, one of Pinot Noir's most important uses outside of Europe. (The variety once called Pinot St George in California, now in sharp decline, is NÉGRETTE.)

There are pockets of Pinot Noir, generally accompanied by enthusiasm and ambition, all over the United States, but cool climates such as that of the FINGER LAKES are generally best. And over the Canadian border in ONTARIO and BRITISH COLUMBIA, there are some seriously successful Pinot Noirs. Climate change has helped eastern Canada's Pinot producers considerably.

Much of South America is too hot for successful Pinot Noir production, but newer, Pacific-cooled wine regions are being developed for the variety in CHILE where total planting had reached 4,178 ha/10,324 acres by 2020. Bío-Bío also shows promise. It can be more difficult to find suitably cool terrain in ARGENTINA, but plantings totalled 1,992 ha/4,922 acres in 2020, mainly at the highest ELEVATIONS of Tupungato.

Across the Atlantic in SOUTH AFRICA, on the other hand, at least one producer, Hamilton-Russell, managed to coax convincingly Burgundian flavours from Pinot Noir vines grown in the hinterland of WALKER BAY on the south coast in the 1980s, and this continues to act as a spur to others, with increasingly encouraging results. Total plantings stood at 1,198 ha by 2020—a figure that would have been unthinkable at the turn of the century.

NEW ZEALAND, along with Oregon, is the New World wine producer that has been staking its red wine fortunes on Pinot Noir. By 2022 total plantings had reached 5,807 ha/13,350 acres, making it this small country's second most popular variety by far, with the most impressive results coming from Martinborough, Canterbury, Marlborough, and rapidly growing Central Otago.

Fine Pinot Noir has been more elusive in Australia, and the total area planted is slightly less than New Zealand's, but increasingly interesting examples are being made in cooler spots such as Geelong, Gippsland, Macedon Ranges, Yarra Valley, and Mornington Peninsula, all relatively cool areas around Melbourne in VICTORIA, as well as in TASMANIA. See AUSTRALIA for more details and more potential areas of exciting Pinot Noir production.

Wherever there is a wine producer with a palate, there will be experimentation with Pinot Noir.

Pinot Noir Précoce, French name for FRÜHBURGUNDER.

Pinot St George, California red grape identified as NÉGRETTE and now difficult to find.

pipe, wine trade term, adapted from the Portuguese *pipa* meaning 'barrel', for a large cask with tapered ends, the traditional measure of PORT as well as of MADEIRA, other Portuguese wines, and MARSALA, although the volume can vary around the country. In the DOURO Valley, where port is produced, the yield of each vineyard is measured in pipes of 550 l/145 gal, while downstream in VILA NOVA DE GAIA, the suburb of Oporto where port is matured, a pipe may vary in size between 580 l and 630 l but is usually taken as 620 l. For shipping purposes, however, a pipe of port is 534.24 l, divided into 21 measures of 25.44 l called *almudes*, while pipes of madeira and

Marsala are 418 and 423 l respectively. Gentlemen in Victorian England traditionally laid down a pipe of port for their sons and godsons, but inflation and changing consumption patterns have made this generosity exceptional.

piperitone, a monoterpene recently identified as contributing to the minty character found in some bottle-aged Bordeaux reds. See FLAVOUR COMPOUNDS.

Pons, A., et al., 'Identification and analysis of piperitone in red wines', *Food Chemistry*, 206 (2016), 191–6.

Pipers River, cool, damp wine region in north-east TASMANIA known particularly for sparkling wine.

pips. See GRAPE.

Piquepoul, ancient grape variety from the Vaucluse *département* of southern France that is encountered in Blanc, Noir, and very occasionally Gris versions, with the white being the most planted today, although they have frequently been mixed in the vineyard in their long history in the LANGUEDOC and ROUSSILLON. Piquepoul was cited as a producer of good-quality wine as early as the beginning of the 17th century and, with CLAIRETTE, formed the basis of PICARDAN, exported northwards in vast quantities in the 17th and 18th centuries. Its susceptibility to FUNGAL DISEASES, however, together with its unremarkable yield, reduced its popularity considerably after PHYLLOXERA arrived. In the early 20th century, the variety's good tolerance of sand made it a popular choice for the coastal vineyards that serviced the then-flourishing VERMOUTH industry. Today many of those vineyards are tourist campsites and vermouth is an Italian phenomenon, but PICPOUL DE PINET has been a significant commercial success, and France's total plantings of Piquepoul Blanc continue to

increase, reaching 1,829 ha/4,520 acres in 2019, virtually all in the Hérault. A small amount is also grown in California under the name Picpoul.

Piquepoul Noir produces alcoholic, richly scented but very pale red that is best drunk young. Although it is allowed as a minor ingredient in CHÂTEAUNEUF-DU-PAPE and LANGUEDOC, it is rarely seen.

piquette, traditionally a thin vinous liquid made by adding water to grape POMACE to extract what has been left behind. From the time of classical GREECE and ROME to the mid 20th century, pomace was given to slaves or low-paid workers for piquette production. (See ancient PRESSES for details of *lorca*, the Roman version.) In the late 20th century, at a time of wine SURPLUS, it was made illegal in the EU except for winegrowers' home consumption. The renaissance of piquette as a commercially available, spritzy, low-alcohol, fermented drink was spearheaded in the US by Wild Arc Farm in New York State in 2017 using an 18th-century French recipe, but there are now pockets of production across North America, Australia, and South Africa. It is particularly popular among proponents of NATURAL WINE. Today's piquette is often made with the addition of sugar, honey or fresh fruit to stimulate fermentation and increase ALCOHOL, or with a small percentage of wine to add BODY. The grape pomace contributes residual grape sugar, as well as colour and TANNINS from prolonged SKIN CONTACT during piquette fermentation. Technically difficult to produce and susceptible to spoilage due to the low-acid, low-alcohol fermentation environment, piquette is nonetheless becoming increasing popular thanks to the FASHION for this style of refreshing drink and the profit margins it gives producers. A.M.R.

Pirque, part of the MAIPO subregion of the Central Valley of CHILE famous for fruity, herbal Cabernet Sauvignon grown at the foot of the Andes.

pisco, aromatic brandy made in Peru, mainly from Quebranta and Negra Criolla (NEGRAMOLL) grapes, and in Chile, mainly from Moscatel (MUSCAT) grapes, rather like Bolivia's *singani*.

pithari (plural pitharia), Greek word for a large clay fermentation or storage vessel, also known more traditionally as *pithos*. It is the equivalent of the DOLIUM and bigger than an AMPHORA, although many producers prefer this last term because it is more internationally recognized.

pithos. See PITHARI.

PiWi. See DISEASE-RESISTANT VARIETIES.

Pla de Bages, CATALAN wine region north-west of Barcelona in Spain with just over 550 ha/1,300 acres under vine. Grape varieties are similar to those in neighbouring PENEDÈS, with INTERNATIONAL VARIETIES such as Merlot and Cabernet Sauvignon planted enthusiastically during the 1990s. In the 2000s, a new generation is turning their attentions to INDIGENOUS VARIETIES such as Mandó, SUMOLL, and Picapoll Negre (see PIQUEPOUL). V. de la S. & F.C.

dopladebages.com

Pla i Llevant, literally 'plain and east coast' in Majorcan dialect, is a DOP on the Spanish island of MALLORCA with 440 ha/1,087 acres spread over the plains and into the hills on its east side. Red wines dominate, with Cabernet Sauvignon and Merlot the most planted, followed by the indigeneous variety CALLET.

Planalto Mirandês, easternmost DOC subregion of TRÁS-OS-MONTES in north-east Portugal, with an extreme CONTINENTAL CLIMATE.

Planta Fina, or Planta Fina de Pedralba, grown in Valencia, south-east Spain, to make fairly neutral whites. DNA PROFILING has shown that it is not, as has been suggested, identical to VERDEJO but is in fact the Damschino of Sicily and Alicante Branco of Portugal and Madeira.

plant cell density (PCD) is a commonly used REMOTELY SENSED indicator of vine VIGOUR or canopy size in Australian viticulture. Like the NORMALIZED DIFFERENCE VEGETATION INDEX (NDVI), it is calculated from measures of reflected light at wavebands corresponding to red and infrared light. R.G.V.B.

Plantet, 5455 SEIBEL, once the Loire's most popular FRENCH HYBRID, has been more successfully eradicated from the French vinescape than some others (see BACO, COUDERC, VILLARD). France had 26,000 ha/63,000 acres planted in 1968 but 764 ha by 2018. Its chief attributes are its productivity and its ability to crop regardless of the severity of the winter and spring frosts (although New York State winters have proved too harsh for it). Varietal versions are occasionally encountered and taste oddly of raspberries.

planting a vineyard ostensibly constitutes that vineyard's birth, but this operation can be undertaken only after other decisions have been taken. The potentially long process of VINEYARD SITE SELECTION is followed by SOIL PREPARATION and the choice of CLONES of both VINE VARIETY and ROOTSTOCK. Decisions must also be made about VINE DENSITY and TRAINING SYSTEM. Following delivery from the NURSERY, the young plants must be properly stored before they are planted.

Planting is normally carried out in winter or spring. It consists of simply digging a small hole sufficient to take the normal dormant ROOTLING, occasionally a CUTTING or, increasingly frequently, a growing plant. The hole can be dug by spade or post-hole auger, but care must be taken, particularly in heavy clay soils, that holes dug by augers do not have such dense sides that form root-growth barriers. Preferably, a high-pressure water jet can create a planting hole and at the same time provide moisture to assist early growth. For large estates, a planting machine adapted from forestry can be mounted behind a tractor to allow workers to put plants into a pre-formed furrow which is then filled in as the machine passes.

A cardinal rule of establishing grapevines, as for other plants, is to press the soil firmly in around the newly planted vine to avoid air pockets and to provide moisture if possible. R.E.S.

planting density. See VINE DENSITY.

planting rights became important when an EU scheme, in force since 1976, restricted the planting of new vineyards in member states. It was part of a group of control measures aimed at reducing the wine SURPLUS within the EU. The 2008 reform of the common market organization for wine (see EU) announced that the scheme would end in 2015 (or, exceptionally, with a transitional period until 2018), raising objections from the majority of wine-producing member states that this would lead to a free-for-all. This opposition led to the creation of a new system of planting authorizations, which is managed by national, sometimes regional, authorities and regulates vineyard plantings not only for PDO and PGI wines but also, more controversially, for WINE WITHOUT GEOGRAPHICAL INDICATION. The annual maximum percentage growth in vineyard area is fixed at 1%.

plastic bottles, form of PACKAGING, usually from the material known to professionals as PET, an abbreviation for polyethylene terephthalate. They have the advantage of being generally much

lighter, cheaper, and less breakable than glass BOTTLES, but the disadvantage is that, depending on what they are lined with, they are not inert and may have a high OXYGEN TRANSMISSION RATE. Wine can start to taste of the package itself after only a few months or may become prematurely OXIDIZED. However, a 75-cl plastic bottle typically has a CARBON FOOTPRINT less than half that of a 75-cl glass bottle weighing 420 g. A 21st-century innovation is the space-saving flat bottle made from recycled PET that cuts the cost and CO_2 emissions of transportation and storage.

Alko, 'Update of wine packaging LCA: final report Alko Oy' (2021). www.alko.fi/INTERSHOP/static/WFS/Alko-OnlineShop-Site/-/Alko-OnlineShop/fi_FI/Tavarantoimittajille/Muut/EN/Alko%20wine%20packaging%20LCA%20update_final%20report.pdf.

plastic corks, a widely used but inaccurate term for synthetic closures. See CLOSURES.

plastic sheeting can be used in the vineyard to modify the climate. Studies in Canada and the UK have shown that transparent sheets suspended either side of the fruit zone (cloches) will raise temperatures and advance vine development. They can also protect the vine from wind and rain and reduce the need for FUNGICIDES. Trials in the UK have shown cloches to be an economical way of increasing yield and ripeness. They are also widely used as canopies over TABLE GRAPES to prevent rain damage.

Sheeting has also been used on the ground to avoid rain uptake towards the end of the ripening period, thus allowing grapes to ripen fully but keeping vegetative growth to a minimum. However, such experiments may fall foul of local regulations, as Michel ROLLAND found to his cost in 1999 in FRONSAC. Plastic sheeting or patches can be used to keep weeds down and retain soil moisture around young

plants (see MULCH). It can also be used on vines to protect grapes destined for EISWEIN from birds and rain. R.E.S. & J.E.H.

Plavac Mali, grape variety with an interesting genetic history producing dense red wines all along the Dalmatian coast and on many of the Adriatic islands in CROATIA. Mali means 'small', and a white grape variety called simply Plavac Žuti, also Plavec Žuti, is also known which results in tart, light wines. Both varieties thrive on SANDY soil. Plavac Mali is Croatia's leading red wine grape and produces wines high in TANNINS, alcohol, colour, and ageability. Dingač is the best-known PDO red made from Plavac Mali. DNA PROFILING at DAVIS provided evidence that Plavac Mali, once suspected of being identical to ZINFANDEL, is a natural cross between it and Dobričić, an obscure and ancient southern Croatian red wine grape.

Plavina, grape variety making light reds on the Dalmatian coast in CROATIA which may also be called Brajdica. DNA PROFILING has shown that it is a cross of VERDECA cultivated in Puglia and Croatia's ZINFANDEL.

Pliny (23/4–79 CE). Gaius Plinius Secundus is known in English as 'Pliny the Elder' to distinguish him from his nephew, Pliny the Younger, also a man of letters and Pliny the Elder's adoptive son. Of Pliny the Elder's many works, the only one to survive is the *Natural History*, 37 books dedicated to the Emperor Titus and published posthumously. Book 14 is devoted exclusively to wine, Book 17 provides important information on the techniques of viticulture, and the beginning of Book 23 is devoted to the medicinal properties of wine (see MEDICINE). Although most of the *Natural History* is based on earlier authors rather than on scientific observation, and his information, invaluable as much of it is, must be used with discrimination, the book on wine seems in large part to be the product of independent enquiry. It contains practical advice as well as

literary and historical learning. Its most interesting part ranks Italian wines according to quality, and sweet wines seem to be favoured (although see also ATHENAEUS). The best wine used to be CAECUBAN, but in Pliny's day it is FALERNIAN, particularly Falernian of the Faustinian CLOS. Setine is also a wine of the first rank. The next best wines are Alban, SURRENTINE, and MASSIC; Pliny awards third prize to Mamertine, of Messina in Sicily. An early proponent of TERROIR, he concludes that it is the country and the soil that determine quality, not the vine variety; in any case, people's tastes differ. Pliny died during the eruption of Vesuvius when his extraordinary curiosity got the better of his common sense. In his much-quoted writings on wine, he drew on VARRO's *De re rustica*; PALLADIUS' treatise on husbandry is indebted to Pliny. H.M.W. & J.J.P.

Pliny the Elder, *Natural History*, translated by H. Rackham (1945).

plonk, vague and derogatory English term for wine of undistinguished quality, is a term of Australian slang that has been naturalized in Britain. During the First World War, the French *vin blanc* with its un-English nasal vowels was adapted in various fantastic ways, from 'von Blink', which sounded like a German officer, to 'plinketty plonk', which suggested the twanging of a banjo. This was shortened to 'plonk', which coincidentally was also British soldiers' slang for 'mud'. By the Second World War this had given rise to 'A/C Plonk' for aircraftman 2nd class, the lowest of the low in the RAF and hence parallel to plonk in the glass.

Despite its etymology, plonk need not be white; and if the word suggests any kind of wine in particular it is cheap red served at a party. For this reason, colour-blind theories have sometimes been proposed, such as that it mimics the sound of a cork being withdrawn from a bottle. But it has no more to do with this sound than with the unceremonious plonking down of glass. L.H.-S.

ploughing. See TILLAGE and LABOUR.

Ploussard. See POULSARD.

Plumpton College in Sussex offers a variety of land-based courses and has been the leading centre of wine ACADEME in the UK since 1988, offering a wide range of degree, school-leaver, and short courses. Plumpton is the only European provider of undergraduate courses in wine production and wine business in English and now also runs the UK's first postgraduate qualification in VITICULTURE and OENOLOGY. With 8 ha/20 acres of its own commercial vineyards as well as a research winery, Plumpton works closely with the local wine industry (see ENGLAND). In 2020 it launched a new national viticulture apprenticeship programme. Its alumni can be found working at and managing vineyards and wineries across the world. J.K.

www.plumpton.ac.uk

podere, Italian for a farm, usually smaller than a FATTORIA and usually a subdivision of one. The word stems from *potere*, meaning 'to be able to' and indicating that the size of the holding was sufficient for one sharecropping family.

points out of 100, common method of SCORING wine promoted notably by American writer Robert PARKER. See also NUMBERS.

Pokdum, Thai name for the dark-skinned Japanese hybrid Black Queen. It was propagated by grower Nong Pok in the Pak Chong area of Nakhon Ratchasima province in the early 1980s. Its future looks uncertain as growers in Thailand continue to switch to white wine grapes such as MALAGA BLANC.

Poland has made wine since the introduction of CHRISTIANITY in 966 CE. The Little Ice Age, increased imports from Hungary, and competition from beer, vodka, and local fruit wines combined to reduce domestic winemaking to near zero by the end of the 15th century. Before the Second World War, pockets of vineyards survived in Podolia (now in UKRAINE) and Warka. After 1945, Poland's border was moved west to include north-west Silesia around Grünberg (renamed Zielona Góra), a major sparkling-wine region in pre-war Germany; this production was eventually discontinued in the 1970s.

Winemaking was resurrected in 1989 by mountaineer Roman Myśliwiec, who planted Ukrainian, Czechoslovak, and Hungarian vine cuttings by his home in Jasło in south-east Poland, later establishing a NURSERY. From 2001 Myśliwiec bottled small batches of grape wine and encouraged growers throughout Poland to plant disease-resistant HYBRIDS such as Hibernal, SEYVAL BLANC, Siberia, Odessa Muscat, LÉON MILLOT, and MARÉCHAL FOCH. A number of commercial wineries followed, and quality grew as new hybrids were trialled including RONDO, REGENT, Cabernet Cortis, Johanniter, SOLARIS, and Souvignier Gris. Five unofficial regions emerged (Lubuskie around Zielona Góra; Lower Silesia around Wrocław; Little Poland around Cracow; Subcarpathia around Jasło; and Małopolski Przełom Wisły around Kazimierz) with their respective growers' associations; local competitions were established, and an annual Polish Vintners' Convention was launched in 2006.

The third wave of Polish wine came in the mid 2010s with the establishment of large commercial wineries, often with outside investment. Winnica Turnau planted 30 ha/74 acres, single-handedly establishing the region of Western Pomerania; wineries such as Srebrna Góra in Cracow, Jaworek, Adoria, and Silesian near Wrocław, and Półtorak in Subcarpathia created a critical mass that reached wider audiences, notably through supermarkets. Meanwhile, smaller estates such as Dom Bliskowice, Dwór Sanna, Jakubów, Kamil Barczentewicz, Kojder, Krojcig, Płochoccy, Skarpa Dobrska, and BIODYNAMIC Wieliczka raised the qualitative bar. While estates catering to local tourists often bottle wines with RESIDUAL SUGAR, the leading

estates embrace contemporary styles such as sparkling (both TRADITIONAL METHOD and PET-NAT), lees-aged and oaked white wines, dry rosé, ORANGE, and AMPHORA-aged wines. VITIS VINIFERA varieties such as Riesling, Chardonnay, the Pinots Blanc, Gris, and Noir, ZWEIGELT, and BLAUFRÄNKISCH account for 15% of the national acreage and are growing.

In 2021 the National Support Centre for Agriculture registered 329 wineries and 564 ha/1,394 acres of vines, but an estimated 40% of hectarage is not officially declared because it is either not yet bearing fruit or is not licensed to sell produce. Poland is not currently a member of the OIV but is included in the EU's viticultural zone A. There are currently no IGPs or PDOs. Forecasts suggest a potential 3,000 ha by 2030. W.M.B.

politics and wine. While winemaking and TERROIR affect how wines taste in the glass, politics determines how and which wines make it to consumers. The relations that wine producers have with the state and with each other vary across winemaking and wine-consuming countries. This variation affects the quality, price, export profile, and availability of wine to consumers.

In France, where grapevines predated Roman times, wine and the state have had as cosy a relationship as the vines and the terroir. Indeed, the Church and aristocrats, key political allies of the monarchy, held many vineyards in feudal times, and it was Emperor Napoleon III who commissioned the famous 1855 CLASSIFICATION of the wines of Bordeaux. Crisis struck in the late 19th century as PHYLLOXERA devastated large swathes of vineyards, threatening the voluminous tax receipts from wine and the livelihood of a large number of citizens engaged in its production. The state came to the aid of the growers by organizing a major campaign to pool scientific knowledge and treatments and, eventually, tamed the pest.

With the resolution of the phylloxera blight, some regions developed an addiction to state aid that took decades to break, if it ever was broken. The wine boom that preceded phylloxera, the

subsequent bust, and an early 20th century boom so devastated producers of low-end TABLE WINES that they convinced the state to guarantee them a minimum price. But the market fluctuations led to other problems for better-quality producers, notably ADULTERATION AND FRAUD. Underscoring the importance of wine in France, the strong French state delegated the power to set quality standards for superior producers through the formalization of the AOC system in 1935. This system continues to this day with an ever-increasing number of qualifying regions. However, the tight historic relationship between French wine producers and the state appears to be weakening as opposition to wine has emerged under the aegis of public health with strict drink-driving and advertising restrictions. Domestic consumption has declined markedly (see Appendix 2C).

The politics of wine in the United States could not be more different. Despite the best early personal and policy intentions of King James I during the colonial period and of Thomas JEFFERSON during the republic, the land proved inhospitable to vines suitable for winemaking until the mid 19th century in California. Even international recognition of some of California's best wines in the 1890s was not enough to propel the industry to success since wine fell victim to political shifts hostile to the industry.

The temperance movement was consolidating as a political force. So abhorrent was its view of any type of alcohol and so strong were its supporters that the movement succeeded in officially banning alcohol throughout the country for 13 years under PROHIBITION. Although no policy enshrined in the Constitution has ever been so quickly repealed, the damage to the wine industry was severe. During Prohibition, vineyard acreage paradoxically expanded through a loophole that permitted HOME WINEMAKING. Yet the quality of the vines plummeted to such an extent that it took the California wine industry three decades to recover.

An even longer-lasting effect was that, at Repeal in 1933, the states were left to regulate the distribution and sale of alcohol within their boundaries. This has left a patchwork of laws and a system that often prohibits wineries and retailers from selling directly to

consumers (online for example), since most states mandate the intervention of a distributor, which can raise prices to consumers and limit choice (see THREE-TIER SYSTEM). Ironically, in a country that prides itself on free markets, the wine industry is arguably even more heavily regulated than that of France.

AUSTRALIA's industry growth and nearly three decades of surging exports (see AUSTRALIAN INFLUENCE) lay in part in overcoming a problem of collective action. With a small domestic market and tremendous productive potential, industry participants realized the importance of export markets. In the 1970s and accelerating in the 1980s, the industry participants and the state coordinated an upgrading of the country's international reputation through setting standards for export and initiating successful marketing campaigns. The relatively low number of producing, or at least exporting, firms made this coordination easier. The Australian example served as a model for other countries, although a reversal of fortunes for Australian wine from the late 2000s has demonstrated limits to this approach.

Changes in the national political regime can revolutionize the wine industry, as the example of SOUTH AFRICA vividly demonstrates. With the collapse of the apartheid regime in 1994, South Africa's international isolation ended as the numerous countries that had trade embargoes in place lifted them. Practically overnight, the number of outlets for South African wines expanded exponentially. Investment flowed in and increasingly high-quality wines flowed out to the rest of the world. A similar political opening has also made for a global market in wines from Central and Eastern Europe, although their export potential has not yet reached the levels of South Africa.

A policy volte face can also lead to significant change: the HONG KONG government slashed import duties from 80% by value to zero in 2008, igniting the local wine trade and propelling Hong Kong to the top spot in the global AUCTION market for wine.

Because wine is an important product in world trade, international politics play a role in structuring the wine. Certainly wine policy is most advanced at the international level within the EU, which now

has the final say on many wine regulations and subsidies in the region and often negotiates the laws of the World Trade Organization for European producers. The EU has also been particularly vigilant in protecting its place names, or GEOGRAPHICAL INDICATIONS. And because of its highly symbolic value, wine, particularly French wine but also Australian wine, has been the target of TARIFFS or, at the grassroots level, demonstrations and boycotts.

Future political struggles in the wine world will almost certainly also provide support for the adage 'all politics is local'. As more regions have sought formal delimitation of smaller growing areas, local conflicts over where to draw the lines have ensued. The issues of environmental responsibility, SUSTAINABLE VITICULTURE, and land use have recently appeared on the agendas of winegrowing communities from Napa to Bordeaux and are likely to remain there for the foreseeable future. pollen, collective term for pollen grains which carry the male gametes in SEXUAL PROPAGATION for vines as for other plants. Pollen develops within sacs of the ANTHER. Mature grains have a sculptured surface typical for each species. See FLOWERING. See also vineyard ECOSYSTEM. B.G.C.

Pollera Nera, ancient dark-berried vine planted in 2015 on 32 ha/79 acres in Liguria and north-west Tuscany.

pollination, the transfer of pollen from the ANTHER to the receptive stigmatic surface. If pollination occurs with the pollen and pistil of the

same flower, the process is called self-pollination and the progeny is known as a SELFLING or selfed vine; if it occurs between two different flowers (whether from the same vine or from different vines), the process is called cross-pollination. In cultivated grapevines, flowers are hermaphroditic and most are self-pollinated before the CALYPTRA has fallen (cleistogamy), but cross-pollination may also occur. Fertilization occurs two or three days after pollination depending on the ambient temperature (see FLOWERING). Wild grapes (*Vitis silvestris*) and some primitive cultivars are dioecious (male-only or female-only plants), therefore cross-pollination is essential.

See also POLLEN. B.G.C. & J.V.

Vasconcelos, M. C., et al., 'The flowering process of *Vitis vinifera*: a review', *American Journal of Enology and Viticulture*, 60/4 (2009), 411–34.

pollution. Air pollution arising from industrial gases and particles, AGROCHEMICALS, and fires can damage grapevines in any part of the world. Principal pollutants are sulfur dioxide, OZONE, and SMOKE, as well as, in restricted areas, phenoxy herbicides such as 2,4-D (see AUXINS) applied to nearby crops.

Of greater concern in relation to CLIMATE CHANGE is the generally under-reported atmospheric pollution caused by the release of CARBON DIOXIDE from wineries. See WINERY WASTE. R.E.S.

Boulton, R., et al., *Principles and Practices of Winemaking* (1999).

Pol Roger, Champagne house founded in Épernay in 1849 and still in family hands. The founder's sons changed their surnames to Pol-Roger by deed poll, Pol being a champenois variant of Paul. The wines rank high among the top champagne houses for quality, although it is one of the smaller GRANDES MARQUES. Pol Roger owns 91 ha/225 acres of vineyards on prime sites in the Vallée d'Épernay, on the Côte des Blancs, and (latterly) on the Montagne de Reims. After a

near-calamitous cellar collapse in 1900, the cellars saw action in the First World War when the population of Épernay sheltered in them from artillery barrages. Sir Winston Churchill was a devotee of the house, even naming his racehorse Pol Roger. The compliment was repaid after his death, when all non-vintage labels exported to Britain were edged in black for 37 years. The Sir Winston Churchill Cuvée was launched in 1984 as Pol Roger's PRESTIGE CUVÉE. The great-grandsons of the original Pol Roger, Christian Pol-Roger and Christian de Billy, were succeeded by the son of the latter, Hubert de Billy, and now sixth-generation Bastien Collard de Billy. Particularly deep, recently modernized cellars house 11 million bottles, representing five years' supply.

polyethylene is a component in wine packaging such as CARTONS, BOXES, and POUCHES and is used for SCREWCAP liners. Since the 1980s and especially in the last fifteen years it has become increasingly important in the construction of ageing and FERMENTATION VESSELS, particularly for small and medium-sized wineries. Available in many different shapes and sizes, including egg-like ovoids (see CONCRETE), they are easy to clean and move and can be stacked to save space. The OXYGEN TRANSMISSION RATE of those used for ageing is typically similar to that of a second-use oak BARREL, making them useful for winemakers who want oxygenation without OAK FLAVOUR. Heavyweight tanks for fermentation are less permeable. In addition to being light and easy to clean, their great advantage is cost, and the only real limit is the maximum size, which is currently around 35 hl/900 gal.

polymeric pigments. See PIGMENTED TANNINS.

polymerization, the molecular process in which smaller molecules combine to form very large molecules. In all living material, the simple amino acids combine, or polymerize, in very

large chains to create the PROTEINS, some of which function as ENZYMES. In AGEING wines, simpler PHENOLIC molecules combine to form larger TANNIN polymers and PIGMENTED TANNINS which eventually grow so large that they fall from the solution as SEDIMENT. A.D.W.

polyphenols and polyphenolics. See PHENOLICS.

polysaccharides, a diverse group of carbohydrates found in all wines and distinguished by their high molecular weight. They can be grouped into three categories according to their origin: from YEAST (MANNOPROTEINS), grape (e.g. PECTINS), and fungi (notably glucans from *Botrytis cinerea*, see BOTRYTIZED wines). Polysaccharides extracted both from yeast LEES and sources other than grapes (e.g. gum arabic) are allowable wine additives in many jurisdictions. Their presence inhibits the formation of undesirable PROTEIN hazes and TARTRATE crystallization. The ability of polysaccharides to form complexes with wine TANNINS and salivary proteins may also influence the perception of ASTRINGENCY and other aspects of MOUTHFEEL in both red and white wine. R.G.

Gawel, R., et al., 'The mouthfeel of white wine', *Critical Reviews in Food Science and Nutrition*, 58/17 (2017), 2939–56.

polyvinylpolypyrrolidone. See PVPP.

pomace, a word used for centuries by English cider-makers (derived from the Latin *pomum* meaning 'apple') for the debris of fruit processing, sometimes referred to as the press cake. In WHITE WINEMAKING, the pomace is the sweet, pale brownish-green mass of

grape skins, stems, seeds, and pulp left after PRESSING. In RED WINEMAKING, the pomace is a similar mass of grape debris coloured blackish red left after the FREE-RUN wine has been drained. Because red-wine pomace is what is left after FERMENTATION rather than before, it also includes dead yeast cells and contains traces of alcohol rather than sugar. It typically accounts for 20% of the original grape weight.

In larger wineries, the significant amount of sugar which remains in white grape pomace may be washed out of the solid mixture and fermented to produce material for DISTILLATION into pomace brandy. Similarly, the smaller amounts of alcohol in red grape pomace may in large wineries be recovered by distillation. Pomace of any colour may be used for the newly fashionable PIQUETTE. OENOCYANIN, a food colouring agent, is also recovered from red-wine pomace, particularly in Italy. In some regions the solids from several wineries may be amalgamated for processing to recover TARTRATES and, occasionally, grapeseed oil. Pomace and its by-products have many other possible applications, for example as a fertilizer or in compost, in the food industry, in biofuels, in cosmetics, and sometimes also as stock feed.

Kalli, E., 'Novel application and industrial exploitation of winery by-products', *Bioresources and Bioprocessing*, 5/46 (2018).

Pomerol , small but distinctive wine region in BORDEAUX producing opulent and glamorous red wines dominated by the Merlot grape. Although challenged by their counterparts in its much larger neighbour ST-ÉMILION, Pomerol's most successful wines are some of the world's most sought after, but the glamour attaches to the labels rather than the countryside.

Pomerol is produced from a steady 800 ha/2,000 acres of vineyard on a plateau immediately north-east of LIBOURNE that is as geographically unremarkable as the MÉDOC but without even any buildings or historical landmarks of note. A confusing network of narrow lanes connects about 140 smallholdings, most of which produce only a few thousand cases of wine a year in one of the world's most monocultural landscapes.

Vines were intermittently grown on this inhospitable, unfertile land from Roman times, but viticulture was abandoned during the HUNDRED YEARS WAR and the vineyards not re-established until the 15th and 16th centuries. For hundreds of years afterwards, Pomerol was regarded merely as a satellite district of neighbouring ST-ÉMILION to the east. It was not until the late 19th century that the wines began to be appreciated, and then only in France. In the early 20th century, they became known in northern Europe, notably in BELGIUM, whose wine merchants would import the wines in bulk; Belgian-bottled Pomerols of this period attract high prices at AUCTION. A succession of hard-working intermediaries from the impoverished inland *département* of Corrèze made Libourne their base and developed markets for RIGHT BANK wines in such markets as Paris, Belgium, and Holland, leaving the traditional BORDEAUX TRADE to provide the British market with Médoc, Graves, and Sauternes. Such famous and well-educated British connoisseurs as George SAINTSBURY do not even mention Pomerol. It was not until the 1950s that British merchants Harry WAUGH and Ronald Avery 'discovered' Pomerol and its most famous property, PETRUS.

The most successful of the Libourne merchants is Jean-Pierre MOUEIX, whose fortunes have been interlinked with those of Pomerol. After establishing a reputation for the appellation, the firm acquired a number of properties, as well as contracts to manage other properties, including Petrus, and still sells a significant proportion of the Pomerol made in each vintage.

The success of Petrus in particular, whose wines regularly fetch prices far above those of the Médoc FIRST GROWTHS, is mirrored by worldwide demand far in excess of supply for the wines of similarly minuscule properties such as Chx Lafleur, LE PIN, L'Église-Clinet, and La Fleur de Gay.

Pomerol's finest wines are in general made on the highest parts of the plateau, which is predominantly layers of GRAVEL interleaved with CLAY, becoming SANDIER in the west, where rather lighter wines are made. The subsoil here is distinguished by a local iron-rich clay, the

so-called *crasse de fer*, of which Petrus has a stratum particularly close to the surface.

Apparently as important in fashioning wines that are plump, voluptuous, and richly fruity enough to drink at less than five years old and yet which can last for as long as many a great Médoc are VINE AGE and low YIELDS. (At Petrus, for example, the wine produced by vines less than 12 years old is usually excluded from the ASSEMBLAGE.) Yields here are often the lowest for red bordeaux and are zealously restricted at the best properties. The early flowering of the Merlot grape, and the fact that a single vine variety accounts for about 80% of plantings in the appellation, unusual in Bordeaux, means that, as in VINTAGES such as 1984 and 1991, the majority of the crop can be lost to, for example, poor weather at flowering or spring frosts.

Pomerol is also unusual in being Bordeaux's only great wine district to have no official CLASSIFICATION. The properties are in general humble farmhouses, and only Ch de Sales has a building of any pretensions to grandeur, with an extent of more than 40 ha/99 acres. The most sought-after wines, depending on the vintage, include Chx Petrus, Lafleur, Le Pin, La Conseillante, Trotanoy, Certan de May, La Fleur de Gay, La Fleur-Pétrus, L'Église-Clinet, Clinet, L'Évangile, and Vieux Château Certan.

Pommard , prosperous village in Burgundy producing the most powerful red wines of the Côte de Beaune district of the CÔTE D'OR, from the usual Pinot Noir grapes. The pendulum of FASHION tends to swing between Pommard and Volnay, until recently favouring the latter. Warm, dry vintages have mitigated the previously rustic TANNINS of Pommard. A fine Pommard will be darker in colour than neighbouring VOLNAY, deeper in flavour, more tannic in structure, less

charming when young but capable of developing into a rich, sturdy wine of great power after ten years in bottle. Claude Arnoux noted in 1728 that Pommard lasted longer than Volnay, only in those days he meant 18 months rather than 12.

Pommard stretches from the border of Beaune to the edge of Volnay. On the Beaune side, the finest vineyards are Les Pézerolles and Les Épenots, including the Clos des Épeneaux MONOPOLE of Comte Armand. Towards Volnay, the most impressive PREMIER CRU vineyards include Les Chanlins, Les Jarolières, Les Fremiers, and, in particular, Les Rugiens. The lower section of the latter, Les Rugiens Bas, has the potential to make the richest wines of all in Pommard and is frequently mentioned as being worthy of elevation to GRAND CRU status.

Pompeii , a Roman port servicing the rich agricultural region which stretched round the southern bay of Naples from the slopes of Vesuvius across the valley of the river Sarno to the Monti Lattari of the Sorrento peninsula. Archaeology has revealed that the area was intensively occupied by moderate-sized farms, many of which were devoted to viticulture. The decorations in the owners' town houses sometimes reflect the activities on their estates, such as a frieze in the House of the Vettii in which cherubs are working a wine press and presenting wine to be tasted by a prospective buyer. Pompeian wine was 'headache-inducing' according to PLINY (*Natural History* 14.70). Four types of ancient grape were associated with the region: Aminea Gemina Minor, Murgentina, Holconia, and Venucula. It is estimated that the area produced four times the needs of the local population and fuelled an export trade, evidenced by the local AMPHORAE found around the Mediterranean. The remarkable work of

Wilhelmina Jashemski from the 1960s onwards has revealed the presence of vineyards within the walls of Pompeii itself, several of which were replanted in the 1990s. Given that many residences had no kitchens, there were numerous eating places and inns serving wine, their walls often painted with lively scenes of inn life. The bar of Euxinus 'At the Sign of the Phoenix', for example, served the wine produced from the tiny vineyard planted behind it. J.J.P.

Pontac, South African name for the distinctive red-fleshed TEINTURIER du Cher grape variety probably imported from SOUTH WEST FRANCE in the late 17th century. Widely planted until PHYLLOXERA devastated the Cape's vineyards from the mid 1880s onwards, Pontac was superseded by higher-yielding and more fashionable varieties, although a vintage port-style wine was made from it as recently as 2008. A campaign to reintroduce the variety has gained some traction, and there are now a few thousand Pontac vines spread across three different viticultural regions. M.F.

Porongurup, subregion of the Great Southern set in the cool elevations of the Porongurup Range in WESTERN AUSTRALIA, notable for floral, taut, long-lived dry RIESLING.

port, a FORTIFIED WINE made by adding brandy to arrest fermenting grape MUST or juice which results in a wine, red or sometimes white, that is both sweet and high in alcohol. Port derives its name from OPORTO (Porto), the second largest city in PORTUGAL, whence the wine has been shipped for over 300 years, notably by English merchants. Port production varies considerably from year to year, partly because of the conditions of each growing season but also reflecting the

benefício, the amount of wine that may be fortified each year, officially calculated according to stocks and sales. The average annual production during the second decade of the 21st century was 116,000 PIPES (64 million l). The production of unfortified DOURO wine averaged just over 50 million l between 2011 and 2020.

Fortified wines are made in the image of port in places as far apart as SOUTH AFRICA, AUSTRALIA, and CALIFORNIA, but within Europe EU law restricts the use of the term 'port' to wines from a closely defined area in the DOURO Valley of northern Portugal (one of the first examples of geographical DELIMITATION). See map under PORTUGAL.

History

Port originates from 17th-century trade wars between the English and the French. For a time, imports of French wines into England were prohibited, and then, in 1693, William III imposed punitive levels of TAXATION which drove English wine merchants to Portugal, a country with whom the English had always shared good relations. At first they settled on the northern coast but, finding the wines too thin and astringent (see VINHO VERDE), they travelled inland along the river Douro. Here merchants found wines that were the opposite of those they had left behind on the coast. Fast and furious FERMENTATION at high temperatures produced dark, astringent red wines that quickly earned them the name 'blackstrap' in London. In a determined effort to make sure that these wines arrived in good condition, merchants would add a measure of brandy to stabilize them before shipment.

The English merchants are supposed to have discovered the winemaking technique which results in port in 1678 when a Liverpool wine merchant sent his sons to Portugal in search of wine. At Lamego, a town in the mountains high above the Douro, they found one of the important Cistercian vine-growing monasteries there where brandy was added to the wine during rather than after fermentation, killing off the active yeasts and so producing the sort of sweet, alcoholic red wine that port was to become.

British trade with France ceased altogether in the early 18th century with the outbreak of the War of the Spanish Succession. By this time, a number of port shippers were already well established, and in 1703 England and Portugal signed the METHUEN TREATY, which laid down further tariff advantages for Portuguese wines. By the 1730s, however, the fledgling port industry was blighted by scandal. Sugar was being added and elderberry juice being used to give colour to poor, overstretched wines. Unprincipled over-production brought about a sharp fall in prices and a slump in trade. Prompted by complaints from British wine merchants, the port shippers contacted the Portuguese prime minister of the day, the Marquis of Pombal. Partly to create a lucrative Portuguese monopoly on port production,

in 1756 he instituted a series of measures to regulate sales of port. A boundary was drawn around the Douro restricting the production of port to those vineyards within it. Vineyards outside the official wine region, in BAIRRADA for instance, were summarily GRUBBED UP by the authorities.

Geography and climate

Pombal's demarcation, modified a number of times since 1756 (see DOURO), corresponds closely to an area of pre-Cambrian SCHIST surrounded by granite. From the village of Barqueiros about 70 km/40 miles upstream from Oporto, the region fans out either side of the river stretching as far as the frontier with Spain. It is referred to by the port shippers as 'the Douro', or by those in charge of the UNESCO World Heritage sites as Alto Douro Wine Region. The vineyards are shielded from the influence of the Atlantic by the Serra do Marão, a range of mountains rising to an elevation of 1,400 m/4,600 ft. Inland, the climate becomes progressively more extreme. Annual rainfall, which averages 1,200 mm/47 in on the coast, rises to over 1,500 mm on the mountains and then diminishes sharply, falling to as little as 400 mm at Barca d'Alva on the Spanish border. Summer temperatures in the vineyards frequently exceed 35 °C/95 °F. It is hard to imagine a more inhospitable place to grow grapes. The topsoils in this mountainous region of Portugal are shallow, stony, and low in SOIL NUTRIENTS. Over a period of 300 years, however, the land has been worked to great advantage. The valley sides are very steep, but TERRACES hacked from the schist, often with little more than a shovel and crowbar support, give vines a metre or two of soil in which to establish a root system. The bedrock fractures vertically, however, and, once established, vines root deeply in search of water and nutrients.

The Douro region divides into three officially recognized subzones. The Baixo (Lower) Corgo is the most westerly of the three and covers the portion of the region downstream from the river Corgo, which flows into the Douro just above the small city of Régua. This is the coolest and wettest of the three zones and tends to produce the lightest wines suitable for making inexpensive ruby and tawny ports (see Styles of port below). Upstream from the river Corgo, the Cima (Higher) Corgo is the heart of the demarcated region centred on the town of Pinhão. Rainfall is significantly lower here (700 mm as opposed to 900 mm or more west of Régua), and summer

temperatures are, on average, a few degrees higher. All the well-known shippers own vineyards or QUINTAS here, and this is where most of the high-quality tawny, Late Bottled Vintage, and vintage port is made. Much of the Douro Superior, the most easterly of the three subregions, is still pioneer country. Although it has long been a part of the demarcated zone, the country is remote and sparsely populated, and in past centuries little headway was made in planting vineyards due to the impossibility of navigating upriver beyond the former rapids of Cachão da Valeira. The Douro Superior is also the most arid part of the region with average temperatures at least 3 °C higher than at Régua 50 km/31 miles downstream. But rising LABOUR costs are forcing producers to consider planting the flatter land close to the Spanish border which is more suitable for MECHANIZATION and has considerable potential for high-quality port and Douro wines.

Viticulture

Viticulture in the Douro has altered radically from the 1970s onwards, more than at any time since PHYLLOXERA swept through the region at the end of the 19th century, leaving many hillsides abandoned. The most noticeable change is the river itself, which was progressively dammed in the 1960s to form a string of narrow lakes.

Methods of cultivation have also changed the Douro landscape. Faced with escalating costs and an acute shortage of labour at the end of the 1960s, growers began to look for alternatives to the tiny, step-like terraces built with high retaining walls in the 19th century. The first bulldozers arrived in the late 1970s to gouge out a new system of terraces called *patamares*. Inclined ramps bound together by seasonal vegetation replaced the costly retaining walls; with wider spacing between the vines (resulting in a VINE DENSITY of 3,500 vines per ha (1,420 per acre) as opposed to 6,000 on some traditional terraces), small caterpillar tractors can circulate in the vineyards.

At much the same time, some growers pioneered a system of planting vines in vertical lines running up and down the natural slope. This 'up and down' planting has been a qualified success, although access and SOIL EROSION are problems where the gradient exceeds 30 degrees. In the 1980s, a flurry of new planting under a World Bank scheme provided farmers with low-interest loans. The traditional, labour-intensive terraces, still impeccably maintained by some growers, now stand alongside newer *patamares* and vine rows planted vertically up the hillside, both of which allow limited MECHANIZATION.

Most of the Douro's vineyards used to be pruned according to the French GUYOT system and were trained on wires supported by stakes hewn from local stone, but now all but the very old vines are SPUR PRUNED and VSP-trained (see VERTICAL TRELLIS) on wires supported by wooden stakes. Most vines used to be GRAFTED *in situ* but now most are bench grafted. IRRIGATION is essential for young vines. July and August are generally dry, and SPRAYING against FUNGAL DISEASES is

necessary only in the early summer or in exceptionally wet years. Aside from the usual vineyard PESTS, most of which can be controlled by spraying, wild boar eat grapes and may occasionally damage new vineyards.

The Douro HARVEST usually starts in August in the Douro Superior and continues until early October. The steeply terraced vineyards, eerily quiet for most of the year, come alive as gangs of pickers descend from outlying villages for the duration of the harvest (see also HARVEST TRADITIONS). Yields in the Douro are among the lowest in any wine region in the world, with 500–750 g/17–26 oz per vine from OLD VINES the norm. From younger plantings, those up to 20 years old, 1.5 kg/3.3 lbs is the average production per vine in the best vineyards.

Vine varieties

More than 80 grape varieties are authorized for port production, but until the 1990s few growers had detailed knowledge of the identity of the vines growing in their vineyards. All old vineyards contain a mixture of varieties—often as many as 20 or 30 intermingled in the same plot (see FIELD BLEND). But research conducted in the 1970s (mostly by Cockburn and Ramos Pinto) identified the best varieties, and all new plantings since then have been more orderly. TOURIGA NACIONAL, TINTA BARROCA, TOURIGA FRANCA (often still referred to by its old name, Touriga Francesa), Tinta Roriz (Spain's TEMPRANILLO), and TINTO CÃO are the five most popular black-skinned varieties, although varieties such as SOUSÃO, Tinta Amarela (see TRINCADEIRA), and MOURISCO find favour with certain growers. GOUVEIO, MALVASIA Fina, and VIOSINHO are generally considered among the best varieties for white port.

Port winemaking

Rapid EXTRACTION of COLOUR and TANNINS is the crux of the various vinification methods used to produce red port. Because FERMENTATION is curtailed by fortifying spirit after just two or three days, the grape juice or must spends a much shorter time in contact with the skins than in normal RED WINEMAKING. The MACERATION process should therefore be as vigorous as possible.

Until the early 1960s, all port was vinified in much the same way. Every farm had a winery equipped with LAGARES, low stone troughs, usually built from granite, in which the grapes were trodden and fermented. Some are still in use, mainly at the small, privately owned quintas, and some of the finest ports destined for vintage or aged tawny blends continue to be trodden in *lagares*. The human foot, for all its many unpleasant associations, is ideal for pressing grapes as it breaks up the fruit without crushing the pips that would otherwise release bitter-tasting PHENOLICS.

Lagares would be progressively filled over the course of a day and trodden by the pickers themselves, thigh-high in purple pulp, in the evening. Most *lagares* hold 10–15 PIPES (about 5,500–8,250 l/1,453–2,180 gal), although a number of the larger quintas have *lagares* with a capacity of up to 30 pipes. As a rule of thumb, one or two people per pipe are needed to tread a *lagar*. Fermentation begins as a result of the action of AMBIENT YEASTS on the grapes' sugar. The alcohol produced and the increasing TEMPERATURE of the mass of purple skins, juice, and stems encourages the extraction of the phenolics vital for the character of port. After about two or three hours of hard, methodical treading, the CAP of skins and stalks starts to float to the surface. Regular PUNCHING DOWN of the cap was traditionally performed with long, spiked sticks from planks run across the top of the *lagares* which ideally need some form of cooling.

After 24–36 hours, the level of the grape sugar in the fermenting must declines from 12–13 °BAUMÉ to 6–8 °Baumé. Depending on the intended sweetness of the wine, the wine would be run off the *lagar*

into a vat, already about one-fifth full with grape spirit whose ALCOHOLIC STRENGTH is 77%. The spirit kills the yeasts, arresting fermentation. At this stage the must becomes young, sweet, fiery port with an alcohol content of 19–20%.

In the 1960s and 1970s, treading grapes in *lagares* became much less widespread. The Douro Valley and the remote TRÁS-OS-MONTES region, which traditionally supplied labour at harvest time, have suffered from marked emigration, and the port shippers were forced to look for less labour-intensive ways to make wine. Many isolated properties were without electricity then, and shippers set about building central wineries to which grapes from outlying farms could be delivered. Most of these were equipped with AUTOVINIFICATION tanks, which required no external power source and have proved to be a successful alternative to treading in *lagares*. The resulting wine is fortified just like foot-trodden young wines were.

In the late 1990s, however, a new generation of winemakers started to experiment with more novel ways of making port. Two key types have emerged: cap plungers, as introduced by the FLADGATE PARTNERSHIP; and automated treading machines or 'robotic lagares', as designed by the SYMINGTON family. Both systems have become widely used for the making of premium quality ports, although they are too expensive to be used to make the large volumes of standard-quality ports.

All wineries are now equipped with PRESSES, and the mass of grape skins and stems that remains after treading or crushing is forked into a press to extract the last of the juice. This deeply coloured, astringent PRESS WINE is run off and fortified separately. It may be blended back at a later stage or used to bolster a lighter wine.

White port is made in much the same way (see Styles of port below).

The fortifying grape spirit for port used to be distilled from wine made in Portugal, mainly from the Ribatejo (see TEJO) and Estremadura (see LISBOA) regions north of Lisbon, although in recent years most of the spirit has been imported, distilled from the Europe's

WINE LAKE. Until 1992, this spirit had to be purchased from the Casa do Douro (see Organization of the industry below), which set a fixed price and controlled distribution. This monopoly was broken by the EU, and producers have since been free to purchase any spirit they choose provided that it complies with the 77% norm of alcoholic strength and is approved by the port industry's regulating authority, the Instituto dos Vinhos do Douro e do Porto (IVDP). Since 2000 there has been a marked improvement in the quality and purity of the fortifying spirit used for premium ports.

See VIN DOUX NATUREL for a comparison of port winemaking techniques with those in the production of French counterparts such as Banyuls.

Organization of the industry

In 2020, 20,000 growers farmed a total of 43,000 ha/106,000 acres of vines in the Douro, mostly in the Cima Corgo where 20,000 ha are under vine. In common with most of the north of Portugal, the region is fragmented into tiny holdings numbering 104,000, although there has been some consolidation in recent years. The average area of vineyard per grower has consequently increased slightly to just over 2 ha/5 acres. The planting of vineyards in the Douro Superior has brought a dramatic reduction in the price of grapes, and there has been a marked reduction in the number of growers, especially in the labour-intensive Baixo Corgo region, over the past decade. Port grapes are supported by the *benefício* (see below), which some argue creates an artificial market.

Vineyards in the Douro are graded according to a complicated points system and classified into nine categories rated A to I. Twelve physical factors including site, ASPECT, EXPOSURE, and gradient are taken into consideration, each of which is allocated a numerical score. In theory, a vineyard could score a maximum of 2,031 points; a property with more than 1,200 points is awarded an A grade. On this basis, the annual *benefício* authorization (the total amount of port that may be made that year) is distributed to individual farmers. This is calculated annually by the IVDP.

Permits are then distributed to farmers detailing the amount of grape must that they may fortify to make port. The amount varies according to the year, but typically A- and B-grade properties may make 550–600 l of port per thousand vines, while properties with a grade of F or below are unlikely to be allowed to make port at all. The surplus is usually made into unfortified wine with its own denomination (see DOURO), but most of this sells for a much lower price than port.

This quality control system, instituted in 1947, served the port industry well for four decades, but pressure for its reform intensified when in 1990 the independence of the Casa do Douro was severely compromised by its purchase of shares in Royal Oporto, then one of

the largest port shippers. After a period of instability, in the mid 1990s the Casa do Douro had most of its regulatory powers withdrawn, and these were transferred to an independent interprofessional body representing both growers and shippers, the CIRDD, Commissão Interprofessional da Região Demarcada do Douro. This in turn was absorbed by the IVDP. The Casa do Douro continues to represent the farmers and to hold the register of vineyards as well as holding stocks of wine.

After vinification, the bulk of the new wine traditionally stayed at the QUINTA or farm until the spring after the harvest when it was transported down the river Douro to the shippers' LODGES in VILA NOVA DE GAIA. The cooler climate and markedly high humidity near the coast are thought to be beneficial for slow CASK AGEING, but some shippers now have temperature- and humidity-controlled lodges in the Douro for ageing premium ports, especially aged tawnies. See DOURO BAKE for the traditional effect on port of maturing it upstream in the Douro Valley.

Both growers and shippers have to submit to the authority of the IVDP, a government-run body that ensures that shippers adhere to the so-called *lei do terço* (law of the third), which restricts shippers from selling more than one-third of their stock in any one year. The IVDP is also empowered to analyse and taste a sample from each port shipment before issuing the guarantee seal stuck to the neck of every bottle of port leaving the region.

The market for port has altered dramatically since the Second World War. The so-called 'Englishman's wine' that used to be drunk everywhere from gentlemen's clubs to corner pubs became the Frenchman's wine when France's imports of *le porto* (largely inexpensive wood ports; see Styles of port below) overtook those of the UK in the early 1960s. The British market is still highly coveted by port shippers, however, especially those of British descent, notably the SYMINGTONS, who control shippers such as Cockburn, Dow, Graham, and Warre and the FLADGATE PARTNERSHIP (Croft, Fonseca, and Taylor). In the late 1990s, the US became another important market for vintage port.

Styles of port

There are two broad categories of port, the style shaped by either CASK AGEING or BOTTLE AGEING. Wood-matured ports, often called simply wood ports, are aged either in wooden casks or, sometimes, stainless steel or concrete tanks and are ready to drink straight after FINING, FILTRATION, and BOTTLING. Ports designed to mature in bottle, however, are aged for a short time in wood and are bottled without filtration. It may then take up to 20 or 30 years before such a wine is ready to drink. Within these two general categories there are many different styles of port. The official legislation governing the different categories of port was tightened up considerably in 2002 and has been amended since. The following categories are now permitted.

Ruby is one of the simplest and least expensive styles of port. Aged in bulk for two or three years, it is bottled young while the wine retains a deep ruby colour and a strong, fiery personality. Young wines from more than one vintage are aged in all sorts of vessels (wood, concrete, and stainless steel) before being blended, filtered, and bottled. PASTEURIZATION is sometimes applied to stabilize such wines and can result in 'stewed' flavours, but good ruby with its uncomplicated berry fruit aromas and flavours is often a good, warming drink. When the British FASHION for ruby port and lemonade faded in the 1960s, many shippers dropped the name 'ruby' from the labels of such ports in favour of their own, self-styled brands.

Reserve/Reserva designates a premium ruby, a wine with more colour, character, and depth than a standard ruby. This category has supplanted 'vintage character', a misleading term which was largely used in English-speaking markets.

Tawny is applied to a confusingly wide range of very different styles of port. In theory, tawny implies a wine aged in wood for so much longer than a ruby that it loses colour and the wine takes on an amber-brown or tawny hue. In practice, however, much of the tawny port sold today is no older than the average ruby and may therefore be found at the same price. The difference between a commercial ruby and its counterpart labelled 'tawny' is that, whereas ruby is made from a blend of deep-coloured wines, tawny is often produced from lighter wines grown in the cooler Baixo Corgo vineyards where grapes rarely ripen to give much depth or intensity of fruit. Vinification methods may also be adapted to produce paler-coloured wines, and the colour of the final blend may be adjusted further by adding a proportion of white port so that the wine ends up with a pale pink hue rather than tawny brown. Many bulk tawnies are left upriver for longer than other wines for the heat to speed up the maturation (see DOURO BAKE). The resulting wines often display a slight brown tinge on the rim but tend to lack the freshness and primary fruit character normally associated with young port. The French typically drink inexpensive, light, tawny-style wines as an APERITIF, and supplying this market has become the major commercial activity for many of the larger port shippers.

Aged tawny has been left to age in wooden casks for six or more years, taking on a tawny colour and a soft, silky character as the PHENOLICS are POLYMERIZED (see CASK AGEING). Most of these tawnies are bottled with an indication of age on the label, although *Tawny Reserve* or *Tawny Reserva* may be applied to wines that have spent at least seven years in wood. The terms 10, 20, 30, 40, and 50 Years Old seen on labels are, however, approximations as tawny ports are blended from several years' production. Most aged tawnies are blended according to house style and must be tasted and approved by the IVDP as conforming to the character expected from the age claimed on the label. Made from wines that might have otherwise ended up as vintage port (see below), aged tawnies mature in cask in the cool of the lodges at Gaia until the shipper considers them ready

to blend and bottle. Labels on these wines must state that the wine has matured in wood and give the date of bottling, which is important since aged tawny port will not improve in bottle. Once the bottle has been opened, younger aged tawnies may be subject to rapid OXIDATION, losing their delicacy of fruit if left on ULLAGE for more than a few days. (Very old tawnies and colheita ports are usually more robust.) Port shippers themselves often drink aged tawny, chilled in summer, in preference to any other, as its delicate, nutty character suits the climate and temperament of the Douro better than the hefty, spicy character of vintage port, which is better adapted to cooler climes.

Colheita means 'harvest' or 'crop' and therefore by extension 'vintage' in Portuguese, yet colheita ports are in fact very different from vintage ports (below). Colheitas are best understood as tawny ports from a single year, bottled with the date of the harvest on the label. The law states that colheita ports must be aged in wood for at least seven years, although most are aged for considerably longer. The wines take on all the nuances of an aged tawny but should also express the characteristics of a single year. All colheita ports carry the date of bottling, and most wines should be drunk within a year or so of that date. Colheita ports, once the speciality of the Portuguese-owned houses, have in the 21st century been taken up enthusiastically by the British shippers, who sometimes use the words 'Single Harvest' on the label. White ports may also be bottled as colheitas. (MADEIRA may also use the word 'colheita'.)

Vintage port is the most expensive style of port. Vintage port accounts for hardly 1% of all port sold, yet it is the wine which receives the most attention. British shippers, in particular, have built vintage port into a flagship wine, 'declared' in an atmosphere of speculation when the quality of the wine, the quantity available, and the market are judged fit. Wines from a single year, or VINTAGE, are blended and bottled after spending between two and three years in wood. Thereafter, most of the wine is sold and the consumer takes over the nurturing for up to 30 or more years, although an increasing

proportion is being drunk much earlier, especially in the US. Vintage port is distinguished from other ports by the quality of the grapes from which the wine is made. Only grapes grown in the best, usually Cima Corgo, vineyards and picked at optimum ripeness following an outstanding summer are made into vintage port. Even then, nothing is certain until at least a year after the harvest when shippers have had time to reflect on the characteristics of the wine and the market. The vintage may be declared only after the IVDP has approved samples and proposed quantities in the second year after the harvest. With the steady improvement in vinification methods since the mid 1980s, some wine of vintage port potential is now made at the best quintas in most years. But a shipper will declare a vintage only if there is sufficient quantity and if it is felt that the market is ready to support another vintage (1931 being a classic example of a qualitatively superb vintage undeclared by most shippers for entirely commercial reasons). Vintage declarations maybe very irregular but very roughly three vintages have been declared in each decade (however, 2016, 2017, 2018, and 2019 were all declared by one or more of the major shippers). Because they should be bottle aged for longer than almost any other style of wine, vintage port bottles are particularly thick, dark, and sturdy. The wines, extremely high in PHENOLICS in their youth, throw a heavy DEPOSIT and need especial care when DECANTING and SERVING.

Single-quinta vintage Just as wine-producing CHÂTEAUX evolved in France in the 18th and 19th centuries, the trend towards the single, winemaking QUINTA has developed in Portugal, and many of the better-known Douro quintas belong to a particular port shipper. Single-quinta ports are made in much the same way as vintage port, aged in wood for two or three years and bottled without filtration so that they throw a sediment (and should therefore be decanted before serving). Although some independent quintas produce a vintage port nearly every year, a number of differences distinguish single-quinta vintages from declared vintage ports. First of all, shippers' single-quinta ports tend to be made in good (but not outstanding) years which are not declared. In years which are declared for vintage port,

many of these wines will be the lots that make up the backbone of the vintage blend and are not therefore available for release as wines in their own right. Second, some single-quinta ports are kept back by shippers and sold only when the wine is considered to be ready to drink, perhaps eight or ten years after the harvest. Single quintas or individual vineyards in the Douro were given a fillip in 1986 when the law requiring all port to be exported via Vila Nova de Gaia was relaxed, opening the way for a number of small vineyard owners who previously had been restricted to selling their wines to large firms.

LBV stands for Late Bottled Vintage, a port from a single year, bottled between the fourth and sixth years after the harvest. Three styles of LBV wines have evolved. First there are LBVs bottled without any filtration or treatment so that, like a vintage port, they need to be decanted before serving. These wines, once designated with the word 'traditional', tend to be made in good but undeclared years and are ready to drink sooner than vintage port, four to six years after bottling. Since the revision of the legislation in 2002, unfiltered LBV may also be sold as Envelhecido em Garrafa or 'bottle matured', provided the wine in question has been aged in bottle for a minimum of three years prior to release on the market. Many of the wines in this second style share much of the depth of a true vintage port.

A third style of LBV is the most common. These are wines which have been fined and sometimes filtered and cold stabilized before bottling to prevent the formation of sediment. These wines are made in large volumes and are popular with restaurateurs (as they do not need decanting) but do not have the intensity or depth of an unfiltered LBV.

Crusted port is named for the 'crust' or DEPOSIT that it throws in bottle. In spite of its rather crusty, establishment name, it is the fairly recent creation of British shippers, notably the SYMINGTON group. It is designed to appeal to vintage port enthusiasts, even though crusted ports are not wines from a single year or vintage but blends from a number of years bottled young with little or no filtration. Like vintage port, the wines continue to develop in the bottle, throwing a sediment or crust, so that the wine needs to be decanted before it is served. Rather like traditional LBVs, many crusted or crusting ports offer an excellent alternative to vintage port, providing the port enthusiast with a dark, full-bodied wine at a much lower price. It may be exported from Oporto three years after bottling.

Garrafeira, meaning 'private cellar' or 'reserve', is more commonly associated with Portuguese table wines than with port. Until 2002 it did not form part of the IVDP's officially authorized lexicon but was a style produced by a single shipper, Niepoort. Now a port may be designated as a garrafeira if it comes from a single year and is aged for a minimum of seven years in glass demijohn before bottling (like some MADEIRA). In practice the wines age in 5- or 10-l demijohns for considerably longer than the minimum. After 20, 30 or even 40 years in glass, the wine is decanted off its sediment and rebottled in conventional 75-cl bottles. The wines combine depth of fruit with the delicate, silky texture associated with tawny port. Three dates appear on the label: date of harvest, date of bottling (i.e. when the wine was transferred to demijohn), and date of decanting (i.e. decanted off the sediment that has formed in the demijohn and transferred to a 75-cl bottle).

White port Ernest Cockburn remarked in the early 20th century that 'the first duty of port is to be red'. Nevertheless a significant proportion of white grapes grow in vineyards in the Douro, and all shippers produce a small amount of white port, with some now giving it serious attention. White port is made in much the same way as red except that MACERATION during fermentation is much shorter or even non-existent. Most white ports have a certain amount of RESIDUAL SUGAR, even those labelled 'dry' or 'extra dry'. Intensely sweet wines, made mainly for the domestic market, are labelled *lagrima* (tears) because of their VISCOSITY (see also MÁLAGA). Another, drier style of white port, described as *leve seco* (light dry), are wines with an alcoholic strength of 16.5–17%, rather than the usual 19–20%. There are two distinct styles of white port. Most commercial white ports are aged for no more than 18 months, generally in stainless-steel tanks. These tend to be pale in colour and FRUIT-DRIVEN and are often used to create a long drink with tonic, the so-called 'Portonic'. There is a movement towards wood ageing, which lends character to white port, turning it gold in colour and giving the wine an incisive,

dry, nutty tang. Superior white ports may also be bottled with a designation of age: 10, 20, 30, 40, 50 Years Old or Colheita. White ports are also sometimes used by shippers for fine-tuning aged tawnies.

Rosé was initiated by CROFT in 2008 and was initially classified by the IVDP as 'light ruby'. Made from red grapes with minimal SKIN CONTACT, it was subsequently introduced by many shippers, albeit with a huge variation in style and colour, from pale salmon to light ruby. Not without controversy when it was launched, it is said by some to have appealed to a new, younger group of port drinkers. Both rosé and white ports are increasingly used as mixers in cocktails.

Moscatel is occasionally used on its own to make a sweet, fortified VARIETAL white wine with the grape aroma characteristic of MUSCAT. The village of Favaios on the north bank of the Douro makes a speciality of Moscatel.

Portalegre, northernmost DOC subregion of the ALENTEJO in central-southern Portugal and the most distinctive. On the lower slopes of the predominantly GRANITE Serra de São Mamede, the vineyards, at up to around 800 m/2,625 ft in ELEVATION, are the Alentejo's highest and therefore coolest. This, combined with its unusual (for the Alentejo) mix of old FIELD BLEND vineyards has attracted successive

waves of newcomers this century, including a rash of talented winemakers who commandeered grapes that had previously disappeared into the ailing CO-OPERATIVE' s melting pot. Sizeable players investing in Portalegre include the Portuguese liqueur company that acquired the co-operative in 2016 and wine producers from both within and without the Alentejo (including luminaries Esporão, Cartuxa, SOGRAPE, and the SYMINGTON family). This together with the successive broadening of permitted grapes to include mainstream Portuguese varieties (and Syrah and Cabernet Sauvignon) has increased its scale of production and profile. S.A.

Portan, like CALADOC and CHASAN, is a CROSS made by French AMPELOGRAPHER Paul Truel at the INRA station at Domaine de Vassal (see INRAE). In this case he crossed GRENACHE NOIR and Portugais Bleu (Blauer PORTUGIESER) to develop a Grenache-like variety that would ripen even in the Midi's cooler zones. Unlike Caladoc, it is waning, planted on just 89 ha/220 acres of Languedoc vineyard in 2019.

Portimão , fishing port and smallest DOC in Portugal's ALGARVE.

Porto, Portugal's second city (OPORTO in English), which has lent its name to PORT wine, Vinho do Porto.

Port Phillip Zone, Australian wine zone surrounding Melbourne, VICTORIA, and encompassing the Geelong, Macedon Ranges, Mornington Peninsula, Sunbury, and Yarra Valley regions.

port tongs, rare instrument for opening a bottle of vintage PORT so old that the cork is likely to crumble under the impact of a CORKSCREW. The specially shaped tongs are heated in a flame and applied to the neck of the bottle, which is then immediately cooled with a cold, damp cloth. The sudden temperature change should

result in a clean break. Such tongs can be used on other venerable bottles.

Portugais, or Portugais Bleu, French name for Blauer PORTUGIESER. Rare in France today.

Portugal . Among European wine-producing nations, Portugal has been something of a paradox, arguably discussed in the greater world of wine more because of the CORK of which it is by far the dominant producer than for its wines. Sitting on the western flank of the Iberian peninsula, this seafaring nation which discovered so much of the NEW WORLD has long clung firmly to the Old—at least in terms of its tradition of myriad INDIGENOUS VARIETIES. Secluded both geographically and, for much of the 20th century until it joined the EU in 1986, politically as well, Portugal has developed in isolation from other countries, including neighbouring SPAIN. However, the sizeable wine industry that has grown up in this small country owes much to foreign trade. Total area under vine has declined from 385,000 ha/951,000 acres in the late 1980s to 194,000 ha by 2021. This reduction in vineyard area reflects the shift from quantity to quality production as exports have re-oriented away from BULK WINE towards bottled wines. Historically, the Portuguese have rivalled the French and trump the Italians in terms of per capita wine consumption. However, the global financial crisis of 2007/08, which prompted the imposition of austerity measures in 2010, turned Portuguese wine producers' attention firmly to export markets. During the second decade of this century, while exports continued to rise, a surge in domestic consumption driven by tourism propelled Portugal to record the highest wine consumption per capita in 2020.

History

The British have always enjoyed an amicable relationship with the Portuguese. As early as the 12th century, wines were being shipped to England from the MINHO in north-west Portugal. In 1386, the Treaty of Windsor set the seal on a friendship that has persisted, virtually uninterrupted, to the present day. When England went to war with France in the 17th century, Portugal was therefore the natural alternative source for wine. PORT, often called 'the Englishman's wine', originated from this conflict. By the time England and Portugal signed the METHUEN TREATY in 1703, which laid down tariff advantages for Portuguese wines, a thriving community of English and German wine shippers was already well established in OPORTO. Out in the Atlantic, the island of MADEIRA, an important trading post for passing ships, began exporting wine to the newly colonized state and yet-to-be United States of America. Renewed conflict between Britain and France over the French invasion of the Iberian peninsula in 1807 rekindled demand for Portuguese wines. BUCELAS, CARCAVELOS, and a red wine simply called 'Lisbon' were popular in Britain until the 1870s.

In the late 19th century, PHYLLOXERA devastated Portuguese vineyards; some wine regions never really recovered. Many growers resorted to planting high-yielding DIRECT PRODUCERS, which can still be found in the smallholdings of north and central Portugal. For much of the 20th century, Portugal turned its back on the outside world. Following 20 years of political and economic turmoil, the demure son of a DÃO smallholder, Antonio de Oliveira Salazar, became prime minister in 1932. His regime, which lasted for over 40 years, fostered a corporate, one-party state. The Junta Nacional do Vinho (JNV), founded in 1937, initiated a programme of co-operativization. Over 100 winery CO-OPERATIVES were built, mostly in northern Portugal, in less than 20 years. At the time they represented a significant advance, but all too often the system imposed by central government was too inflexible and winemaking standards deteriorated.

It is paradoxical that, against this background of self-imposed seclusion, Portugal should give birth to one of the greatest international wine success stories of modern times: medium-sweet, lightly sparkling rosés called MATEUS and Lancers.

In 1974 Portugal was once again thrown into turmoil by a military-led revolution. But after two years of upheaval the soldier politicians returned to barracks and subsequent democratically elected governments eventually returned Portugal to the European mainstream. Portugal's winemakers have benefited enormously from EU entry in 1986. Monopolistic legislation was overturned and EU money poured in to help update the wine industry, much of which had been hidebound by a lack of investment in modern technology.

During the 1980s and 1990s, the relaxation of state bureaucracy and the availability of grants and low-interest loans resulted in a country-wide wine revolution. It encouraged single estates, or QUINTAS, to cut their links with local co-operatives or PORT shippers and to make and market their own more distinctive wines. Private investors injected a new entrepreneurial spirit into the business of winemaking, establishing state-of-the-art wineries (notably in the ALENTEJO, whose sprawling, flatter landscape offers relative economies of scale). In the second decade of this century, a lively micro-NÉGOCIANT scene has emerged making LOW-INTERVENTION and playful GLOU-GLOU wines. The use of traditional Portuguese techniques, OLD VINE parcels, and lesser-known INDIGENOUS VARIETIES brings a splash of colour to the global wine scene. Forced to adapt, some co-operatives survived (indeed thrived) and others went under. In 2020 there were 74 active co-operatives, producing 36% of Portuguese wine. Inevitably, vineyard transformation was slower, but the benefits of experimentation with non-local and INTERNATIONAL VARIETIES, plus a considerable amount of research into Portugal's unique array of indigenous grapes (see below), have become increasingly apparent, especially in the DOURO, DÃO, and the ALENTEJO, and more recently TEJO and LISBOA.

Geography and climate

For such a small country, Portugal produces a remarkable diversity of wines, perhaps because grapes are grown from tip to toe and on its far-flung islands. Additionally, grape growing represents a high percentage of overall crop production—at 35%, the highest in the world or at least in Europe, according to a study published in 2017 by Adelaide University. Roughly rectangular in shape, it is under 600 km/360 miles long and no more than 200 km wide. The wines produced on the flat coastal littoral are strongly influenced by prevailing Atlantic westerly winds, which buffet the temperate VOLCANIC islands of MADEIRA and the AZORES, lashing the most exposed vineyards with atomized salt. Rainfall, which reaches 2,000 mm/78 in a year on the mountain ranges north of Oporto, diminishes sharply to less than 500 mm in some inland wine areas. The littoral's temperate MARITIME CLIMATE, with warm summers and cool, wet winters, diminishes inland; easternmost areas experience an extreme continental climate. An average annual temperature of around 10 °C/50 °F in the northern hills compares with more than 17.5 °C on the southern plains, where, in summer, temperatures frequently exceed 35 °C/95 °F. Reflecting these contrasting climatic conditions, no two wines could be more dissimilar than VINHO VERDE and PORT, which are produced in adjoining regions.

Vine varieties

Portugal's vineyards have evolved in isolation, leaving Portugal like a viticultural island with a treasure trove of INDIGENOUS VARIETIES, 248 of them according to a 2013 study produced by the Associação Portuguesa para a Diversidade da Videira (PORVID). Since Portugal joined the EU, the most promising have been identified and the overall quality and consistency of wines has commensurately improved. Among whites, LOUREIRO, ALVARINHO, and AVESSO (in Vinho Verde), BICAL and MARIA GOMES (in Bairrada), ENCRUZADO (in Dão), ARINTO (in Bucelas and throughout southern Portugal for blends), ANTÃO VAZ in the Alentejo, and RABIGATO, CÓDEGA DE LARINHO, VIOSINHO, and GOUVEIO (in the Douro) have emerged as leading varieties. Red-wine grapes account for around two-thirds of production. Some of the most celebrated are TOURIGA NACIONAL (originally from Dão and Douro but now prized country-wide), TEMPRANILLO (known as Tinta Roriz in the Douro and Aragonez in the Alentejo), BAGA (in Bairrada), TRINCADEIRA, and the French cross ALICANTE BOUSCHET (in the Alentejo). But as confidence and pride in native varieties and traditional wine styles has grown, more indigenous varieties are being sought out and celebrated. CLIMATE CHANGE concerns have also inspired winegrowers to re-evaluate the tradition of FIELD BLENDS (and/or CO-FERMENTING varieties) and to seek out lesser-known local indigenous varieties well adapted to DROUGHT and heat. INTERNATIONAL VARIETIES have made the most substantial inroads in LISBOA and TEJO, neither of which had a strong heritage of quality wines, unlike BAIRRADA, where the relaxation of DOC rules about varieties has been controversial. Cabernet Sauvignon, Petit Verdot, and Syrah are now not uncommon blend components of wines from the south of Portugal, especially the Alentejo.

Wine laws

Portugal's wine law predates that of most other European countries (although see also TOKAJ in Hungary). In 1756, the then prime minister, the Marquis of Pombal, drew a boundary around the vineyards of the Douro Valley to protect the authenticity of port, one of the wine world's first examples of geographical DELIMITATION. Bucelas, Colares, Carcavelos, Dão, Madeira, Setúbal, and Vinho Verde were all awarded *região demarcada* (demarcated region) status between 1908 and 1929, followed by Bairrada, Algarve, and Douro (for TABLE WINE) in 1979 and 1980. Since Portugal joined the EU, the Regiões Demarcadas or RDs were initially redesignated Denominação de Origem Controlada (DOC), now Denominação de Origem Protegida (DOP). A second tier, Indicação de Proveniencia Regulamentada (IPR), has been replaced by generally larger regions known as VINHO REGIONAL (also called Indicação Geográfica Protegida (IGP), meaning Protected Geographical Indication). Underpinned by the WINE WITHOUT GEOGRAPHICAL INDICATION designation, labelled VINHO if Portuguese, this brings the country's wine laws roughly into line with that of other EU countries.

For details of Portugal's extremely varied wine regions, see also ALENTEJO, ALGARVE, AZORES, BAIRRADA, BUCELAS, CARCAVELOS, COLARES, DÃO, DOURO, LISBOA, MADEIRA, MINHO, PENÍNSULA DE SETÚBAL, TEJO, TRÁS-OS-MONTES, VINHO VERDE, and, most importantly, PORT.

Portugieser, or Blauer Portugieser, black grape variety that has long been in decline in both Austria and Germany because of its association with overcropping, inexpensive rosé, and pale reds, its name suggesting completely unsubstantiated Portuguese origins. DNA PROFILING has shown it to be a spontaneous SILVANER × Blaue Zimmettraube CROSS, the latter an old dark-skinned variety still found in Germany's Rheinhessen and Hessische Bergstrasse, as well as in Friuli, north-east Italy (as Sbulzìna), and now known to be a parent of BLAUFRÄNKISCH. The birth of Portugieser most likely took place in Lower Styria (today part of Slovenia). The vigorous, precocious vine is extremely prolific and resistant to COULURE, easily producing 120 hl/ha (almost 7 tons/acre) of generally pale, low-acid red.

Blauer Portugieser remains relatively popular with Austrian growers in Pulkautal, Retz, and the Thermenregion although the vineyard area has declined to 1,263 ha/3,121 acres, making it the country's third most planted dark-berried vine. In the right hands it can occasionally yield concentrated wines.

Brought from Austria in the 19th century, Portugieser overtook even SPÄTBURGUNDER (Pinot Noir) in Germany in the 1970s in terms of total plantings, before Dornfelder surpassed it in satisfying German thirst for locally grown if uninspiring red wine. By 2020 Portugieser's total area had fallen to 2,548 ha/6,296 acres (Spätburgunder's was almost 12,000 ha), mainly in Rheinhessen and the PFALZ, where a high proportion is encouraged to produce vast quantities of pink WEISSHERBST.

The variety is so easy to grow that it has spread throughout central Europe and beyond (as PORTUGAIS Bleu it was once grown widely in south-western France). It was ingeniously named Oportó or

KÉKOPORTÓ (*kék* meaning 'blue') in Romania and Hungary. It is also grown in northern Croatia as Portugizac Crni, or Portugaljka.

J.V. & D.S.

Pošip, impressive southern CROATIAN white wine grape probably originating on the island of Kořcula.

post, substantial support for wires and vines common in vineyards with TRELLIS SYSTEMS, usually made from wood, and driven into the ground at intervals down the row. Other materials used include concrete, steel, and plastic. Woods used for such posts are soft woods such as pine, treated to withstand insect and fungus attack, or naturally resistant hardwoods. A common spacing of about 6 m/20 ft between posts is close enough to stop the wire sagging. Smaller-diameter posts placed one beside each vine are called STAKES and are more common on steep or windy HILLSIDE VINEYARDS, for example in the MOSEL and the RHÔNE valleys.

R.E.S.

potassium, one of the macronutrients required by the vine for healthy growth, along with NITROGEN and PHOSPHORUS (see VINE NUTRITION). It constitutes about 1–3% of the vine's dry weight and is an important component of grape juice. Potassium deficiencies show up first in older leaves as CHLOROSIS, which may become a marginal burn when severe. Potassium-deficient leaves are often shiny. Severe deficiencies can inhibit growth, YIELD, and sugar content. They can be confirmed easily by analysing for potassium levels in leaves or PETIOLES, and 1–1.5% potassium is the optimal range. Potassium deficiency is more evident during DROUGHT or in cold soils in spring, both of which reduce the roots' uptake of potassium. However, soils containing a significant proportion of mica-type CLAY minerals can supply too much potassium, as occurs in parts of Sunraysia and the Riverland, Australia.

Potassium is widely regarded as the most important element directly affecting wine quality. This is because high potassium levels

in grape juice cause high PH, which adversely affects wine quality. Juice potassium levels are influenced by soil potassium levels, although this is not always a straightforward relationship. (Studies in Bordeaux in the 1980s showed positive linear correlations between plant potassium levels and juice potassium, but this was for vines with potassium contents up to and exceeding three times the optimal value.) ROOTSTOCKS also have an important effect on juice potassium, with lower-vigour rootstocks giving lower juice potassium. This effect has been shown both in France and in Australia. In hot climates with low humidity, juice potassium and pH are high, which may be the result of the high TRANSPIRATION rate of vines growing in such an environment.

Studies with Shiraz have shown that SHADE in the canopy causes accumulation of potassium in leaves, stems, and petioles, which is redistributed to the fruit during ripening, causing high juice pH. CANOPY MANAGEMENT techniques which reduce shade can therefore be effective in reducing juice potassium and pH. While skins are only about 10% of the berry weight, they contain 30–40% of grapes' potassium. R.E.W. & R.E.S.

potential alcohol, measurement of a wine, juice or MUST which equates to its total ALCOHOLIC STRENGTH if all the sugar were to be fermented out to alcohol. Thus, a SWEET WINE might have an alcoholic strength of 13% but a POTENTIAL ALCOHOL of 20% if all the RESIDUAL SUGAR were fermented into alcohol.

pouches, relatively recent form of wine PACKAGING made from polyethylene and aluminium. They are light (much lighter than a BOX, for example) and the 1.5-l size has a CARBON FOOTPRINT about one-fifth that of a 420-g, 75-cl glass bottle. Small sizes are convenient but may have a much shorter shelf life than the larger size, in which the wine typically stays fresh for up to six months. Plastic taps ensure that wine in an opened pouch keeps reasonably fresh for three or four weeks. Slightly higher levels of free SULFUR DIOXIDE are needed compared with those in a glass bottle, however. See also SUSTAINABILITY.

Alko, 'Update of wine packaging LCA: final report Alko Oy' (2021). www.alko.fi/INTERSHOP/static/WFS/Alko-OnlineShop-Site/-/Alko-OnlineShop/fi_FI/Tavarantoimittajille/Muut/EN/Alko%20wine%20packaging%20LCA%20update_final%20report.pdf.

Pouilly-Fuissé, white-wine appellation which commands the highest prices in the MÂCONNAIS district of Burgundy. The appellation, restricted to the Chardonnay grape, covered 759 ha/1,876 acres in 2018 in the communes of Fuissé, Solutré-Pouilly, Vergisson, and Chaintré (see also MÂCON-VILLAGES). The richest wines are said to come from Fuissé and Pouilly, those of Solutré and Vergisson being fresher and more mineral from vineyards at a higher ELEVATION. From 2020 the best single-vineyard sites have been classified as PREMIER CRU.

As well as in the amphitheatre of Fuissé, grapes are grown in sun traps beneath the two impressive crags of Solutré and Vergisson which mark the end of the LIMESTONE plateau on which all burgundy save Beaujolais is grown. A popular myth is that the soil beneath the crags was enriched by the remains of animals driven from the top of the cliff by Stone Age hunters. The wines are full-bodied and ripe but do not usually attain the elegance of the finer wines from the Côte de

Beaune. Normally bottled after a year's BARREL AGEING, they are capable of AGEING well thereafter, particularly those of Domaine Barraud, Ch de Beauregard, Domaine Ferret, Ch de Fuissé, Olivier Merlin, Domaines Saumaize, Saumaize-Michelin, and Guffens-Heynen (the family domaine associated with the NÉGOCIANT Verget). Prices can vary enormously depending on the demands of major export markets in a given year.

The small village of Pouilly also lends its name to two adjacent lesser appellations, POUILLY-VINZELLES and POUILLY-LOCHÉ. J.T.C.M.

Pouilly-Fumé, also known as Pouilly Blanc Fumé and Blanc Fumé de Pouilly, one of the Loire's most famous wines, perfumed dry whites that epitomize the SAUVIGNON BLANC grape (along with nearby MENETOU-SALON, QUINCY, REUILLY, and, most notably, SANCERRE). All Sauvignon in the AOC is Sauvignon Blanc (no Gris allowed), which totalled 1,342 ha/3,316 acres in 2019. It was often called Blanc Fumé, because wines made from this variety, when grown on the predominantly LIMESTONE soils with some FLINT (*silex*), supposedly exhibit a 'smoky' flavour or a whiff of gunflint (*pierre à fusil*). The wines are certainly perfumed, and it takes extensive local knowledge to distinguish a Sancerre from a Pouilly-Fumé in a blind tasting of both. Pouilly-Fumé is arguably a more homogeneous appellation than Sancerre, which is not surprising since about half as much Pouilly-Fumé is made as white Sancerre, and the appellation is smaller and much flatter. (Some of the finest vineyards are on the slopes of St-Andelain on the right bank of the Loire.) Unlike that of Sancerre, the Pouilly-Fumé appellation applies only to white wines. The best Pouilly-Fumé is both taut and dense and is capable of long ageing. Some producers began experimenting with OAK for both fermentation and maturation in the mid 1980s, and the wines of the region have become more complex. The appellation takes its name from the small town of Pouilly-sur-Loire in the Nièvre *département*.

Pouilly-sur-Loire is also an AOC for wines made from the CHASSELAS grape. Just 27 ha/67 acres remain planted in 2021, typically

producing a light and early-drinking wine. See also LOIRE, including map. J.R. & C.P.

Friedrich, J., *Earthly Delights from the Garden of France, Wines of the Loire*, Vol 1: *The Kingdom of Sauvignon Blanc* (2011).

Pouilly-Loché. See POUILLY-VINZELLES.

Pouilly-Vinzelles. Borrowing the prefix from its more famous neighbour in southern Burgundy POUILLY-FUISSÉ, the village of Vinzelles has its own small appellation of 61 ha/151 acres, most of which forms a steep, east-facing slope overlooking the valley of the Saône. The best vineyard is Les Quarts and the leading producer Domaine de la Soufrandière. Otherwise most production is in the hands of the local CO-OPERATIVE, as is the case also for Pouilly-Loché, an even smaller appellation of 34 ha.

Poulsard, sometimes called Ploussard, is a relatively rare speciality of the JURA, planted on a declining 251 ha/620 acres in 2019. Its long, thin-skinned, almost transluscent grapes make distinctive light tomato-red wines which may be left on the skins for as long as two weeks without colouring the wine too deeply and are sometimes sold as rosé. It does particularly well on MARL in the northern vineyards of the Jura, especially at Pupillin near Arbois, self-proclaimed capital of Ploussard. Its delicate pigment makes it much prized for adding colour to VIN DE PAILLE, and it is also used for rosé CRÉMANT du Jura. Very prone to REDUCTION, Poulsard wines benefit from low or no SULFUR DIOXIDE additions, and in the 21st century they have often been made with semi-CARBONIC MACERATION. Poulsard may also be blended with TROUSSEAU and Pinot Noir. It is also grown to a very limited extent in BUGEY, mainly for the semi-sweet sparkling wines from the CRU of Cerdon.

pourriture, French for ROT. *Pourriture noble* is NOBLE ROT. *Pourriture grise* is GREY ROT, or malevolent BOTRYTIS BUNCH ROT.

Poussard, or Guyot-Poussard, a PRUNING system developed by French viticulturist Eugène Poussard in the early 20th century that maintains the sap flow in the vine. More recently promoted by Italian pruning consultants Simonit & Sirch, it is seen as a way of minimizing pruning wounds, helping to protect vines from TRUNK DISEASES.

Lafon, R., *Modifications à apporter à la taille de la vigne dans les Charentes: Taille Guyot-Poussard mixte et double* (1921).

powdery mildew, sometimes called oidium, the first of the vine FUNGAL DISEASES to be scientifically described, in 1834 in the United States. It is native to North America, where it causes minor damage on native grapes. The fungus was given the name *Oidium tuckerii* after the gardener, a Mr Tucker, who first recognized it in Europe, in Margate, England, in 1845. Today the fungus is more widely known by its scientific name *Erysiphe necator* (formerly *Uncinula necator*). The disease was first noted in France in 1847, where it quickly spread and caused widespread havoc to vineyards and wine quality. Today it is the most widespread fungal disease of cultivated grapevines worldwide, as it proliferates under both wet and dry conditions.

Fruit infected with powdery mildew is universally avoided in winemaking. Wine made from infected bunches loses its fruity aromas, to be replaced by mouldy, wet fur, and earthy characters; wines are described as 'oily' and 'viscous'. The greater the infection, the more obvious the effects.

There is a difference in susceptibility between vine species, with many AMERICAN VINE SPECIES and their HYBRIDS being relatively resistant. Varieties of the European vine VITIS VINIFERA are generally very susceptible, although some variation is noted. For example, Carignan, Colombard, Chardonnay, and Cabernet Sauvignon are

extremely susceptible whereas Aramon, Pinot Noir, Malbec, Merlot, and Riesling are more tolerant.

All green parts of the vine are attacked and the infection is very visible. Unlike other fungal vine pathogens, germinated powdery mildew spores penetrate only the outer epidermal cell to feed, then form a fine, translucent, cobweb-like growth that spreads on the surface around this spot. After one to two weeks, grey-white ash-like spores are produced on short, upright stalks. The infection looks powdery, hence the common name. Spores are spread by wind and, with favourable conditions, new infections occur rapidly. The fungus survives over winter within specialized spore bodies on the surface of the vine and also, where temperatures remain mild, within infected buds. If bunches are infected before flowering, then FRUIT SET and YIELD may be considerably reduced. Yield and quality are more commonly reduced when berries are infected during the first weeks of their development, while highly susceptible. Surface cells are killed so that the berries never grow to full size and are susceptible to colonization by spoilage microorganisms. Fruit of darker-skinned varieties also fail to colour properly.

The disease develops and spreads most rapidly in warm weather (20–27 °C/68–80 °F) but is inhibited at temperatures above 32 °C/90 °F. Unlike most fungal diseases, wetness is not required for spores to germinate and cause infection. Exposure to bright sunlight strongly inhibits disease development, due to the negative effects of ULTRAVIOLET RADIATION on the surface-growing fungus and the elevated temperature of irradiated vine tissues. The disease thrives within dense, shaded CANOPIES, and control is greatly aided by CANOPY MANAGEMENT techniques that avoid these and promote sunlight exposure.

Fortunately, control of this disease via applications of SULFUR dust was discovered soon after it appeared in Europe. Sulfur remains the most widely used FUNGICIDE against powdery mildew today, both as dusts in dry climates and as sprayable formulations in higher-rainfall regions. A number of other organic fungicides—including potassium salts, peroxides, oils extracted from plants and distilled from

petroleum, and various microbial preparations and by-products (see BIOLOGICALS)—have been developed more recently and used with significant success, based upon their ability to harm the surface-growing fungus on contact. Several different synthetic fungicide families are also very effective and widely used, although the development and spread of resistance to them is an increasing problem. The application of UV radiation in the vineyard at night, using a light carried on a tractor or robotic vehicle, is showing promising results.

Recent developments in vine breeding have produced varieties with natural resistance and acceptable wine quality. These DISEASE-RESISTANT VARIETIES use the natural tolerance of native American species somewhere in their pedigree. W.W.

Prädikat

Germany

A Prädikat is a 'distinction' awarded to PDO wines on the basis of increasing grape MUST WEIGHT: either KABINETT, SPÄTLESE, AUSLESE, BEERENAUSLESE, TROCKENBEERENAUSLESE or EISWEIN. Long collectively known as Qualitätswein mit Prädikat (QmP), the wines are now officially known simply as Prädikatsweine. Depending on region and grape variety, the minimum must weights in OECHSLE (and equivalent potential alcohol) set by German wine law for each Prädikat range as follows (with the low end applying in each case to the minimum for Riesling in the Mosel):

Kabinett 70–82 °Oe / 9.1–10.9%
Spätlese 76–90 °Oe / 10–12.2%
Auslese 83–100 °Oe / 11.1–13.8%
Beerenauslese and Eiswein 110–128 °Oe / 15.3–18.1%
Trockenbeerenauslese 150–154 °Oe / 21.5–21.9%

In practice, producers set their own estate-specific standards for what counts as Spätlese, Auslese, and so on, with the result that one grower's Spätlese may be another's Auslese. In general, producers opt for far higher must weights than the legal minima, which is unsurprising in this era of CLIMATE CHANGE. The choice of Prädikat is often made on the basis of intended style from among musts of nearly identical sugar content.

Germany's most prestigious growers' association, the VDP, may have 'Prädikatswein' in its name, but it took the lead in eliminating designations of Prädikat from the labels of TROCKEN (dry) wines, including those of their prestige class known as GROSSES GEWÄCHS. The idea is that a Prädikat designation should immediately indicate significant SWEETNESS, typically increasing with must weight. Dry German wines are more likely to be described as QUALITÄTSWEIN.

Austria

Prädikatswein officially excludes Kabinett wine in Austria but includes, in addition to the other Prädikats, Strohwein (or 'straw wine', see VIN DE PAILLE) and AUSBRUCH. As commonly used in Austria, Prädikatswein refers to overtly sweet wines of Auslese or higher must weight. The following minimum KMW must weights (with equivalent Oechsle and potential alcohols) are set for Prädikatswein:

Spätlese 19 °KMW / 94 °Oe / 12.8%
Auslese 21 °KMW / 105 °Oe / 14.5%
Beerenauslese 25 °KMW / 127 °Oe / 18%
Ausbruch 27 °KMW / 139 °Oe / 19.8%
Trockenbeerenauslese 30 °KMW / 156 °Oe / 21.8%
Eiswein 25 °KMW / 127 °Oe / 18%
Strohwein/Schilfwein 25 °KMW / 127 °Oe / 18%

Both German and Austrian laws stipulate certain characteristics that should be met by Prädikatswein over and beyond minimum must weights, such as that Spätlese or Auslese must be harvested from 'fully ripe' grapes; Beerenauslese from BOTRYTIZED grapes; and Trockenbeerenauslese from 'predominantly shriveled botrytis-affected' grapes. But in practice such unquantifiable criteria are virtually assured by the requisite must weight and are not enforced, except for two categories. EISWEIN must be pressed from grapes that have frozen on the vine and not been allowed to thaw. And (in Austria) Strohwein/Schilfwein must be made from grapes suspended on racks or dried on straw or reed mats for at least three months without any use of heaters, fans or dehumidifiers. D.S.

precipitates, solids which are deposited on the bottom of barrels, casks, tanks, or vats by wine stored in them.

Technically, precipitates are solids which deposit from solutions because of reactions or temperature changes; they differ from SEDIMENTS, which are suspensions of solids which settle from the mixture when agitation ceases. Strictly speaking, therefore, the stem, pulp, and skin fragments and the seeds and dead yeast cells which settle after fermentation as gross LEES are not precipitates, while subsequent deposits of TARTRATES and oxidized PHENOLICS are.

precision viticulture is an approach to wine-grape production which recognizes that the productivity of individual vineyard blocks can show marked spatial variation in relation to variation in the land (SOIL, TOPOGRAPHY) underlying the vineyard. Thus, vineyard management is targeted rather than implemented uniformly over large areas. Research from around the world suggests that grape YIELD, vine VIGOUR, and GRAPE COMPOSITION can vary substantially within a single vineyard under conventional uniform management. In Australia, for example, yield may vary ten-fold (i.e. 2–20 tonnes/ha).

Critical to this approach to grape and wine production is the collection and use of large amounts of data relating to vine performance and the attributes of individual production areas (vineyards, blocks, sub-blocks, zones, etc.) at a high spatial resolution. This approach relies on a number of key enabling technologies including the GLOBAL NAVIGATION SATELLITE SYSTEM (GNSS), GEOGRAPHICAL INFORMATION SYSTEMS (GIS), REMOTE SENSING, PROXIMAL SENSING, and YIELD MONITORS, which, when used in conjunction with the GNSS, enable geo-referenced records of yield to be collected on the go during harvest. Such technologies, and the data derived from them, enable precision viticulture (PV) practitioners to manage vineyards by 'zones' rather than by blocks using targeted management to tailor production according to expectations of vineyard performance and desired goals in terms of both YIELD and/or GRAPE COMPOSITION AND WINE QUALITY. This is feasible given research

which has shown that patterns of spatial variation in vineyard performance tend to be constant from one vintage to another, which in turn lends itself to the adoption of ZONAL VITICULTURE and SELECTIVE HARVESTING and the use of data collected in previous years to predict likely performance in subsequent years. Such data also offer hope for improved understanding of TERROIR.

Targeted management may mean the timing and rate of application of water, FERTILIZER, ameliorants such as MULCH or sprays, or the use of machinery and labour for a range of vineyard operations such as pruning or shoot or crop thinning, but selective harvesting is the most widely adopted form of targeted management. See ZONAL VITICULTURE.

Yield monitors and proximal CANOPY sensors are available as 'on the go' sensing technologies for attachment to existing vineyard machinery; methods to simultaneously predict yield and assess grapevine canopy conditions and grape composition are under development. R.G.V.B.

premature oxidation, known colloquially as premox, or even pox, is a phenomenon widely seen in white burgundy since the mid 1990s but also evident in many other white wines and occasionally in reds. The first vintage to exhibit the problem clearly was 1996, at about five years old, although it subsequently became clear that 1995 was also implicated.

A white wine which has oxidized naturally over a long period (see OXIDATION and AGEING) is likely to be deep yellow in colour, perhaps browning, with aromas of cooked fruit, sometimes quince, and eventually dank, dead fruit, possibly sherrified and acetic (see ACETALDEHYDE). Typically these negative effects will be immediately apparent on opening and pouring.

A prematurely oxidized white wine will also show some advance in the colour, more in the dull yellow range, and this may happen after the bottle has been open for a minute or two. The first danger sign in terms of aroma is bruised apples or furniture polish, which can strengthen considerably with AERATION. A compound called SOTOLON, characterized by honey or beeswax, is also commonly identified in these wines. Aromas of stewed fruit and prunes are common in prematurely oxidized red wines.

Two specific reasons were identified early on: inadequate CORKS and low SULFUR DIOXIDE levels. This was the worst period for cork quality, with an increase in demand due to growing world wine production but prior to the widespread introduction of SCREWCAPS and alternative CLOSURES. Many producers had also reduced sulfur dioxide levels in the interests of consumer sensitivity.

These problems coincided with a period in which the oxidation potential of white wines has been higher than in the past thanks to CLIMATE CHANGE and the desire for riper styles of wine which may be enjoyed earlier in their life.

Leading Bordeaux researchers Denis DUBOURDIEU and Valérie Lavigne believe that the production of the antioxidant GLUTATHIONE in vineyards is vital to the prevention of premox. Their overall preventive strategy comprises the following steps:

- ensuring adequate supply of NITROGEN to the vine for sufficient and appropriate VIGOUR in order to produce grapes low in PHENOLICS and rich in glutathione and FLAVOUR PRECURSORS
- limiting extraction of phenolic compounds during PRESSING to preserve glutathione

- protecting MUST and wine from oxidation (INERT GAS, sulfur dioxide)
- ensuring a rapid and complete alcoholic fermentation
- reducing the time lag between fermentation and MALOLACTIC CONVERSION (by LEES STIRRING or inoculation with LACTIC ACID BACTERIA)
- ageing the wines in REDUCTIVE conditions (sulfur dioxide, LEES, moderate amounts of new oak)
- limiting the amount of dissolved oxygen when preparing the wine for BOTTLING (see TOTAL PACKAGE OXYGEN)
- choosing a closure that is suited to the wine.

premier cru, or premier cru classé, is a CRU judged of the first rank, usually according to some official CLASSIFICATION. The direct translation of the French term *premier cru*, much used in the context of BORDEAUX, is FIRST GROWTH. A premier grand cru (classé) or premier cru supérieur may, as in the case of ST-ÉMILION and Ch d'YQUEM, be a rung higher even than this. In Burgundy, scores of vineyards are designated premiers crus, capable of producing wine distinctly superior to VILLAGE WINE but not quite so great as the produce of the GRANDS CRUS. See BURGUNDY in general and each of the villages on the CÔTE D'OR in particular. See also ERSTES GEWÄCHS, ERSTE LAGE, CHAUME, and CHAMPAGNE, geography and climate.

Premières Côtes de Bordeaux, AOC created in 2011 specifically for sweet wine made in the narrow strip extending for 60 km/40 miles along the south-western edge of the ENTRE-DEUX-MERS appellation on the right bank of the GARONNE from Langon almost as far as the city of Bordeaux. It used to apply to the region's red wines too, but from 2011 the reds have been known as CADILLAC CÔTES DE BORDEAUX. In 2020 just 71 ha/175 acres of vineyard were devoted to the production of these blends of Sémillon, Sauvignon Blanc, Sauvignon Gris, and Muscadelle that lack the intensity of great SAUTERNES. Dry whites are sold as BORDEAUX AOC.

premium wine, debased and virtually meaningless term, not unlike RESERVE. See also ICON WINE.

Prensal, also spelt Premsal. See MOLL.

pre-phylloxera, term used to differentiate vines, especially European ones, planted before the arrival of phylloxera towards the end of the 19th century from those GRAFTED on to phylloxera-resistant American ROOTSTOCKS which replaced them. In the first half of the 20th century, there was much discussion about the relative merits of wines made from pre- and post-phylloxera vines with, perhaps inevitably, overall agreement that the earlier generation of wines were distinctly superior. As pointed out at the end of PHYLLOXERA, however, it was probably not the grafting itself which resulted in an apparent drop in quality but the effects of the VIRUS DISEASES imported into European vineyards along with all this phylloxera-resistant plant material from across the Atlantic. As OLD VINES are increasingly venerated as the source of distinctive wines, the terms *préphylloxerique* (French), *pre-fillossera* (Italian), and *prefiloxérica* (Spanish) appear more frequently on wine labels.

pre-pruning. See MECHANICAL PRUNING.

preservation systems for wine proliferated in the late 20th and early 21st centuries. Enomatic and similar systems which preserve wine under INERT GAS, usually argon, and dispense the wine from multiple bottles in a temperature-controlled cabinet were designed for retail and hospitality settings. Coravin, invented by a wine-loving medical engineer with a practically teetotal wife, was aimed at the domestic wine drinker, although it is much used by wine professionals for small pours of fine wine. It allows wine to be withdrawn from an unopened bottle via a thin needle through the cork, inert gas being substituted for its volume via rather expensive cartridges. Other systems rely on vacuums or inert gas, while the Eto decanter has a valve designed to halt OXIDATION.

press in a wine context usually means wine press, a particularly ancient piece of winemaking equipment, used for the PRESSING operation of separating grape juice or wine from solids. Wine presses or their remains provide some of the longest-surviving evidence of the ORIGINS OF VINICULTURE. In ancient times, the design of presses was varied and ingenious. See ancient EGYPT and GREECE for more details.

Ancient history

CATO (*De agricultura* 18–19) in the 2nd century BCE provided the first detailed description of a press room. He describes a beam or lever press. This would be constructed on an elevated concrete platform with a raised curb, which formed a shallow basin, which sloped gently to a run-off point. On this was constructed the press, consisting of a long, heavy horizontal beam which slotted into an upright at the back and ran between two uprights at the front. The front end of the beam was attached by a rope to a windlass. The grape solids were put under the beam and pressure applied by winding down the end. As the pulp compacted, so wedges were hammered into the slot at the pivot end to lower it. Over time various refinements were introduced. Most notably, according to PLINY (*Natural History* 18. 317), a 'Greek-style' press was introduced during the late republic or early empire in which the windlass was replaced with a vertical screw thread, sometimes with a heavy counterweight. There is ample archaeological evidence from Italy, and elsewhere, for the use of presses. All the Roman AGRICULTURAL TREATISES, apart from the writings of Palladius, assume the use of a press in their descriptions of winemaking. However, the press was an elaborate and comparatively expensive piece of equipment, and its use was far from universal. Some farmsteads have large tanks for treading the grapes in but no evidence of a press. It is not clear whether the must from the treading was always kept separate from that from the pressing. The grape pulp could be subject to a second pressing; but this was carefully kept separate. The pressed grape skins could even be soaked in water to produce *lorca*, a drink to be given to the farm hands (VARRO, *De re rustica* 1. 54), a forerunner of PIQUETTE. J.J.P.

White, K. D., *Farm Equipment of the Roman World* (1975), 112–15.

Presses today

Wine presses have evolved over the last thousand years or more into the relatively complicated machines used today. The basket presses used during the Middle Ages by religious orders were large devices built of wood in which grapes were squeezed by a horizontal wooden disc which just fitted into a cylindrical basket made of wooden staves bound into the cylinder shape by encircling wooden hoops. The juice from the crushed berries escapes through the spaces between the basket staves and flows into a tray below. Some of these traditional presses, usually depending on a giant lever for pressure, still exist and are occasionally used in Burgundy and parts of Italy. Similar, usually smaller versions of the basket press reliant on hand or hydraulic power can be found in many of Europe's less mechanized wineries today, and most producers of CHAMPAGNE and SAUTERNES still rely on variations on this vertical-pressing theme, demanding though they are in terms of time and labour. Modern basket presses, the wooden slats often replaced by stainless steel, are gaining in popularity among producers who wish to work with smaller batches and are willing to tolerate longer set-up and cleaning times in order to treat their fruit as gently as possible. If whole bunches are included, the stems improve drainage.

In modern horizontal presses, the basket-press principle has been turned on its side. They can be divided into either batch or continuous presses, the latter almost never used for fine wines. Most batch presses depend upon squeezing a charge of crushed grapes or POMACE against a perforated screen. Pressure may be applied by a moving press head as in the old basket press or, more gently in theory, by using a pneumatic press, in which an airbag or membrane expands to squeeze the pomace against the inner wall of the cylinder. However, more common today are the fully enclosed tank presses, which reduce the exposure of the pomace and juice to air. Further protection from oxygen is achieved by flushing the tank with INERT GAS prior to pressing or, in the latest generation of horizontal presses, using NITROGEN during the inflation and deflation of the membrane.

Continuous presses, more common in the 1980s and 1990s, are much harsher and usually worked by either a screw or a belt. With a screw press, the decreasing pitch of an Archimedes screw subjects the pomace to increasing pressure as it is moved along within the perforated cylindrical housing. Belt presses are much rarer and function by pressing intact berries between two perforated moving belts arranged so that the clearance between them decreases. The screw press allows faster throughput and is therefore the cheapest form of press. Both screw and belt presses can also be enclosed. The belt press was really more of an alternative to the crusher since it was still necessary to drain the juice and press the skins further in some other form of press.

Winemakers also use **vertical** presses, which are better suited to pressing reds and FORTIFIED WINES. The pressure is higher than in a pneumatic press but it is impossible to break up the cake, which is why this type of press is rarely used on grapes for white wine.

Many modern presses are controlled by a computer programme designed to optimize the pressing cycle for each grape variety and wine type. The screw press is still found in some large commercial wineries, but tank presses and modern basket presses are increasingly common for fine-wine production. V.L.

Pressac, Bordeaux RIGHT BANK name for the red grape variety Cot or MALBEC.

pressing, winemaking operation whereby pressure is applied, using a PRESS, to grapes, grape clusters or grape POMACE in order to squeeze the liquid out of the solid parts.

For most white wines, pressing takes place prior to FERMENTATION (for exceptions, see ORANGE WINES, QVEVRI, and SKIN-FERMENTED whites, for example). There are various options for extracting juice from grapes: immediate pressing of whole grapes without CRUSHING, immediate pressing of crushed and/or DESTEMMED grapes, or pressing

after the crushed and destemmed grapes have undergone a period of SKIN CONTACT.

The most commonly used PRESSES in white winemaking are pneumatic bladder or membrane presses. Using gentle pressure, this type of pressing makes it possible to extract juice containing little PULP. It also results in only a small increase in the level of PHENOLICS in the juice. However, it is necessary to make sure that pressing lasts long enough for the grapes' aromatic qualities to be released into the juice. In certain instances, for example for grapes high in acidity and low in phenolics, skin contact may take place in the press.

Red wines are usually pressed after fermentation (or just before the end) or following extended MACERATION, but see RED WINEMAKING for alternative approaches. The timing and the pressure influences the level of phenolic extraction. The use of vertical presses in red winemaking is increasingly common because the juice filters through the cake to yield particularly clear juice.

See also PRESS, PRESS WINE, and FREE-RUN. D.D. & V.L.

pressure bomb, or pressure chamber, a device for measuring water potential in plants developed by the American plant scientist Per Scholander in the 1960s. It has since been used for studies in grapevine physiology and more recently in California as a guide to the timing of vineyard IRRIGATION. The blade of the leaf is placed in an airtight chamber and pressure is increased until XYLEM fluid exudes from the cut PETIOLE end. However, water potential of the grapevine can vary from hour to hour, depending on sunshine, temperature, humidity, and soil moisture content, so it is difficult to interpret this dynamic value as an irrigation guide. R.E.S.

Bogart, K., 'Measuring winegrape water status using a pressure chamber'. www.grapes.extension.org/measuring-winegrape-water-status-using-a-pressure-chamber.

Smart, R. E., 'Aspects of water relations of the grapevine (*Vitis vinifera*)', *American Journal of Enology and Viticulture*, 25 (1974), 84–91.

press wine, dark-red wine squeezed from POMACE (grape skins, stem fragments, pulp, dead yeast) in a wine PRESS. Press wine is generally more astringent than FREE-RUN wine, especially when a continuous screw press has been used. A certain proportion of press wine may be usefully incorporated into the free-run wine, adding colour and powerful but not astringent TANNINS, as well as increasing the volume on the mid PALATE. Whether to include press wine in the blend, and how much to include, depends very much on the winemaking process, the desired style of the wine, and the vintage conditions. Otherwise it is used for a lesser bottling.

All white wine except for the free-run juice is effectively press wine, although its quality and characteristics are shaped considerably by how gently the white grapes were pressed and whether there has been any SKIN CONTACT. See also the TAILLE produced in CHAMPAGNE.

V.L.

prestige cuvée, one of several names given to a CHAMPAGNE house's highest-quality wine. At one time the houses saw their NON-VINTAGE wine as their greatest expression. Vintage-dated champagne was added to the range and a premium usually charged for it. ROEDERER's Cristal bottling and MOËT & CHANDON's named after Dom PÉRIGNON scaled new heights, however, and today most of the major champagne firms offer one such product, available—at a price and, often, in a specially created bottle—in limited quantity at the top of their range. Also sometimes known as de luxe or luxury cuvées.

price is probably the single most important aspect of a wine to most consumers, just as the price of grapes is one of the most important variables of the viticultural year to most grape-growers. The price of

vineyard land is not directly proportional to the price fetched by grapes grown on it, however. See below.

Grape prices

Wine grapes are an important item of commerce throughout the world, and the economic fortunes of many rural communities rise and fall with local wine-grape prices. Although many wine consumers have the impression that most wine grapes are grown on estates which also process them into wine, the majority of the world's wine grapes are sold in the form of fresh fruit, to be vinified quite independently of the grape-grower, whether by commercial wineries or CO-OPERATIVES.

The means to determine prices for wine grapes varies from region to region. Prices are normally fixed annually, taking into account supply and demand as well as individual VINTAGE characteristics. A buoyant wine market bolsters grape prices, whatever the size of the crop, with some wineries attracting fruit away from others by paying higher prices. When the market is depressed it is not unusual to see fruit left on the vine (as in some vintages in Australia, for instance), since the cost of harvesting can be more than the potential income. In many areas, notably Europe and South Africa, SURPLUS grapes have been distilled into alcohol.

Normally grapes are bought and sold according to VINE VARIETY and sugar content. The demand for different varieties is relatively stable, but prices can reflect longer-term changes as varieties move in and out of FASHION. In many European regions, there is some sort of representative body which oversees grape prices. The regional organization in Champagne is the oldest of the French regional associations and has powers and services which extend beyond grape price determination. The Comité Interprofessionnel du Vin de Champagne (CIVC) has in its time determined grape prices by means of a relatively complex series of calculations (see CHAMPAGNE). For many European producers, grape prices are set by co-operatives; although the formulae may not be so rigid as those traditionally employed in Champagne, they must take into account the same factors concerning supply, demand, and intrinsic quality.

Outside Europe the majority of grape-growers sell their produce to private wineries with which they negotiate freely. The US government reports in detail on prices paid after each vintage. The world's record grape prices are probably for Napa Valley Cabernet Sauvignon. Nationwide, however, according to the official report on the 2021 harvest, the average price paid per ton of grapes was just over $8,000, but some producers will pay $20,000 a ton for grapes from the finest sources.

A basic problem in buying and selling wine grapes is that their true value is not known until they are made into wine—and, indeed, until that wine is sold. Region of origin, however, is well recognized as affecting wine style and quality. Concentration of SUGAR IN GRAPES was long regarded as the most important factor in determining wine quality and therefore grape price, but in the era of CLIMATE CHANGE this is giving way to more subtle criteria. Increasingly, progressive wineries are implementing GRAPE QUALITY ASSESSMENT schemes to reward growers for producing high-quality fruit. These schemes may be related to the vineyard site as well as to ROOTSTOCK and CLONE, vineyard management methods, and also perhaps to a detailed chemical ANALYSIS of the fruit. Wineries may keep wine batches from different growers separate and so are able to pay a bonus based on performance. Some enlightened wine producers pay growers per ha/acre and effectively manage grape quality themselves.

Vineyard land prices

Needless to say, those vineyards with a reputation for high wine quality attract high land prices. Perhaps the clearest examples are to be found in the Bordeaux region, where, thanks partly to several important CLASSIFICATIONS of individual châteaux, land prices are also clearly stratified. In 2021, for example, the price of planted vineyard entitled to the basic Bordeaux appellation had fallen to €12,000 per ha (it was about €25,000 per ha in the mid 2000s), while Pauillac, home of three FIRST GROWTHS, commanded €3 million per ha.

Official land transactions in France are overseen by the agency SAFER. According to its statistics for 2021, average land prices in Burgundy (including much less valuable Beaujolais) were by far the highest of any wine region at more than €200,000 per ha, with average Bordeaux land prices overtaking those of Alsace at nearly €120,000. Champagne vineyard land was long considered some of the world's most expensive, but the average prices reported by SAFER fell each year from 2019 to 2021. In the Napa Valley in the early 2020s, an acre of highly sought-after vineyard could sell for as much as $1 million an acre, the equivalent of about €2.37 million per ha.

But there are also extensive tracts of land which have suitable soils and climate to grow quality grapes economically but which are still yet to be 'discovered' and planted to vineyards. As such, they have the value only of their existing land use, which could be low-value grazing.

Wine prices

The price of a wine is a function of the price of the grapes, the price of LABOUR, the price of a winery or the debt outstanding on it, pricing policy on the part of the producer, pricing policy on the part of any merchants involved in selling it, and the cost of TRANSPORT, BOTTLING, LABELLING, and marketing, quite apart from any DUTIES and TAXATION. The interest for the wine producer must be to maximize return on capital without acquiring a reputation for profiteering.

GLOBALIZATION continues to give bigger retailers increasing power to dictate prices and PRICE POINTS, which has had a generally deflationary effect on retail prices, if hardly an inflationary one on absolute value. See also ECONOMICS OF WINE.

The interesting question for the consumer, however, is the extent to which retail wine prices, which can vary more than a thousandfold, reflect wine quality. The answer is, of course, not very closely. All sorts of factors can depress the price of a wine to make it a bargain relative to the competition. Some national economies offer particularly low production costs (such as SOUTH AFRICA and some of SOUTH AMERICA) when translated into the currencies of many potential importers. Currency movements in general have far more (upward) impact on wine prices than most wine drinkers realize (merchants do not always pass on to consumers the benefit of downward movements). Other political events can also affect wine prices. The fall of communism and the effect of GORBACHEV's anti-alcohol policies on Eastern Europe left SURPLUS PRODUCTION in countries such as BULGARIA, HUNGARY, and ROMANIA, which used to ship enormous quantities to the Soviet Union, and in the 1990s these emerging economies' desire for hard, western currency led them to export goods such as wine at extremely keen prices or as part of barter deals. Specific countries may also benefit, or suffer, as a result of TARIFFS.

Pricing policy in general may be geared to gaining a foothold in a new market, as, for example, South Africa needed to do after the

lifting of sanctions in the early 1990s. Or it may have the result of bolstering prices in the belief that high prices automatically buy respect and prestige, a phenomenon associated with some aspirant CALIFORNIA CULT wines.

The above considerations relate to the prices of wine when it is first offered for sale. Serious wine COLLECTORS and those considering investing in wine are interested in what happens to the price of FINE WINE over time. As detailed in INVESTMENT and AUCTIONS, this depends on the precise wine, the era, and period of time, as well as on the rarity value of a given wine, its PROVENANCE and condition, and the general state of the market.

Most ordinary wine drinkers took a certain comfort in the story of what happened to what was then the world's most expensive bottle of wine sold, at Christie's for a record £105,000 in 1985: this particular bottle of Ch Lafite 1787, supposedly once the property of Thomas JEFFERSON, was stood upright on display under warm lights by its owners, the Forbes family, so that, unnoticed, the cork dried out and dropped into the bottle, rendering the wine OXIDIZED and undrinkable. In October 2018 a new record price was set at Sotheby's in New York: $558,000 for a 75-cl bottle of Domaine de la Romanée-Conti 1945 Romanée-Conti, paid by a Chinese buyer.

Not least because of the ASIAN economic boom, the late 1990s saw the prices of the most sought-after fine wines, the so-called TROPHY WINES, draw away from those of other wines, a gap that widened as the Chinese buyers poured into the market for top 2009 and 2010 bordeaux. It is ironic perhaps that, at a time when the difference in quality between wines at the top and bottom ends of the market has never been narrower, the price difference has never been greater. But presumably this reflects the hugely increased number of affluent wine consumers, the finite volumes of wine produced, and the significant position that wine now holds in a number of cultures round the world. Billionaires need billionaires' drinks.

price points, the supposedly particularly significant retail prices, often x.99, that dominate mass-market wine selling. Bigger retailers impose a carefully planned timetable of retail discounts and promotions on their main suppliers, thereby sometimes entailing artificially inflated base price points from which these 'reductions' can be made. In common usage 'price point' is often used instead of 'price'.

Prié, rare but genetically important AOSTA white wine grape that has close relatives in both Switzerland and Spain.

Prieto Picudo, unusual, musky, Spanish medium-red grape grown on 2,871 ha/7,094 acres in 2020, mainly around the city of LEÓN in north-central Spain. These red wines are deeply coloured, often tannic, aromatic, potent, and distinctive.

primeur, French word for 'young produce', which has been adapted to mean 'young wine'. French AOC rules allow all of the following to be released on the third Thursday of November following the harvest: Beaujolais, Côtes du Rhône, Grignan-les-Adhémar, Ventoux, Languedoc, Gamays from Touraine, Anjou, and Gaillac, Coteaux du Lyonnais, Côtes du Roussillon, Mâcon Blanc, Tavel Rosé, Rosé d'Anjou, Cabernet d'Anjou, Saumur Rosé, Bourgogne Blanc, Bourgogne Aligoté, Muscadet, and Gaillac Blanc. For more details of this style of wine, see NOUVEAU.

See also EN PRIMEUR for details of fine wines offered for sale as futures before they are bottled.

Primitivo, Italian name for the originally Croatian ZINFANDEL grape (see also TRIBIDRAG), grown principally in PUGLIA. Once highly prized for blending, in the 1990s it fell victim to the same EU VINE-PULL SCHEME as NEGROAMARO. Plantings fell to under 8,000 ha/19,770 acres by the turn of the century, but the 1994 confirmation by DNA

PROFILING that Primitivo was Zinfandel led to commercial success as a VARIETAL (rather than as a blending ingredient) and staunched the loss of vineyards in the 21st century. Since 1999 Italian exporters have been allowed to label their Primitivo as Zinfandel, and by 2015 there were 13,896 ha/34,338 acres planted in Italy. A move to limit the use of the name 'Primitivo' solely to DOC wines was rejected by producers in 2005, to the advantage of the growers, for the success of IGT Primitivo has meant that higher prices are now being paid for the grapes. This in turn has ensured that the variety is being replanted after years in which it was only grubbed up, as the backbreaking work involved in cultivating the BUSH VINES was not remunerative.

It was presumably brought across the Adriatic Sea from Croatia to Puglia in the 18th century. Its Italian name derives from the latter part of the 18th century, when a priest in Gioia del Colle selected vines from promiscuous old vineyards and noted that fruit from these vines matured earlier than those from other vines. As a result, he called the variety *primativo*, from the Latin *primativus*, or 'first to ripen'. In 1799, he planted these cuttings in a vineyard in Liponti, just outside Gioia del Colle.

Historically, it suffered from a poorly conceived DOC in Manduria: a minimum alcohol level of 14% for the regular production and higher alcohol for the *liquoroso* versions (both sweet and dry), which reach a leg-wobbling 18%. Puglians report it is highly prized as a high-strength blending ingredient by many producers of AMARONE.

It is also DOC in its original homeland of Gioia del Colle. As an IGT Salento wine, it has enjoyed a boom since the late 1990s, where careful selection and modern vinification can result in wines of great appeal and value.

Priorat, one of Spain's most inspiring red wines, made in an isolated zone in Catalunya (see CATALUÑA) inland from Tarragona (see map under SPAIN), one of the country's only two to qualify as a DOCA (or DOQ in Catalan). In the 1990s, a true revolution engulfed the

region, where production methods for Priorat had barely altered since the 12th century when the Carthusian MONKS first established the priory after which the wine is named.

Priorat is one of the world's few first-class wines to be made from GARNACHA and Mazuelo/Cariñena/CARIGNAN vines. The VINE AGE and concomitantly extremely low YIELDS undoubtedly contribute to the intensity and strength of Priorat.

The landscape is extreme: of the region's 1,900 ha/4,695 acres of vines in 2020, 600 ha are planted on slopes steeper than 35%; 23 ha are dramatically steep, at 90%. Poor, stony soils derived from the underlying SLATE and QUARTZ, called locally *llicorella*, support only the most meagre of crops. MECHANIZATION is almost impossible, and many steeply terraced smallholdings had been abandoned as the rural population left to find work on the coast. The success of new-wave Priorat has been reviving viticulture, however.

The region was long dominated by CO-OPERATIVES, but the 1980s saw an explosion of top-quality independent estates, led by Scala Dei, whose 1975 Priorat was still drinking well in 2022. René Barbier, the scion of the Franco-Spanish winemaking family (whose eponymous firm in Penedès belongs to HENKELL FREIXENET), located some particularly promising vineyard sites, renaming them CLOS. Such French vine varieties as Cabernet Sauvignon, Merlot, and Syrah were planted. Complex blends including small proportions of French varieties, careful winemaking, and ageing in new French oak barrels were the key innovations. The wines of Barbier (Clos Mogador), Costers del Siurana (Clos de l'Obac), Álvaro PALACIOS (Finca Dofí, L'Ermita), Mas Martinet (Clos Martinet), and Clos & Terrasses (Clos Erasmus) had won worldwide acclaim by the late 1990s, with L'Ermita one of Spain's most expensive wines.

By the mid 2000s there were more than 50 bodegas in Priorat; by 2018 there were over 100, many also producing rich, full-bodied white wines from GARNACHA BLANCA, MACABEO, PEDRO XIMÉNEZ, and some VIOGNIER.

In 2019 a new classification system was introduced for both dry red and white wines with the intention of demonstrating Priorat's diverse and special TERROIRS. Wines bottled under the basic DOQ Priorat may come from anywhere within the delimited area. The new designations all require a minimum of 60% Carignan and/or Garnacha for reds, with increased minima for vine age and tighter yield restrictions. In addition, Vins de Vila must come solely from one of Priorat's 12 named villages: Bellmunt, Gratallops, El Lloar, La Morera, Porrera, Poboleda, Escaladei, Torroja, La Vilella Alta, La Vilella Baixa, and areas in Masos de Falset and Les Solanes del Molar. Paratge wines come from one of 459 single plots recognized by the Consell Regulador (see CONSEJO REGULADOR), and 90% of the vines must also be at least 15 years old. Vinya Classificada may be used for specially recognized vineyards with 80% of vines at least 20 years old; Gran Vinya Classificada must come from vines planted more than 75 years ago and have a track record of producing exceptional wines. The first three Gran Vinya Clasificada wines to be announced in 2020 were Vall Llach Mas de la Rosa, Mas Doix 1902, and Alvaro Palacios L'Ermita.

Priorat's success has directed increased attention to the surrounding DOP MONTSANT, which can be a source of similar wines at more affordable prices.

Priorat also has a tradition of FORTIFIED WINES, from the nutty, dry or sweet RANCIO wines called Vi Ranci to Vino Dulce Natural, akin to France's VIN DOUX NATUREL. V. de la S. & F.C.

proanthocyanidins, oligomers and polymers of flavanols. Proanthocyanidins are PHENOLICS belonging to the FLAVONOID group, also called condensed TANNINS. The term proanthocyanidin refers to the reactivity of these molecules that release red anthocyanidin

pigments (i.e. anthocyanin aglycones) when heated in an acidic medium, still commonly used for their analysis.

Several classes can be distinguished by the differing nature of the anthocyanidin released. The most common proanthocyanidins are procyanidins, based on CATECHIN and epicatechin units, which release cyanidin when heated in acidic media. Grape proanthocyanidins also comprise prodelphinidins based on gallocatechin and epigallocatechin units, which release delphinidin when heated in acidic media. Procyanidins are the only proanthocyanidins in grape seeds, whereas tannins of grape skins and stems consist of both procyanidins and prodelphinidins. V.C.

Probus, Marcus Aurelius (232–282 CE), Roman emperor (276–282) who employed troops in the planting of vineyards in GAUL and along the Danube. (See GERMAN HISTORY.) This positive encouragement of viticulture was in marked contrast to the earlier Emperor DOMITIAN.

Procanico, Umbrian name for TREBBIANO Toscano.

processing aids, unlike ADDITIVES, are added to juice, MUST or wine in order to react with and thus remove another component in the wine, so that only trace amounts will remain in the finished product. The purposes of such transient additions include CLARIFICATION, STABILIZATION, FINING, and the removal of off-flavours. However, in some countries the use of certain processing aids, especially those based on animal products such as CASEIN, ISINGLASS, or GELATIN, must be stated on the label for the benefit of VEGETARIANS AND VEGANS or those with ALLERGIES AND INTOLERANCES. See also LABELLING INFORMATION.

procymidone, a systemic FUNGICIDE used to combat BOTRYTIS.

production of a particular vineyard is normally measured as YIELD. The world's production of wine typically totals 260–290 million hl (6,800–7,650 million gal) annually, although 2017 and 2021 fell below that level mainly due to very small crops in parts of Europe, and is considerably in excess of CONSUMPTION, leading to continued surplus, but there is wide variation according to VINTAGE. See WORLD PRODUCTION and, for annual totals, SURPLUS PRODUCTION. The tables in Appendix 2 show the world's significant wine-producing countries and OIV figures for their total area of vineyard, annual wine production, and per-capita consumption.

(See map under WORLD PRODUCTION for the location of different countries' wine regions.)

Prohibition in common parlance most often means a prohibition on the consumption of alcohol (which suggests the importance generally attached to the possibility of intoxication). Prohibition has officially been in force throughout the world of ISLAM for 12 centuries, and elsewhere there have been periods throughout history (usually just after a period of particularly heavy consumption) during which the arguments for Prohibition have seemed convincing. One of these periods was the early 20th century, when Prohibition was enforced in parts of Scandinavia, was put to a referendum in New Zealand, and was enforced most famously in the United States.

Prohibition in the US

'Prohibition' is generally considered the period in the United States, 17 January 1920–5 December 1933, during which, according to the language of the 18th Amendment to the Constitution, the 'manufacture, sale, or transportation of intoxicating liquors' was prohibited throughout the country. The passage of the 18th Amendment crowned a movement going back to the early 19th century.

Beginning with local, voluntary organizations concerned to foster temperance in a hard-drinking country, the movement then undertook to pass restrictive legislation on a local or state basis (Maine went 'dry' in 1851). As the movement increased in vigour and confidence, total prohibition of alcohol consumption rather than temperance became the object. By the last quarter of the 19th century, the aim was to secure a complete national prohibition by means of a constitutional amendment. The work of propaganda to this end was in the hands of organized reformers, especially the Woman's Christian Temperance Union (1874) and the Anti-Saloon League (1895); they had the support of many Protestant churches, especially in the South and Midwest. By the time the 18th Amendment was passed, 33 of the then 48 states were already dry.

The working out of the amendment was provided for by the National Prohibition Act (October 1919), usually called the Volstead Act: it defined 'intoxicating liquor' as anything containing at least 0.5% alcohol, so extinguishing the hope that wine and BEER might escape under a less stern definition. Some uses of wine were, however, allowed under the act: it could be used in religious ceremonies; it could be prescribed as medicine; and it could be used as a food flavouring or in other 'non-beverage' applications. All of these provisions could be and were greatly abused, and the act had to be amended and supplemented as experience showed the problems of enforcement.

The popular conception of Prohibition is that speakeasies abounded, gangsters and bootleggers of all sorts flourished, and

every American gladly flouted the law. The reality is harder to determine, but there can be no question that the consequences for the American wine industry were disastrous. A number of American wineries, by obtaining licences to manufacture wine for the permitted uses, managed to continue a restricted operation (the apparent needs of communicants, for example, soared during this period). Effectively, however, the industry was wrecked. In 1919 the official production of wine in the US was 55 million gal/2 million hl; by 1925 it had sunk to just over 3.5 million gal. Winemakers received no compensation. Most wineries simply went out of business and their establishments were broken up.

The Volstead Act permitted the heads of households to manufacture up to 200 gal/7 hl of fruit juice annually; by a benevolent inconsistency, this provision was construed to allow HOME WINEMAKING. In consequence, vineyard acreage in CALIFORNIA shot up to unprecedented size to meet the national demand for fresh grapes: the 300,000 acres/121,000 ha of vineyard in 1919 had nearly doubled by 1926. Most of the new planting was in very inferior grape varieties, however (THOMPSON SEEDLESS and ALICANTE BOUSCHET, for example), and the degradation of the California vineyards thus induced by the conditions of Prohibition had seriously damaging effects on California wine long after Repeal. Nor can the quality of the average home-made wine have done much to enhance national CONNOISSEURSHIP.

The first efforts of the opponents of Prohibition were to achieve 'modification' of the terms of the Volstead Act. They tried for example to alter the definition of 'intoxicating liquor' or to allow individual states to make regulations different from those of the act. These efforts got nowhere; in consequence, the 'Wets' concentrated on achieving Repeal by constitutional amendment. Aided by the economic collapse of 1929 (invalidating the argument that Prohibition was economically sound) and by the adoption of Repeal as a political question (the Democratic party made Repeal a plank in its platform for the 1932 elections), the Repeal movement succeeded: in December 1933 the 21st amendment, repealing the 18th, was

ratified. Unfortunately, the amendment left to the separate states the entire regulation of the 'liquor traffic' within their borders, with the result that US liquor laws—including local and state prohibition—remain a crazy quilt of inconsistent and arbitrary rules, another lastingly destructive effect of national prohibition.

The forces that achieved prohibition in the US remain potent and protean. National prohibition in the simple terms of the 18th amendment is not likely to come again; but liquor—wine very much included—continues to be an object of punitive taxation, of moral disapproval in some quarters, and of obstructive legislation in the United States today. See UNITED STATES for more details. T.P.

Sinclair, A., *Prohibition: The Era of Excess* (1962).

Prokupac, old red grape variety being revived in many regions of SERBIA, where the medium-bodied wines it produces are red-fruited and have the TANNIN structure to suit oak and to age for up to a decade. Its stronghold is Župa south of Belgrade, but elegant versions are now appearing in Šumadija and Tri Morave. It may be blended with INTERNATIONAL VARIETIES or used to produce dark rosé. It is also grown in Kosovo (as Prokupë) and North Macedonia (Prokupec).

proles, three categories of VINE VARIETIES of the VITIS VINIFERA species, grouped according to their geographical origin and, to some extent, their common end use (see BOTANICAL CLASSIFICATION). The classification is the work of Russian ampelographer Negrul in 1946. The differences between these groups may not only be a matter of response to environment but also be partly due to human selection for particular features related to end use, such as berry size for TABLE GRAPES. Detailed observation of vine characteristics can reveal

particularly close relationships which indicate that they are likely to have come from the same area. Thus are linked, for example, the CABERNET SAUVIGNON, CABERNET FRANC, MERLOT, PETIT VERDOT, and FER varieties.

Proles occidentalis: varieties native to western Europe, which were selected mostly for winemaking use. Most of the important wine grape varieties are in this group—RIESLING, CHARDONNAY, Cabernet Sauvignon, and so on—and they have common features of small bunches with small, juicy berries.

Proles pontica: the oldest varieties, and those native to the Aegean and Black Seas, which have shoot tips and leaf undersurfaces covered with dense white hairs. Examples of varieties in this group are CLAIRETTE, FURMINT, HÁRSLEVELŰ, and Zante CURRANT.

Proles orientalis: varieties originating in the Middle East, Iran, and Afghanistan. These varieties were selected mainly for TABLE GRAPES and so tend to have large, oval berries in loose, straggly bunches. The berries are often crisp, with less juice and sugar. This group of vines includes most varieties for RAISINS as well as most table grape varieties, such as SULTANA and MUSCAT OF ALEXANDRIA. R.E.S. & J.V.

Negrul, A. M., 'Origin and classification of cultured grape', in A. Baranov et al. (eds.), *The Ampelography of the USSR* (1946), 159–216.

propagation, the reproduction of a plant, whether by sexual or asexual means. Sexual propagation means reproduction by seed and involves the combination of two separate sets of chromosomes, one from the male (POLLEN) and the other from the female (the egg cell inside the ovule); their fusion during fertilization produces an individual with a set of genes different from its two parents. Asexual or vegetative propagation means reproduction without seed, by taking vegetative bits of the parent plant and getting them to form SHOOTS and ROOTS; the progeny are genetically identical to the parent unless MUTATIONS produce distinct CLONES.

For details of micropropagation, see TISSUE CULTURE. For more details of specific propagation methods, see SEXUAL PROPAGATION and VEGETATIVE PROPAGATION. See also LAYERING. B.G.C. & J.V.

Prosecco, extremely popular sparkling wine made in north-east Italy. Italy's largest DOC by far, the Prosecco zone extends from the city of Vicenza in the VENETO to Trieste in FRIULI Venezia Giulia and comprises around 34,000 ha/84,015 acres. Extraordinarily high permitted yields of 18 tonnes/ha produced more than 486 million bottles of light sparkling white wine in 2019 made by the tank method (see SPARKLING WINEMAKING). As suggested by its extent, the DOC was once an IGT. To ensure that no one outside the region was able to jump on the Prosecco bandwagon, the eponymous grape variety on which the wine is based was renamed GLERA in 2009, and Prosecco was registered as a protected denomination of origin (DOC). This was enabled by enlarging the region to include the village of Prosecco in Friuli, which triggered a frenzy of plantings, mostly on plains.

The classic production zone was already considerable, with over 8,446 ha/20,870 acres in the hills between the towns of Conegliano and Valdobbiadene, an area now elevated to DOCG Conegliano-Valdobbiadene. Although most of these DOCG vineyards are on hills and TERRACES at 50–500 m/164–1,640 ft in ELEVATION, the high YIELDS can result in rather neutral wines whose apparent fruitiness owes much to the DOSAGE. Although dry versions exist, more common are Extra Dry (with RESIDUAL SUGAR of 12–17 g/l) and Dry (17–32 g/l). Allowed additions of up to 15% of INTERNATIONAL VARIETIES such as Chardonnay, Pinot Bianco, and Pinot Grigio can help to increase alcohol and flavour. Prosecco Rosato, containing up to 15% Pinot Noir, is allowed as of 2020.

Superior wines are said to come from the CRU of Cartizze, its 107 ha/264 acres on steep hills of San Pietro di Barbozza, Santo Stefano, and Saccol in the commune of Valdobbiadene where yields are not

markedly lower but the grapes are generally much riper than most. Most Cartizze wines are Extra Dry.

Ambitiously, the Conegliano-Valdobbiadene DOCG has introduced a system of crus, 43 communes or hamlets (called locally *rive*) whose names may be mentioned on the label if yields are below 12 tonnes/ha, although little expression of origin has so far been evident.

Prosecco col fondo, labeled as *sui lieviti* (on the LEES) now that the Col Fondo name has been trademarked by an industrial-sized producer, can offer more interest. Initially made by small-scale producers—often espousing ORGANIC techniques and, besides Glera, favouring other INDIGENOUS VARIETIES such as Verdiso, Bianchetta, and Pepera in the final blend—these wines are bottle-fermented, left on the lees for at least 90 days, and bottled undisgorged (see PÉTILLANT NATUREL). They are released with the original crowncap and with a sediment at the bottom of the bottle (*col fondo* means 'with sediment'). These wines are bone-dry, somehow mineral in character, and, unlike most Prosecco, worth AGEING for a year or two. Conventional Prosecco producers have begun to experiment with this style, not least because it is more profitable than most Prosecco.

The DOCG Asolo Prosecco (previously Colli Asolani Prosecco), from a hilly outcrop on a plain south-east of Treviso, is similar to Conegliano-Valdobbiadene's vineyard area and structure, only its maximum permitted yields of 12 tonnes/ha are markedly lower.

Protected Designation of Origin. See PDO.

Protected Geographical Indication. See PGI.

protected viticulture, a form of vine-growing where the vines are protected from climatological excesses to avoid stress. In a conventional agricultural sense, this would involve protection from low temperatures using glass or plastic houses or cloches; such structures are rare in commercial wine grape vineyards because of the prohibitive costs, although they can be seen in the cool climate of ENGLAND or very occasionally in cooler parts of California to protect some Chardonnay vines from poor FRUIT SET. Protected viticulture is more usual for TABLE GRAPES, as in northern Europe, Japan, and New Zealand.

Vines may also be protected from the wind by WINDBREAKS, from frost by various techniques (see FROST PROTECTION), and from drought by IRRIGATION. R.E.S.

protective juice handling, grape- and MUST-processing techniques with the aim of minimizing exposure to OXYGEN and therefore the risk of OXIDATION. This is regarded as especially important for white wines since, once grapes are crushed and juice liberated from the berry, the PHENOLICS react rapidly with oxygen to produce amber to dark-brown polymers (see POLYMERIZATION), which can in turn react with THIOLS and GLUTATHIONE, with a consequent loss of aroma and greater risk of oxidation. Some ordinary wines are made encouraging this oxidation, the brown pigments being removed subsequently by FINING. Most better-quality white wines result from minimal oxygen exposure, saving the phenolics for later contribution to AROMA and BODY. Some ambitious winemakers experimented with deliberate pre-fermentation oxidation of the must in the early 1980s, but this is uncommon today even if some winemakers in Burgundy, for example, choose not to protect their Chardonnay must from oxidation. The introduction of tank PRESSES has aided protective juice handling during the lengthy PRESSING operation enormously, as has

the judicious use of SULFUR DIOXIDE in musts and the use of INERT GAS. Grapes for red wines are far less vulnerable to damage from oxygen since they contain much greater concentrations of TANNINS and PIGMENTS.

See also SKIN CONTACT. V.L.

protective winemaking, winemaking philosophy founded on the need to minimize exposure to OXYGEN and concomitant risk of OXIDATION. It is less popular than it was at the end of the 20th century because, while most winemakers understand the need to limit oxidation, they are also aware of the potential risk of REDUCTION in wines that have been made too protectively. Nevertheless, this philosophy is still adhered to for many large-volume commercial white wines. It usually incorporates PROTECTIVE JUICE HANDLING. White wines are then fermented in closed-top tanks to exclude oxygen as much as possible while allowing for the escape of CARBON DIOXIDE from fermentation. All subsequent operations are then conducted as far as possible in closed equipment, and small amounts of SULFUR DIOXIDE are added if exposure to oxygen occurs. Storage and processing at low temperatures favours the retention of some of the carbon dioxide, which has the effect of sweeping out any accidentally dissolved oxygen. Red wines, because of their greater PHENOLIC content, are much less sensitive to exposure to oxygen. Indeed, if they undergo BARREL AGEING, some exposure to oxygen during TOPPING UP contributes to the wine's maturation. V.L.

proteins, very large polymers of the 20 natural AMINO ACIDS. Proteins are essential to all living beings.

In grapes

Proteins may function as ENZYMES, or as structural components of cells. While all functions are important, the enzymatic properties of proteins are the basis of all reactions within living systems.

In wines

Proteins from the grape remain in solution in all white wines, but in some (notably those vinified from MUSCAT, GEWÜRZTRAMINER, SAUVIGNON BLANC, and SÉMILLON grapes) the concentration is often so high that the proteins coagulate to form an unsightly haze or cloud. Such haziness, which can be initiated when the wine is warmed, is irreversible. To avoid this happening after bottling, which renders the wine unstable, the heat-unstable proteins are removed by BENTONITE fining as part of normal winemaking STABILIZATION procedures. Research has shown that the troublesome, heat-unstable proteins of white wines belong to a particular group from the grape known as pathogenesis-related or PR proteins. The unique properties of PR proteins—their stability in acid conditions and resistance to degradation by proteolytic ENZYMES—means that fermentation and the other processes of winemaking selectively eliminate other proteins of the grape leaving the PR proteins as virtually the sole survivors.

The greater concentration of PHENOLICS in red wines means that much of the protein is removed in the LEES as an insoluble tannin–protein complex. See also PRECIPITATES and BOTTLE DEPOSIT.

D.D. & V.L.

Waters, E. J., et al., 'Preventing protein haze in bottled wine', *Australian Journal of Grape and Wine Research*, 11/2 (2005), 215–25.

provenance, details of a wine's previous owner(s) and, ideally, storage conditions (see STORING WINE) that have become increasingly important in the FINE WINE market. Gone are the days when 'Property of an English Gentleman' would suffice as an AUCTION catalogue description, effectively implying that the source of the wine in question was beyond reproach. A number of factors have combined to bring provenance centre stage in the buyer's increasing need for a copper-bottomed guarantee of origin.

The growth of the ASIAN market has seen a new kind of collector, both more knowledgeable and more wary than many, keen to ensure as impeccable a source of origin and storage for his or her wines as possible. At the same time, the huge increase in wine PRICES in recent years has generated a parasitic underworld of COUNTERFEITERS, fraudsters, forgers, and confidence tricksters keen to cash in on the bounty that a bottle of expensive fine wine (traded more often than opened) can bring. Budd tries to expose those he encounters from his UK base.

Most auction houses and BROKERS have responded to this growing demand for transparent provenance and optimum storage conditions by sharpening up their inspection and AUTHENTICATION procedures, scrutinizing BOTTLES, CORKS, LABELS, and CAPSULES with greater care and rejecting wines of dubious origin or condition. Some, however, have failed to see the warning signs or, worse, turned a blind eye.

The need for provenance and a history of optimum storage conditions and good-quality transportation goes beyond the auction room and back to the producer. Many now realize that taking measures to ensure traceability and authentication is a key part of protecting their BRAND. Despite this growing awareness, the relevant proofs are often neither required nor given.

RFID (Radio Frequency Identification) temperature sensor technology has been used to monitor wine-shipment temperatures across distribution channels. The RFID chip can be linked to a sequential serial number and a randomly generated number for authentication purposes. It tends to be on the wine case, although some producers have added a temperature sensor to the bottle itself.

One of the upshots of the demand for impeccable provenance has been the growing number of sales direct from a single owner or producer (see AUCTIONS). A.H.L.R.

Provence, region with considerable potential in the far south-east of France (see map under FRANCE) whose associations with TOURISM and hedonism have perhaps focused too much attention on its relatively expensive rosés.

The precise period during which viticulture was introduced to the region is disputed. Certainly it appears unlikely that the Phocaeans, Greeks from Asia Minor, encountered vines when they founded Massilia (Marseilles) in about 600 BCE. It is likely, however, that the Provincia of ancient GAUL produced its own wines under the influence of classical ROME (although it is not certain that it preceded Narbo, or Narbonne, in the LANGUEDOC as a wine producer). See FRANCE for more details.

The region was much fought over, being under the influence in successive eras of the Saracens, the Carolingians (see CHARLEMAGNE), the Holy Roman Empire, the counts of Toulouse, the Catalans, René of ANJOU, and the House of Savoy. At the end of the 19th century, Provençal viticulture was nearly killed by PHYLLOXERA and struggled into the 1930s, with vineyards near to the coast and RAILWAY recovering more quickly.

As a result of its rich cultural heritage, Provence enjoys a distinctive range of vine varieties which show various historical influences from Italy, notably Sardinia. While Grenache is by far the region's most planted variety, followed by Cinsaut and Syrah, another ten varieties are allowed in Côtes de Provence, including particularly Mourvèdre and TIBOUREN, although the indigenous dark-berried Calitor (known in Provençal as Pécoui Touar) and Barbaroux are being phased out. Historic varieties such as Rousseli, foreign varieties such as XINOMAVRO, ASSYRTIKO, and NIELLUCCIU, and new CROSSES such as

Vidoc and Artaban are also being considered to deal with CLIMATE CHANGE.

The climate here is France's most MEDITERRANEAN, with an average of 3,000 hours of sunshine a year and with less than 700 mm/27 in annual RAINFALL, which is concentrated in spring and autumn. Winters are mild but usually allow full vine DORMANCY. The greatest climatological threat is WIND, in particular the famous mistral, a cold wind from the north. Proximity to the sea and careful vineyard siting on south-facing slopes can offer some protection. It has the advantage of minimizing the risk of FUNGAL DISEASES, and Provence is particularly suitable for ORGANIC VITICULTURE.

The magic attached to such names as the Côte d'Azur, St-Tropez, and Provence in general may have increased urban development and pushed up land prices in habitable parts of the region, but it has also attracted outsiders prepared to make significant investments in vine-growing and winemaking, thereby raising standards overall.

Côtes de Provence

At 20,100 ha/51,892 acres of vineyard, this is by far the most significant appellation in Provence, although the sites vary enormously. The AOC applies to a large part of the Var *département* (other than the enclave entitled to the Coteaux VAROIS-EN-PROVENCE appellation) from the sub-Alpine hills above Draguignan, cooled by the influence of the mountains to the north, to the coast at St-Tropez, the epitome of a Mediterranean wine zone. But it also includes pockets of hotter terrain between CASSIS and BANDOL, as well as land immediately south and east of the PALETTE appellation near Aix-en-Provence. The appellation even encompasses a tiny, isolated area of vines at Villars-sur-Var high up in the mountains 50 km/30 miles north of Nice in the Alpes-Maritimes *département*.

About four-fifths of production is of pale pink dry rosé, which seems to find a growing local and export market almost regardless of quality. There is renewed interest in producing 'serious' rosé, however, with a distinctive style combining flavour with a fashionably pale hue (see STABULATION), and many producers even use a limited amount of OAK AGEING. The best really do seem to have a special affinity with the garlic- and oil-based cuisine of Provence, particularly *aïoli*.

Most rosé is based on Cinsaut and Grenache, leaving old-vine Carignan, Syrah, Mourvèdre, and sometimes TIBOUREN for the reds, which now constitute just 10% of production. As Tibouren can add real interest to a blend, the variety is experiencing a revival. White grapes may constitute 20% of rosé blends.

An increasing number of producers, especially in the coastal sector, are paying close attention to white wines, which may be made from various permutations of Clairette, Sémillon, Ugni Blanc, and Vermentino (known locally as Rolle), albeit in much smaller volumes than rosés. Many of the technical innovations brought about by ROSÉ WINEMAKING have been applied to white-wine production as well.

Within the Côtes de Provence appellation, there are subregions called DÉNOMINATIONS GÉOGRAPHIQUES COMPLÉMENTAIRES created to emphasize the regional character of individual zones. In 2022 there were five, applicable to reds and rosés: Fréjus, La Londe, Notre-Dame des Anges, Pierrefeu, and Ste-Victoire. La Londe, a strip of seaside vineyards south-west of the Maures, also allows for VERMENTINO-based white wines.

See also the Provence AOCs of Coteaux d'AIX-EN-PROVENCE, BANDOL, LES BAUX DE PROVENCE, BELLET, CASSIS, PALETTE, and Coteaux VAROIS-EN-PROVENCE. E.A.G.

syndicat-cotesdeprovence.com

proximal sensing is the measurement of attributes of the soil, vine CANOPY, or fruit using sensors mounted on vehicles or vineyard machinery operating in the vineyard (i.e. the sensor is operated close to the target of interest; cf. REMOTE SENSING). Handheld sensors may also be used, especially in support of ZONAL VITICULTURE if zones have already been otherwise established, but are unlikely to be cost-effective if the intention is to collect sufficient data to produce a map.

Proximal soil sensing is a common application in PRECISION VITICULTURE and provides key data input to zonal viticulture. Electromagnetic induction (EMI) is the most common form of proximal soil sensing and is used to identify variation in soil properties which affect the electrical conductivity of the soil (SALINITY, SOIL TEXTURE, SOIL WATER status) or which are correlated with them. Research has shown that patterns of variation in vine performance often closely mimic patterns of variation in these soil attributes. A possible alternative to EMI sensing is to use electrical resistance tomography (ERT) to measure resistivity. Since resistivity is the inverse of conductivity, the information provided by these two types of sensors is essentially the same. However, the requirement for contact with the soil in the case of ERT, coupled with the much larger

size of sensor, tends to make them a poor option in established vineyards or where the soil is stony; EMI instruments are generally smaller and do not require contact with the soil.

Proximal canopy sensing is being used increasingly to provide essentially the same PLANT CELL DENSITY and NORMALIZED DIFFERENCE VEGETATION INDEX information as is obtained by remote sensing, but it has the advantage of timeliness, especially when CANOPY changes within the season are of interest, although timeliness is also an attribute of data collected by DRONES. One variation on this theme gaining increasing interest is the use of thermal sensors, which, by sensing canopy temperature, can provide useful input to IRRIGATION scheduling through the detection of WATER STRESS. Another is the use of various forms of digital camera coupled with sophisticated image analysis as tools to improve the accuracy of YIELD estimation, especially early in the season, through the assessment of bunch, berry, and flower number. Such information may promote an accurate yield estimate early enough in the season for it to inform management decisions—whether in the vineyard (e.g. CROP THINNING), at the winery (e.g. installation of additional tanks), or in the marketing or supply-logistics departments.

New proximal sensors for the measurement of fruit attributes related to GRAPE COMPOSITION AND WINE QUALITY are being developed. The ability to use such sensors on the go during harvest is of key interest in precision viticulture, especially to support strategies such as SELECTIVE HARVESTING. R.G.V.B.

Bramley, R. G. V., 'Precision viticulture: managing vineyard variability for improved quality outcomes', in A. G. Reynolds (ed.), *Managing Wine Quality 1: Viticulture and Wine Quality* (2nd edn, 2021), 541–75.

Computers and Electronics in Agriculture, 173 (2020), 105360.

Prugnolo Gentile, synonym for SANGIOVESE in VINO NOBILE DI MONTEPULCIANO.

pruners, devices used for winter PRUNING of grapevines. A pruning hook or knife was used from ancient times until the development of handheld SECATEURS in the mid 19th century, coming into widespread use in the latter half of the century. Secateurs cut with a scissor action, and there are various forms available (including power-assisted versions). Sometimes pruning saws may be needed to remove old CORDONS or ARMS. Vineyard winter pruning is now being mechanized with tractor-mounted machines doing most of the cutting, as described in MECHANICAL PRUNING. R.E.S.

pruning of vines involves cutting off unwanted vegetative parts, typically in the form of CANES in winter. For details of cutting off unwanted vegetative growth in the form of excess SHOOTS in early spring and shoot tips in summer, see SHOOT THINNING and TRIMMING respectively.

Pruning is a vineyard practice developed primarily to produce fewer but larger bunches of riper grapes and is particularly important in cooler climates. More than 85% of a growing season's shoot growth may be removed at winter pruning. There is an important relationship between vine pruning and VINE TRAINING, as the pruning method used depends on the training system employed.

Vines growing in their natural state, as in the WILD VINES of America and the Middle East, are not pruned. At the top of such vines, which are many-branched and often grow up trees, and on other parts of the vine exposed to the sun are many small bunches of grapes. While the vine may have had thousands of buds present in winter which could have produced shoots and fruit, only a small proportion—the highest buds and those near the end of the canes—

will burst in spring. This reduced BUDBREAK is the principal means by which unpruned vines in their natural state avoid OVERCROPPING, which may weaken the vine and shorten its life. (See APICAL DOMINANCE.)

History

It is not known when people began to prune vines, but vine pruning was certainly known in ancient EGYPT and was already well established by the beginning of the Roman era, described in detail by such writers as PLINY and VIRGIL. There are also numerous references to vine pruning in the BIBLE. For example, 'a Sabbath of rest unto the land, a Sabbath for the Lord: thou shalt neither sow thy field, nor prune thy vineyard' (Lev. 25. 4). Vine pruning also figures in the description of the Last Days (Mic. 4. 3): 'and they shall beat their swords into ploughshares, and their spears into pruning hooks'.

Aims of pruning

Among the early aims of vine pruning as practised by the ancient Egyptians would have been to increase the size of individual berries and bunches, an important consideration even today in the production of TABLE GRAPES. A vine which is lightly pruned has many buds and will produce numerous shoots and bunches with smaller berries.

Another aim of vine pruning is to establish or maintain the shape of the vine, which makes all other vineyard operations easier. For example, keeping vines pruned back to a more or less constant structure means they can easily be neatly trained and maintained in rows. Otherwise, vines would sprawl and quickly cover the space between rows.

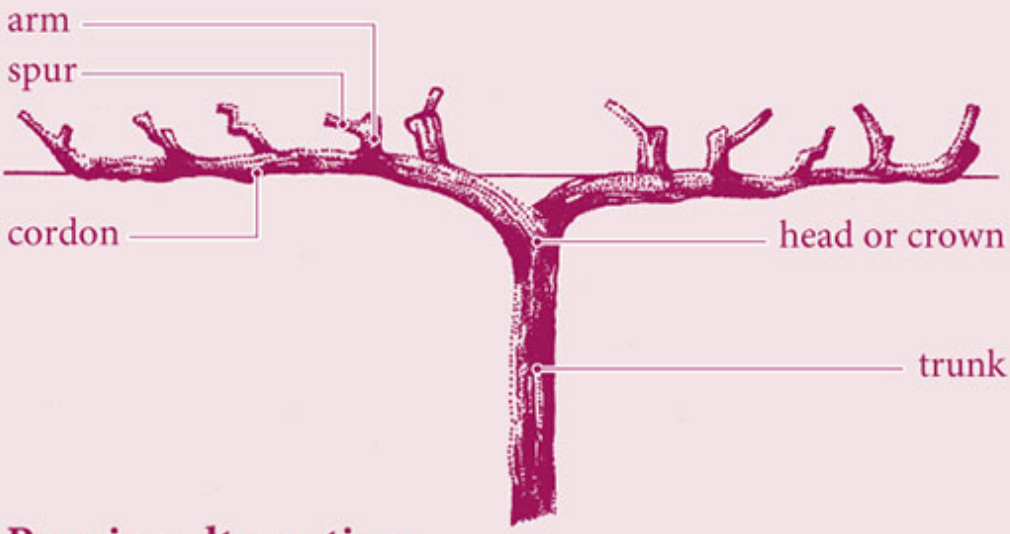
But perhaps the most important aspect of pruning is that it regulates the next season's YIELD by controlling the number of buds which can burst and produce bunches of grapes. The number of buds retained after winter pruning may be influenced by TRADITION, local CONTROLLED APPELLATION regulations, the scientific principles behind BALANCED PRUNING, or chance, as in MECHANICAL PRUNING.

Timing

Pruning is carried out in winter, normally once the first frost causes the leaves to fall, thereby exposing the woody canes. Although the precise timing is not generally critical, it is usually completed by the time of budbreak in spring, ideally before the stage when vines will lose water (see BLEEDING) from pruning wounds (just prior to budbreak). Some early-budding varieties may be pruned very late in an effort to delay budbreak and minimize FROST DAMAGE. As CLIMATE CHANGE brings HARVEST dates forward from the cooler autumn to the hotter conditions of late summer (sometimes referred to as HARVEST COMPRESSION), delayed pruning, sometimes even after budbreak, can help to delay ripening and harvest, but typically by only one or two weeks. (See also DOUBLE PRUNING.) In regions with warm winters, such as tropical and subtropical regions, the vines may not become completely dormant, and vines may have to be pruned when they are covered in leaves. See also TROPICAL VITICULTURE.

Head-trained vine with cane pruning

Bilateral cordon trained vine with spur pruning



Pruning alternatives

Source: B. G. Coombe and P. R. Dry (eds.), *Viticulture, ii: Practices*

Two basic options

The fundamental principles of pruning have changed remarkably little since classical times, although the French viticulturist GUYOT in 1860 introduced firm suggestions as to the length and position of canes, formalizing some of the old ideas.

Along the woody canes—which were green, soft shoots during the previous growing season—are buds which are arranged on alternate sides of the cane about 8 cm/3 in or so apart. Basically there are two types of vine pruning: either to SPURS, or to CANES.

Spur pruning Spurs are cut to retain only two buds, while canes are longer, typically with five to 15 buds. In the spring, each bud on the two-bud spur normally produces one shoot, although up to three is possible. In autumn, these shoots become woody canes. During winter pruning the cane growing from the uppermost bud on the spur is removed, and the cane from the bottom bud is cut back to two buds, creating the new spur. The vine's physiology determines that, when a cane is cut, the last two buds will burst. This is the reason for the common two-bud spur. If spurs were left with three buds, the bottom bud would often not produce a shoot, and so the spur position would move further and further from the cordon or head as the years passed.

Spur pruning is commonly used with free-standing GOBELET-trained vines. The spurs arise from the trunk or from short arms on the trunk, requiring no supporting POSTS or WIRE; spur pruning is therefore among the oldest forms prevailing and was already known to the Roman writers COLUMELLA and PALLADIUS. This method is common in the Languedoc and Roussillon and in the lower-rainfall areas of Spain, Italy, and Portugal, such vineyards being of lower VIGOUR, to which the system is best suited. Some of the older vineyards in California, Australia, and South Africa, for example, also have such vines, often described as head-trained or bush vines.

Another spur-pruned form which is more common with higher-vigour vineyards is cordon training for trellised vines. Here the spurs arise from one or more horizontal arms or CORDONS, which are trained along a wire. Known in France as CORDON DE ROYAT, this pruning method has been used for wine grapes since the end of the 19th century. Of all pruning methods, this one lends itself most readily to MECHANICAL PRUNING since all of the canes to be pruned are more or less in the one plane.

Cane pruning Cane pruning became common after the 1860 studies of the Frenchman Dr Guyot. In traditional French vineyards each vine is typically pruned to one cane with six to eight buds and one spur with two buds. During winter pruning, the cane from the previous year is cut off and a new one laid down, using one of the canes arising from the spur. The number of buds on the cane depends on regional tradition and the small print of the AOC laws. For example, eight buds may be left on Syrah canes in the Côtes du Rhône; eight on all major varieties in Burgundy; in Bordeaux seven buds is the maximum for Sémillon in Sauternes but six for Muscadelle. These small bud numbers per cane (and hence shorter canes) contrast greatly with those used for wine grapes in other regions where vine vigour is higher. For example, in vigorous irrigated vineyards in Australia it is not uncommon to see up to six canes, each with up to 15 buds, left on a single vine after winter pruning. These vines are planted further apart than their Old World counterparts, as discussed in NEW WORLD.

A common observation with cane pruning is that buds in the middle of the cane often do not burst. There are often a few shoots growing near the head of the vine (at the base of the cane), and the last two shoots at the cut end of the cane will invariably grow. See APICAL DOMINANCE. Where the cane was growing in shade the previous year the budburst is invariably poor, as outlined in CANOPY MICROCLIMATE.

In France the colloquial name for canes varies regionally: *courgée* in the Jura, for example, but *aste* in Bordeaux, *baguette* in Burgundy, *archet* or *archelot* in Beaujolais.

Controlling yield

A fundamental question in relation to vine pruning is how many buds to leave on each vine at winter pruning. Does it matter? For some vignerons this first question is never posed, as TRADITION or CONTROLLED APPELLATION laws dictate how the vines are to be pruned, and traditional practices are vigorously defended against any suggestion of change despite scientifically verified alternatives to fixed bud numbers. The winter-pruning period can be a time when the mind is put into neutral and the body is braced to survive long days spent outdoors, often in unpleasant, cold, wet weather.

When vines are pruned to just a few buds, most of them burst successfully, and the emerging shoots will typically grow vigorously. They will be very long, with large leaves, and produce many LATERAL SHOOTS. Early shoot growth is stimulated by the vine's food reserves in the trunk and roots being spread around only a few shoots. As more buds burst per vine, so the amount of food reserves available per shoot decreases. Therefore, a low-vigour vine which has limited reserves of CARBOHYDRATES must be pruned to few buds only compared with one of higher vigour which contains more reserves.

A vine that is very lightly pruned, to scores or even hundreds of buds, will produce many more shoots and bunches of grapes. Individual shoots will be shorter, and the number and size of berries will be reduced. However, the total yield of grapes will typically be greater, and the grapes will take longer to ripen. This may cause no problems in warm and sunny climates but can be disastrous in cooler climates, where it can be a struggle to ripen the grapes anyway before autumn chill and frosts stop the ripening process.

There is therefore more concern about pruning levels in cooler climates than in warmer ones. In Germany, for example, the common rule is to leave about ten buds at winter pruning for each square metre of vineyard land surface. In New York State, Professor Nelson SHAULIS developed balanced-pruning guidelines which rely on the vine's growth as assessed by PRUNING WEIGHT (the weight of annual

growth as canes removed at pruning); about 35 buds should be retained per kg of pruning weight. Having weighed a few vines, growers can assess the pruning weight by eye as part of their pruning decisions. For more vigorous vines with higher pruning weights, more buds are retained.

For high-vigour vineyards it may not be sufficient just to prune lightly, as this will lead to crowding of shoots in the vine CANOPY. Recognition of this problem has led to the development of CANOPY MANAGEMENT strategies to avoid dense canopies for vigorous vineyards. Similarly, yield cannot be limited by pruning high-vigour vineyards to just a few buds. The yield will still be considerable, and berries will be large, considered undesirable for wine quality (see BERRY SIZE). Bunches will be tight, increasing the risk of BUNCH ROT, and there will be considerable shoot and leaf growth, which is likely to result in SHADE rather than vine BALANCE.

Mechanization

Winter pruning is one of the most labour-intensive aspects of vine growing, along with hand-harvesting. During the 1960s and 1970s, increases in LABOUR costs and reductions in labour supply in Australia led to experimentation with and eventual development of MECHANICAL PRUNING. This in turn has led to the even more iconoclastic option of MINIMAL PRUNING, or not pruning at all, although the latter is now viewed with increasing disfavour.

By the 21st century, a full spectrum of vine-pruning practice was evident around the world, from the hand-pruning of a lower-vigour vine in a traditional vineyard to less than 10 buds; to one essentially unpruned following the passage of a machine, with hundreds of buds remaining; to mechanical pruning using a tractor-mounted circular saw.

The time taken to prune a vineyard depends on how the vineyard is trained, the VINE DENSITY, and the pruning method. Pruning times can be up to 200 hours or more per ha for high-density cane-pruned vineyards. For wide-row, spur-pruned vineyards trained to cordons, the figure may be as low as 50 hours per ha, and in combination with mechanical pre-pruning this may be reduced even further to less than 10 hours per ha.

Pruning and vine health

TRUNK DISEASES which invade pruning wounds, especially during wet weather, are an increasing concern worldwide. Pruning systems such as cane pruning, which involve fewer wounds per vine than spur pruning and far fewer than mechanical pruning, are preferred, although, since the cane and spur originate in the head, diseases can travel down the trunk and be more destructive. Care must be taken to treat pruning wounds, most commonly with a FUNGICIDE or with natural antifungal products, for example antagonistic fungi such as *Trichoderma*, garlic extract or vanillin. Australian research has led to the widespread use of a range of fungicide products, but in wine regions such as Bordeaux pruning-wound protection is rare, leading to high levels of infection in older vineyards.

Marco Simonit of Italy promotes a modification to the Guyot and other systems which encourages the maintenance of sap flow in the vine, thereby avoiding the potentially damaging effects of pruning wounds and increasing vine longevity. This method, based on studies by Lafon in the Charentes, France, published in 1921 (see POUSSARD), has won fervent admirers around the world despite scepticism in some quarters. R.E.S.

pruning machines. See MECHANICAL PRUNING.

pruning weight, a measure of vine VIGOUR, or, more strictly, capacity, obtained by weighing the canes removed from a vine at winter PRUNING. This is the most useful and common measure of vine growth during the previous growing season. The value may be used, for example, to assess how many buds might be retained at winter pruning to achieve the best vine performance (see BALANCED PRUNING). Similarly, the ratio between the weight of prunings and the fruit produced is a good indication of BALANCE. R.E.S.

Puente Alto , part of the MAIPO subregion of the Central Valley of CHILE, at the foot of the Andes in what is known as Alto Maipo, where ALLUVIAL soils and mountain breezes produce some of Chile's classic Cabernet Sauvignon wines, including Almaviva, Don Melchor, and Viñedo Chadwick. P.T.

Puerto de Santa María, one of the three main towns making and maturing SHERRY.

Puglia, known by English speakers as Apulia, the long (350 km/210 mile) and fertile region on the 'heel' of Italy (see map under ITALY) which has long been of major importance for the production of wine and TABLE GRAPES. A MEDITERRANEAN CLIMATE and a predominance of soils well suited to grape-growing (a CALCAREOUS base from the Cretaceous era overlain by topsoils rich in iron oxide from the Tertiary and Quaternary eras) have created an ideal viticultural environment. Its name derives from the Roman *a-pluvia* or 'lack of rain'.

With 9 million hl/237.75 million gal of wine produced in 2020, Puglia is Italy's second most productive wine region, after Veneto. Many growers have taken subsidies from the EU to grub up their vineyards, but unfortunately many of these were of low-yielding BUSH

VINES, while many of the 89,991 ha/222,372 acres of vines remaining in 2020 are high-cropping inferior varieties planted on fertile soils.

While much of Puglia's viticulture is still focused on BULK WINE, the abolition of compulsory DISTILLATION to drain the EU wine lake has forced producers to adopt a more market-oriented approach. Cue INTERNATIONAL VARIETIES, especially Chardonnay and Pinot Grigio, both unremarkable, the first also explicitly allowed in several of Puglia's 32 DOCs and DOCGs, while the majority is sold in bulk to large bottlers in the north to satisfy international supermarket demand.

Puglia's propensity for bulk wine production combined with excessively high YIELDS even at DOC level has tended to overshadow its unique wine styles based on INDIGENOUS VARIETIES. While grape-growers, as opposed to wine producers, are the norm here, with CO-OPERATIVES responsible for most winemaking, many have begun to bottle at least part of their production. Few of these first-timers have knowledge of or formal training in winemaking, which explains what is often very modest quality, although improvements are noticeable.

However, a growing international demand for indigenous varieties provides a commercial impulse; although the region's production of DOC wine is still tiny, a proper framework already exists to accommodate Puglia's most important terroirs and varieties. An overarching IGT Puglia comprises, from north to south, five regional IGTs—Daunia, Murgia, Valle d'Itria, Tarantino, and Salento—each divided into smaller DOCs.

The most important of its 28 DOCSs in 2022 are Cacc'e e Mmitte di Lucero for NERO DI TROIA-based red wine in the region of Daunia; Castel del Monte for full-bodied reds mainly from Nero di Troia but also AGLIANICO and Moscato di Trani for sweet wines in the central plateau of Alta Murgia; Gioia del Colle for deep reds with tangy acidity from PRIMITIVO and Locorotondo for white wines of VERDECA and Bianco d'Alessano on the lower-lying Bassa Murgia and Valle d'Itria; Primitivo di Manduria in Magna Grecia, north-west of Taranto; and Salice Salentino and neighbouring Copertino in the narrow Salento peninsula, where NEGROAMARO, grown on bush vines within

reach of cooling breezes from the Adriatic and Ionian seas, can produce robust, spicy wines of considerable interest.

Unfortunately, because most of its production is either bulk or IGT, Puglia has very few producer associations to help market the higher-quality wines. Puglia's very few CONSORZIOS are practically defunct. What Puglia urgently needs is to ensure the survival of its centenarian bush vines and most interesting indigenous varieties—and, ideally, a viticultural and winemaking institute identical to SAN MICHELE ALL'ADIGE to help shape its future. W.S.

www.winesofpuglia.com

Puisseguin-St-Émilion, satellite appellation of ST-ÉMILION in Bordeaux on about 700 ha/1,750 acres of CLAY and LIMESTONE.

Puligny-Montrachet , village in the Côte de Beaune district of Burgundy's Côte d'Or producing very fine wines from CHARDONNAY and a tiny amount of less-exalted red. Puligny added the name of its most famous vineyard, the GRAND CRU Le Montrachet, in 1879 and has benefited from the association ever since.

Puligny contains two grand cru vineyards in their entirety, Chevalier-Montrachet and Bienvenues-Bâtard-Montrachet, and two which are shared with neighbouring Chassagne: Le Montrachet itself and Bâtard-Montrachet. Below this esteemed level, yet still among the finest of all white wines of Burgundy, are 17 PREMIER CRU vineyards. At the same ELEVATION as Bâtard-Montrachet lie Les Pucelles (made famous by the excellence of Domaine Leflaive's version), Clavoillon, Les Perrières (including the Clos de la Mouchère), Les Referts, and Les Combettes, which produces the plump wines to be expected of a vineyard adjacent to Meursault-Perrières.

A little higher up the slope, at the same elevation as Le Montrachet, lie Les Demoiselles, Le Cailleret, Les Folatières (including

Clos de la Garenne), and Champ Canet. Part of Les Demoiselles is classified as grand cru Chevalier-Montrachet, but a very small slice remains as premier cru, being regarded, along with Le Cailleret, as the finest example.

Further up the slope, where the terrain becomes rockier and the soil almost too sparse, are Le Champ Gain, La Truffière, Les Chalumeaux, and the vineyards attached to the hamlet of BLAGNY, which are designated as Puligny-Montrachet premier cru for white wines and Blagny premier cru for reds.

The VILLAGE WINES of Puligny-Montrachet are less impressive, perhaps because the water table is nearer the surface here than in neighbouring MEURSAULT, for example. This phenomenon also means that the deep cellars ideal for AGEING wine are rare in Puligny, and few of the village's growers can prolong BARREL AGEING for more than about a year. Although the Leflaive and Carillon families can both trace their origins as vignerons back to the 16th century, there are surprisingly few domaines in Puligny, and a substantial proportion of its produce is contracted to the NÉGOCIANTS of Beaune.

In centuries past, Puligny, though less noted than Chassagne for its red wines, grew a significant amount of Pinot Noir grapes. They are now almost extinct.

See also MONTRACHET, CÔTE D'OR, and map under BURGUNDY.

J.T.C.M.

Loftus, S., *Puligny-Montrachet* (1992).

pulling out. See GRUBBING UP.

pulp, viticulturally, the soft tissue of grape berries inside the skin (also called the flesh or PERICARP) which is the source of the juice of the grape. The word may also be used by winemakers to refer to the solid matter that settles from the juice after must SETTLING. For more detail of grape pulp, see GRAPE.

B.G.C.

pumping over, winemaking operation involving the circulation of fermenting red wine through the CAP created by the grape skins and other solids. The French term is *remontage*. This can be carried out with or without AERATION, depending on the fermentation rate and the reducing conditions (see REDUCTION). It prevents drying out of the cap and encourages the EXTRACTION of the skins' valuable colouring matter and TANNINS into the wine. It may be done either in a closed or open-top vat, from one to three times a day depending on the temperature and rate of fermentation. The mechanical systems involved include some adaptation of the AUTOVINIFICATION system, ROTOFERMENTERS, and tanks which incorporate automatic PUNCHING DOWN. However, automation cannot replace the winemaker's decisions about the volume of fermenting wine that needs to be pumped over each day to get the right level of extraction. See also RACK AND RETURN, SUBMERGED CAP, and MACERATION.

pumps, mechanical devices for pumping, moving liquids such as wine, grape juice, and suspensions of solids such as MUST from one location to another. Pumps are avoided by some of the most traditional—and some of the most modern (see WINERY DESIGN)—wineries that depend on gravity to move liquid from one level to another for different winemaking processes.

Must from the DESTEMMER-CRUSHER is usually moved to the draining tank or FERMENTATION VESSEL by means of a peristaltic or off-centre helical screw-type pump because this type performs particularly well with solid suspensions. Cloudy juice from the draining tank might well be moved by means of a rotor pump to the fermentation tank, and most of the semi-clear and clear wines being processed are also moved using these types of pump at any step of the winemaking process.

punching down, the winemaking operation of breaking up and submerging the CAP of skins and other solids during red-wine

fermentation to stop the cap from drying out, to encourage the EXTRACTION of colour and TANNINS, and to encourage useful AERATION in the making of a deeply coloured red wine. Keeping skins and liquid in contact is relatively simple with small batches of fermenting grapes. In tanks filled to a depth of 1–1.5 m/3–4 ft, a person can physically mix the floating solids into the fermenting grape juice using a wooden punch, stick or paddle or even with their feet. The cap may also be punched down by special metal devices, either by hand or mechanically. It is usually done between one and three times a day depending on the fermentation rate. The French term is *pigeage*. See also MACERATION, RACK AND RETURN, and SUBMERGED CAP.

punt, optional indentation in the bottom of wine BOTTLES, particularly common in bottles of sparkling wine.

pupitre, French name for a rack traditionally used for RIDDLING sparkling wines by hand. For more details, see SPARKLING WINEMAKING.

Puy-de-Dôme, IGP used for white, red, and rosé wines grown in the VOLCANIC soils of the Puy-de-Dôme *département* west of Lyons. As in the AOC Côtes d'AUVERGNE which sits within it, GAMAY and PINOT NOIR predominate. Red wines make up 75% of production, rosés another 15%. What few whites are made tend to be from CHARDONNAY, ALIGOTÉ, and PINOT BLANC.

PVPP, or **polyvinylpolypirrolidone**, a synthetic material used as a FINING agent. Its particular property is the removal of PHENOLIC components from white wine, especially those that are suffering from 'pinking' or 'browning' resulting from mild OXIDATION. D.B.

PX, common abbreviation for the Spanish grape variety PEDRO XIMÉNEZ, particularly for the dark, sticky, ultra-sweet varietal FORTIFIED

WINE made from it in Spain. MONTILLA-MORILES is the usual source, and top-quality wines can be almost as dark and viscous as molasses, though are generally lower in alcohol than the SHERRIES of nearby JEREZ.

pyrazines. See METHOXYPYRAZINES.

Pyrenees, hilly, TEMPERATE-climate Australian wine region in the Western Victoria Zone, sandwiched between the Grampians to the west and Bendigo to the east, chiefly known for Cabernet Sauvignon and Shiraz. See VICTORIA.

pyruvic acid, three-carbon compound formed by YEAST at a midway stage in the complex FERMENTATION process. It is converted to ACETALDEHYDE and then to ETHANOL.

Q

QbA, or Qualitätswein bestimmter Anbaugebiete, see QUALITÄTSWEIN.

QmP, or Qualitätswein mit Prädikat, German wine category now officially known as Prädikatswein. See PRÄDIKAT.

Qualitätswein is what PDO wines are called in German. This is Germany's largest wine category and in practice includes all those wines once known as QBA (as opposed to QMP wines which have been renamed Prädikatswein; see PRÄDIKAT). The grapes must originate in one of GERMANY's 13 official wine regions and reach minimum MUST WEIGHTS specified for each region, which may vary by grape variety from 6 to 9% POTENTIAL ALCOHOL. Wines in this category may still be CHAPTALIZED but, thanks to CLIMATE CHANGE and improved viticultural techniques, chaptalization has become much rarer. Increasingly many German producers—including members of the VDP as official policy—bottle dry (TROCKEN and HALBTROCKEN) wines as Qualitätswein, reserving Prädikatswein designations for noticeably sweet wines.

Austria sets a national minimum for Qualitätswein equivalent to 9.7% POTENTIAL ALCOHOL.

quality assurance is a general concept covering the way in which a business is organized so that the quality of the product is assured at all stages. As applied to a wine business, good quality assurance will ensure that the original potential of the grapes and

wine is not lost on the way to the bottle. Quality assurance is the totality of all the management actions and procedures that set out to achieve this high standard and therefore incorporates QUALITY CONTROL.

An internationally recognized standard of quality management is ISO 9001:2015. This standard imposes a discipline that demands a uniformity of action throughout the business every time, all of the time.

Another useful though simple tool is Hazard Analysis and Critical Control Points (HACCP). The manufacturing process is divided into its basic stages, then each stage is examined to determine the problems that could occur at each one (hazard identification). Each hazard is then assessed for its potential danger to the process (the hazard analysis). Those that constitute the greatest danger are identified as the critical control points, to which the maximum attention is given. This procedure is now considered so important that it is mandatory throughout the EU for anyone involved in food and beverage handling, and it is gaining worldwide recognition.

D.B.

Bird, D., and Quillé, N., *Understanding Wine Technology* (4th edn, 2021).

quality control is a hands-on process of monitoring and controlling all parameters that verify a wine's palatability, STABILITY, compliance with regulations, TYPICALITY, and freedom from FAULTS and CONTAMINANTS. Most large wineries maintain laboratories capable of conducting all but the most difficult of the required ANALYSES, while smaller wine enterprises send samples to an independent commercial laboratory. For complete quality control, a chemical analytical laboratory, a microbiological laboratory, and a statistically controlled tasting panel are required. See also QUALITY ASSURANCE and SAMPLING.

D.B.

quality in wine. The concept of quality is regularly used in connection with wine, both for marketing purposes and as a marker of personal evaluation. It is also widely used as an element in JUDGING in wine SHOWS. Nevertheless it is notoriously hard to pin down its precise nature. Even wine professionals comment at times that 'it is a matter of personal taste'. There are many—including Émile PEYNAUD—who argue that the denotation of quality is essentially the subjective enjoyment of pleasure, while others claim that it exists only relative to other factors, such as PRICE or the circumstances of consumption. It is certainly true that our response to wine is in part idiosyncratic, dependent on varying physiological responses and the drinker's cultural background (see PHILOSOPHY AND WINE and TASTING), but that has not precluded a number of ways of trying to define quality. Whether wine quality has a SUBJECTIVE or objective nature is complex, as is the relationship of quality to preference. Arguably it is possible to assess a wine as being of high quality without actually liking it.

Some wine professionals believe that quality can be precisely measured. Certainly there are means such as INFRARED SPECTROSCOPY to evaluate grape quality, but Somers, formerly of the AWRI, argues that, for red wines at least, it is possible to predict a wine's quality by using its ultraviolet absorbance to measure its PHENOLIC concentration. A more marketing-focused perspective is that a high-quality wine is one that is fit for its purpose, but, given the complex motivations for drinking wine, this raises the question of precisely what the purpose is. The American oenologist Maynard AMERINE believed that wine is an aesthetic object and that its evaluation therefore calls for the use of aesthetic criteria.

Some commentators have suggested quality can be measured by such intrinsic indicators as a wine's BALANCE, LENGTH, intensity, harmony, varietal purity, and COMPLEXITY. Such concepts are used in assessing wine throughout the world, although without any consistent application. Other means of grading quality, extrinsic to the drink itself, have also been used. These include the relationship

of wine to the price it fetches, as in the best-known CLASSIFICATIONS. This does not however guarantee the actual organoleptic 'quality' of the drink as measured by critical or popular response.

Charters and Pettigrew suggest that drinkers consider wine quality to have a number of dimensions. Some of these are extrinsic to the wine, such as how it has been made; others are intrinsic, including how the wine tastes (involving subdimensions such as concentration, balance, smoothness, drinkability, and interest), its capacity for AGEING, and its TYPICALITY. However, the most important quality dimension for consumers is the amount of pleasure afforded by the wine. Thus one can argue that for most drinkers quality has two components: a series of dimensions which catalyse quality; and a sense of pleasure in the product which is the end result of those catalytic dimensions.

They also suggest a way out of the objective versus subjective quality conundrum. Employing a paradox which mirrors the sociological concept of intersubjectivity, it can be noted that wine drinkers often hold both perspectives simultaneously. Thus quality is partly objective, measured by external criteria which depend on a broad commonality in our response to the components of a wine (such as its balance and intensity) and subject to debate and agreement between drinkers. It is also partly personal and related to the consumer's individual preference. S.J.C

Somers, C., *The Wine Spectrum: An Approach Towards Objective Definition of Wine Quality* (1998).

quality wine is an expression widely and loosely used for any wine of good quality and was, until 2008, an official wine category

throughout the EU and therefore throughout most of Europe. It has been superseded by the PDO and PGI categories. Similarly, everything else, called 'table wine' in its strict pre-2008 EU sense, has been superseded by the cumbersome but clear phrase WINE WITHOUT GEOGRAPHICAL INDICATION.

quarantine of imported plant material plays an important part in international viticulture and can put a (necessary) brake on its spread in new jurisdictions. Like any form of agricultural quarantine, it can annoy travellers but is designed to protect farmers and regional and national economies from the ravages which may be caused by the inadvertent introduction of new pests and diseases from other countries or regions (see the history of DOWNY MILDEW, POWDERY MILDEW, and PHYLLOXERA). Most of the devastating pests and diseases of the European vine species used commonly for wine production, VITIS VINIFERA, have in fact been spread from America, AMERICAN VINE SPECIES having developed a tolerance to these diseases which *vinifera* lacks.

Quarantine systems for viticulture are in place at national borders and also sometimes at regional levels. Most wine-producing countries maintain strict quarantine on vine imports in an attempt to keep out the likes of PIERCE'S DISEASE and FLAVESCENCE DORÉE, both of which could ravage a region's viticulture if they were to spread. Quarantine also works to reduce the spread of other FUNGAL, VIRUS, and BACTERIAL DISEASES as well as insect and nematode VINE PESTS which might not be lethal but may cause significant economic damage. Licences issued for vine importation are typically restricted to a few CUTTINGS per import, which are then subjected to disease testing. The quarantine delays can be up to two or three years, but certification programmes and diagnostic tests such as ELISA developed in the 1980s may reduce this period. Some countries, for example China and Canada, do allow imports of young GRAFTED vines, but these are subject to guarantees about virus status.

Nursery plants move freely around the EU with a plant passport to guarantee freedom from virus disease, but they are widely infected with TRUNK DISEASE fungi not currently covered by the passport. Smuggling of vines is not unknown, especially by impatient producers who believe that they are disadvantaged by not having access to better varieties or CLONES and are tempted to resort to what are sometimes referred to as 'suitcase clones'.

Sometimes there are quarantine areas within national boundaries, such as those that exist in South Australia, Tasmania, and Western Australia, in an attempt to avoid the further spread of phylloxera. Some countries and regions are free of major pests or diseases. CHILE, for example, has remained free of phylloxera, even though it is present in Argentina just over the Andes. Increasing international competition in the wine market makes the possibility of sabotage from another region or nation by introduction of a pest or disease less fanciful. The economic health of many of the world's viticultural regions depends on effective vine quarantine being maintained, and continuing vigilance and community support are essential.

R.E.S.

Quarts de Chaume, extraordinary yet minuscule enclave within the Coteaux du LAYON appellation producing historically praised sweet white wines from BOTRYTIZED Chenin Blanc grapes. The well-protected, steep slopes of varied carboniferous soils, *poudingues*, and brioverian SCHIST overlooking the right bank of the Layon river is a remarkable TERROIR for high-quality NOBLE ROT development, leading in the best vintages to exceptional natural concentration. Yet as the minimum grape-sugar level in the MUST is extremely high (298 g/l for 85 g/l of RESIDUAL SUGAR at bottling), total annual production can often be as little as a few thousand cases from just over 26 ha/64 acres of planted vineyard, supposedly the finest quarter, or *quart*, of the CHAUME part in Rochefort-sur-Loire (see FRANCE, history, for details). Domaine des Baumard tried to secure permission to use CRYOEXTRACTION, but in 2014 it was decreed that this freeze-concentration technique would be outlawed from 2019. Richer and

rarer than those of nearby BONNEZEAUX, and forbidding CHAPTALIZATION, Quarts de Chaume became officially the Loire's first GRAND CRU in 2011. As NOBLE ROT is getting less consistent with CLIMATE CHANGE, more remarkable dry white wines mentioning the main LIEUX-DITS (Rouères, Veau, Zerzille, etc.) are produced under the ANJOU Blanc AOC. P.Le.

quartz, silicon dioxide (silica), a very common rock-forming mineral. It is seen as glassy, colourless grains in rocks such as GRANITE and SANDSTONE, producing sandy soils of low fertility. It also occurs as opaque white veins filling gashes in bedrock, which weathering loosens into fragments that become the milky white stones seen in many vineyard soils. See also GEOLOGY. A.J.M.

quartzite, a metamorphic rock that was originally a quartz-rich sandstone (see GEOLOGY). It is usually pale-coloured or white, with a 'sugary' appearance. It should not be confused with the mineral QUARTZ since it is a rock composed of myriad constituent grains. Once used for any tough quartz-rich rock, in modern usage quartzite refers to a compact, metamorphic fusion of the quartz grains and silica cement of the original SANDSTONE, which makes it robust and resistant to SOIL EROSION.

Quartzite therefore tends to form relatively higher ground with thin, poorly fertile soils, generally not well suited to viticulture, although it does occur in Germany's NAHE and RHEINHESSEN regions, in Spain's CALATAYUD, and in the BAROSSA and CLARE VALLEYS, South Australia. Quartzite is much more commonly seen in vineyards as rock fragments in the soil, including the archetypal GALETS of CHÂTEAUNEUF-DU-PAPE. A.J.M.

Quatourze, an obscure CRU within the LANGUEDOC AOC in southern France for reds based on Grenache, Syrah, and Mourvèdre.

Production of appellation wine in this little windswept zone just west of Narbonne is small and dominated by Ch Notre-Dame du Quatourze.

Quebec is the third largest wine region in CANADA. Its modern industry dates to the 1980s, with early plantings at Domaine des Côtes d'Ardoise in 1981. Today there are seven delineated wine regions, with the largest concentration of vineyards to the south and south-east of Montreal close to the United States border. The growing season is relatively short but ranges from warm to hot, while winter temperatures can often dip below −20 °C/−4 °F in some regions, necessitating WINTER PROTECTION for the vines. The Appalachian Foothills region is Quebec's warmest, counting 1171–1348 C° growing degree days (compared with 1315 C° in Burgundy). (See CLIMATE CLASSIFICATION.) Topographical features also create highly localized warm areas that allow vines to survive, if not flourish. In 2021 the province had 163 wineries and 825 ha/2,040 acres of vines, primarily French and Minnesota HYBRIDS, for example VIDAL, MARQUETTE, SEYVAL BLANC, and FRONTENACs Blanc, Gris, and Noir, but with increasing amounts of VITIS VINIFERA varieties such as Chardonnay, Pinot Noir, and Pinot Gris. There are two Protected Geographical Indications (PGIs): Vin du Québec, for still and sparkling wine; and Vin de glace du Québec, for ICEWINE. J.D.

Queensland, state comprising the north-east quadrant of Australia, its wine regions concentrated in the south-east of the state

at the northern end of the Great Dividing Range. The region has supported a wine industry since the 1860s, shortly after Samuel Bassett obtained CUTTINGS from the HUNTER VALLEY and founded Romavilla near the town of Roma. As in other Australian states, wine production waned after the 1890s but was rejuvenated in the 1970s and 1980s. Many of the new wave of pioneers were Italian, such as Angelo Puglisi, who founded Ballandean Estate in 1970. By the 1990s, Queensland wines were seen and talked about in Brisbane, the state capital and a significant population centre.

The early 2000s saw further growth when the Queensland State Government provided assistance with grants and resources and changed the liquor licence laws to allow wineries to open a retail outlet, or CELLAR DOOR, outside of the vineyards and winery. It also allowed a business to be classed as a winery even if it arranged for someone else in Queensland to grow the grapes and make the wine. A plethora of new wine businesses grew as a result—some in wine regions, some in Brisbane, and several in or near the touristic Gold Coast and Sunshine Coast. These developments have been good for dynamism but have made tallying wineries difficult. In 2022 the Queensland Wine Industry Association (QWIA) counted 127 licensed wine producers, while aerial survey data from Wine Australia measured 630 ha/1,557 acres of vineyards in Queensland.

The state has two GEOGRAPHICAL INDICATIONS (GIs). The GRANITE BELT, about three hours south-west of Brisbane, dominates production, the vines planted on the high-ELEVATION tableland of the Great Dividing Range to take advantage of the cooler temperatures and DIURNAL TEMPERATURE RANGE. (Some producers here also take advantage of plantings in the NORTHERN SLOPES ZONE, across the state line in NEW SOUTH WALES.) The smaller, warmer, and hilly SOUTH BURNETT GI sits two-and-a-half hours north-west of Brisbane.

The mainstream varieties Shiraz, Chardonnay, and VERDELHO dominate production volumes, but in recent years there has been a growing interest among both producers and consumers in

ALTERNATIVE VARIETIES such as FIANO, VERMENTINO, TEMPRANILLO, TANNAT, and SAPERAVI. A.C.

www.queenslandwine.com.au

quercetin, also spelt quercitin, a yellow dyestuff with ANTIOXIDANT properties belonging to the FLAVONOL family, originally extracted from the bark of black oak (QUERCUS), hence the name.

Quercus is the botanical genus to which oak belongs and is therefore the most important family of plants to wine after the vine genus VITIS since it provides both CORK and wine's most classic storage material, OAK. According to the most recent (2017) classification, it is subdivided into two subgenera, *Cerris* and *Quercus*. All oaks used for wine containers and corks belong to the latter. The species most commonly used for BARRELS are the American white oak *Quercus alba* and the European oaks *Quercus robur* and *Quercus petraea*. For more details, see OAK.

The species whose bark is stripped to provide cork is *Quercus suber.*

quercusportal.pierroton.inra.fr/index.php?p=TAXONOMY

Quercy, Coteaux du, a small AOC between Cahors and Gaillac in SOUTH WEST FRANCE devoted to sturdy, rustic reds and some rosés, both made from Cabernet Franc with Cot (MALBEC), Merlot, and TANNAT.

Quincy, rapidly expanding, historic white-wine appellation in the greater Loire region that encompasses just two villages. It produces racy dry wines from Sauvignon Blanc (with up to 10% Sauvignon Gris) grapes from a total area of vines that by 2019 had grown to 317 ha/783 acres of SAND and GRAVEL on the left bank of the Cher tributary. Its long history (it was the second AOC created, after CHÂTEAUNEUF-DU-PAPE, in 1936) and early popularity owe much to its proximity to RIVER transport (especially in comparison with the smaller nearby appellation REUILLY). The wines tend to be a little less delicate than those made in Menetou-Salon and Sancerre to the east.

See also LOIRE, including map. C.P.

quinta, Portuguese word meaning 'farm', which may also refer to a wine-producing estate or vineyard. Single-quinta ports are those made from a single year and from a single estate in the Douro Valley; see PORT.

Quinta do Noval. Founded in 1715, Noval is the name of both the estate and this historic, unusually vineyard-based, PORT shipper. Quinta do Noval was owned by the firm António José da Silva, who in 1973 changed their name to Quinta do Noval-Vinhos, because Noval represented their finest wine (and they also wanted to avoid confusion with all the other da Silva companies in OPORTO). The estate of Quinta do Noval, in the Pinhão Valley, enjoyed a heyday in the mid 20th century when run by Luiz Vasconcellos Porto, before being inherited by the Van Zeller family. Noval's most prestigious, rarest, and expensive wine is Nacional, produced from 2.5 ha/6 acres of UNGRAFTED VINES which, not having American ROOTSTOCKS, are therefore 'national'. The Nacional 1931 VINTAGE (which Noval was virtually alone in declaring) enjoys legendary status.

Quinta do Noval suffered a devastating fire at its lodges in Vila Nova de Gaia in 1981 and has continued to age its wines in air-

conditioned lodges in the Douro Valley rather than in Gaia. In 1993 the firm was acquired by the French insurance company AXA; under port-lover Christian Seely, its winery, vineyards, and reputation have since been comprehensively restored with more than three-quarters of the vineyard area having been replanted, mainly with Touriga Nacional, Touriga Franca, and Tinto Cão, innovatively retaining the original vineyard TERRACES while adapting them for modern cultivation wherever possible. A third vintage port, Silval—sometimes produced in a generally declared vintage year alongside Quinta do Noval, sometimes on its own when Quinta do Noval is not declared—was introduced in 1995. Since 2004 Noval has produced a range of DOURO red and white wines under the labels Quinta do Noval and Cedro. The firm's vineyards produce well over 90% of their needs, with the remainder being bought in from other properties in the Douro Valley. Neighbouring Quinta do Passadouro was acquired by Noval in 2019.

quintal, *quintale* in Italian, unit of weight equivalent to 100 kg/220 lbs.

qvevri, uniquely GEORGIAN clay vessel used for FERMENTATION and AGEING of red and white wines for many centuries, especially, but by no means exclusively, in Kakheti in the east. The rounded, wide-mouthed earthenware jars, given their very own PGI in 2021, vary enormously in size, from 50 l/ 13 gal for a family's domestic production to 700–4,000 l for commercial use, the larger ones for ageing rather than fermentation. Unlike Roman AMPHORAE and Spanish TINAJAS, qvevri are buried underground, requiring no TEMPERATURE CONTROL and benefiting from natural SETTLING and CLARIFICATION. Procuring and then cleaning and maintaining these vessels are the main obstacles to their wider use.

The Kakhetian tradition for both red and white wines is to put the lightly crushed whole berries—including skins, pips, and stems,

known as *chacha*—into the qvevri. Further west, where the jars are also known as *churi*, less *chacha* is used and MACERATION times are shorter. With red wines, the wine may be moved to a clean qvevri, or even to oak BARRELS, post fermentation. After fermentation and MALOLACTIC CONVERSION, the wide mouth of the qvevri is closed with a slate (occasionally wooden) lid and sealed with clay. Qvevri wines are quintessentially tannic, the best deeply satisfying and flavourful, but the whites are particularly distinctive thanks to their golden colour, tannic structure, and aromas of hay and chamomile, the winemaking sometimes obscuring the grape variety. Qvevri winemaking, recognized as a UNESCO 'intangible heritage' in 2013, is also practised by a few producers in Europe, most notably in Friuli in north-east Italy and western Slovenia. Qvevri is both singular and plural.

R

Rabigato, grape that adds class and acidity to DOURO white blends and grown particularly in the Douro Superior. Total plantings in the Douro were 1,744 ha/4,310 acres in 2020.

Rabo de Ovelha, white grape variety grown in Portugal, particularly the Alentejo, taking its name from the 'ewe's tail' shape of its bunches. Noted for its freshness and elegant floral and white-fruit notes, it is probably closely related to CAYETANA BLANCA. Total plantings had fallen to 239 ha/591 acres by 2020.

Raboso, name of two closely related but distinct tough red grape varieties grown in the VENETO region of north-east Italy. Raboso Piave is more common, on 641 ha/1,584 acres in 2015, as opposed to Raboso Veronese grown on 295 ha. Rabosa Piave is characteristic of the flat valley floor of PIAVE, and most is grown in the province of Treviso. Raboso Veronese is sometimes interplanted with Raboso Piave but is also grown in Ferrara and Ravenna in Emilia-Romagna. The name is thought to derive from the Italian *rabbioso*, meaning 'angry', presumably a reference to consumer reaction to the uncompromisingly high ACIDITY and rough TANNINS which characterize the grape and its wine. This is a grape variety which has excellent resistance to disease and ROT but which makes CABERNET SAUVIGNON look rather mellow. Unfortunately Raboso is not high enough in alcohol to compensate for its ASTRINGENCY and can therefore taste extremely austere in youth. Stalwart defenders of the variety insist that, with full ripeness and careful handling in the winery, wines produced can be truly distinguished, the Veneto's answer to the

Nebbiolo of Piemonte or the Sangiovese of Tuscany. The reputation and price level of Raboso make it difficult to justify this kind of investment, and vineyard plantings, which continue to decline, reflect this fact.

Raboso Veronese is also planted, to an extremely limited extent, in Argentina, presumably taken there by Italian immigrants.

rachis, the main STEM that runs through a BUNCH of grapes and is joined to the berry by the PEDICEL. See GRAPE.

rack, wine, common horizontal storage for wine bottles, keeping the cork damp and avoiding OXYGEN ingress. See CELLAR.

rack and return, or drain and return, *délestage* in French, is a CAP management procedure which optimizes contact between MUST and solids during fermentation and homogenizes the temperature in the must and the cap. When the cap has risen to the top of the tank, fermenting wine is taken from a bottom valve to a separate receiving vessel. The wine is then gently pumped back over the top of the cap, using a low-pressure pump or sprinkler system. This procedure, usually conducted once or twice during fermentation, is designed to ensure optimum diffusion of TANNINS and PIGMENTS from the fruit into the wine. It is best carried out in the early stages of fermentation when the alcohol is still low to avoid over-EXTRACTION. When the tank is wide rather than tall, MACERATION is more efficient so that rack and return is not as useful. D.D. & V.L.

racking, the winemaking operation of removing clear wine from the settled SEDIMENT or LEES in the bottom of a container. The verb to rack has been used thus at least since the 14th century.

Racking is usually achieved by pumping or siphoning the wine away from the sediment into an empty container, but special large racking tanks are used by some large wineries. They are equipped

with drain lines, the lower ends of which can be adjusted to just clear the sediment layer and permit more rapid and more complete wine removal from the solids.

Racking forms an important part of the annual cycle of cellar work, or ÉLEVAGE, in the production of most fine wines matured in small BARRELS. Racking from barrel to barrel is very LABOUR-intensive, and each racking inevitably involves a barrel that needs thorough cleaning and sulfuring to avoid any risk of BACTERIAL SPOILAGE or BRETTANOMYCES.

According to classical *élevage*, the first racking takes place soon after FERMENTATION and the ensuing MACERATION to separate the new wine from the skins and the gross LEES, with the second one after MALOLACTIC CONVERSION. In cooler regions, another racking typically takes place just after the first FROSTS of winter have precipitated some of the TARTRATES and MICROORGANISMS, while in many cellars there is a fourth in spring and another before the full heat of the summer. Wines may be racked once or twice during a second year in barrel. NEW WORLD winemakers have tended to rack less frequently.

Racking is not only part of the CLARIFICATION process but also provides AERATION, which, in the case of red wines, is essential to the formation of PIGMENTED TANNINS and beneficial to the sensory properties of the wine. Aeration also discourages REDUCTION of any excess SULFUR to malodorous MERCAPTANS.

Raffiac, sometimes Raffiat, alternative names for ARRUFIAC.

railways. Until the arrival of a railway in their region, wine producers were almost totally dependent on waterborne means of transport. Without access to the sea or a navigable RIVER or canal, transport was too difficult and expensive for all but the finest and rarest wines. This gave an overwhelming advantage to regions such

as BORDEAUX, which were served by a major port, or CHAMPAGNE, with access to the river system of northern France.

The construction of the railways enabled a number of wines previously unknown outside their region to be exported. In some cases—notably CHIANTI in central Italy and RIOJA in northern Spain—this enabled high-quality wines to achieve their deserved recognition for the first time. The construction of a railway line between the town of JEREZ and the coast in the mid 19th century greatly encouraged exports of SHERRY.

The railways also facilitated the transport of inferior wines. They allowed the late 19th century development of the mass-production vineyards of the LANGUEDOC and ROUSSILLON in the south of France, whose rough wines were transported in vast quantities to northern France and Belgium, thus ruining such marginal northern European vineyards as those around ORLÉANS and, to a lesser extent, those of the French MOSELLE. The railways in ARGENTINA were also crucial in establishing Mendoza as an important wine region far from the capital Buenos Aires. During the 15 years of PROHIBITION in the United States, efficient rail transport of fresh grapes from California to the suddenly numerous HOME WINEMAKERS in the eastern states played a part in maintaining a winemaking tradition in the U.S. N.F.

rainfall, a component of climate which affects grapevines in many and sometimes conflicting ways.

For vines depending directly on rainfall (see DRY-FARMED), there needs to be enough rain, at the right times, to promote adequate growth and to avoid severe WATER STRESS during ripening. On the other hand, more than enough rainfall can lead to excessive vegetation growth and a poor CANOPY MICROCLIMATE. Too much rain during FLOWERING can lead to COULURE, and, in wet regions, soils with poor internal DRAINAGE may become waterlogged. Similarly, rainfall can promote fungal diseases such as DOWNY MILDEW and BOTRYTIS BUNCH ROT by wetting foliage and fruit.

Average annual rainfall in wine regions globally is roughly 700 mm/28 in but ranges from extremely dry, less than 100 mm/4 in (e.g. in Chile's ELIQUI VALLEY), to quite wet, greater than 1,700 m/67 in (e.g. Portugal's VINHO VERDE). Wine regions with 40–60% of their annual rainfall during the growing season (e.g. northern France, eastern US) are less likely to use IRRIGATION, while those in winter-wet, summer-dry seasons (e.g. western US, central Chile), with less than 20% of annual rainfall during the growing season, tend to depend on irrigation. These irrigation needs are supplied by rivers, aquifers, wells, or communal irrigation. The normal unreliability of rainfall means that full wetting of the SOIL PROFILE seldom occurs naturally, and frequent heavy watering is usually needed throughout the growing and ripening season.

No particular upper limit of rainfall is apparent for viticulture, provided that the soils are well drained, leached SOIL NUTRIENTS can be replaced, SUNLIGHT is enough, and HUMIDITY is not so high that FUNGAL DISEASES cannot be controlled. However, heavy rain leading up to harvest is nearly always detrimental to wine quality. The berries often split, resulting in fungal and bacterial infection of the bunches (see BUNCH ROT). At a minimum, the juice and its flavour are diluted. HAIL at this time is especially disastrous. R.E.S. & J.V.G.

rain-fed. See DRY-FARMED.

raisins, from the French *raisins secs*, are dried grapes, the third most common commercial use for viticulture, after wine and TABLE GRAPES. Terminology varies around the world, but this book uses the word 'raisins' as a catch-all that also includes sultanas and currants.

Drying is a means of preserving grapes for eating (and precedes fermentation in the production of DRIED-GRAPE WINES). Dried grapes are an ancient food supply. The low moisture content of the dried grape (10–15%) and high sugar concentration (70–80%) make the product relatively unsuitable for survival of food-spoilage organisms.

Grapes have been dried since antiquity. Records of grape drying found in EGYPT date back to 3000 BCE, and records of dried grapes are found in biblical times. Aristotle in 360 BCE referred to the seedless character of the Black Corinth grape, today's CURRANT. Legend has it that Hannibal fed his troops with raisins during the crossing of the Alps in 218 BCE.

Three varieties dominate world trade in raisins: SULTANA (also known as Thompson Seedless in America, and Kishmish or Sultanina in Asia and the Near East); Zante Currant (Australia and the US) or Black Corinth (California); and MUSCAT OF ALEXANDRIA (Muscat Gordo Blanco in Australia and White Hanepoot in South Africa). In Australia and California, grapes usually destined for the dried-grape industry have been diverted into wine at times of severe wine-grape shortage.

World production of raisins is gradually increasing, reaching a record of 1.33 million tonnes in 2019/20. The biggest producer of dried grapes is Türkiye (around 23% of global production), followed by the US (17%), China (13%), Iran (12%), and India (11%). Greece is the leading producer within Europe. Climate is a major factor determining where grapes are grown for drying. Temperatures should be high, with plenty of sunshine, while post-harvest humidity and rainfall should be low. In such conditions the evaporation rate is reliably high, and this usually means that the vineyards need

IRRIGATION. Rainfall prior to harvest or during drying has catastrophic results, as the fruit can split and rot.

Harvested grapes are placed outside on wooden or paper trays, or concrete or clay slabs. After about 10–14 days, the bunches must be turned over to dry the other side. The grapes may be dipped in solutions containing vegetable oils and potassium carbonate to speed their drying. Drying racks with roofs can help reduce rain damage and allow drying solutions to be sprayed on the fruit. Grapes may also be dried indoors.

Alternative methods of drying fruit on the vines have been developed in Australia and California. The canes supporting the bunches are cut at the base but left on the TRELLIS wires. (See CUT CANE for this method of producing sweet wines in Australia.) The vines may be sprayed with the drying emulsion and then mechanically harvested when dried. Dried grapes should not be packed with more than 13% moisture, and sometimes grapes dried in the field need to be dried further.

Quality factors in raisins are size, hue and uniformity of colour, surface condition, texture of both skin and pulp, and lack of any contamination. The highest-quality raisins are produced from the ripest fruit. R.E.S. & J.E.H.

Whiting, J. R., 'Harvesting and drying of grapes', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn 2006).

Rajinski Rizling and Rajnai Rizling, various Eastern European names for the true RIESLING grape of Germany.

Ramandolo. See VERDUZZO.

Ramisco, red grape variety grown exclusively in the shrinking COLARES region of Portugal and therefore probably the only VITIS VINIFERA vine variety never to have been GRAFTED. These rare wines

can be tannic in youth but complex and perfumed after AGEING in bottle.

rancio, imprecise tasting term used in many languages for a distinctive style of wine, often FORTIFIED WINE or VIN DOUX NATUREL, achieved by deliberately MADERIZING the wine by exposing it to OXYGEN and/or heat. The wine may be stored in barrels in hot storehouses (as for some of Australia's TOPAQUE AND MUSCAT), or immediately under the rafters in a hot climate (as for some of ROUSSILLON's vins doux naturels), or in glass BONBONNES left out of doors and subjected to the changing temperatures of night and day (as in parts of Spain). The word 'rancio' has the same root as *rancid*, and the wines which result have an additional and powerful smell reminiscent of overripe fruit, nuts, and melted, or even rancid, butter.

Key FLAVOUR COMPOUNDS identified in aged vins doux naturels arise by MAILLARD REACTION of sugars with AMINO ACIDS and by OXIDATION. These compounds are known to be present in, and responsible for, the characteristic flavour of other sweet food products. Thus, for example, furaneol, cyclotene, maltol, and SOTOLON, which are known contributors to the flavour of honey and caramelized sugar products, have been found in these wines along with several lactones that are important to the flavour of dried fruits.

This richness emerges in a complex series of sensations on the nose and palate. 'Rankness, a special character of fullness and richness' was the unflattering description given by Charles Walter Berry, the wine merchant who was Britain's leading cognac connoisseur between the World Wars (rancio can often be found in oak-aged brandies). Tasting descriptors include Roquefort cheese or rich fruit cake with its flavours of candied fruits, apricots, sultanas, almonds, and walnuts. N.F., J.R. & P.J.W.

Cutzach, I., et al., 'Study of the formation mechanisms of some volatile compounds during the aging of sweet fortified wines', *Journal of Agricultural and Food Chemistry,* 47/7 (1999), 2837–46.

random oxidation, also known as sporadic post-bottling oxidation, describes the premature browning that occurs in some white wines some months after BOTTLING. All closures have some variability in their OXYGEN TRANSMISSION RATE (OTR), so some bottles will be exposed to more oxygen than others during bottle AGEING. Wines are protected against oxidation through the addition of SULFUR DIOXIDE at bottling, but if the level of free sulfur dioxide added then is low, some bottles with high OTR will exhibit oxidation when the sulfur dioxide in those bottles is exhausted. The variability in OTR is caused by the closure itself, which is greater for CORKS than for manufactured CLOSURES, but other factors can be as important. These include flaws in bottlenecks or lips where sealing with CORKS or SCREWCAPS occurs, improperly adjusted jaws that crimp corks during bottling, or improper screwcap application. Another proposed cause is poor procedure or intermittent failure on the bottling line, allowing some wines to have much higher levels of dissolved oxygen from the outset (see TOTAL PACKAGE OXYGEN). Random oxidation is mainly a problem with white wines: while oxygen ingress through the closure will certainly damage red wines, they are more resistant to oxidation because of their high PHENOLIC content. Oxidation is also more likely to be noticed in white wines because of the visible browning that accompanies it. See also PREMATURE OXIDATION. A.L.W.

Ranina, Slovenian synonym for the BOUVIER grape.

Rapel, subregion of the Central Valley of CHILE, including Cachapoal and Colchagua.

Rasteau, southern Rhône CRU (promoted from Côtes du Rhône-Villages in 2010) on the east bank of the RHÔNE river. Its 940 ha/2,323 acres of vines are situated on the eastern half of a large hill of MARL and pebbles between the rivers Ouvèze and Aigues; CAIRANNE occupies the western half. Rasteau has an appellation for dry red

wines as well as for white, rosé, and red VINS DOUX NATURELS (VDNs). The dry wines are blends based on Grenache with Syrah and/or Mourvèdre; many other minor grapes are also permitted. These are typically concentrated, powerful wines with a sweet ripeness to the fruit flavours, smooth TANNINS, and high alcohol. The VDNs are made in much smaller volumes (just 142 hl/3,751 gal produced in 2020) although the appellation dates to 1944. They also depend on Grenache (Noir, Gris, and Blanc) and come in several styles dependent on grape variety, vinification, and ageing, from the non-OXIDATIVE styles Blanc and Grenat to the oxidative Ambré, Tuilé, and RANCIO. Hors d'Âge indicates a Rasteau aged at least five years.

M.C.W.

ratafia is an old, usually domestically produced wine-based APERITIF made in the French countryside by drying grapes to a raisin-like state and then moistening and fermenting them in the spring. Ratafia de Champagne is a mistelle (see MISTELA), made by adding marc (distilled spirit) to unfermented grape juice from Champagne.

ratings, scores applied to individual wines. See NUMBERS AND WINE and SCORING.

Ratti, Renato (1934–88), industrious and dedicated winemaker based at La Morra in BAROLO in the north-west Italian region of Piemonte, now run by his son Pietro. One of a group of so-called modernist Barolo producers seeking a more accessible Barolo (see BAROLO for more details), he was particularly keen to promulgate the notion of TERROIR. In 1979 he became one of the first to draw up a map of the best Barolo vineyards, or CRUS, which, with qualifications, is still valid today.

W.S.

Räuschling, historic white grape variety today most commonly planted in German-speaking SWITZERLAND, where it can produce fine,

crisp wines. In the Middle Ages it was very widely cultivated in Germany, particularly Baden (see GERMAN HISTORY). DNA PROFILING has shown it is a natural GOUAIS BLANC × SAVAGNIN cross.

Ravat , French vine breeder who gave his name to a number of FRENCH HYBRIDS.

raya, Spanish word meaning 'stripe' or 'streak' and a term for the symbol used to classify SHERRY must. A *raya* is also a coarse style of OLOROSO used in blending medium-dry sherry.

RDI. See REGULATED DEFICIT IRRIGATION.

Rebe, German for 'vine'. Rebsorten are vine varieties.

Rebula, Slovenian name for RIBOLLA Gialla.

Recioto, distinctive category of north-east Italian DRIED-GRAPE WINES, a historic speciality of the VENETO. The word derives from the Italian for ear, *orecchio*, because the wine was originally produced only from the ripest grapes in the bunch, from the upper lobes, or ears, although selected whole bunches have long been substituted. The most common forms of Recioto are sweet red Recioto della VALPOLICELLA and the rare sweet white Recioto di SOAVE and Recioto di GAMBELLARA. Even rarer still is Refrontolo, made of dried MARZEMINO grapes, and Torchiato di Fregona, based on GLERA, both in the province of Treviso.

Recioto della Valpolicella, like its dry counterpart AMARONE, is produced from 45–95% CORVINA, the great INDIGENOUS VARIETY of Valpolicella, up to half of which may be replaced by CORVINONE, and 5–30% RONDINELLA, with up to 25% of the INTERNATIONAL VARIETIES

authorized in the province of Verona. As for Amarone, these grapes are raisined during the late autumn and winter months after the harvest in special drying rooms equipped with air conditioning and humidity control to avoid the development of BOTRYTIS, which can lead to PREMATURE OXIDATION (although more traditional producers tend to embrace the COMPLEXITY that botrytis under more natural drying conditions can add). Like Amarone it is produced in the Valpolicella DOC zone which has been divided into a CLASSICO subzone and a larger zone whose wines are simply called Recioto. The white Recioto di Soave must be made from at least 70% GARGANEGA and a maximum of 30% TREBBIANO di Soave, Pinot Bianco, and/or Chardonnay (although quality-oriented producers tend to eschew the last two, which are generally included to compensate for lack of flavour and alcohol in grapes from high-yielding vineyards). Recioto di Gambellara must be 100% Garganega.

These wines can represent some of Italy's finest sweet wines, but, owing to sluggish demand and the mediocre quality associated with some dry Soave and Gambellara, the number of producers willing to sacrifice time and LABOUR to produce these wines has been declining, and Valpolicella producers now favour the much more lucrative Amarone. W.S.

récolte, French for HARVEST. A récoltant is therefore a GROWER. In CHAMPAGNE, a récoltant-manipulant (identified by an 'RM' on the label) is a grower who also makes his or her own champagne, of whom there are more than 1,600 in the region, as opposed to a récoltant-coopérateur (RC), who sells champagne made by a CO-OPERATIVE, of whom there are more than 2,000.

recorking, a potentially hazardous exercise conducted by some top wine producers and some fine-wine traders. The aim is to prolong a wine's potential longevity after extended bottle AGEING may have weakened the cork. Estimates of a cork's longevity range from 15 to

30 years, depending on the quality of the cork and the wine's storage conditions. Ch LAFITE used to send its MAÎTRE DE CHAI on recorking tours which doubled as public relations exercises but, having encountered too many bottles of doubtful PROVENANCE and poor condition, they abandoned this practice. Today PENFOLDS is the world's most determined recorker, holding 'clinics' for those who own Penfolds wines of more than 15 years old. Since they began in 1999, Penfolds have certified 130,000 bottles, typically topping them up with wine of a similar age and quality before recorking with advice on when to drink them. The FINE WINE market became suspicious of recorking in any circumstances other than the most public in the late 1980s, as it potentially offers too much possibility for ADULTERATION AND FRAUD.

rectified grape must, or RGM, is preserved GRAPE JUICE that has been rectified (i.e. processed to reduce the concentration of solids other than SUGARS). It is generally further treated by removing water to yield rectified concentrated grape must, or RCGM, which is a common commodity used principally in Europe for ENRICHMENT. The EU authorities were at one time keen to promote its use in place of sugar as a way of helping reduce the European WINE LAKE. Many winemakers who need to use it in northern Europe have a natural antipathy to introducing a product made from what they view as inferior grapes. There are several major producers of RGM in Europe who absorb SURPLUS grape production from areas such as the LANGUEDOC, LA MANCHA, SICILY, and PUGLIA. They submit it to such modern technological processes as ION EXCHANGE and REVERSE OSMOSIS together with super-efficient FILTRATION and evaporators to produce what is in effect a concentrated invert sugar (GLUCOSE and FRUCTOSE) solution from grape juice. See also CONCENTRATION.

red blotch virus. See GRAPEVINE RED BLOTCH VIRUS.

Redding, Cyrus (1785–1870), England's answer to the great wine explorer of France, André JULLIEN. As a young journalist in London, Redding was sent to Paris in 1814, where he was based for five years. There he was introduced to wine regions and a wine-producing culture. Jullien's book was published two years after Redding's arrival in Paris, and his own most important work, *A History and Description of Modern Wines*, written in 1833 when he had returned to England, takes full account of both Jullien and CHAPTAL's previous publications but seems to have been independently inspired by the disparity between the wines then available in Britain (see ADULTERATION) and what he tasted in cellars all over Europe. Like Jullien, he was an intrepid traveller, and his book includes observations not just on European wines but on those of Asia, Africa, and both North and South America. His emphasis on the word 'Modern' owes much to his criticism of earlier writers such as Sir Edward Barry and Alexander HENDERSON (see LITERATURE OF WINE), whose reverence for CLASSICAL WINES he felt was misplaced.

Red Hills, California AVA. See LAKE COUNTY.

Redondo, DOC subregion in central ALENTEJO in southern Portugal whose consistent climate owes much to the sheltering influence of the Serra d'Ossa.

redox potential, or oxidation–reduction potential, is in theory a measure of the summation of all of a wine's components' potentials to oxidize. Since wine is made up of components that are either oxidized or reduced (see OXIDATION and REDUCTION), it is a system composed of many joined redox pairs. Oxidation reactions are always coupled to reduction reactions. Electrons made available from an oxidation are taken up by the compound being reduced until an equilibrium is established. The reaction with the most positive value (in which electrons are most easily accepted) will occur at the

expense of reactions with lower values. Thus an equilibrium is reached from all the redox pairs and a net redox potential can be determined.

Redox potentials are of only limited value to even the most scientific winemaker, however, since they do not express how rapidly the various reactions will occur. They reveal only the potential situation that will obtain given unlimited time. Redox potentials can also prove to be difficult to measure in practice, and the ability of standard methods to measure the wine's redox chemistry have been disputed. A determination of the concentration of dissolved OXYGEN in a given wine can often prove to be of more value in guiding the winemaker in his or her choice of cellar treatments. A.L.W.

Danilewicz, J. C., et al., 'Wine reduction potentials: are these measured values really reduction potentials?', *Journal of Agricultural Food Chemistry*, 67/15 (2019), 4145–53. doi.org/10.1021/acs.jafc.9b00127

reduced-alcohol wine. See ALCOHOL REDUCTION and LOW-ALCOHOL WINE.

reducing sugars are sugars that can act as very mild reducing agents (see REDOX and REDUCTION). In wine, GLUCOSE and FRUCTOSE are the primary reducing sugars. See also RESIDUAL SUGAR, which shares the same abbreviation but has a different meaning.

reduction, chemical reaction that is in effect the complement of OXIDATION and one in which an element or compound gains electrons. The essential feature of an oxidation is that electrons are transferred from the component being oxidized to the one being reduced. The reaction cannot be isolated; to have a reduction, something else must be oxidized. Common reduction reactions are those of iron ore to iron the metal, or the reduction of ACETALDEHYDE to ETHANOL as happens in

the final stage of alcoholic FERMENTATION. Wine in a stoppered bottle or other airtight container is said to be in a reductive state.

Reducing conditions are desirable towards the end of fermentation so that alcohol is produced along with the carbon dioxide from the acetaldehyde. Reducing conditions are also generally preferable throughout ÉLEVAGE of wine in the cellar, especially for white wines, which can withstand oxidation much less well than reds with their higher content of PHENOLICS.

Wines, especially red wines held in the absence of oxygen, may suffer from excess reduction, resulting in the slow POLYMERIZATION of TANNINS and PIGMENTED TANNINS. Reduction and reductive are also used as convenient, but rather loose, terms to describe the perception of SULFIDES in wine by a taster (see MINERALITY). The presence of sulfides is usually considered to be a wine FAULT, although sulfur compounds can add complexity at lower levels, depending on the wine style. In some cases, reduction faults can be cured by AERATION, perhaps careful RACKING, an operation which introduces some oxygen, an oxidizing agent strong enough to prevent the reduction of most sulfur compounds.

Reduction has become a much-debated topic in the wine trade since the more widespread adoption of tin-lined SCREWCAPS as closures. While this phenomenon is not caused by screwcaps, the low permeability of screwcaps is less forgiving to wines with residual sulfides at bottling. Very good corks typically show a similar level of permeability to that of screwcaps (see OXYGEN TRANSMISSION RATE). See also REDOX POTENTIAL. V.L. & M.J.T

Goode, J., *Wine Science: The Application of Science in Wine* (3rd edn, 2021).

reductive winemaking, the use of various techniques to minimize the presence of oxygen in GRAPE JUICE and/or wine. Such techniques include the addition of SULFUR DIOXIDE with or without ASCORBIC ACID, blanketing of juice trays and tanks with INERT GAS, and

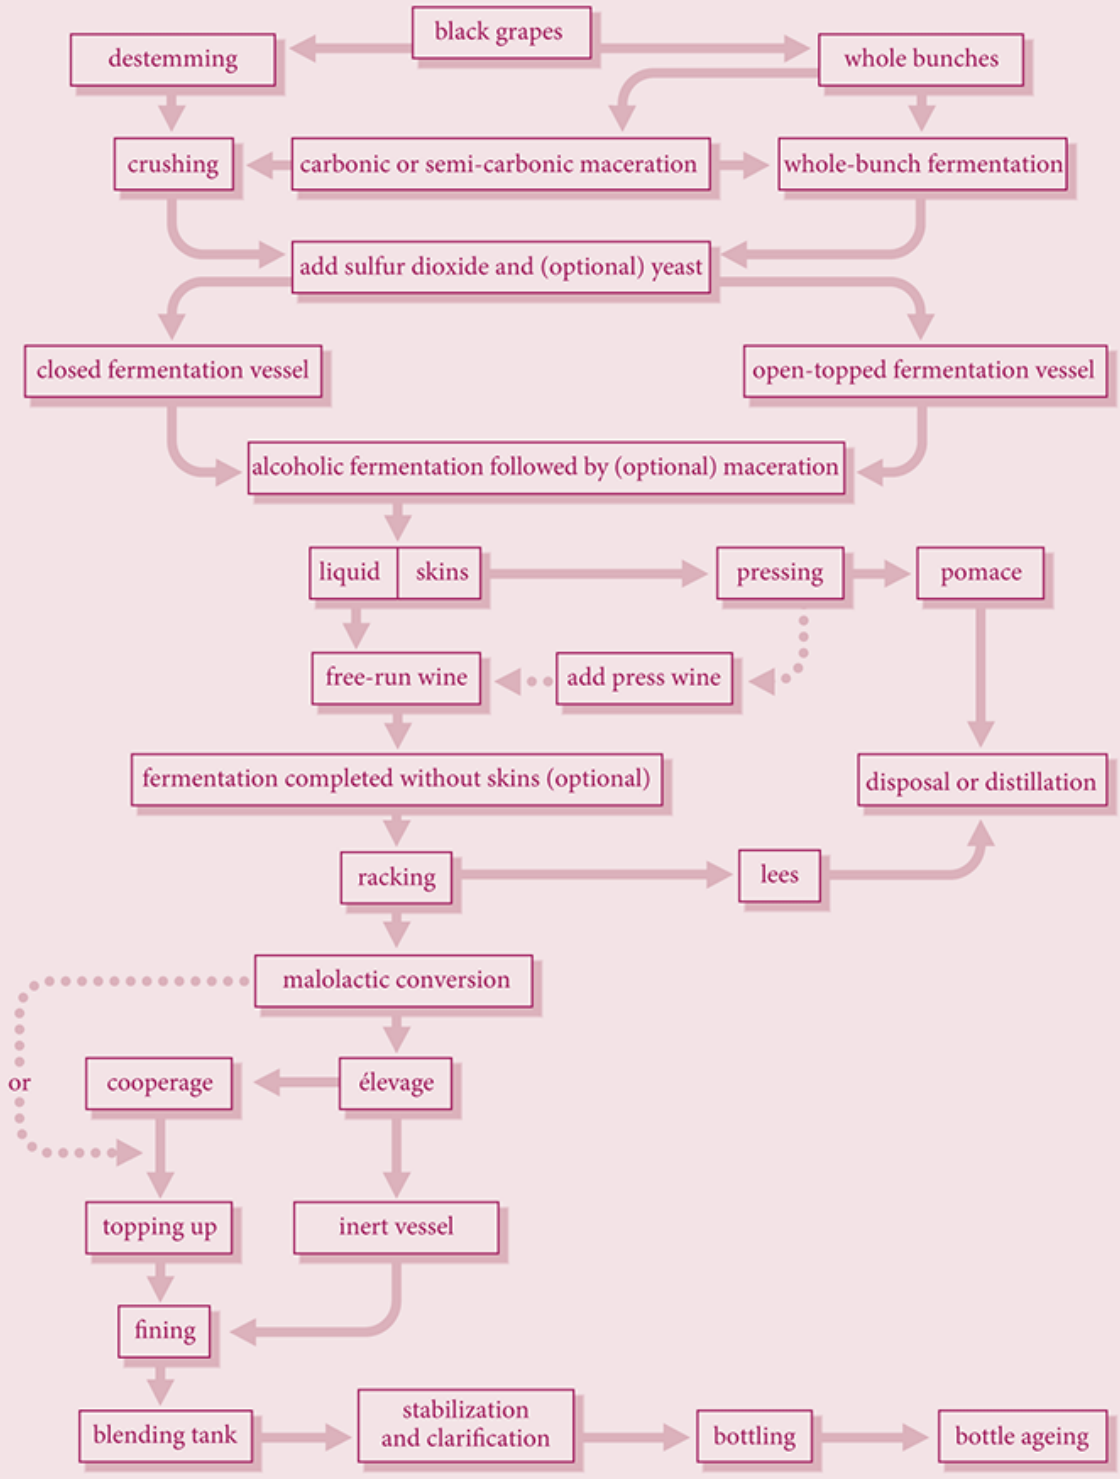
SPARGING with nitrogen during all transfers. This approach, which can enhance the fruitiness of wines, is typically used when the winemaker wants to protect delicate flavours and their FLAVOUR PRECURSORS from OXIDATION. However, it means that PHENOLIC compounds are also protected from oxidation and cannot therefore be removed prior to fermentation so that the final wines can show more bitterness and require more FINING. See REDUCTION for the common but inexact use of 'reductive' as a tasting term. M.J.T.

red winemaking, the production of wines with reddish to purple colours. The great majority of today's red wines depend on CRUSHING and DESTEMMING of the grape clusters as a first step in their production (but see also WHOLE-BUNCH FERMENTATION and CARBONIC MACERATION).

The mixture of skins, seeds, and occasionally some stem fragments, along with the juice, then goes into a FERMENTATION VESSEL, where YEAST converts SUGARS into ALCOHOL. The natural ANTHOCYANIN pigments, which are contained in the skins of black grapes, along with FLAVOUR COMPOUNDS, FLAVOUR PRECURSORS, and large amounts of PHENOLICS (the latter originating from both the skins and the seeds) are extracted into the fermenting wine by the alcohol produced by yeast during FERMENTATION and MACERATION. Without some maceration of juice and skins, wine made from dark-skinned grapes is merely pink (as described in ROSÉ WINEMAKING). Duration of this EXTRACTION process can be anything from a fast two- or three-day fermentation for an everyday wine to a week-long fermentation followed by a further one, two, or even three weeks' maceration for a full-bodied red wine that is designed to age.

Red-wine fermentations are almost always conducted at TEMPERATURES higher than those used for white wines. Red wines fermented at lower temperatures tend to be lighter in colour and body and to display the fruitier range of ESTERS. Some producers deliberately fashion light reds in this style to be consumed chilled.

Red winemaking



Red winemaking differs from white winemaking not only in terms of skin–juice contact and temperature but also because some exposure to OXYGEN is more generally desirable than with white wines; BARREL AGEING, or at least CASK AGEING, is also more common for red wines than white. The phenolic compounds extracted from skins, seeds, and stem fragments react more or less slowly with oxygen dissolved in the wine to form PIGMENTED TANNINS, and these, together with the colourless TANNINS that were extracted directly or formed during the maceration, contribute to the TEXTURE of the wine. Another important difference between red and white winemaking is that most red wines undergo MALOLACTIC CONVERSION whereas with whites it is generally a deliberate choice on the part of the winemaker, related to factors such as grape variety, the level of ACIDITY in the grapes, and the intended wine style.

During barrel ageing, when the oxygen supply to the wine is restricted, both the substances produced in the earlier reactions between grape phenolics and oxygen and those derived from extraction of the wood phenolics interact and contribute an entirely new range of flavours (see OAK FLAVOUR).

Further reactions of the grape- and wood-derived phenolic constituents, and augmentation of the grape-derived flavour compounds, all progress during AGEING in bottle. The abundance and great diversity of compounds available in a red wine are the reasons that ageing assumes particular importance for fine red wines. See also WINEMAKING.

P.J.W.

red wines actually vary in COLOUR from dark pink to almost black, with an enormous variation in the amount of blue or yellow to be seen at the rim. Their colour depends on the grape varieties used, the vintage characteristics, the health of the grapes, the winemaking methods (in particular the extent of MACERATION and the method of EXTRACTION), the wine's PH, and the amount of time it has spent in tank, barrel, and bottle. A red wine that has suffered OXIDATION or is

many decades old may be the same deep tawny colour as a very old white wine.

Red wines are produced in virtually all of the world's wine regions, although the proportion of red wines produced at the cool limit of wine production is low, since it can be difficult to develop sufficient pigmentation of most grapes' skins to produce a proper red wine (although see also TEINTURIERS).

French for red is *rouge*, Italian is *rosso*, Spanish and Portuguese more expressively *tinto*, and German is *rot*.

It has been only since the development of BOTTLES suitable for AGEING wine that red wines have been seen as in any sense superior to white (see ancient GREECE, ROME, medieval ITALY, and FASHION). A general market preoccupation with white wines in the 1970s was overtaken in the 1990s by what was called the red-wine boom, encouraged in the US by a TV programme about the FRENCH PARADOX and by a belief in the emerging markets of ASIA that red wine was HEALTHIER.

reflection from soils and in some cases from water is considered by some to influence wine quality. 'Albedo' is the term which describes reflectance of SUNLIGHT. Very white soils, such as the ALBARIZA soils of JEREZ, have high albedo and so can add to the heating of vines growing on them. This is easy to demonstrate by calculation. More difficult to prove or measure is the theory that sunlight reflected from rivers may benefit nearby vineyards, as in the Mosel Valley. While the eye can behold the silvery sheen of water at low sun angles (specular reflection), it is unlikely that this can have any significant warming effect on adjacent vineyards. R.E.S.

Refosco is a group of distinct red varieties cultivated in north-east Italy, Slovenia, and Croatia producing very similar wines. The finest variety is known in Friuli as REFOSCO DAL PEDUNCOLO ROSSO, but others include Refosco d'Istria (also called TERAN, Terrano, and Refošk).

Refosco dal Peduncolo Rosso, named after its red stem, is a member of the REFOSCO group of red grape varieties that makes usefully vigorous wine in the FRIULI region of north-east Italy. It has a long history in the area, apparently praised by PLINY the Elder and reputedly producing the favourite wine of Livia, the second wife of Augustus Caesar, cited in the *Annals of Friuli* of Francesco di Manzano in 1390. DNA PROFILING at SAN MICHELE ALL'ADIGE revealed a parent–offspring relationship with MARZEMINO, another ancient variety of northern Italy.

This vine is cultivated both in HILLSIDE VINEYARDS and in flatter parts of Friuli and gives a deeply coloured wine with plummy flavours and a hint of almonds, a medium to full body, and rather elevated ACIDITY, which can be difficult to control or moderate, the variety being a notoriously late ripener. Refosco has the advantage of good resistance to autumn rains and ROT.

There was a significant return of interest in Friuli's Refosco in the 1980s, and much greater care was taken in its cultivation and vinification in an effort to improve the wine's quality, although total plantings in 2015 were only 1,267 ha/3,131 acres.

The most promising zone for Refosco is FRIULI COLLI ORIENTALI and the Koper district in SLOVENIA. Others include FRIULI GRAVE, LISON-PRAMAGGIORE (in the area outside Friuli), Latisana, and Aquileia.

refractometer, an instrument for measuring a refractive index, which is related to the amount by which the angle of a light wave is changed when passing through the boundary between two media. The amount of refraction is a convenient way to measure solute concentration of a solution and is widely used in viticulture and winemaking to follow the ripeness of grapes (by measuring MUST WEIGHT) and changes during vinification. Refractometers may be precision laboratory instruments or pocket versions that can be used in the vineyard. In either case, TEMPERATURE correction or control is important for accuracy. B.G.C.

refrigeration, cooling process that has had a profound effect on how and where wine is made and how it tastes (see TEMPERATURE), enabling the winemaker to have a much greater degree of control than was possible before mechanical refrigeration became the norm for all but the least sophisticated wineries in the second half of the 20th century. More than any other factor, refrigeration has permitted warm and hot regions to produce wine of internationally acceptable quality.

Making wine

The essence of refrigeration is the transfer of heat from the body being refrigerated to some other place. The most obvious winery application of refrigeration is in the TEMPERATURE CONTROL of FERMENTATION—although refrigeration also allows winemakers to delay the processing of freshly picked grapes or must (see MUST CHILLING) until convenient, even in hot areas, where the use of chilled rooms to cool and store grapes prior to pressing has increased. The energy generated by the conversion of sugar to alcohol, carbon dioxide, and water is only partly used by the YEAST in building cells and by-products. The rest appears as heat, which, above a certain temperature, risks killing the yeast and therefore arresting the fermentation process. The amount of heat generated by fermentation is large: for example, 10 hl/260 gal of grape juice containing 20% sugar will generate about 3.6 million kilocalories, or enough to melt 45 tons of ice.

Not all the heat generated has to be removed by refrigeration, however. Because heat moves naturally by conduction from hotter bodies to cooler ones with which they are in contact, warm fermenting wine loses heat to the walls of the FERMENTATION VESSEL and from the outside of the wall to the atmosphere. Some of the fermentation heat will be removed by radiation from the outside of the fermenting vessel too, provided its temperature is higher than that of the objects in its vicinity. Heat may also be lost by radiation if open-topped fermentation vessels are used or by volatilization of some of the water and alcohol in the wine.

All of these natural heat-removal processes that function independently of refrigeration occur at the surfaces of the fermenting mass. Heat production, on the other hand, occurs throughout the entire volume of the mass. The amount of heat removed from a fermenting mass therefore depends on the surface-to-volume ratio of the fermentation vessel. A 225-l/59-gal BARRIQUE, for example, will probably lose enough generated heat for the temperature to remain within an acceptable range for fermentation. A typical large tank, on

the other hand, which might contain several hundred hectolitres, will certainly need active heat removal to keep the temperature of the fermenting mass below danger point.

The development of mechanical refrigeration in the early 20th century made cooling at least a possibility in areas where insufficient naturally cold water was available. Early efforts to control temperature, used in France as recently as the 1970s, included the simple addition of blocks of ice to the fermenting wine (with concomitant dilution). More mechanical early systems of refrigeration cooled the wine by running cold water through metal tubes suspended in the tank. The development of more efficient PUMPS permitted systems which moved wine from the tank through coils immersed in cold water and then back into the tank.

In modern wineries, however, wines are seldom moved for cooling purposes. STAINLESS STEEL tanks with cooling devices, usually coils, inside the tank and cooling jackets incorporated in the external walls are now standard wine equipment. Temperature-sensing probes in tanks signal a computer system which controls the supply of refrigerant to the coils to a level predetermined for each tank by the winemaker.

Refrigeration has become increasingly important in other winemaking processes, however. Some producers, notably in Australia, store grape juice in refrigerated conditions for several months before fermentation. Pre-fermentation cold MACERATION occasionally calls for refrigeration too. In warmer wine regions, some degree of refrigeration may be needed during wine maturation, and refrigerated tanks are routinely used for everyday wines to ensure that TARTRATES are not precipitated in bottle (see STABILIZATION).

A.D.W.

Serving wine

Refrigeration plays a part, and all too often a villainous part, in the SERVING of wine. Long before the advent of mechanical refrigeration, and its domestication, wine was deliberately chilled prior to serving (see ancient GREECE, for example). It was fashionable to chill both red and white wines before serving at least from the 16th century. A wide range of wine coolers was used to achieve this until the 20th century, when mechanical refrigeration was domestically available. The modern successors of these large containers for both ice and bottles are the single-bottle wine coolers known as ice buckets and the gel-filled flexible sleeves kept frozen and ready for use.

See also TEMPERATURE.

regenerative viticulture, a system for growing wine grapes that follows the principles of regenerative agriculture, an approach not yet widely defined in regulatory terms and also known as agro-ecology. Advocates of this increasingly discussed approach suggest that it regenerates rather than depletes agricultural land by building soil ORGANIC MATTER to mitigate and undo the adverse consequences of conventional farming and CLIMATE CHANGE. Practices include planting multispecies COVER CROPS in the mid rows to sequester carbon from the atmosphere and put it back into the soil, keeping mid rows and under-vine soil covered by MULCH or sympathetic plants, avoiding soil disturbance (see NO-TILL), increasing biodiversity on the farm, using organic products to promote microbially rich soils (see SOIL BIOTA) with healthy MYCORRHIZAL fungal networks, and carefully grazing cattle and sheep for organic matter and weed management.

I.S.-B.

Newton, P., et al., 'What is regenerative agriculture? A review of scholar and practitioner definitions based on processes and outcomes', *Frontiers in Sustainable Food Systems*, 4 (2020), 194. doi.org/10.3389/fsufs.2020.577723

Regent, particularly successful dark-skinned DISEASE-RESISTANT VARIETY bred at Geilweilerhof in Germany and first registered in 1989. This complex HYBRID of a SILVANER × MÜLLER-THURGAU cross with CHAMBOURCIN reaches full ripeness easily and makes wine with good colour and moderate ACIDITY. It is grown on a total of 1,722 ha/4,255 acres in Germany, particularly in Rheinhessen and the Pfalz, and is also planted in Switzerland, England, Belgium, Scandinavia, and New Mexico.

Reggiano, a DOC in EMILIA-ROMAGNA that used to be called Lambrusco Reggiano until its name was changed to allow the production of still and sparkling reds of up to 60% ANCELLOTTA. (It is notable that total plantings of Ancellotta in Emilia-Romagna in 2017 were 4,300 ha/10,626 acres, almost as much as the 4,635 ha of the most planted LAMBRUSCO, Salamino—presumably a reflection of producers' desire to add colour from the deep-tinted Ancellotta grape to their various Lambrusco grapes.) A wide range of Lambrusco varieties as well as Sangiovese, Cabernet Sauvignon, and Merlot are allowed in DOC Reggiano. YIELDS may be as high as 140 hl/ha. W.S.

Região Demarcada, (RD), Portuguese for 'demarcated region', although the expression is no longer seen on labels. See DOC for more details.

regionality, NEW WORLD term for the concept, now fully accepted there, that the location of a vineyard plays an important part in shaping the character of the wine produced from it. It is less geographically precise and, importantly, less French than the term TERROIR, although the latter is increasingly used worldwide.

More and more wines in, for example, California and Australia, where the word was coined, are labelled and marketed on a geographical as well as VARIETAL basis, even if many producers are

wary of the restrictions that would ensue from CONTROLLED APPELLATIONS.

régisseur, French term used particularly to refer to the director or manager of a Bordeaux estate.

Régnié, the most recently created BEAUJOLAIS cru (in 1988), out of land in the neighbouring communes of Régnié-Durette and Lantignié. In a way this was rectifying past oversights: both towns historically had parcels as respected as some in neighbouring CHIROUBLES or BROUILLY. With 391 ha/966 acres under vine, it continues to grow in prominence, its sandy and stony GRANITIC soils both interesting and affordable—especially in the hilly western portion, where ELEVATION and ASPECT conspire to merge its typically fragrant, subtle character with more STRUCTURE. J.F.B.

Reguengos, subregion of the ALENTEJO in southern Portugal, home to a successful CO-OPERATIVE winery and ORGANIC pioneer Herdade do Esporão.

regulated deficit irrigation (RDI), an IRRIGATION scheduling technique which uses mild WATER STRESS at key stages of fruit development to reduce vegetative growth and improve berry RIPENING and thus improve grape quality.

RDI was first applied on peach and pear orchards in Australia in the 1980s. Research showed that it restricted SHOOT growth without significantly affecting YIELD. It is now common practice in many vineyards around the world, especially in those planted to black grape varieties, due to the greater benefits to grape colour.

The main benefits of this strategically managed water stress are less competition between berry ripening and vegetative growth, better water conservation, and reduced BERRY SIZE. Successful

application requires careful monitoring of EVAPOTRANSPIRATION and SOIL WATER content and typically results in slightly lower yields. It is most effectively applied through DRIP IRRIGATION, which allows the application of small amounts of water at frequent intervals.

RDI is more stressful to the vine than PARTIAL ROOTZONE DRYING, and its use in hot regions can cause problems if its application is followed by a spell of hot, windy weather with low humidity: vines with limited soil moisture can suffer extremes of water stress, which may, for example, lead to leaf desiccation and even loss of leaves. This situation can be alleviated by carefully monitoring weather forecasts and applying some irrigation.

Water deficit is generally applied from the time berries are pea-sized to a week or so after VERAISON but is generally avoided in the later stages of berry ripening. J.E.H. & R.E.S.

Reichensteiner, white grape variety whose GEISENHEIM creator Heinrich Birk maintained was the first EU CROSS, with French, Italian, and German antecedents. In 1939 he developed this cross of MÜLLER-THURGAU with a cross of the French table grape MADELEINE ANGEVINE and the Italian Calabre. Both wine and vine most closely resemble its undistinguished German parent, but Reichensteiner with its looser bunches is less prone to ROT, and well-pruned plants stand a good chance of reaching Prädikatswein must weights in good years (see PRÄDIKAT). Just 37 ha/91 acres remained in Germany in 2020. Also planted in England and to a limited extent in Switzerland, Japan, and

British Columbia. Along with GAMAY, it is a parent of the Swiss crossings GAMARET, GARANOIR, and Mara.

religion and wine. The relationship between religion and wine is as ancient as wine itself.

The earliest archaeological evidence of wine (see ORIGINS OF VINICULTURE) goes back to ancient China, though we know little of the relationship between religion and wine at that time. Our earliest archaeological evidence of religion and wine is found in ancient Egyptian pictorial records (see EGYPT) and Hittite texts and images. These ancient civilizations were profoundly attuned to the spiritual world and used wine in their religious cults, rituals, and celebrations. They offered up wine as LIBATIONS, their priests drank wine, and they placed sealed wine jars in royal and priestly tombs, presumably in preparation for the afterlife.

In the ancient world, agricultural products including wine were seen as gifts from the gods. The Greeks, Etruscans, and Romans even had their own wine gods—Dionysus, Fufluns, and Bacchus, respectively—to whom they offered libations. Various cults developed around the worship of the Greek god of DIONYSUS, often accompanied by religious seasonal festivals and celebrations, and at certain times and places these included ritual dancing, theatrical performance, DRUNKENNESS, and ecstasy. Wine was widely used for medicinal purposes and placed in tombs for the afterlife. Wine was also linked to the pursuit of truth, as the Greek phrase *in vino veritas* suggests. The Greek SYMPOSIUM, however, was a secular affair devoid of religious rituals.

We know little about the Etruscan wine god Fufluns. The Roman god of wine, BACCHUS (Latin from Dionysus), was celebrated in religious rituals, festivals, and processions. Images of Bacchus appear in Roman mosaics, where he is depicted with a lyre player celebrating the kinship between wine and music. Bacchus also adorned Roman tombs and sarcophagi, anticipating and preparing the deceased for the afterlife.

The connection between wine and religion was likewise important in pre-Islamic PERSIA. The mystical poetry of the 14th-century poet Hafez of Shiraz harks back to ancient Persia, and his poetry speaks of ruby red wine in the goblet as a symbol for divine radiance, and the wine shop as an image for the realm of angels.

The most comprehensive understanding of wine and religion can be found in Judaism and Christianity, as recorded in the BIBLE, where wine is described as a blessing from God with the explicit purpose of 'gladdening' people's hearts. They seem to be the only religions practised today that ascribe significant religious import to wine and actively use it in their religious celebrations (the Passover and the EUCHARIST).

Inspired by the Bible and the need for wine in the Eucharist, Christian monks and nuns played a central role in developing viticulture and wine in Europe and beyond. By the 12th century, monasteries were the largest producers of wine in Europe. (See MONKS AND MONASTERIES for further details.)

The theme of wine in the Bible became an inspiration for artists as they carved vines into the stone pillars that upheld some of the great cathedrals of Europe and made stained-glass windows for these cathedrals and churches depicting the spies with a grape cluster returning from the Promised Land (Num. 13. 21–7). In the later Middle Ages, depictions of Christ in the wine PRESS became popular, as did paintings of Jesus celebrating the Lord's Supper with his disciples. Western art history is saturated with biblical imagery, and the theme of wine has a central place in it.

To this day, winemakers such as Aubert de Villaine from DOMAINE DE LA ROMANÉE-CONTI and Tim Mondavi from Continuum take inspiration from the Bible and from the medieval monks and nuns whose passion was to make wine to glorify God—wines that lift attentive drinkers out of the mundane and inspire them towards a sense of wonder, awe, and reverence. remontage, French word for various systems of PUMPING OVER.

The term may also be used in French for soil replacement after erosion in vineyards (see SOIL EROSION).

remote sensing is the detection and/or measurement of features on the Earth's surface using sensors mounted on satellite, aircraft or DRONE platforms. Its application in viticulture is almost entirely confined to the inference of VIGOUR and CANOPY condition. This is achieved by sensing the amount of SUNLIGHT that is reflected from a vineyard in the visible (blue, green, red) and near infrared parts of the electromagnetic spectrum and calculating ratios between them. Commonly used indices in viticulture are PLANT CELL DENSITY (PCD) and the NORMALIZED DIFFERENCE VEGETATION INDEX (NDVI). Research has shown VERAISON to be the optimal time to acquire remotely sensed imagery of vineyards, especially with respect to its use in PRECISION VITICULTURE or ZONAL VITICULTURE to underpin SELECTIVE HARVESTING. However, more frequent acquisition of imagery may be needed when the objective is to assess vine water status to support IRRIGATION management. R.G.V.B.

remuage is French for the RIDDLING process. A person or machine that performs remuage is a remueur.

rendement, French for YIELD, usually expressed in hl/ha.

rendzina, a term, originally Polish, used in some soil classifications for a dark, well-drained soil formed on CALCAREOUS bedrock. Typically, rendzina soils are recently developed, stony, and thin, showing a distinctive natural vegetation. They are common on the LIMESTONES and CHALKS of England and France, as well as in Eastern Europe.

A.J.M.

research into grape-growing and wine production is officially and principally in the domain of academe, although some individual viticulturists and winemakers are more prone to experimentation and more subject to the rigour of SCIENCE than others. For a list of important wine research institutions, see ACADEME.

Reserva, term used in both Spain and Portugal to distinguish wines from a supposedly good vintage. In Portugal, a Reserva is a wine from a single vintage with outstanding organoleptic characteristics and an ALCOHOLIC STRENGTH at least 0.5% above the regional minimum. In Spain, a red wine labelled Reserva will have had at least three years' AGEING in cask and bottle, with at least a year of this period in OAK (*barricas* are stipulated for Rioja). Spanish white and rosé wines labelled Reserva must spend a total of at least two years in cask and bottle to qualify, including at least least six months in oak.

See also GRAN RESERVA.

Reserve is a term liberally used by wine producers for various bottlings and one that should indeed be reserved for superior wines. However, unlike RESERVA and RISERVA, the English term 'Reserve' has few controls on its use. Some wineries release several bottlings incorporating the word in their names (Proprietor's Reserve, Estate Reserve, Reserve Selection, Private Reserve, Vintner's Reserve, and the like). The (unregulated) French term is Réserve leading to the use of terms such as Cuvée de Réserve. In CHAMPAGNE, reserve wines are those held over from a given year for future blending, typically into the NON-VINTAGE cuvée.

residual sugar, occasionally RS, the total quantity of SUGARS remaining unfermented in a finished wine. This may include both fermentable sugars, mainly GLUCOSE and FRUCTOSE, which have for some reason (see below) remained unconverted to alcohol during FERMENTATION, and small amounts of those few sugars which are not readily fermented by typical wine YEAST. Some, but by no means all, residual sugar is tasted as SWEETNESS. REDUCING SUGARS, a term used by both the EU and the OIV, refers to all the sugars measured in a finished wine, including residual sugar and any sugars added post fermentation (e.g. in the form of SWEET RESERVE).

Residual sugar in wine is usually measured in grams of total sugars per litre of wine and can vary between about 1 g/l (0.1%) and 150 g/l (15%) or more. Wines with a residual sugar content of less than 2 g/l, such as the great majority of red wines and many white wines that do not taste at all sweet, are generally described as 'dry' (but see SWEETNESS for some more specific definitions). It is rare to find a wine with much less than 1 g/l residual sugar because some sugars are almost invariably impervious to the action of the yeasts. On the other hand, some wines with a residual sugar level even as high as 25 g/l may taste dry because the sweetness is offset by high ACIDITY. Some ordinary wines (usually white) that are naturally high in acids may have sugars (usually the particularly sweet fructose), sweet GRAPE JUICE, or sweet RECTIFIED GRAPE MUST added deliberately

to increase their palatability or commercial appeal (see SWEET RESERVE).

Exceptionally sweet wines may be produced either in extraordinarily ripe years or by unusual winemaking techniques such as those involved in freeze CONCENTRATION or in BOTRYTIZED or DRIED-GRAPE WINES. The sweetest form of the unique Hungarian sweet wine TOKAJI, for example, must have a minimum residual sugar of 250 g/l—the 1947 vintage of Tokaji Essencia managed 488 g/l.

Sugar levels in grapes are measured as MUST WEIGHT by various different scales, of which BAUMÉ, BRIX, and OECHSLE are the most common.

One German wine harvested at Nussdorf in the Pfalz in 1971 was picked at 326 °Oechsle, or about 870 g/l sugar, and had reached only 4.5% alcohol in a particularly slow fermentation 20 years later, producing a wine with about 480 g/l residual sugar.

Between 16 and 17 g/l of sugar are required to produce 1% of alcohol in white and rosé wines, and about 18 g/l in reds.

There are many reasons why fermentable sugars may remain unfermented: yeasts vary enormously in their potency, especially their tolerance of higher sugar and higher alcohol concentrations; grape MUSTS vary in their micronutrient and growth-factor content; low TEMPERATURES and chemical additions can also arrest fermentation; and, probably the most influential factor, the expertise of the winemaker plays a deciding role.

Residual sugar presents no great danger in a wine that is yet to be processed in BULK, but in a bottled wine the presence of such sugars may cause FERMENTATION IN BOTTLE. Small amounts of sugar are furthermore readily used by yeast or BACTERIA to produce unwanted ACETIC ACID, off-flavours, and, sometimes, CARBON DIOXIDE gas. The winemaker therefore must ensure either that a wine is effectively free of fermentable sugars (less than 0.2 g/l) for dry wines or that, in the case of most sweet and medium-dry wines, the wine undergoes full STABILIZATION against the risk of further microbiological activity. This can be achieved by FILTRATION. A.D.W.

residues. Residues of AGROCHEMICALS, the commercial preparations used in vineyards for the control of pests, diseases, or weeds, are that portion which is found on the grapes at harvest or in wine. The time between permitted last application and harvest, known as the 'withholding period', commonly results in degradation of the agrochemical. Most of any residue borne on the grapes at harvest is likely to be eliminated with the skins after PRESSING, and more is removed or degraded during juice CLARIFICATION, FERMENTATION, and subsequent FILTRATION.

PESTICIDES may leave deposits or by-products that persist in plant or animal tissues or in soil, water, or air. Some pesticides are rapidly inactivated after application; others (or their by-products) may persist for years. Such residual contamination may affect human or livestock health, limit subsequent crop growth, and pollute the environment. Excessive or illegal pesticide residues in wine may lead to rejection on domestic and/or international markets, perhaps as a result of the use of inappropriate pesticides, incorrect application methods, or application too close to harvest. Residue effects on non-target organisms should also be considered. Useful insects such as bees or natural parasites and predators of insect pests (see ECOSYSTEM) may be affected by pesticide residues.

FUNGICIDE residues may inhibit fermentation by YEAST, as discussed by Caboni and Cabras, but extensive trials have shown that the proper use of fungicides has no adverse effect on the taste or smell of wines, although residues of elemental SULFUR used to prevent FUNGAL DISEASE in the vineyard can be transformed, in REDUCING conditions (see REDUCTION), into foul-smelling HYDROGEN SULFIDE.

Maximum residue limits (MRLs) are established by governments for particular agrochemicals or their metabolites (breakdown products) in particular foodstuffs. MRLs are typically set at levels which are not likely to be exceeded if the chemicals are used in accordance with good agricultural practice and if a dietary-exposure evaluation shows no undue hazard to human health, although some winegrowers and consumers firmly reject the suggestion that even a

very low level of residues is safe. Trade in wine internationally can be hindered when markets differ in their MRLs. See also AGROCHEMICALS.

resinated wines. Of the earthenware vessels in which the ancient Greeks and Romans kept their wines (see AMPHORAE), only the very best were airtight. Normally they were porous, and it is clear from the Roman writers on agriculture that the insides of jars were therefore coated with resin. It was therefore probably as a purely practical measure that resin was initially used. But soon people must have discovered that the wine would keep even better if they added resin to the wine itself. COLUMELLA deals at length with the different kinds of resin that can be employed in this way (*De re rustica* 13. 20–14), but he emphasizes that the best wines should not have resin put into them. Yet many people came to like the taste of resin and used it not only as a preservative but also as a flavouring agent. PLINY recommends that resin should be added to the fermenting MUST (*Natural History* 14. 124) and discusses which kinds of resin are best: resin from mountainous regions has a more pleasant smell than resin from low-lying areas (16. 60).

The Romans abandoned amphorae in favour of wooden casks in the 3rd century CE because BARRELS were lighter and easier to handle. Wooden casks do not need an inside coating of resin, and this saved the winemaker time and money. Thus the Romans ceased to make resinated wines. Winemakers in Transalpine Gaul, most of whom did not have pine trees nearby, and those of Cisalpine Gaul, Illyria, and the alpine region, where the climate is cooler and wood does not crack so easily, had started using wooden casks in the 1st century CE. Unlike the West, however, Byzantium did not lose its taste for resin when it was no longer needed as a preservative. The pine forests of the eastern part of central Greece and of Euboea still provided the

resin to enhance the flavour of some Greek wines after the 7th century.

This was very much not to the taste of one Western visitor to Constantinople. In 968 Liudprand, bishop of Cremona, was sent there to arrange a marriage between the daughter of the late Emperor Romanos and the son of his own patron, Otto I, the Holy Roman Emperor. The mission was not a success. The Emperor Nicephorus treated Liudprand rudely and kept him a virtual prisoner. Liudprand's *De legatione Constantinopolitana* ('The mission to Constantinople') was his revenge. He has not a good word to say for the Byzantines in general and Nicephorus in particular. The work is a masterpiece of invective, and, since Liudprand's purpose is satirical, we should not believe his every word. But his observations on the food and wine he had are interesting. Horrified, he relates how he was given goat stuffed with onions, garlic, and leeks, swimming in fish sauce. Worst of all, and mentioned in his very first chapter, is the wine: undrinkable because it is mixed with resin, pitch, and gypsum. Like the fish sauce, this would not be remarkable in the least to an ancient Roman, but it was not a thing to serve a modern Lombard. Of course, Liudprand may have also encountered perfectly decent, unresinated wine at times during his enforced stay, but it would have spoilt his story to tell us about that.

Still, not all Greek wine was resinated in the Middle Ages. The strong, sweet wines that reached the markets of western Europe were not, but pilgrims travelling to the Holy Land recounted that some local wines were. The account of Pietro Casola, who sailed to Jerusalem in 1494, stopping frequently along the way, is particularly valuable because he takes pains to describe the customs, food, and wines of every region. He often speaks of the excellent sweet wines in Greece, but in Modone, on the south-western tip of the Peloponnese (near Monemvasia, which gave its name to MALVASIA), he is given a wine that has had resin added to it during fermentation in order, he explains, to preserve it. He objects to its strong unpleasant odour but goes on to describe the fine Malmsey, Muscatel, and Tumney of Modone. Of Cyprus he says that he loves everything about it except the wine, which has resin in it. He must have been unlucky

not to have tasted the famous sweet wines that Cyprus exported, but an earlier account by an anonymous French cleric, *Le Voyage de la Saincte Cyte de Hierusalem* of 1480, confirms what he observes about Cyprus and Modone.

resins used in winemaking are natural or synthetic materials usually composed of long chains of simpler molecules that are capable of POLYMERIZING. Gum acacia is a natural resin used to stabilize the PIGMENTS in red wine. Another natural resin is Aleppo pine resin, which is used in the preparation of RETSINA.

Synthetic resins, manufactured by polymerization processes, have several uses in winemaking. One of the commonest is epoxy resin, which can be used in the form of a two-part paint for coating the inside of CONCRETE vats, producing an inert and easily cleaned surface. Epoxy-resin compounds are also used for surfacing floors in wineries and bottling halls, being much more resistant than concrete to the acids in wine.

Silicone resins are used in the manufacture of BUNGS for wooden BARRELS; they have the flexibility of rubber but are TAINT-free and non-perishable.

ION EXCHANGE resins can be used in some countries for TARTRATE stabilization and for the manipulation of PH. They are prepared in the form of small beads which are packed into a vertical cylindrical tank known as a column, through which the wine is passed. The particular property of these resins is their ability to exchange the ions which are loosely held on their surface with ions in the liquid phase. D.B.

respiration, biochemical process in animals and plants, including vines, which provides the chemical energy required for other reactions and for growth. Respiration may be considered the opposite of PHOTOSYNTHESIS in that OXYGEN is consumed and CARBON DIOXIDE and energy released, according to the following formula:

$$H_{12}O_6 \text{sugar} + 6O_2 \rightarrow 6CO_2 + 6H_2O + \text{energy}$$

In addition to SUGARS, other compounds such as STARCH, fats, AMINO ACIDS, organic ACIDS, and more may be broken down to release energy.

In plants, temperature has a major effect on respiration rate. The rate of respiration approximately doubles for each 10 °C/18 °F increase in temperature. Of particular interest to wine drinkers is the respiration of MALIC ACID, which takes place in the grape during RIPENING. This reaction depends on temperature, an important reason acidity levels are higher in wines from cooler climates.

See BERRY CELL DEATH for a condition caused by excessive respiration. R.E.S.

resveratrol. PHENOLIC compound produced by grapevines (and other plants such as blueberry, peanut, and eucalyptus), particularly in response to microbial attack (see PHYTOALEXINS) or artificial agents such as ULTRAVIOLET RADIATION. It is one of a number of compounds (including CATECHIN and QUERCETIN) found in wine thought to

contribute to HEALTH aspects of its moderate consumption, though resveratrol is also found in grape juice and raisins. Resveratrol belongs to a class of compounds called stilbenes. In grapevines this also includes its derivatives, piceid, pterostilbene, and polymers of the base resveratrol unit viniferin. Woody parts of the vine normally contain large amounts of stilbenes, principally viniferins, which are thought to protect against wood decay.

In the vineyard, leaves and berry skins produce resveratrol in response to some action, such as fungal attack from DOWNY MILDEW or BOTRYTIS, where its subsequent accumulation at the infection point may slow or stop the infection. Vine species, variety, CLONE, ROOTSTOCK, environment, disease pressure, and vinification methods can affect resveratrol concentration in the finished wine. For example, wines made from MUSCADINIA grapes, from the interspecific HYBRID Castor or from PINOT NOIR tend to have high levels of resveratrol, whereas CABERNET SAUVIGNON has lower levels. Wines produced in cooler regions or areas with greater disease pressure such as Burgundy and New York often have more resveratrol, while wines from hot, dry climates such as Australia and California frequently have less.

The gene for resveratrol synthesis, stilbene synthase, was cloned from VITIS VINIFERA vines and inserted into ROOTSTOCK 41 B. The transgenic plants produced high concentrations of resveratrol and were more resistant to botrytis infection, showing its value as a natural defence agent.

External agents, such as UV radiation or yeast extracts, can induce resveratrol production in vine tissues, which has led to the development of UV trailers that can be towed through the vineyard in an attempt to control diseases.

Red wines have about ten times the resveratrol concentration found in whites. This is not because white grapes make less resveratrol but rather because stilbenes are made in the grape skins, and MACERATION, integral to the production of a red wine, allows EXTRACTION of more of these compounds. Much of the interest in

resveratrol comes from its suspected connection to the health benefits of moderate wine consumption. It was reported to be the active component of an Asian medicinal herb made from *Polygonum cuspidatum* root in 1982, but it was not until 1992 that New York researchers Siemann and Creasy made the link between it, wine, and its possible contribution to the FRENCH PARADOX.

Resveratrol has been reported to have many beneficial effects on health, particularly in relation to cardiovascular disease, cholesterol, diabetes, and cancer. However, research has not reached a consensus due to the complexity of running clinical trials and other factors, such as the bioavailability of resveratrol and other phenolic compounds.

retsina, classified in Greece as an *appellation traditionnelle* (one of the EU's TRADITIONAL TERMS), is a term exclusive to dry, RESINATED WINES from Greece. With one South Australian exception, resinated wines are rarely made outside Greece and southern Cyprus.

Modern retsina is made like any other white (or rosé) wine, except that small amounts of resin from the Aleppo pine (*Pinus helepensis*) are added to the juice and left with the wine until the first RACKING or

before, the timing determined by taste. The selection of resin is itself an art. Major producing areas are Attica, Evvia, and Viotia, all in southern central Greece close to Athens, but retsina is made all over the country, with 15 areas awarded PGIs for their particular versions. SAVATIANO is usually the principal grape, often enlivened with some RODITIS or occasionally ASSYRTIKO, but a wide range of local varieties are also used, such as ATHIRI on the island of Rhodes and Muscat on Samos.

A profusion of poor-quality retsina damaged Greek wine's image in the 1970s and 1980s, but by the 2000s producers such as Kechris and Gaia were creating exceptional retsinas based on top-quality wine made from Assyrtiko or high-ELEVATION Roditis elegantly flavoured with high-quality, carefully sourced pine resin. Their efforts have inspired a new generation of resinated wines that prove that great retsina is no oxymoron. Top examples can be enjoyed in the same way as a FINO sherry. K.L.

Reuilly. This small but expanding AOC (under 300 ha/740 acres in 2019, up from 30 ha in the early 1990s) sits between the tributaries of the Cher and Arnon in the middle LOIRE. Its LIMESTONE slopes are planted predominantly with Sauvignon Blanc, which makes a fruity, pungent wine. Simple, juicy reds are made from Pinot Noir, and pale rosés from Sauvignon Gris. Denis Jamain is one of the most dedicated producers in the region and one of the few to have converted to ORGANIC VITICULTURE. The wines tend to be earlier-drinking and less complex than those of SANCERRE and MENETOU-SALON. This appellation is not to be confused with that of RULLY in the Côte Chalonnaise.

See also LOIRE, including map. C.P.

Réunion, a French island in the Indian Ocean, its VOLCANIC soils once mainly planted with ISABELLA, now produces small quantities of wines from French varieties such as CHENIN BLANC, GAMAY, PINOT NOIR,

and SYRAH at ELEVATIONS of up to 1,300 m/4,625 ft. The CO-OPERATIVE Le Chai de Cilaos, founded in 1992, dominates production.

reverse osmosis is an increasingly popular though rather controversial winemaking intervention or MANIPULATION based on the principle of cross-flow or tangential membrane filtration and osmosis. In standard FILTRATION procedures, the liquid flows perpendicularly to the filter surface, making clogging a major problem. In cross-flow filtration, the liquid flows parallel to the membrane filter so that it helps scour the surface and prevent clogging.

The use of techniques based on cross-flow filtration has become popular for wine STABILIZATION (see ULTRAFILTRATION). Pressure is applied to force small molecules such as water and some salts to pass through the membrane filter (i.e. the permeate) while concentrating the remaining wine compounds (i.e. the retentate).

It is currently used chiefly for two distinct purposes: ALCOHOL REDUCTION and must or juice CONCENTRATION. In the former, a possible alternative to HUMIDIFICATION, a portion of a high-alcohol wine is passed through a reverse-osmosis installation, which removes a colourless permeate that consists almost entirely of water and alcohol and returns the retentate (the rest of the wine) to the tank. The alcohol may then be removed from the permeate by distillation or EVAPORATIVE PERSTRACTION and the water returned to the wine, to produce a wine of reduced alcohol content. This low-alcohol wine can then be used as a blending component to produce a final wine of the desired alcohol level. An advantage of this technique is that only a portion of the wine need be subjected to this potentially intrusive process, typically less than one-quarter.

In the case of must or juice concentration, reverse osmosis is used to remove water from the unfermented grape juice, for example after a rainy harvest, achieving a similar result to that of vacuum evaporation. Controversially, some have seen it as a way of producing more concentrated, denser wines of the sort that appeal to influential critics and the modern marketplace. In countries such as Australia

and the United States, the main use of reverse osmosis is on finished wines, where the selective removal of water and alcohol concentrates all other components.

Another important use for reverse osmosis is the reduction of excessive levels of VOLATILE ACIDITY. STUCK FERMENTATIONS are sometimes coupled with high levels of ACETIC ACID, which, because of its low molecular weight (small size), will be removed together with ETHANOL and water.

More recently this technique has been proposed as a way of removing negative flavour compounds (volatile phenols) that result from BRETTANOMYCES spoilage in red wines. J.E.H. & A.O.

reviews, wine. See TASTING NOTES.

Rèze , very rare Swiss Valais white grape responsible for the sherry-like *vin des glaciers*. In 2005, DNA PROFILING at SAN MICHELE ALL'ADIGE revealed that Rèze has parent–offspring relationships with NOSIOLA and Groppello di Revò in Trentino and Cascarolo in Piemonte. And in 2007, DNA profiling proved its presence in the Alpine Maurienne Valley and in the JURA. Coupled with additional genetic relationships, this makes Rèze one of the main founder varieties of the Alps. In Switzerland, the area of cultivation fell from 400 ha/1,000 acres at the beginning of the 20th century to fewer than 3 ha at the beginning of the 21st century because Rèze and other Valais grapes were superseded by CHASSELAS. Rhein, German name for the river RHINE.

Rheingau, for generations the most economically successful wine region in GERMANY and still one of its most famous abroad. The Church and nobility provided the discipline and organization necessary for a solid business in wine, which survived the unrest and secularization in the early 19th century (see GERMAN HISTORY). The region had 3,185 ha/7,870 acres of vines in 2019, over 90% of which lie on the right bank of the RHINE, between Wiesbaden and the MITTELRHEIN boundary below Lorchhausen (see map under GERMANY). The remainder of the Rheingau vineyards are near Hochheim (the origin of the word HOCK) on the banks of the Main, shortly before its confluence with the Rhine at Mainz.

The region has a favoured MESOCLIMATE. With its primarily southern ASPECT, it is marginally warmer than much of RHEINHESSEN to the south, and its annual RAINFALL of a little over 600 m/23 in means that there is an adequate supply of water for the RIESLING vine to ripen its grapes long into the autumn. Critical to the differences among the Rheingau's diverse cast of Rieslings are SOIL TYPE, proximity to the Rhine, and ELEVATION, with higher, cooler, breezier sites often performing better in recent warmer growing seasons than some of the traditionally most prestigious riverside vineyards, where POTENTIAL ALCOHOLS and the risk of GREY ROT can be excessive.

At GEISENHEIM, the Rheingau has one of the world's leading viticultural institutes, but the region has not been invaded by GERMAN CROSSES to the same extent as other German regions such as Rheinhessen and the PFALZ. Rather, it has stuck by the grapes that

brought it fame: Riesling (78% of surface area in 2019) and Pinot Noir (12%, concentrated in Assmannshausen near the region's northern edge).

No German wines have ever achieved higher international standing (or prices) than did the Rieslings of the Rheingau in the late 19th century, and even into the mid 20th century prices were much higher than those of many of Bordeaux's CLASSED GROWTHS. The record of the late 20th century was mixed. Under the stylistic inspiration of the late Bernard Breuer of Rüdesheim and the late proprietor of Schloss Vollrads, Graf Matuschka-Greiffenclau, this region led Germany in a trend towards dry Rieslings, purporting to be closer to a late 19th century model and inherently more adaptable to late 20th century cuisine. The Rheingau CHARTA organization and the local VDP association were early activists in the promotion of low YIELDS, of TROCKEN (dry) Riesling, and of the CLASSIFICATION of top vineyards (see ERSTES GEWÄCHS).

Proximity to the metropolitan markets of Mainz, Wiesbaden, and Frankfurt has further helped Rheingau wines re-establish high reputations, although not enough to secure the continued fortunes of many of the large, formerly noble, estates, many of which have in recent years been sold, closed, or continuing to struggle economically. The Rheingau has also had stiff competition within Germany for both white and red wines from the dynamic, warmer BADEN and Pfalz regions as well as from impressive Rieslings grown in formerly unfashionable sectors of Rheinhessen. And for those craving delicacy in Riesling or wines with a dynamic synergy of fruit, ACIDITY, and RESIDUAL SUGAR, heightened awareness of the NAHE has brought the Rheingau further domestic competition.

The Rheingau's best-known estates (and the state-owned KLOSTER EBERBACH) typically have holdings in multiple, far-flung villages, and many of today's family wineries follow a similar pattern, if usually on a smaller scale. When windows of opportunity become compressed, as has been the case with so many recent vintages, and as mustering crews of pickers becomes increasingly difficult despite the EU's open

borders for LABOUR, having such scattered vineyards presents a huge challenge. It is not surprising then that the Rheingau's new elite consists largely of estates with vineyards in just one or two adjacent villages. The Rheingau was traditionally Germany's leader in selective picking of botrytis-affected Riesling (see SCHLOSS JOHANNISBERG) and continues to treasure its AUSLESE, BEERENAUSLESE, and TROCKENBEERENAUSLESE wines even though almost 60% of Rheingau wine today is bottled trocken and a further 27% HALBTROCKEN. In fact, picking out BOTRYTIZED Riesling berries has become essential to ensuring healthy fruit and a suitable potential alcohol level in the dry Riesling made from the remaining grapes.

At Lorchausen and Lorch—the westernmost limit of the Rheingau—the slopes resemble those of the adjacent Mittelrhein. Because Riesling traditionally struggled to ripen here, SILVANER is common and can produce highly distinctive wines, though they are overshadowed by the Rieslings emerging from Lorch's Kapellenberg, Krone, and Schlossberg vineyards. Immediately upstream at Assmannshausen, Pinot Noir dominates, above all in the south-facing Höllenberg. At Rüdesheim, the Rhine begins an east–west orientation, creating the so-called Rüdesheimer Berg, the first of the Rheingau's famous progression of Riesling-dominated south-facing slopes. The steep, stony SLATE- and QUARTZITE-dominated Berg Schlossberg, Berg Roseneck, Berg Rottland, and Berg Kaisersteinfels sites, all directly overlooking the Rhine, can generate Rieslings of peachy richness, spiciness, and depth. Less steep and ostensibly lesser Rüdesheim sites (Bischofsberg, Drachenstein, Kirchenpfad, Klosterlay, Rosengarten) are sometimes also home to impressive Riesling or Pinot Noir. The progression of small villages (and top-class vineyards) continues with Geisenheim (Kläuserweg, Rothenberg), Johannisberg (Goldatzel, Hölle, Mittelhölle, Klaus, Schloss Johannisberg), Winkel (Jesuitengarten, Hasensprung, Schloss Vollrads), Mittelheim (St Nikolaus), and Oestrich (Doosberg, Lenchen, Rosengarten). All are capable of producing Riesling wines of a high order but receive stiff competition from the best Rieslings of Hattenheim (Hassel, Pfaffenberg, Nussbrunnen, Schützenhaus, Wisselbrunnen) and

Erbach (Marcobrunn, Siegelsberg, Schlossberg, Steinmorgen). Soils of LOESS, SAND, and MARL alternate in these central Rheingau villages, and sites further from the river are generally later-ripening and more ventilated due to their elevation. The wines of Hallgarten (Hendelberg, Jungfer, Steinberg, Schönhell), Kiedrich (Gräfenberg, Klosterberg, Wasseros, Turmberg), and Rauenthal (Baiken, Gehrn, Nonnenberg, Rothenberg, Wülfen), which lie on higher, stony, phyllite (between SLATE and SCHIST) soils some distance from the Rhine, can yield long-lived, extraordinarily fine wines. At lower elevations near the eastern edge of the Rheingau, Riesling from Eltville (Langenstück, Sonnenberg) and Walluf (Walkenberg), while perhaps never quite rivalling the best Rieslings of the region, can also be memorably complex and long-lived. On the other side of metropolitan Wiesbaden (whose own Neroberg is a serious source of Riesling), Hochheim (Stielweg, Domdechaney, Kirchenstück, Hölle, Königin Viktoriaberg, Herrenberg) boasts gentle slopes with CALCAREOUS underpinnings, generating its own distinctive style of often corpulent but MINERALLY complex Rieslings. D.S.

Rheinhessen, Germany's largest wine region in 2019 at 26,860 ha/66,373 acres, south and south-west of Mainz. (See map under GERMANY.) For some time it was best known as a source of inexpensive blending wine but that has changed.

The part of the region traditionally most associated with quality is often referred to as the Rheinterrasse, where one-third of the region's RIESLING vines grow. Its most famous vineyards are those in the so-called Roter Hang composed of *Rotliegenden* (Permian red SANDSTONE) at Nierstein (with notable vineyards Hipping, Oelberg, Orbel, and Pettental) and neighbouring Nackenheim (Rothenberg). Aromas of peach and citrus and a smoked-meat pungency characterize wines grown on these red soils.

Immediately south of Nierstein, the communes of Oppenheim, Dienheim, and Ludwigshöhe also boast excellent eastern exposure on the edge of the river RHINE. Most of Rheinhessen is protected from

winds and excessive rain by the hills on its western border, which rise to over 600 m/2,000 ft. But the temperature in the vineyards nearest the Rhine is warmer throughout the year than that of the rolling country away from the river, and in severe winters they avoid the worst effects of FROST. LOESS, SAND, and CALCAREOUS soils in most of these villages can also yield distinctive Riesling such as in the underrated Brückchen and Paterberg, while Silvaner—a traditional Rheinhessen stalwart now reduced to 8% of surface area—is resurgent qualitatively in the hands of ambitious producers.

The north of Rheinhessen has its best-known vineyards at Ingelheim (traditionally associated with SPÄTBURGUNDER), at Bingen in the Scharlachberg site, and in the region's highest sector, immediately south-east of Bad Kreuznach, most notably the porphyric Heerkretz and Höllberg of Siefersheim but also sandstone- and melaphyr-based sites in neighbouring Neu-Bamberg and Fürfeld.

But it is the south, the so-called Wonnegau, whose wine villages feature predominantly calcareous vineyards, that has since the 1990s gained international attention for strikingly distinctive Rieslings as well as promising Pinot Noir and a revival of Silvaner. Dittelsheim (Geiersberg, Kloppberg, Leckerberg), Mölsheim (Frauenberg, Am Schwarzen Herrgott), and Hohen-Sülzen (Kirchenstück) but most especially Flörsheim-Dalsheim (Bürgel, Hubacker) and Westhofen (Aulerde, Benn, Brünnenhäuschen, Kirchspiel, Morstein, Steingrube) now loom large in the pantheon of German wine thanks to ambitious winegrowers such as Klaus Peter Keller, Oliver Spanier, and Philipp Wittmann farming sites whose potential had been largely overlooked from the Middle Ages.

Much of Rheinhessen still produces uninspiring wines from GERMAN CROSSES, but once-ubiquitous MÜLLER-THURGAU now takes up only 7.6% of the vineyard area, less than half of its share two decades ago; KERNER only 4%, and DORNFELDER 13%.

The tide has turned in terms of this region's overall reputation, and the notion that it merely divides into Roter Hang and hinterlands has been definitively demolished. A significant number of Germany's pioneers in ORGANIC and BIODYNAMIC VITICULTURE have come from the

ranks of Rheinhessen growers, further helping to attract attention to the region. D.S.

Rheinpfalz, German wine region. See PFALZ.

Rhein Riesling, or Rheinriesling, synonym in German-speaking countries for the great White RIESLING grape variety of Germany.

Rhenish, commonly used term in the Middle Ages to describe wine produced along the Rhine River, in what is now GERMANY and ALSACE.

Rhine, English name for the river known in German as the Rhein and in French as the Rhin (where it lends its name to the two ALSACE *départements* Haut-Rhin and Bas-Rhin). See also SWITZERLAND and LIECHTENSTEIN.

'Rhine' is sometimes used to indicate German wines not from the MOSEL and has been incorporated into a host of names associated in the English-speaking world with white, usually medium-dry, but not necessarily at all Germanic wines.

Rhine Riesling, synonym once common in Australia for the great white RIESLING grape variety of Germany.

Rhizopus. See BUNCH ROTS.

Rhoditis. See RODITIS.

Rhône, one of the most important wine RIVERS, linking a range of vineyards as dissimilar as those of CHÂTEAUNEUF-DU-PAPE in southern France, sparkling SEYSSEL in Savoie, and Fendant du Valais in SWITZERLAND.

In wine circles, however, the term 'Rhône' usually refers to the wines made in the Rhône Valley in south-east France, which themselves vary so much—north and south of a sparsely planted 50-km/30-mile stretch between approximately Valence and Montélimar—that they are divided into two very distinct zones, the southern Rhône and northern Rhône (although the regional appellation Côtes du Rhône encompasses the less ambitious wines of the north and a much larger area of the south). The Rhône regularly produces more AOC wine than any region other than Bordeaux, with 75% of the 2.7 million hl/71 million gal produced in 2020 being red, 16% rosé, and 9% white.

Of the two zones, the southern Rhône (*Rhône méridional* in French) represents around 94% of production. It is responsible for the overwhelming majority of the approximately 1.6 million hl/42 million gal of wine that qualifies as Côtes du Rhône or Côtes du Rhône-Villages each year.

More prestigious is the northern Rhône (*Rhône septentrional* in French), which includes the appellations of HERMITAGE and CÔTE RÔTIE, representing serious rivals to the great names of Bordeaux and Burgundy in the quality and longevity of their best wines. The northern Rhône is quite different from the southern Rhône in terms of climate, soils, topography, and even vine varieties.

A third district, small but extremely ancient, lies about 40 km/25 miles east of Valence up the Drôme tributary; it comprises the Diois appellations, named after the town of Die, of CHÂTILLON-EN-DIOIS, CLAIRETTE DE DIE, CRÉMANT de Die, and Coteaux de DIE.

And finally there are the outlying appellations that surround the central Côtes du Rhône growing area of the southern Rhône: COSTIÈRES DE NÎMES, CLAIRETTE DE BELLEGARDE, DUCHÉ D'UZÈS, Côtes du VIVARAIS, GRIGNAN-LES-ADHÉMAR, VENTOUX, and LUBERON.

History

Finds of AMPHORAE show that the inhabitants of the Rhône Valley drank wine from Baetica, the eastern province of Roman-occupied SPAIN, in the 1st century BCE. In the 1st century CE, the Romanized elite of the Rhône Valley drank FALERNIAN. From the 1st century BCE onwards, wine was carried up the Rhône: Chalon-sur-Saône was a river port for the GAULS (see Côte CHALONNAISE). In his *Geography*, completed in 7 CE, Strabo emphasized the importance of good RIVER connections for trade in Gaul. From the Mediterranean one can get to the Atlantic Ocean and the Channel by river (*Geography* 4. 1. 2).

Strabo asserted categorically that viticulture was impossible beyond the Cévennes, which was north of the territory of the evergreen oak, *Quercus ilex*, and hence too cold for the vine, which he assumed needed a MEDITERRANEAN CLIMATE. He was proved wrong by the Gauls, who even in Strabo's day had probably discovered that the Côte Rôtie and the hill of Hermitage were superb sites for vineyards. They were certainly making wine by 71 CE, when PLINY said that in Vienne the Allobroges were producing an excellent wine, still unknown to VIRGIL (*Natural History* 14. 18). There were three CRUS, Taburnum, Sotanum, and Helvicum. Pliny's observation that they tasted naturally of resin cannot be correct, for all wine was then stored and transported in earthenware vessels which were lined with resin to make them impermeable, so any wine, and particularly a wine that had come from afar or was old, would have tasted of resin (see RESINATED WINES).

Pliny calls the vine that the growers of Vienne used Allobrogica. It has black grapes and is resistant to cold (*Natural History* 14. 26–7). Given the latter, Allobrogica is unlikely to be SYRAH—unless Pliny, like Strabo, thought that the Rhône Valley's climate was inclement and decided therefore that any vine variety growing there must be able to withstand the cold. The Allobroges are proud of their wines, which fetch a high price (*Natural History* 14. 57). Elsewhere, Pliny remarks that the Gauls have mastered the art of GRAFTING and improved on

CATO: the Romans in turn have learned from them (*Natural History* 17. 116). The Allobroges exported their wines not only to Rome but also to Britain.

The people living in the Rhône Valley doubtless carried on making wine after the Romans left, but we have hardly any records at all until the late Middle Ages. Medieval wine merchants eagerly bought and sold the wine of Bordeaux, Gaillac, La Rochelle, the Île-de-France, and the Loire, but there was no trade in Rhône wines until the 14th century. This cannot have been because they were bad wines, for when Pope Clement V moved the papal court to Avignon in 1309 his entourage was quick to discover the local wines (see CHÂTEAUNEUF-DU-PAPE). Some three-quarters of the wines consumed at the papal court came from the Rhône Valley, although the court was fond of Burgundy, too. When Urban V went back to Rome for three years from 1367 to 1370, he had a vine from the Côtes du Rhône planted there.

It was his hatred of political infighting, not his love of French wines, that drove Clement back to Avignon. After his successor Gregory XI returned to Rome for good in 1377, the pope and his Roman household continued to drink the wines of the Rhône.

Châteauneuf-du-Pape owes its name to a new castle built by John XXII, a summer residence in the hills 16 km/10 miles north of Avignon. It was destroyed by German bombers in the Second World War.

The name Hermitage La Chapelle has its origins in medieval legend. When the Crusader Gaspard de Stérimberg returned from the Holy Land, he gained the permission of Blanche of Castille, queen of France and regent during the minority of her son Louis IX (1226–70), to build a chapel and dedicate it to St Christopher; there he lived as a hermit for 30 years until he died. The white Hermitage Chevalier de Stérimberg from Paul Jaboulet Aîné is named after this knightly recluse on the Hermitage hill.

It was not only the Rhône which benefited from the extravagant habits of the papal court at Avignon: BURGUNDY, too, saw demand for its wines soar. As Burgundy became a major wine-producing region, it realized the dangers of competition from the south, especially because the wines of the Rhône were heavier than its own and hence more likely to survive transport unscathed. The duchy of Burgundy was in a powerful position, for in order to reach the markets of Paris and the north of France the wine of the Rhône had to be carried up the Saône through Burgundian territory. The solution was simple: Burgundy imposed severe restrictions on the entry and transit of all non-Burgundian wines. In 1446 the city of Dijon banned wines from Lyons, Vienne, and Tournon altogether, for the spurious reason that they were 'très petits et povres vins'. These measures remained in force from the 14th to the 16th centuries and were successful. The wines of the Rhône Valley were excluded from the trade with England and the Low Countries, and they were not available in Paris until the 17th century, when transport overland had become less expensive and merchants could afford to carry their wines to the lower reaches of the Loire by ox-drawn cart and then ship them down the Loire.

Livingstone-Learmonth, J., *The Wines of the Northern Rhône* (2005).

Northern Rhône

The northern Rhône growing area begins just south of Lyon, stretching from Vienne to Valence. It closely follows the Rhône River as it runs north to south along the eastern edge of the Massif Central. Many of the best vineyards are planted on steep terraces that scale this granitic mass, facing south, south-east, and east on the river's right bank. The largest appellation, however, is Crozes-Hermitage on the left bank, representing nearly half of all wine produced in the northern Rhône. The total production of the northern Rhône is around 6% of total Rhône Valley wine.

The northern Rhône is under the influence of a CONTINENTAL CLIMATE, with hard winters and summers whose effect on the grapes can be exaggerated by the region's steep slopes. The north wind, known locally as *la bise*, blows powerfully and often—a mixed blessing, as it helps to reduce disease pressure in the vineyards but also can cause damage, so growing individual vines on stakes known as *échalas* is commonplace. The steep banks of this now heavily industrialized river naturally limited vine cultivation for many centuries, and the best wines are produced on inclines which are expensive to work and help to maximize the effect of the available SUNLIGHT (see TOPOGRAPHY). Since the 1980s, however, when the better wines of the Rhône were recognized as offering some of the best fine-wine value (and winemaking recognized as a potentially noble way of earning a living), there has been considerable expansion, particularly in such appellations as St-Joseph and Crozes-Hermitage but also in, and especially around, more restricted appellations such as Côte Rôtie and Condrieu. Most appellations are based on the right bank of the river, but the left-bank vineyards of Crozes-Hermitage and especially Hermitage are particularly well exposed to afternoon sunshine.

This is the prime territory of the SYRAH grape, which is the only red-wine grape permitted in northern Rhône crus. VIOGNIER is the defining grape variety of the white wines Condrieu and Château-

Grillet, while other white northern Rhône wines depend on Marsanne and/or Roussanne, alone or blended.

Most winemaking and vine-growing is in the hands of individuals working small family holdings. About half of all wines are bottled by merchants, of which Paul Jaboulet Aîné, CHAPOUTIER, Delas, and GUIGAL are some of the best known. There are very few CO-OPERATIVES.

For more details, see the specific appellations CHÂTEAU-GRILLET, CONDRIEU, CORNAS, CÔTE-RÔTIE, CROZES-HERMITAGE, HERMITAGE, ST-JOSEPH, and ST-PÉRAY.

Livingstone-Learmonth, J., *The Wines of the Northern Rhône* (2005).

Southern Rhône

The southern Rhône has only the river and a few grape varieties in common with the northern Rhône. The countryside here is flatter and definitively southern, with both houses and vegetation demonstrating the influence of a MEDITERRANEAN CLIMATE. Many other fruits are grown here. One of the chief hazards is the mistral, a cold WIND that can blow down the Rhône valley. Most vines are BUSH-trained, although Syrah vines are usually trained on wires in single GUYOT or CORDON DE ROYAT. If drought persists, some IRRIGATION is permitted during certain periods. Soil types are more diverse than in the northern Rhône, varying from appellation to appellation. The most common are sand and sandstone, limestone, and clay (with greater or lesser quantities of pebbles or larger rounded stones known locally as *galets roulés*).

Most wines are blends rather than made from a single grape variety. Although many growers have experimented with Syrah, much of the southern Rhône is too hot for it to ripen gracefully, and around twice as much GRENACHE is grown. The dominant Grenache can in theory also be supplemented or seasoned by a wide range of other local varieties, but in practice only CARIGNAN, CINSAUT, and MOURVÈDRE are planted to any extent, with Mourvèdre becoming increasingly popular. Of white-wine grapes, the most widely planted for AOC wines are Viognier, Grenache Blanc, Marsanne, Roussanne, and Clairette.

CO-OPERATIVES are very important in the southern Rhône, responsible for about two-thirds of total production. The NÉGOCIANTS of the northern Rhône also have a long tradition of buying wine here for blending and bottling. There is also an ever-increasing number of private estates. Winemaking techniques for red wines are varied. Most choose to destem their crop, but WHOLE-BUNCH vinification is increasing in popularity. CARBONIC MACERATION is rare but increasingly fashionable. Fermentation is typically carried out in concrete tanks, stainless-steel tanks or large wooden *foudres* (see CASK). ÉLEVAGE

varies according to grape variety; small barrels and new oak are typically reserved more for Syrah and Mourvèdre than for Grenache.

The southern Rhône is the only part of France other than the LANGUEDOC and ROUSSILLON to have a tradition of making sweet VIN DOUX NATUREL: a Muscat version in BEAUMES-DE-VENISE and varied colours and styles from the Grenache family in RASTEAU.

For more details, see also ARDÈCHE, BEAUMES-DE-VENISE, CAIRANNE, CHÂTEAUNEUF-DU-PAPE, CHÂTILLON-EN-DIOIS, CLAIRETTE DE BELLEGARDE, CLAIRETTE DE DIE, COSTIÈRES DE NÎMES, DUCHÉ D'UZÈS, GIGONDAS, GRIGNAN-LES-ADHÉMAR, LIRAC, RASTEAU, TAVEL, VACQUEYRAS, VENTOUX, VINSOBRES, and VIVARAIS, CÔTES DU.

Côtes du Rhône

is often used colloquially to denote the wines of the Rhône Valley in its broadest sense, but it really refers to the wines of the southern Rhône, in particular those from AOC Côtes du Rhône. This appellation stretches 180 km/112 miles from Vienne in the north to Avignon in the south, but the vast majority is produced south of Montélimar, which is closer to 70 km north to south, and the growing area spans roughly 50 km east to west. It covers 171 communes and nearly 50,000 ha/123,553 acres of vines. Of the 1.3 million hl/34 million gal of AOC Côtes du Rhône produced in 2020, 87% was red, 8% rosé, and 5% white. There is a particularly generous number of permitted secondary grape varieties, but red and rosé wines produced from vineyards south of Montélimar must contain Grenache and either Syrah or Mourvèdre (or both). Principal grape varieties for whites are Bourboulenc, Clairette, Grenache Blanc, Marsanne, Roussanne, and Viognier. Being at the most basic level of the AOC pyramid, the wines, though perfectly enjoyable, are rarely thrilling. There are some exceptions to this rule, however, such as Domaine des Tours, Ch de Fonsalette, and Domaine Gramenon.

Côtes du Rhône-Villages

In theory, AOC Côtes du Rhône-Villages denotes a step up in quality from the more lenient rules of AOC Côtes du Rhône. The appellation covers fewer communes (95 instead of 171); allows the same grape varieties, save for CROSSES; and requires marginally higher minimum alcohol levels and marginally lower maximum YIELDS.

There is a further step up the appellation pyramid with even stricter production criteria, which is AOC Côtes du Rhône-Villages plus a more specific geographical name. This appellation is reserved for the 22 communes or demarcated geographical areas listed below, which are considered to be of particular interest and are allowed to append their name to Côtes du Rhône-Villages—for example AOC Côtes du Rhône-Villages Sablet. All of the following can produce red, rosé, or white wine unless otherwise stated: Chusclan (red and rosé only), Gadagne (red only), Laudun, Massif d'Uchaux (red only), Nyons (red only), Plan de Dieu (red only), Puyméras (red only), Roaix, Rochegude, Rousset-les-Vignes, Sablet, St-Andéol (red only), St-Gervais, St-Maurice, St-Pantaléon-les-Vignes, Sainte-Cécile (red only), Séguret, Signargues (red only), Suze-la-Rousse (red only), Vaison-la-Romaine (red only), Valréas, and Visan. These appellations are a source of some of the best-value wines in the Rhône Valley.

M.C.W.

Rhône Rangers, loose affiliation of wine producers in the United States who, in the 1980s, seeking to break free from what they perceived as a 'conventional' domestic wine scene, sought out and planted the grape varieties of France's RHÔNE Valley. Early advocates included Californians Sean Thackrey, Bob Lindquist of Qupé, Randall GRAHM of Bonny Doon, John Buechsenstein of McDowell Valley Vineyards, and Steve Edmunds of Edmunds St John.

Their efforts led to resurgent interest in the US in SYRAH and VIOGNIER, as well as the old-vine GRENACHE and Mataro (MOURVÈDRE) that had languished in California vineyards. Syrah plantings went on to post exponential growth, increasing in California from 80 ha/200

acres in 1990 to over 7,700 ha in 2012. Viognier's rise was almost as dramatic (32 ha/80 acres in 1990; 1,214 ha in 2012).

In 1989 the Perrins of Ch de Beaucastel and US wine importer Robert Haas established Tablas Creek, a winery devoted to Rhône varieties. Based in PASO ROBLES, the partnership has been instrumental in the importation of Rhône varieties—16 in all, including the 13 varieties found in CHÂTEAUNEUF-DU-PAPE. Their effort led to a second planting surge, of such varieties as Grenache Blanc, Picpoul, Vermentino, Clairette, Counoise, Cinsaut, and Terret. Rhône Ranger efforts in California inspired similar endeavours in WASHINGTON, embodied by the likes of Christophe Baron (Cayuse), Charles Smith (K), Greg Harrington (Gramercy Cellars), and Jean-Francois Pellet (Amavi).

The movement created thousands of fans and launched festivals, celebrations, and loose-knit cadres of rootin'-tootin' enthusiasts, who revelled in the category's contrarian exuberance, providing, as it did, welcome alternatives to the usual California diet of VARIETAL Cabernet Sauvignon, Merlot, and Chardonnay. Owing to the Rangers' efforts, Rhône varieties are now planted in nearly every region in the US where VITIS VINIFERA plantings are found. P.C.

Rías Baixas, the leading DOP wine zone in GALICIA, north-west Spain (see map under SPAIN), producing some of the country's most sought-after dry white wines. Between 1987 and 2021 the DOP's vineyard area grew from 237 ha/570 acres to 4,051 ha/100,010 acres with the number of wineries rising from 14 to 161. Named after the flooded coastal valleys, or *rías*, that penetrate up to 30 km/19 miles inland, the zone's reputation is based on the white ALBARIÑO grape. Wines were exported to northern Europe in the 16th and 17th centuries, but after the ravages of PHYLLOXERA many of the traditional vine varieties were abandoned, and by the 1900s the region's vineyards were largely planted with high-yielding HYBRIDS and by Jerez's PALOMINO FINO, producing poor-quality wine. The revival began in the late 1970s, when growers were encouraged to replant

INDIGENOUS VARIETIES and producers were given incentives to invest in modern winemaking equipment. The metamorphosis gathered pace with the application of EU funds following Spain's accession to the EU in 1986.

Rías Baixas has five subzones, all within the province of Pontevedra. Many of the purest Albariño wines come from Val do Salnés zone centred on the town of Cambados on the west coast. O Rosal and Condado do Tea are on the northern slopes of the river Miño facing Portugal's VINHO VERDE region. A fourth, small subzone, Soutomaior, was admitted in the late 1990s, to be joined later by Ribeira do Ulla in the far north. All five zones share the same GRANITE-based subsoils and relatively cool, damp MARITIME CLIMATE. The Atlantic influence is strongest in Val do Salnés, where annual RAINFALL averages 1,300 mm/50 in. Vines were traditionally cultivated on pergolas (see TENDONE) to protect grapes from the constant threat of FUNGAL DISEASES, although modern vineyards are planted on a more practical local variant of the GENEVA DOUBLE CURTAIN vine-training system.

Fourteen vine varieties are officially permitted in Rías Baixas, although Albariño accounts for 90% of the vineyard area. Other white grapes which may be blended with Albariño according to local regulations include CAÍÑO BLANCO, as well as TREIXADURA and LOUREIRA, (known locally as Marqués), both of which are found in the VINHO VERDE region. TORRONTÉS and GODELLO are also permitted. On its own, Albariño produces a fragrant, intensely fruity, dry white wine with a natural minimum alcohol often above 12%. YIELDS used to be low, which made the wines expensive, but abusive yield increases began to occur in the 1990s, sometimes aggravated by over-reliance on aroma-enhancing YEASTS. There have been experiments with OAK. Red grapes represent less than 1% of the vineyards, with Sousón (see SOUSÃO) the main variety, yet the wines have gained attention thanks to the work of growers such as Eulogio Pomares (Zárate) and Gerardo Méndez (Forjas del Salnés). Ribatejo, former name of TEJO in Portugal.

Ribbon Ridge, wine region and AVA within the WILLAMETTE VALLEY of Oregon.

Ribeira Sacra, growing Spanish DOP created in 1996. It is the only GALICIAN region specializing in red wines, from the MENCÍA grape, and some less well-known local varieties such as Sousón (SOUSÃO) and Brancellao (ALVARELHÃO). Whites are mainly GODELLO and ALBARIÑO. Most vineyards are situated on hugely impressive terraced SLATE and SCHIST slopes at 400–500 m/1,312–1,640 ft in ELEVATION, their slopes angled at 30–80° and facing south and south-west. The area is divided into five subregions, but only Amandi ('beloved land') appears on labels with any regularity. The other subregions are Chantada, Quiroga-Bibei, Ribeiras do Miño, and Ribeiras do Sil. F.C.

Ribeiro means 'riverbank' or 'riverside' in the Galician language and is the name of a red and white wine DO zone in GALICIA, north-west Spain (see map under SPAIN). Ribeiro spans the valleys of the river Miño and its tributaries and Arnoia downstream from Orense. In the 16th and 17th centuries wines from Ribeiro were exported as far afield as Italy and England, but PHYLLOXERA put paid to the region's prosperity at the end of the 19th century. As in RÍAS BAIXAS, farmers seeking a quick return to profit replanted their holdings with the sherry grape PALOMINO FINO. Over recent years, growers have been encouraged to uproot this productive but unsuitable variety in favour of TREIXADURA, TORRONTÉS, Lado, and other INDIGENOUS VARIETIES that

perform well in the damp MARITIME CLIMATE and can be made into the aromatic, crisp white wines that make up 90% of the region's production. The little red wine that is made is dominated by CAÍÑO and other local varieties. There is a very limited production of Tostado, a sweet DRIED-GRAPE WINE. With help from EU funds, wineries have been updated, and the traditional, labour-intensive pergolas (see TENDONE) are being replaced by lower vine-TRAINING SYSTEMS. V. de la S. & F.C.

Ribera del Duero, important wine zone in CASTILLA Y LEÓN in north-central Spain that challenged RIOJA as the leading red wine-producing region in Iberia towards the end of the 20th century when it grew substantially. By 2021 it had a total of 23,500 ha/58,070 acres of vineyard, one-third as much as Rioja. Ribera del Duero spans the upper valley of the River Duero (known as DOURO in Portugal), starting some 30 km/18 miles east of the city of Valladolid (see map under SPAIN). Although Bodegas VEGA SICILIA on the western margin of the denomination has been producing one of Spain's finest wines since the mid 19th century, the region was awarded DOP status only in 1982, when there were just seven wineries. In 2021 there were 310.

At first sight, the Duero Valley is not the most congenial place to grow grapes. At 700–850 m/2,800 ft in ELEVATION, the growing season is relatively short. FROST, commonplace in winter, continues to be a threat well into the spring. Temperatures, which can reach nearly 40 °C/104 °F in the middle of a July day, fall sharply at night, the DIURNAL TEMPERATURE RANGE extending the ripening period to such a degree that the harvest in Ribera del Duero is one of the latest in Europe, sometimes lasting until the end of November.

The region's potential was recognized by the late Alejandro Fernández, who played a key role in the development of the region in the 1980s. Pesquera, his wine vinified from grapes growing around the village of Pesquera del Duero just upstream from Vega Sicilia, was released in the early 1980s to international acclaim. Other

growers (many of whom had previously sold their grapes to CO-OPERATIVES) were thereby encouraged to make their own wines and soon challenged Rioja's traditional hegemony inside Spain. In the 1990s, consumption of top-quality Ribera wines soared within Spain, causing deepening concern in Rioja. Several Ribera producers attained quality levels not much below those of Vega Sicilia and Pesquera. The movement has continued in the 21st century, with wineries such as Dominio de Atauta, Bodegas La Loba, and Antídoto transforming Soria, a cool, high area in the north-west, from a source of cheap rosés to one of top-quality reds.

The region's principal vine variety, the Tinto Fino (also called Tinta del Pais), is a local variant of Rioja's TEMPRANILLO. It seems to have adapted to the Duero's climatic extremes and produces deep-coloured, occasionally astringent, firm red wines without the support of any other grape variety (although Cabernet Sauvignon, Merlot, and Malbec, introduced by Vega Sicilia 130 years ago, are allowed throughout the denomination). Garnacha is used in the production of rosé, and ALBILLO Mayor, allowed in DOP wines since 2019, now produces some promising white wines. R.J.M., V. de la S. & F.C.

Peñín, J., *Guía Peñín* (annual).

Ribera del Guadiana, DOP encompassing about 34,000 ha/84,016 acres of vineyards in Spain's EXTREMADURA region. Its subzones (Cañamero, Matanegra, Montánchez, Ribera Alta, Ribera Baja, Tierra de Barrios) are rarely seen on wine labels. The autonomous Extremadura government is actively encouraging improvements in wine quality, but the results have been slow in coming. V. de la S. & F.C.

Ribera del Júcar, promising Spanish DOP in the Cuenca province of CASTILLA-LA MANCHA whose first vintage was 2003.

Ribéreau-Gayon , dynasty of important OENOLOGISTS closely associated with the history of the Institut d'Oenologie at the University of BORDEAUX.

Ribolla, white grape variety also known as Ribolla Gialla to distinguish it from the less interesting Ribolla Verde, best known in FRIULI in north-east Italy but also grown, as Rebula, in SLOVENIA. It is distinct from the ROBOLA of the island of Kefalonia in GREECE and is not related to Ribolla Nera. DNA PROFILING found it to be one of the numerous progenies of the prolific GOUAIS BLANC.

Ribolla was first documented in Friuli in 1296, as Rabola. It lost ground steadily in the 19th and 20th centuries, however, in the wake of the PHYLLOXERA epidemic and Friuli's subsequent enthusiasm for French INTERNATIONAL VARIETIES when vineyards were replanted. In the mid 1990s, Ribolla accounted for less than 1% of all the white DOC wines of Friuli, but by 2015 Italy's total plantings were 362 ha/895 acres, and there were champions of the variety on both sides of the Slovenian border. Rosazzo and Oslavia are generally considered Friuli's two classic areas for Ribolla Gialla, but there is even more planted in western Slovenia, in both Brda and Vipava. Extended contact with the variety's particularly yellow skins is increasingly common, and the wine produced can have firm STRUCTURE and, neatly, yellow-fruit flavours. There are very limited plantings in California. J.V.

Ricasoli, one of the oldest noble families of TUSCANY in central Italy, important landholders between Florence and Siena for over a thousand years. The vast size of their holdings led the medieval republic of Florence to bar them from holding public office lest the combination of territorial dominion and civic position create a threat

to republican liberties. Bettino Ricasoli (1809–80), a dominant figure in the political life of his time and the second prime minister of the newly united Italy in 1861, as well as a dedicated agricultural experimenter and reformer, played a fundamental role in the revitalization of the viticulture of his time and invented what came to be the standard varietal formula for the production of CHIANTI. Like all Tuscan landowners of the time, he believed that the sharecroppers should grow the grapes and the large commercial houses—principally controlled by the Tuscan nobility such as ANTINORI and FRESCOBALDI—would age and distribute the finished wines.

He founded the Ricasoli NÉGOCIANT firm, which would assume a position of leadership in Tuscany for the better part of a century.

The 1970s and 1980s were less kind to the fortunes of the house: a partnership with American distillers Seagram in the négociant part of the business in the 1960s, and another with Hardys of Australia, led to huge expansion of production and a general lowering of quality, and the marketing of Ricasoli wines in supermarkets and other mass distribution centres was extremely damaging to their image. In 1993 Francesco Ricasoli repurchased the family business and set about modernizing the estate. By the second decade of this century all the vineyards had been replanted, and Ricasoli was a very substantial producer of Chianti Classico. Very much in the model of a Bordeaux GRAND VIN, they produced a Castello di Brolio Chianti Classico for the first time in 1997. This wine became a GRAN SELEZIONE in the 2011 vintage.

The distinctive character of the neo-Gothic *castello*, combined with the fame of both Brolio and the Ricasoli name, ensures a steady stream of visitors to the CELLAR DOOR tasting room and osteria.

D.C.G. & W.S.

rich is a positive tasting term for, generally, a red wine that gives an appealing impression of power and sweetness even though it may have negligible RESIDUAL SUGAR. It may also be found as a label description on bottles of relatively sweet CHAMPAGNE (see DOSAGE).

Richebourg, great red GRAND CRU in Burgundy's CÔTE D'OR. For details, see VOSNE-ROMANÉE.

riddling, an integral stage in the traditional method of making SPARKLING WINES, known as *remuage* in French. It involves dislodging the deposit left in a bottle after a second fermentation has taken place inside it and shaking it into the neck of the inverted bottle. It can be achieved either by hand or, more speedily, by machine (see GYROPALETTE). Modern alternative techniques may eventually render this cumbersome process superfluous, but they have not so far been commercially adopted. A riddling rack is English for a PUPITRE. For more details, see SPARKLING WINEMAKING.

Ridge Vineyards, the most internationally admired producer of American Cabernet Sauvignon, from the historic Monte Bello vineyard in the SANTA CRUZ MOUNTAINS. Ridge produces ageworthy, TERROIR-driven, SINGLE-VINEYARD Cabernets and Zinfandels that demonstrate vineyard character and vintage variance over winemaking wizardry and homogeneity. Ridge's Sonoma outpost Ridge Lytton Springs, acquired in 1991 but a source of OLD VINE Zinfandel grapes for a quarter-century before that, is famous for its suave yet durable wines, as is their historic Geyserville vineyard.

Monte Bello was first planted in 1886, and the stone and redwood winery deep in a ravine at 2,600 feet/792 m above Silicon Valley produced its first wine in 1892. The vineyards were abandoned during PROHIBITION (1920–33) but were replanted to Cabernet Sauvignon in the 1940s. In 1959 Dave Bennion and two fellow Stanford Research Institute engineers purchased the winery and vineyard land as a weekend retreat and made a half barrel of such complex Cabernet that it inspired them to rebond the winery in time for the 1962 vintage. During the 1960s the group also made some exceptional Zinfandel from old vineyards both locally and in Sonoma. In 1969 Paul Draper, with winemaking experience from setting up a

small winery in the coastal range of CHILE, joined the enterprise and was in charge until 2016 when he turned 80, having identified and secured long-term single-vineyard sources of top-quality grapes. A small amount of Chardonnay has also been made since 1962. Draper, self-taught through tasting fine wines and studying 19th-century techniques, was an outspoken critic of deliberately extended HANG TIME and of what he might call DAVIS dogma in winemaking.

Monte Bello 1971 performed particularly well in both JUDGMENT OF PARIS tastings. In 1987 a decidedly hands-off Japanese wine lover acquired the business, whose export and pricing policies have been admirably and unusually consistent.

Ried , traditional term in AUSTRIA for a vineyard site that is sometimes seen on labels just before the site name.

Rieslaner, increasingly rare, late-ripening SILVANER × RIESLING cross that was grown on a total of 72 ha/178 acres in Franken and the Pfalz in southern Germany in 2020. Provided it reaches full ripeness, it can produce wines with race and curranty fruit.

Riesling has long been arguably the world's most undervalued, often mis-spelt, and most often mispronounced grape. ('Reece-ling' is correct.) Riesling is the great vine variety of Germany and could claim to be the finest white grape variety in the world on the basis of the longevity of its wines and their ability to transmit the characteristics of a vineyard without losing Riesling's own inimitable style; in this sense it is very much more like Cabernet Sauvignon than Chardonnay (although DNA PROFILING in Austria in 1998 revealed a parent–offspring relationship with GOUAIS BLANC, a parent of Chardonnay, Pinot Noir, et al.; see PINOT). Riesling suffered when OAK and heft were considered the height of FASHION because it is no friend of BARRIQUES, and its wines tend to be relatively low in alcohol. In the 1960s and 1970s, the name 'Riesling' was debased by being applied

to a wide range of white grape varieties of varied and often doubtful quality, the ultimate backhanded compliment. Rieslings were also associated with SWEETNESS (another black mark in the modern era) and lack the common please-all blandness of, say, Pinot Grigio.

In the late 19th and first half of the 20th centuries, on the other hand, German Riesling wines were prized, and priced, as highly as the great red wines of France. Connoisseurs knew that, thanks to their magical combination of ACIDITY and EXTRACT, these wines could develop for decades in bottle, regardless of ALCOHOLIC STRENGTH and RESIDUAL SUGAR. Riesling is made at all levels of SWEETNESS, and in the second half of the 20th century residual sugar, typically SÜSSRESERVE, was used by producers of basic German wine to compensate for a lack of full ripeness and uncomfortably high acidity. Today, thanks to CLIMATE CHANGE and more widespread determination to increase quality, fine dry Riesling is common in Germany. But while the average residual sugar of Riesling made everywhere has been declining fast, the variety is distinguished for its ability to produce great sweet wines, whether they be the cold-weather speciality EISWEIN or ICE WINE or BOTRYTIZED wines such as BEERENAUSLESE and TROCKENBEERENAUSLESE and their counterparts outside Germany. Riesling's high natural level of TARTARIC ACID provides it with a much more dependable counterbalance to high residual sugar than, for example, the Sémillon grape of Sauternes.

Riesling wine, wherever produced, is also notable for its powerful, rapier-like aroma variously described as flowery, citrus, steely, honeyed, and whichever blend of quasi-mineral elements is conveyed by the individual vineyard site. This distinctive aroma, usually experienced in conjunction with Riesling's natural raciness and tartness, is particularly high in MONOTERPENES, 10 to 50 times higher, for instance, than WELSCHRIESLING, the quite unrelated white grape variety prevalent in central Europe which, much to German fury, borrowed the word 'Riesling' for many of its aliases (RIESLING ITALICO, for example). An important contributor to the bottle-aged bouquet of

Riesling wines is the norisoprenoid hydrocarbon 1,1,6-trimethyl-1,2-dihydronaphthalene (see TDN for more detail).

Viticulturally, true Riesling (sometimes called Weisser, White, Rhein, Rhine, or Johannisberg Riesling) is distinguished by the hardness of its wood, which helps make it particularly cold-hardy, thus a possible choice for relatively cool wine regions, even if it needs the most favoured, sheltered site in order to ripen fully and yield economically. So resistant is it to FROST that winter pruning can begin earlier than with most other varieties. Its growth is vigorous and upright, and it seems able to produce yields of 60 or 70 hl/ha (4 tons/acre) without any necessary diminution of quality. (Maximum yields allowed by the French INAO authorities are higher in Alsace, France's Riesling enclave, for example, than for any other comparable fine wine.) Its compact bunches of small grapes make it relatively prone to BOTRYTIS, and COULURE can be a problem, but its chief distinction in the vineyard is its late budding. Riesling ripens early relative to most INTERNATIONAL VARIETIES but late relative to most other varieties planted in Germany such as the GERMAN CROSSES. In cool vineyards in the northern hemisphere, it is often not picked until mid October or early November (and sometimes even later). Riesling can ripen so early in warmer regions, however, that its wines can taste dull; a long, slow ripening period suits Riesling best and results in maximum flavour and EXTRACT, while maintaining acidity. Thus, many of Germany's (and therefore most of the world's) most admired Rieslings are grown on particularly favoured sites in cooler regions such as the MOSEL, whose crackling, racy, feather-light style of Riesling is unique.

Germany

As outlined in GERMAN HISTORY, Riesling is by no means the oldest documented vine variety grown in Germany (including, as it did for so long, Alsace). ELBLING and SILVANER were widely grown throughout the Middle Ages, while RÄUSCHLING was the speciality of Baden in the south. An invoice dated 1435, from a castle in the extreme south-east of the Rheingau on the river Main, mentions 'riesslingen in die wingarten', presumably Rieslings in the vineyard. Early spellings of words like 'Riesling' have to be treated with care, since the similarly named Räuschling was so much more common then than today, but Riesling seems to have been recognized as a top-quality variety from the late Middle Ages and was planted throughout the Rhine and Mosel from the middle of the 16th century.

Riesling is first mentioned in connection with Alsace as one of its finer products in 1477 by Duke René of Lorraine, even if we have to wait until 1628 for the first documentary evidence of its actually being planted there.

In the 18th century, various prince-bishops and other ecclesiastical authorities did their utmost to encourage Riesling plantings at the expense of other lesser varieties, notably in the Mosel. But the habit of picking grapes earlier than is today customary did the late-ripening Riesling no favours, and by 1930 the proportion of the Rheingau region, supposedly the classic Riesling heartland, planted with Riesling had fallen to 57% (as opposed to 80% by the turn of the century).

This provided a stimulus to Germany's burgeoning viticultural researchers (see GEISENHEIM) to select and develop top-quality CLONES of the variety. Today, partly thanks to the efforts of a special centre for the CLONAL SELECTION of Riesling at Trier, the German vine-grower can choose from more than 60, whereas France has just eight certified clones of Riesling.

Much of the work of these viticultural institutes was also focused on developing the famous GERMAN CROSSES, designed to produce high

yields of grapes with high MUST WEIGHTS but without the viticultural inconveniences of Riesling. In the second half of the 20th century, with their country awash in new money and an ocean of high-sugar grape juice, many Germans gave up winegrowing, or at least the steep-slope cultivation of the demanding Riesling vine, trends which sadly continue. In 1980 Riesling represented less than 20% of German vineyard area; even amid signs of a Riesling renaissance among sophisticated wine drinkers, its share of area has barely increased since then, although, after being overtaken by the lacklustre MÜLLER-THURGAU, it has re-established itself as the most planted vine variety with a rising total of 24,150 ha/59,676 acres widely spread throughout the country in 2020.

Undeniably, though, the top winegrowers and sites not just of the Rheingau and the Mosel but also of the Nahe, Mittelrhein, Rheinhessen, and the Pfalz are largely devoted to Riesling despite—or in fact, precisely because of—its precarious, slow ripening in the face of climatic challenge. In these growing areas, Riesling is selected for the sunniest hillsides, the steepest slopes, the most sheltered rocky crenellations, and pockets of reflected heat. In such spots, Riesling shows dazzling diversity. It can be as delicate as a 7% Saar wine that is somehow satisfyingly complete—or it may be a refreshing, nervy, bone-dry GROSSES GEWÄCHS with 13.5% alcohol, with many of the finest examples grown in Rheinhessen and the Nahe. For more details, see GERMANY.

Elsewhere

For some wine drinkers, Riesling is acceptable only in its French form, a wine from ALSACE, the only part of France where this German vine is officially allowed—a cause of some frustration with the strictures of the INAO. Alsace's plantings of the variety wine producers there view as their most noble have slowly increased, passing the 3,000-ha mark in the late 1980s and standing at 3,441 ha/8,503 acres in 2019. What is needed to produce Alsace Riesling of real class is, as in Germany, a favoured site of real interest such as many of Alsace's famous GRAND CRU vineyards.

The hallmark of Alsace has been dry wines from aromatic grapes such as Riesling, and certainly the great majority of Alsace Rieslings follow the variety's alluring perfume with a taste that is generally full-bodied and dry. The number of authorized clones of Riesling may be a fraction of those available to German growers, but the dry climate of Alsace minimizes the risk of ROT and makes extended ripening a real possibility, however, often resulting in the prized late-harvest wines which qualify as VENDANGES TARDIVES or, even sweeter, SÉLECTION DE GRAINS NOBLES, the richest, most sumptuous ripeness category of Alsace wines. See ALSACE for more detail.

To the north, about 13% of the LUXEMBOURG vineyard is planted with Riesling, which tends to produce dry, relatively full-bodied wines (thanks to CHAPTALIZATION), closer in style to those of Alsace than to those of the Mosel just over the German border.

In AUSTRIA, Riesling is quantitatively not nearly as important as Grüner Veltliner and was planted on 2,040 ha/5,040 acres in 2022, but it is regarded as one of the country's finest wines when made on a favoured site. The most hallowed Austrian Rieslings are dry, full-bodied, concentrated, and aromatic, and a high proportion of them come from terraced vineyards in Lower Austria. Select sites in the Wachau, Kremstal, and Kamptal enjoy an especially high reputation for their aristocratic, whistle-clean Rieslings. Riesling is an important variety in the vineyards of Vienna as well.

Not surprisingly, Riesling works well in the CONTINENTAL CLIMATE of CZECHIA and SLOVAKIA (where Egon Müller of Germany's Saar Valley makes fine Riesling) to the immediate north of Austria's vineyards, where relatively light wines have real crackle and race. Most of Switzerland is too cool to ripen Riesling properly, with the exception of some of the more schistous soils and warmest vineyards of the Valais around Sion.

Although practically unknown in Iberia (*pace* FAMILIA TORRES in Spain's high Penedès), Riesling has infiltrated the far north of Italy, where plantings totalled 1,461 ha/3,610 acres in 2015. It is grown with real enthusiasm in the high vineyards of ALTO ADIGE, where it produces delicate, aromatic wines quite unlike most Italian whites. It is also grown quite successfully in FRIULI, where it is known as Riesling Renano; and over the border in Slovenia, delicate Renski Rizling is produced in Podravje. Riesling, known as Rajinski Rizling and variants thereof, is also planted southwards in Croatia.

It is planted throughout the rest of Eastern Europe, with 1,167 ha/2,884 acres of Rajnai Rizling in Hungary, 959 ha of Riesling de Rhin in Moldova, 255 ha of Rhine Riesling in Bulgaria, and apparently more than 2,000 ha of an unspecified Riesling in Ukraine, although in each of these countries summers can be too warm to coax real excitement from the variety and Welschriesling tends to reign supreme—as it does, for instance, in Romania.

Outside of Europe, true Riesling was for a long time most widely grown in AUSTRALIA, where it was encouraged by the 19th-century influx of Silesians (see POLAND) and remained the most planted white wine grape variety of all until Chardonnay caught up with its nearly 4,000 ha/10,000 acres in 1990. But few new Riesling vines went into the ground, and by 2015 total Australian plantings had fallen to 3,178 ha/7,853 acres in 2022 and become increasingly concentrated on proven hot spots of the Eden and Clare Valleys, Tasmania, and Great Southern, all producing dry Rieslings with a minerally raciness underlying the tangy, lime-accented fruit. A tiny quantity of BOTRYTIZED sweet Riesling is also made. The wines are less phenolic than those of Alsace and less alcoholic than Alsace or Austrian

Riesling. They can also richly repay cellaring for up to, or even beyond, 20 years. In the early 21st century, NEW ZEALAND began to produce convincing wines from its total plantings of 619 ha in 2022, mainly in Marlborough and North Canterbury, notably when some producers started making scintillating LATE HARVEST sweet wines, but its production is dwarfed by that of Sauvignon Blanc, Chardonnay, and Pinot Gris.

Riesling (of some sort) is cultivated more widely in South America than one might think wise. Chile has a few hundred hectares, some grown in the far south to good effect, while Argentina had just 74 ha/183 acres in 2020.

But the major change in Riesling's fortunes in the early 21st century was in North America, to the extent that by 2012 the US had the world's second biggest area of Riesling vineyard after Germany. The Riesling revolution began in WASHINGTON State, which claims a special affinity for Riesling, even organizing the world's first truly international conference on the subject (to be followed by similar events in Australia and the Rheingau). By 2017 Washington's total area devoted to Riesling had reached 2,709 ha/6,695 acres, not that far behind Chardonnay plantings. This growth was largely driven by a JOINT VENTURE between the dominant Washington wine producer Château Ste Michelle and Ernst Loosen of the Mosel, with the Eroica BRAND of Riesling a particular success. Washington Riesling is conveniently winter-hardy, and at their best the wines, with varying sweetness levels, benefit from the state's general brightness of fruit. While Oregon's 185 ha/457 acres puts the variety at just over 1% of the state's vineyards, the dedication of a handful of specialist Riesling producers has shown that Oregon can make compelling examples. California's total area of what is occasionally known as White Riesling remained at around 1,600 ha/4,000 acres throughout the 1980s; it declined to 750 ha/1,850 acres by 2003 but rose again to more than 3,659 acres by 2020, perhaps encouraged by Riesling's success in Washington. In recent years, the variety has become more popular from small-scale producers making dry and off-dry Rieslings, though it is still made in small volumes across a range of styles, including

some very sweet. Riesling is planted all over the state, but it tends to be found at either higher ELEVATION or in coastal areas.

Because of its winter hardiness, Riesling tends to be treasured in the coolest wine regions of North America. In CANADA, Riesling is cultivated with particular success in Ontario, making fine, delicate ICEWINES just over the border from the Finger Lakes region of NEW YORK State, where it is increasingly recognized as the region's most successful variety. Riesling has also emerged as a major VARIETAL in MICHIGAN.

Price, F., *Riesling Renaissance* (2004).

Riesling Italico, or Riesling Italianski, white grape variety which Germans would like to see called RIZLING Italico to distinguish it from true RIESLING, known as Riesling Renano in Italy. In Austria it is called WELSCHRIESLING (under which more details can be found); in much of what was YUGOSLAVIA it is called LAŠKI RIZLING, in CZECHIA it is called Ryzlink Vlašský, and in HUNGARY it is called OLASZ RIZLING. In Romania it is known as Italian Riesling and Graševina. Within Italy, it is most common in LOMBARDY in the north. Provided its tendency to overcrop is curbed, it can produce delicate, crisp, mildly flowery wines. It is grown to a limited extent in ALTO ADIGE, FRIULI and COLLIO.

Riesling-Silvaner is the flattering and misleading name for MÜLLER-THURGAU that is preferred in SWITZERLAND, where the canton of Thurgau is to be found (neighbouring cantons such as Zurich would rather not see Thurgau on their labels). It was also widely used in New Zealand, where it was for some time the most planted variety.

right bank refers to the right side of a river as you face downstream. The expression is much used in BORDEAUX to denote that part of the wine region that is on the right bank, or north, of the GIRONDE and DORDOGNE rivers. It includes, travelling downstream, the

Côtes de Bordeaux appellations of FRANCS and CASTILLON, as well as ST-ÉMILION and its satellite appellations, POMEROL and LALANDE-DE-POMEROL, FRONSAC and Canon-Fronsac, and BOURG. The most obvious characteristic shared by these appellations, as distinct from LEFT BANK appellations, is that Merlot and Cabernet Franc dominate rather than Cabernet Sauvignon. The right bank also has more CLAY and less GRAVEL in its soils.

ringing vines. See CINCTURING.

Rioja. La Rioja is the oldest winemaking province in ARGENTINA, but Rioja is probably best known in the wine world as the leading wine region of SPAIN, producing predominantly red wines in the north of the country. Named after the *río* (river) Oja, a tributary of the Ebro, most of the Rioja wine region lies in the autonomous region of La Rioja in north-east Spain, although parts of the zone extend into the neighbouring BASQUE country to the north-west and NAVARRA to the north-east. Centred on the regional capital Logroño, Rioja divides into three zones along the axis of the river Ebro. Rioja Alta occupies the part of the Ebro Valley west of Logroño and includes the winemaking town of Haro. Rioja Alavesa is the name given to the section of the zone north of the river Ebro which falls in the Basque province of Alava. Rioja Oriental extends from the suburbs of Logroño south and east to include the towns of Calahorra and Alfaro. In 2021 Rioja had 65,700 ha/162,348 acres of vines.

History

There is archaeological evidence that the Romans made wine in the upper Ebro Valley (see SPAIN, history). Wine trade was tolerated rather than encouraged under the Moorish occupation of Iberia, but viticulture flourished once more in Rioja after the Christian restoration of the territory at the end of the 15th century. The name 'Rioja' was already in use in one of the statutes written to guarantee the rights of inhabitants of territory recaptured from the Moors. Rioja's wine industry grew around the numerous monasteries (see MONKS AND MONASTERIES) that were founded to serve pilgrims en route to Santiago de Compostela, and the region's first wine laws date from this period.

For centuries Rioja suffered from its physical isolation from major population centres, and the wines found a market outside the region only in the 1700s, when communications improved and Bilbao became an important trading centre. In 1850, Luciano de Murrieta (subsequently the Marqués de Murrieta) established Rioja's first commercial BODEGA in cellars belonging to the Duque de Vitoria and began exporting wines to the Spanish colonies. The Rioja region benefited unexpectedly, but substantially, from the all too obvious arrival of POWDERY MILDEW in French vineyards in the late 1840s. Bordeaux wine merchants crossed the Pyrenees in large numbers, and in 1862 the Provincial Legislature in Alava employed a French adviser to help local vine-growers. Shunned by smallholders who were concerned only with the requirements of the local Basque market, Jean Pineau was finally employed by the Marqués de Riscal, who set about building a bodega at Elciego along French lines. It was finished in 1868, four years before Murrieta built its own similar installation at Ygay.

When PHYLLOXERA began to devastate French vineyards in the late 1860s, yet more merchants came to Spain in search of wine. The inauguration in 1863 of the Tudela–Bilbao railway line, which passed through Haro, encouraged the wine trade between Rioja and France, as did the relaxation of French duties. Rioja enjoyed an

unprecedented boom, sometimes exporting as much as 500,000 hl/13.2 million gal of wine a month to France in the late 19th century. New bodegas were established, among them the Compañía Vinícola del Norte de España (CVNE), López de Heredia, La Rioja Alta, and Bodegas Franco-Españolas, all of which were heavily influenced by the French. During this period the 225-l/59-gal oak *barrica*, or BARRIQUE, was introduced from Bordeaux, and these influential maturation containers are still sometimes referred to as *barricas bordelesas* in Rioja (although American OAK was the popular choice).

By the time phylloxera reached Rioja in 1901, Bordeaux had returned to full production with vines grafted on to phylloxera-resistant ROOTSTOCKS. Spain also lost its lucrative colonial markets, and Rioja's wine industry declined rapidly. Several bodegas were established in the period following the First World War, and Spain's first CONSEJO REGULADOR was established in Rioja in 1926, but the Civil War (1936–9) and the Second World War which followed put paid to further expansion. Recovery came in the late 1960s and 1970s, when, encouraged by growing foreign markets and the construction of a motorway connecting Logroño and Bilbao, a number of new bodegas were built in the region, several with the support of multinational companies, which later sold back the wineries to Spanish firms.

By the late 1970s, Rioja had become the calling card for Spanish wines, wooing non-Spanish consumers with its well-aged, vanilla-scented reds. Towards the late 1990s, RIBERA DEL DUERO began to challenge Rioja's hegemony with its darker, richer reds, inspiring many Rioja producers to make richer, riper reds and release them with less age. Two camps emerged: modernists such as Artadi, Roda, and Telmo Rodriguez and staunch traditionalists such as CVNE and R. López de Heredia. By the late 2010s, a third group of producers, such as Badiola, focused on site, with less wood ageing and earlier releases to retain freshness in the wines. This coincides with a trend towards 100% GARNACHA wines, led by producers such as Juan Carlos Sancha.

Climate and geography

Rioja enjoys an enviable position among Spanish wine regions. Sheltered by the Sierra de Cantabria to the north and west, it is well protected from the rain-bearing Atlantic winds that drench the Basque coast immediately to the north. Yet Rioja's wine producers rarely experience the climatic extremes that burden growers in so much of central and southern Spain. It is difficult to make climatic generalizations, however, about a region that stretches about 120 km/75 miles from north-west to south-east. Indeed, Spanish critics argue that within this single DOP there are several entirely different wine-producing regions.

The vineyards range in ELEVATION from 300 m/984 ft above sea level at Alfaro in the east to nearly 800 m on the slopes of the Sierra de Cantabria to the north-west. Average annual RAINFALL increases correspondingly from less than 300 mm/12 in in parts of Rioja Oriental to over 500 mm in the upper zones of Rioja Alta and Rioja Alavesa.

Rioja Alta and Rioja Alavesa share a similar climate and are distinct from each other for mainly administrative reasons, although there are soil differences between the two. Many of the best grapes are grown here on the cooler slopes to the north-west around the towns and villages of Haro, Labastida, San Vicente, Laguardia, Elciego, Fuenmayor, Cenicero, and Briones. These zones share similar CLAY soils based on LIMESTONE. Downstream to the east, the climate becomes gradually warmer, with rainfall decreasing to less than 400 mm/16 in at Logroño. Where the valley broadens, there is a higher incidence of fertile ALLUVIAL soils composed chiefly of SILT. Around Calahorra and Alfaro in Rioja Oriental the climate is more MEDITERRANEAN. In summer DROUGHT is often a problem here, and temperatures frequently reach 30–35 °C/86–95 °F.

In 2017 the Consejo introduced a new classification to bring more attention to Rioja's varied TERROIRS. Vino de Zona are made with at least 85% fruit coming from one of the three zones (Alta, Alavesa, or

Oriental). Vino de Municipio contain at least 85% fruit from a single village, and—much to the chagrin of many producers—the winery must be in that same village. Viñedo Singular indicates a wine sourced from a single vineyard at least 35 years old with a maximum yield of 5,000 kg/ha (for reds). These classifications are open to all colours of wine, still and sparkling.

Viticulture and vine varieties

Rioja's vineyards are split among nearly 15,000 growers, most of whom tend their plots as a sideline and have no winemaking facilities of their own. Many growers have an established contract with one of the merchant bodegas, whose numbers rocketed from about 100 in the mid 1990s to more than 500 a decade later. Others belong to one of the 30 CO-OPERATIVES that serve the region and receive around 35% of the grapes.

The number of permitted grape varieties was increased in 2009 to 14 (five red, nine white), and their distribution varies throughout the region. The most widely planted variety is the dark-skinned TEMPRANILLO, which ripens well on the clay and limestone slopes of Rioja Alta and Rioja Alavesa and in 2021 was planted on 51,000 ha/130,000 acres, comprising almost 88% of the total vineyard surface.

Most Riojas are blends of more than one variety, however, and wines made from the GARNACHA vine—which, after phylloxera, superseded native varieties in the Rioja Oriental—are often used to add BODY to Tempranillo. However, 100% Garnacha wines are a promising trend, especially those from around Tudelilla in Rioja Oriental, historically a Garnacha stronghold, and from the old Garnacha vineyards in Nájera in Rioja Alta. In 2021 Garnacha comprised 7.5% of all red grapes in Rioja.

Two further red varieties, Mazuelo (Cariñena or CARIGNAN) and GRACIANO, each make up about 2% of red-grape plantings. Owing to its susceptibility to disease and its low productivity, Graciano fell from favour with Rioja's vine-growers before a strong revival in the 1990s. VARIETAL versions are no longer oddities.

The fifth red-wine variety, authorized in 2009, was Maturana Tinta. But in a chaotic turn of events, in some places a different variety has actually been planted under that name. When regional viticulturists began recovering old, minority grape varieties around the turn of the 21st century, several red ones showed good potential. Maturana Tinta

was one. It was later identified through DNA PROFILING as Galicia's Merenzao, which, in turn, is the Jura's TROUSSEAU—present for centuries, under several names in Spain, Portugal, and the Canary Islands. Another red grape was named Maturana Tinta de Navarrete because it was recovered and reproduced from a few vines in that Rioja village. Although the 'Trousseau' Maturana Tinta was the one registered with the Ministry of Agriculture, the deep-coloured, peppery one from Navarrete was preferred by growers and planted commercially. The Consejo Regulador looked the other way when it was identified as just 'Maturana Tinta' on labels. In 2011 it was shown to be CASTETS, an almost extinct member of the Bordeaux grape family.

Historically, until PHYLLOXERA arrived Rioja's chief white grape variety was called MALVASIA, a synonym for the lowly ALARIJE of west-central Spain. On its own, it produced rich, alcoholic, dry white wines which responded well to OAK AGEING. However, Viura (known elsewhere in Spain as MACABEO) took over as the most planted light-berried variety in the region; from the early 1970s, fresher-tasting, cool-fermented, early-bottled white wines were in FASHION all over Spain. By the 1990s, most white Riojas were made exclusively from Viura, and Malvasía vines were extremely difficult to find, although some of the traditional oak-aged whites and new BARREL FERMENTED wines are blends of Malvasía and Viura.

A third traditional grape, Garnacha Blanca, was legal but rare. In 2009 Verdejo, Sauvignon Blanc, and Chardonnay were also permitted, but there has been very little interest in them. Also legalized then were three recovered local white varieties that have attracted considerably more attention: Tempranillo Blanco, a relatively recent MUTATION of Tempranillo; Maturana Blanca, which is not related to either one of the Maturana Tintas; and Turruntés, a local name for ALBILLO Mayor, which is more common further south, around the Duero/Douro River.

Vineyards in Rioja tend to be small, especially in Rioja Alta and Rioja Alavesa, where vines are often interspersed with other crops.

Vines used to be free-standing BUSH VINES trained into low goblet shapes (see GOBELET), but of the thousands of hectares of vineyard which have been planted since the 1970s, most are trained on WIRES. This resulted in a marked and alarming increase in YIELDS in the region in the 1990s, even before IRRIGATION was legalized in the late 1990s. Official DOP limits are 63 hl/ha (3.5 tons/acre) for white wines and 45 hl/ha for reds.

Winemaking

Rioja winemaking is characterized not by fermentation techniques but by BARREL AGEING, so much so that there were an estimated 1,300,000 barrels in Rioja in 2021, most of them the 225-l *barrica bordelesa* introduced by the French in the mid 19th century. The regulations also specify the minimum ageing period for each officially recognized category of wine. In Rioja, red wines labelled CRIANZA and RESERVA must spend at least a year in oak, while a GRAN RESERVA must spend at least two years (plus another two years in bottle). In common with other Spanish wine regions, Rioja favours American OAK, its soft, vanilla flavour now accepted as typical of Rioja, but a similar effect can also be achieved by slow, OXIDATIVE maturation in older barrels. French oak is used increasingly, however. Over 50% of all Rioja falls into one of the three oak-aged categories above (the rest is either white, rosé, or sold as young, unoaked JOVEN red, much of it within Spain), and the larger bodegas therefore need tens of thousands of casks. Most bodegas renew their *barricas* on a regular basis, and the number of traditional producers who pride themselves on the age of their casks is dwindling. Some producers are also spurning the traditional categories and bottling their oak-aged wine with a basic, generic Rioja label so that they can use different-sized barrels or larger oak VATS.

After the widespread adoption of cool-fermentation techniques in the 1970s, the amount of oak-aged white Rioja progressively diminished. López de Heredia, Marqués de Murrieta, and only a few other bodegas upheld the traditional style by ageing their white wines in oak *barricas*. For white and rosé wines labelled Crianza, Reserva, or Gran Reserva, the minimum wood-ageing period is just six months, with a further year, two years, or four years respectively before the wines may be released for sale. By the mid 1990s, however, many producers had switched back to BARREL FERMENTATION.

Espumosa de Calidad de Rioja is the DOCa's sparkling wine category, introduced in 2017 as an alternative to the CAVA label. It

allows for white and rosé sparkling wines made from any of the white grape varieties permitted in still Rioja; rosés must contain at least 25% red grapes. All must be made by the TRADITIONAL METHOD, with 15 months' ageing for Crianza wines and 24 and 36 months respectively for those classified as Reserva or Gran Añada. V. de la S. & F.C.

Ripaille, CRU from a historic vineyard on the southern shore of Lake Geneva whose name may be added to the French appellation SAVOIE for wines from the CHASSELAS grape. Ch de Ripaille is the only producer.

riparia. See VITIS RIPARIA.

ripasso, Italian term meaning literally 'repassed', for the technique of adding extra flavour, BODY, and alcohol to VALPOLICELLA by re-fermenting the young wine on the unpressed skins of AMARONE and/or RECIOTO wines after these DRIED-GRAPE WINES have finished their fermentation in the spring and have been RACKED off. Regularly aged in new BARRIQUES to add a sweet note of vanilla and often with residual sweetness, Valpolicella Ripasso became a roaring success as a cheaper alternative to Amarone, with production rising from 7.5 million bottles in 2007 to more than 30 million bottles in 2020. The marked increase in the volume of Ripasso has been at the expense of straight Valpolicella, which decreased in the same period from 35.9 million bottles to 18.2 million in 2020. W.S.

ripeness, term used to describe that stage of the continuous process of grape RIPENING or development which is chosen by the winemaker and/or grape processor as that desired at HARVEST. What constitutes the ideal chemical and physical composition of grapes at this point is a subjective judgement dependent on wine style, the winemaker's current belief about optimal ripeness, FASHION, and many other factors, so ripeness is a relative term. Grapes considered at perfect ripeness by one winemaker for one purpose may be considered overripe or underripe by different winemakers for other uses. A commercial grower paid by weight may have yet another opinion.

Ripeness is often related to MUST WEIGHT or grape-sugar concentration. Being directly related to POTENTIAL ALCOHOL, the concentration of SUGAR IN GRAPES has a major impact on wine type. The commercial TABLE WINES of the world fall between two extremes. One is represented by very light whites made from grapes harvested early and from cooler regions to give bottled wines that are refreshing, lower in calories, and low in ALCOHOLIC STRENGTH (11–12%). At the other extreme are rich reds such as those of the southern Rhône dominated by alcohol-rich GRENACHE or examples of Cabernet from California's NAPA Valley that have been subjected to extended HANG TIME. These blockbusters may reach 16% alcohol or even more.

Sugar levels are not the only aspect of grape composition to affect what is considered ripeness. Especially in cool climates, ACIDITY levels can be closely monitored to determine the grapes' ripeness. The acidity in grapes declines with ripening and must be below certain values, depending on wine style, so that the resultant wine will not be too tart. In warm to hot regions, it is more common that the acidity is too low and the PH is too high when sugars have reached the desired potential alcohol level.

Measures of sugar, acidity, and pH have been commonly used around the world to define grape ripeness and optimal harvest time, but winegrowers continue to search for better definitions of ripeness

to improve wine quality. (See GRAPE QUALITY ASSESSMENT and PHYSIOLOGICAL RIPENESS.) For all grapes, a measure that indicates flavour is so eagerly sought that it may be said to be the grape researcher's holy grail. This is a particularly difficult measurement that can only be done in a laboratory because of the minute concentrations of FLAVOUR COMPOUNDS. INFRARED SPECTROSCOPY is proving to be useful in the ANALYSIS of many different grape and wine components.

It is common for grapes to be tasted in the field, often by the winemakers, in an attempt to assess optimal harvest date. However, the ability to taste PHENOLICS and other compounds in a sugar-rich substrate makes the practice subjective, requiring many years of experience. Flavour is also difficult to assess when it is partly present only as FLAVOUR PRECURSORS.

Individual grapes' physical condition, especially skin thickness and integrity, is also considered as an aspect of grape ripeness relevant to wine quality. The phenomenon of BERRY CELL DEATH in the later stages of ripening and associated with berry shrivel, generally due to heat and WATER STRESS, is a current area of concern.

ripeness measurement. See MUST WEIGHT, RIPENESS, and RIPENING, GRAPE.

ripening, grape. The important process of grape development which is a prelude to HARVEST. Ripening begins when the berries soften and start to change colour at the stage called VERAISON and is concluded normally by harvest, which can occur at different stages for different wine styles. Ripening can be affected by many plant, pest and disease, and environmental factors, and is in many ways the most important vine process affecting wine quality since it is so

critically related to the chemical and physical composition of the harvested fruit.

Following FRUIT SET, grape berries grow in size but are hard, green, and very acidic (see GRAPE). When almost half their final size, veraison occurs. The timing of this will depend on variety and climate, but it is normally 40–60 days after fruit set, longer for cooler climates. The period from veraison to harvest depends on the stage of ripeness required, but for grapes destined for dry TABLE WINE the period varies from about 30 days in hot regions to about 70 days in cooler regions. However, the phenomenon known as HARVEST COMPRESSION is making such estimates less predictable. For early-ripening varieties such as Pinot Noir and Chardonnay, the ripening period is shorter than for a variety such as Cabernet Sauvignon, which ripens relatively late.

Not all bunches on a vine nor berries on a bunch are at the same stage of development; the first flowers to open set the first berries, which in turn go through veraison and ripen first. This means that there can be substantial variation in degree of ripeness, both within and between bunches, and from vine to vine, depending on factors such as CANOPY MICROCLIMATE, PRUNING level, and soil variation. The use of indices of ripeness to determine optimal harvest date is therefore complicated, and SAMPLING requires skill and care. During the latter stages of ripening when the sugar content is above 20 °BRIX or more, depending on variety and the weather, the berry skin may lose some water. So for very ripe grapes the increase in berry-sugar concentration, for example, is due to a loss of water rather than more sugar accumulation in the berry.

It is relevant to consider ripening in terms of the various chemical compounds of most interest to the winemaker. Sugar, or more precisely SUCROSE, is the most important. It is moved from the leaves to the berries by TRANSLOCATION and is broken down to the constituent molecules GLUCOSE and FRUCTOSE by the enzyme INVERTASE. Sucrose typically originates from current PHOTOSYNTHESIS, less likely from stored CARBOHYDRATE reserves in the woody parts of the vine such as

its TRUNK, ARMS, and ROOTS. Heavy crop loads relative to active leaf area (see LEAF TO FRUIT RATIO) slow the increase in concentration of SUGAR IN GRAPES, as do factors slowing photosynthesis such as low or high temperatures, WATER STRESS, and low levels of SUNLIGHT. There can also be competition for the products of photosynthesis; if shoot tips are growing actively, for example, then fruit ripening is slowed (see VIGOUR).

The second major indicator of grape ripening is ACIDITY. The concentration of TARTARIC ACID falls during ripening, due to dilution effects associated with berry growth. The concentration of MALIC ACID falls more quickly than that of tartaric during ripening because of temperature-dependent RESPIRATION in addition to dilution. Grapes ripening in COOL CLIMATES therefore tend to have higher acidity as less malic acid is respired. Juice PH rises throughout ripening due to the decreases in free acids and increases in POTASSIUM. In hot regions, high juice pH is a great concern for wine quality, and ACIDIFICATION of the must is usually necessary. Shahood et al.'s proposed analysis of the kinetics of sugar accumulation and malate metabolism (2020) provides better understanding of variations in ripening within a vineyard.

The skin colour of red grapes is due to ANTHOCYANINS; veraison is signalled when they replace the green colour of chlorophyll, the timing of which typically varies even within one bunch. Anthocyanin concentration rises during ripening, and the value at harvest depends on both environmental and plant factors. Temperature and sunlight exposure have major effects; high temperatures and SHADE within the canopy reduce skin coloration in many varieties. Grape TANNINS are distributed between the skins, seeds, and stems. They increase during ripening at a rate comparable to anthocyanins.

The most abundant minerals in the grape are POTASSIUM, CALCIUM, MAGNESIUM, and SODIUM, and they increase in concentration during ripening. Potassium, which is distributed between flesh and skins, is predominant and has a major effect on juice pH. Potassium extracted

from skins during fermentation is one reason why red wines have a higher pH than white wines.

FLAVOUR COMPOUNDS are all-important factors in wine quality, even if their measurement is many years away from becoming a common practice. In the early 21st century, analytical techniques (see ANALYSIS) as well as knowledge about their role are still developing sciences.

ripping is a viticultural operation conducted in many parts of the world before PLANTING a vineyard in order to to break up compact soils so that water can penetrate and roots can grow to a greater depth. Normally bulldozers or heavy tractors are used along row lines, which also makes it easier to insert vineyard posts.

Ripping also provides the opportunity to incorporate FERTILIZERS and soil amendments (see SOIL AMELIORATION) such as phosphates, forms of potassium or lime, as they will not readily leach through the soil.

Ripping is a procedure, like IRRIGATION, which can modify some important properties of the soil affecting wine quality; see TERROIR.

Coombe, B. G., and Dry, P. R. (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006). R.E.S.

ripping out. See GRUBBING UP.

Riserva, nebulous Italian term usually denoting a wine given extended ageing before release, and suggesting a higher quality than the normal version of the same wine. However, only in the rarest of cases do Riservas have stricter production regulations, such as higher minimum ALCOHOLIC STRENGTH (therefore mirroring the SUPERIORE designation) and higher minimum EXTRACT. Chianti Classico, for example, questionably allows CHAPTALIZATION in Riservas to add up to 0.5% alcohol by volume. The ageing requirement for Riservas varies from DOC to DOC but normally is a minimum of one year—and up to 62 months for Barolo Riserva. In many cases this includes a mandatory period of CASK AGEING as well as AGEING in bottle (with the notable exception of Chianti Classico Riserva, which does not require any wood ageing, however common it is in practice). In some cases the prolonged oak ageing accelerates the wine's development, resulting in PREMATURE OXIDATION and stewed fruit flavours, even though the category is meant to denote wines with the inherent capacity for prolonged ageing.

In most cases Riserva does not guarantee higher quality because producers are not required to declare a Riserva before the harvest. This latitude has allowed some producers simply to reclassify their unsold inventory as Riserva in an effort to obtain a higher price, prompting calls for the abolition of the entire category. W.S.

Rivairenc. See ASPIRAN.

Rivaner, another name for MÜLLER-THURGAU, used in Luxembourg, where it is the most planted grape variety, and in Austria.

Riverina, the largest wine-producing region in NEW SOUTH WALES, its 20,113 ha/49,700 acres of vines spread across the flat south-west plains of the state. This is home base for many of Australia's largest wine companies, including Casella of YELLOW TAIL fame. Sunny and warm, with just 229 mm/9 in annual rainfall, the region is reliant on IRRIGATION for its vineyards, planted mainly to Shiraz, Chardonnay, and Cabernet Sauvignon (in that order). Production volume is substantial, with much fruit going into wines labelled SOUTH EASTERN AUSTRALIA. Interest is increasing in less water-intensive Mediterranean varieties. A.R.P.

Riverland, the most productive wine region in Australia, with a sprawl of vineyards irrigated by the Murray river mainly in the state of SOUTH AUSTRALIA. As in neighbouring MURRAY DARLING, CLIMATE CHANGE and water issues have prompted increased interest in warm-climate grape varieties. Petit Verdot is an established speciality, and Italian varieties such as Vermentino, Fiano, Montepulciano, and Nero d'Avola are catching on. SOUTH EASTERN AUSTRALIA is the catch-all description usually found on labels.

rivers have played an important role throughout the history of wine, both as arteries of trade and also through their action in helping to shape valley slopes particularly well suited to the cultivation of the vine. More recently they have provided valuable water for IRRIGATION.

A river is crucial to the earliest detailed account of the wine trade. HERODOTUS, writing in the 5th century BCE, records how in MESOPOTAMIA wine in palm-wood casks was loaded on to boats in the upper reaches of the river Tigris and then sailed down to Babylon, where the boats were broken up because of the impossibility of paddling them upstream against the current.

During the Roman era, rivers continued to play a vital role in the transport of bulky items such as wine. There were two main trade

routes in GAUL: a western one from Narbonne to Toulouse and then along the river GARONNE to Bordeaux and the Atlantic; and a northern one up the RHÔNE to Lyons and thence along the Saône, before cutting across country to the MOSEL and the RHINE and eventually reaching the North Sea. These routes witnessed the transport of thousands of AMPHORAE of wine, but they were also a highway along which the idea of vine cultivation and winemaking passed. By the 1st century CE, viticulture was thus well established along the Rhône and the Garonne, and gradually vineyards came to be cultivated along most of the other major river valleys of Gaul such as the LOIRE and the Seine (see PARIS).

By the year 1000, although vineyards were relatively widely established throughout southern Europe, in the north they were found most frequently in river valleys. The main reason for this was the high cost of overland transport, which gave those with easy access to the main fluvial transport routes a distinct competitive advantage. Environmental factors were also important, with the south-facing slopes of such valleys providing ideal sites because of the extra exposure to the sun that they afforded (see VINEYARD SITE SELECTION). This is particularly evident in the development of vineyards in the cool Mosel–Rhine area, where most of those established before 1050 were in close proximity to rivers.

Coastal transport became increasingly important during the later medieval period, but rivers maintained their role as arteries of the wine trade, and, with the opening-up of eastern Europe, rivers such as the Dnestr, the Vistula, and the Danube also came to play as significant a role as did the Garonne, Loire, Seine, Rhône, and Rhine in the west.

In the 19th and 20th centuries, with the development of the RAILWAYS and, subsequently, efficient road transport, it is environmental factors that have been most important in determining the location of vineyards along the slopes of river valleys. Above all, these locations provide additional sunshine, generally alleviate the problems associated with FROST and excess humidity (see HILLSIDE

VINEYARDS), and frequently have soils well suited to vine cultivation (see TOPOGRAPHY). Moreover, in some special locations, as in SAUTERNES and along the Rhine, the proximity to water provides the ideal conditions for NOBLE ROT, which can result in some of the world's greatest sweet wines.

In the NEW WORLD, certain rivers have also been important for the development of several wine regions. The Murray river in Australia, for example, is responsible for the existence of that country's extensive RIVERLAND vineyards, California's CENTRAL VALLEY depends on river water, and most of the vineyards in WASHINGTON State depend on water from the Columbia River. Rivesaltes , town just north of Perpignan in southern France that gives its name to two of the biggest appellations of ROUSSILLON for VINS DOUX NATURELS, namely Rivesaltes and MUSCAT DE RIVESALTES. Muscat de Rivesaltes, which represents about 70% of France's total fortified Muscat production, can in fact be made throughout Roussillon's recognized wine-producing area, together with the nine villages of the inland part of the appellation of FITOU in the Aude *département* to the north. The Rivesaltes production zone is similarly generous but specifically excludes those vineyards that produce BANYULS. In 2020 a total of 1,533 ha/3,788 acres were dedicated to the production of Rivesaltes.

Rivesaltes comes in four colours: Grenat, Rosé, Tuilé, and Ambré. Grenat, recognized in 2001, is pure Grenache Noir; for the others,

Grenaches Blanc and Gris, Macabeo, Malvoisie du Roussillon, MUSCAT OF ALEXANDRIA, and MUSCAT BLANC À PETITS GRAINS also feature. The minimum ageing for Grenat, the youngest style of wine, is eight months, and its essence is fresh red fruit. The base wine for Tuilé concentrates on black grapes that turn a brick colour with age, whereas for Ambré white grapes dominate and the wine turns amber-golden with age. Both are aged in an OXIDATIVE environment for a minimum of 30 months. With five years or more of ageing, the wine is classified as Hors d'Âge. The sugar level must be at least 45 g/l but in practice is usually 60–70 g/l and may be as high as 120. MUTAGE usually takes place *sur grains* (on the skins) rather than *sur jus* (after pressing). After fermentation, often in stainless-steel vats, the wines are usually aged in wooden casks of all ages and sizes and sometimes in a SOLERA. Some wines are made to taste RANCIO, with deliberate exposure of the maturing wine to the punishing heat and light of a Roussillon noon, either outside or alternatively under a cellar roof. A period outside in glass BONBONNES may also be part of the ageing process. Old Rivesaltes features among the vinous treasures of Roussillon, with flavours of raisins, coffee, chocolate, fruits, or nuts, with notes of rancio. The most concentrated can, like Banyuls, be some of the few wines that happily partner chocolate. The colour of the wine is a good guide as to the dessert that will best accompany it. R.E.G.

Riviera di Ponente, or Riviera Ligure di Ponente, extensive, overarching Ligurian DOC along the north-western coast of Italy producing wines made of VERMENTINO (called Pigato here), ALICANTE (probably GRENACHE), and ROSSESE di Dolceaqua. For more details, see LIGURIA.

Rizling, term for the white grape variety known variously in central Europe as WELSCHRIESLING, OLASZ RIZLING, LAŠKI RIZLING, RIESLING ITALICO, and Graševina. The Germans disapprove of any name for this

inferior grape variety which suggests a relationship with their own noble RIESLING vine but will accept 'Rizling' as a suitably distinctive alternative.

Rkatsiteli, ancient, cold-hardy Georgian white grape variety which was so widely planted in what was the Soviet Union that in 1990 it was estimated to be the world's third most planted overall. Thanks to President GORBACHEV's VINE-PULL SCHEME, however, it had fallen to fourteenth place by 2000 and to sixteenth by 2016. It is still widely planted in the former Soviet republics, though, being grown in all of its wine-producing independent republics with the exception of TURKMENISTAN. It is, understandably, most important in GEORGIA, particularly in Kakheti, but also widely planted in Ukraine, Bulgaria, MOLDOVA, RUSSIA, and ARMENIA. As Baiyu it reached China and has adapted well to the inland wine regions there with their cold winters. Presumably its cold resistance was what inspired FINGER LAKES grower Konstantin Frank to plant it in New York State, and it is now planted in Virginia and several other American states as well.

Much is demanded of this productive variety, and it achieves much, providing a base for a wide range of wine styles, including FORTIFIED WINES and brandy. The wine is distinguished by a keen level of ACIDITY, easily 9 g/l even when picked as late as October, and by good sugar levels, too.

Roannaise, Côte. Situated only one range of hills west of the BEAUJOLAIS region, this 20-km-long AOC runs just south-west of the N7 as it makes its way to Lyons. It was the direct RIVER and canal links with Paris, however, that gave the region's wines relative fame and popularity in the 19th century, such that annual production was almost 800,000 hl/21.1 million gal at the beginning of the 20th century. Production was down to 4,000 hl by 1994 when AOC status was won; by 2019, just 215 ha of vines were left, planted in GRANITIC soils on slopes at 350–550 m/1,148–1,904 ft in ELEVATION. Lightish

reds and some rosés (15% of total production) are made from locally adapted GAMAY grapes, called St-Romain à Jus Blanc here, using Beaujolais cellar techniques, usually CARBONIC or SEMI-CARBONIC MACERATION. White and sparkling wines, mainly Chardonnay and Viognier, must take the IGP Urfé. Wine quality is in the hands of individual winemakers, egged on by the Troisgros family at their famous restaurant near the town of Roanne.

Robe, wine region on the Limestone Coast of SOUTH AUSTRALIA sandwiched between the Southern Ocean and a string of inland lakes that help moderate the cool MARITIME CLIMATE. Soils vary from sandy LOAM to CALCAREOUS sand and TERRA ROSSA. Both white wine grapes (Chardonnay, Sauvignon Blanc) and red (Cabernet Sauvignon, Shiraz) make up the 681 ha/1,683 acres of vineyards.

Robertson, important warm, dry, wine-producing district within the Breede River Valley region in South Africa. Home to many estates and CO-OPERATIVES, it produces some fine whites, including Chardonnays and Sauvignon Blancs, and an increasingly creditable array of reds, most notably Shiraz and Cabernet. Bonnievale is the best-known of the district's wards. Most vineyards fringe the Breede River, which provides the essential IRRIGATION (rainfall is less than 400 mm/16 in annually) and ALLUVIAL soils although CALCIUM-rich outcrops are also found. Most of the INTERNATIONAL VARIETIES perform well here, although Robertson has long enjoyed a reputation for fortified MUSCADELS. Robertson produces more than 15% of the national harvest. Average daily growing-season temperatures are high, though with marked DIURNAL TEMPERATURE RANGE.

roble, Spanish for 'oak', is used on wine labels in SPAIN to indicate red and rosé wines that have been aged at least three months in oak BARRELS. The term is very popular in RIBERA DEL DUERO, the appellation

that has taken the most credit for it, although it can be used throughout Spain. F.C.

Robola, wine and grape variety for which the Ionian island of Kefalonia in GREECE is most famous. The distinctively powerful, lemony dry white is made entirely from Robola grapes, which are cultivated almost exclusively on the island. The wine made from these early-ripening grapes is high in both ACIDITY and EXTRACT and is much prized within Greece. DNA PROFILING established that Robola is quite distinct from Rebula (RIBOLLA Gialla). The country's 406 ha/1,003 acres of this variety are mainly limited to the Ionian Islands.

robotic lagar, a computer-operated LAGAR pioneered by the SYMINGTONS for the production of PORT.

robots are an emerging technology in vineyards. They are most commonly designed to replace vineyard operations that are already mechanized using implements carried by a manned tractor, such as TILLAGE or mowing for weed management, or SPRAYING for disease control. Concerns about the use of HERBICIDES for under-vine weed management and the high number of tractor passes required for the mechanical cultivation and mowing alternatives to herbicides (see SOIL COMPACTION) make this the likely first area of adoption. Robots can also be used to carry other sensors to facilitate PRECISION VITICULTURE.

Robots usually navigate a previously mapped area based on high-accuracy satellite positioning, with additional local guidance and safety management by other sensors such as cameras, radar, LiDAR (Light Detection and Ranging), ultrasound, and bump sensors. There is no clear distinction between a robot and an automated TRACTOR. Robots are more likely to be electric and powered by batteries, but some are also driven by diesel combustion engines like conventional tractors or are hybrids.

See also LABOUR and MECHANIZATION. S.N.

Rochelle, La. See LA ROCHELLE.

rock, a rigid, naturally bonded aggregate of geological MINERALS. A mass of SAND or VOLCANIC ash, or a molten lava, would not be regarded as rock although this is the case in some historical texts; neither would concrete. The solid Earth is made chiefly of rock. Its outermost surface is known as bedrock (see GEOLOGY), which is generally overlain by a more or less disintegrated zone of SUBSOIL and then possibly by agricultural SOIL, although in vineyards such divisions are unusually hazy.

A fragment of bedrock is commonly called a rock or a STONE, with more specific names used to indicate its size or smoothness (see GEOLOGY). The stones seen in many vineyard soils may or may not represent the local bedrock (see ALLUVIUM and COLLUVIUM). Vines cannot obtain nutrition directly from bedrock or from stones, except by the action of MYCORRHIZAL fungi. A.J.M.

Rockpile, California AVA nested within Dry Creek Valley AVA. See SONOMA.

Roditis, or Rhoditis, slightly pink-skinned grape variety that is Greece's second most common after SAVATIANO, which DNA PROFILING suggests is one of its parents, planted on a total of 9,398 ha/23,223 acres in 2021. Although its name is probably derived from the island of Rhodes, it was traditionally grown, often as a FIELD BLEND with other, differently coloured, varieties called Roditis Something, in the Peloponnese and was even more important in the pre-PHYLLOXERA era. The vine is particularly sensitive to POWDERY MILDEW. It ripens relatively late and keeps its ACIDITY quite well even in such hot climates as that of Ankhialos in Thessaly in central Greece, although

it can also ripen well in high-ELEVATION vineyards. It is often blended with the softer Savatiano, particularly for RETSINA. J.V. & J.H.

Roditis Kokkinos, or Rhoditis Kokkino, meaning 'red of Rhodes', is a red-skinned Greek grape variety traditionally grown in the Peloponnese that has been shown by DNA PROFILING to be distinct from, even if often planted with, the more common pink-berried RODITIS. Also known as Tourkopoula.

Roederer, Louis , family-owned Champagne house known both for its early links with the Russian court and for its extensive vineyard ownership. The original company was founded by a M. Dubois around 1776; Louis Roederer joined in 1827, becoming owner in 1833. By the second half of the century, RUSSIA had become the major market for Champagne Louis Roederer: 666,386 bottles out of a total company production of 2.5 million were exported there in 1873. In 1876 Louis Roederer was commissioned by Tsar Alexander II to create a special personal cuvée in clear glass crystal bottles that was named Cristal. But in 1917 the Russian Revolution brought the immediate loss of the company's principal export market. Camille Orly-Roederer, widow of the great-nephew of Louis, rebuilt the company after this blow, in particular by strengthening Roederer's vineyard holdings at a time when other houses were selling, a move many later regretted. In 1924, responding to demand for the legendary Cristal, she reintroduced it, bottled in the original design of crystal glass with no PUNT, creating the first PRESTIGE CUVÉE champagne. By the mid 2010s, the company's vineyards extended over 240 ha/593 acres, much of it in the grands and premiers crus villages. By 2022, 115 of the 240 ha were certified organic, and the certification process continues. Both white and rosé Brut Nature and Cristal wines are all farmed BIODYNAMICALLY, followed by vintage Blanc de Blancs from the 2018 vintage. They also have 10 ha of experimental vineyards in which to research their own CLONES, PRUNING, and TRAINING SYSTEMS in order to meet the challenges of

CLIMATE CHANGE and have their own vineyard nursery for their MASS SELECTION project.

Mainly thanks to these vineyard holdings, Roederer produces more vintages of Cristal than is usual for a prestige cuvée. The company, unusually for a substantial champagne house, remains independent. Jean-Claude Rouzaud, Camille's grandson, continued in the expansionist vein, buying more vineyards and investing in other wine regions. Roederer Estate in ANDERSON VALLEY, first released in 1988, is one of California's finest sparkling wines. An investment in Jansz in TASMANIA was terminated. The company, now headed by Frédéric Rouzaud, the seventh generation to lead the company, also owns Ramos Pinto in Portugal, Champagne Deutz, Delas Rhône wines, Domaines Ott in Provence, and in Bordeaux Chx de Pez in St-Estèphe and, since 2007, second-growth Ch Pichon Longueville Comtesse de Lalande in Pauillac. In 2019 and 2020 respectively, Merry Edwards and the revered Diamond Creek in California were added.

Roero, increasingly important vineyard area and DOCG on sandy hills on the left bank of the River Tanaro in the PIEMONTE region of north-west Italy which takes its name from the villages of Montaldo Roero, Monteu Roero, and Santo Stefano Roero to the north-west of Alba. Geographically and administratively it is not part of the LANGHE, from which it is separated by the River Tanaro, but it shares its most important red grape variety, NEBBIOLO, although the wines tend to be softer and earlier-maturing than those from BARBARESCO and BAROLO. Despite ongoing marketing efforts, red Roero has proven such a hard sell that most producers resort to the generic Langhe Nebbiolo. Commercially much more significant is Roero Bianco, made from ARNEIS, planted on 832 ha/2,056 acres compared with 184 ha of Nebbiolo. In 2017 the region introduced the MGA system, an official list of 135 single vineyards which may appear on labels. W.S.

Rolland, Michel (1947–), the most famous CONSULTANT oenologist, responsible in several ways for the late 20th century FASHION for overtly ripe, deep-coloured, supple red bordeaux. From 1973 he and his wife Dany ran a laboratory in POMEROL on which many local growers depended for ANALYSIS. They led a team of younger OENOLOGISTS with hundreds of clients all over the world, though especially in Bordeaux. In 2020 the business was transferred to three of the senior staff and renamed Rolland et Associés. In 2013, after separating, Michel and Dany sold Michel's family properties Chx Le Bon Pasteur in Pomerol, Bertineau St-Vincent in LALANDE-DE-POMEROL, and Rolland-Maillet in ST-ÉMILION to Asian investors, but the Rolland team continue to be responsible for their winemaking. They also farm Ch La Grande Clotte in Lussac-St-Émilion, and Dany lives at Ch Fontenil in Fronsac, acquired in 1986. The Bordeaux RIGHT BANK enterprises to which he is consultant are too numerous to list (although they have included L'Angélus, Beau-Séjour Bécot, Clinet, Clos L'Église, La Dominique, La Gaffelière, Grand Mayne, Larmande, Pavie, Pavie-Decesse, and Troplong Mondot). In the MÉDOC and GRAVES they have included many properties managed by NÉGOCIANTS Dourthe as well as Chx Fieuzal, Kirwan, Léoville Poyferré, Malescot St-Exupéry, Pape-Clément, Smith Haut Lafitte, and La Tour Martillac. But it is his consultancies outside France that set him apart from all but a handful of his compatriots in the breadth of his experience. They include, for example, HARLAN in the Napa Valley, Ornellaia in Italy (after TCHELISTCHEFF), and (one of his more novel clients and evidence of his love of travel) Grover in India. The Rollands and their two daughters have also had holdings outside France: Bonne Nouvelle in South Africa (with Remhoogte Estate), Campo Eliseo in Toro (with François LURTON), and Clos de los Siete, Val de Flores, and Mariflor in Argentina. He studied oenology at the University of BORDEAUX during the PEYNAUD era and has continued to declare his

philosophy that wine should give maximum pleasure, although he has been criticized for a certain uniformity of style.

Rolle, official alternative southern French name for the increasingly popular VERMENTINO used traditionally in BELLET and parts of the Languedoc and Roussillon. DNA PROFILING has shown it to be distinct from ROLLO.

Rollo, ancient Ligurian white wine grape with several names but distinct from ROLLE, planted on just 15 ha/37 acres in 2015.

Romagna, eastern part of EMILIA-ROMAGNA.

Romagna Albana, white wine made in central Italy from ALBANA grapes and much-maligned despite its long historic presence in the region. Unreasonably high YIELDS of 100 hl/ha and careless winemaking by large CO-OPERATIVES led to Albana's mediocre reputation, which is why its elevation to DOCG in 1986 spurred criticism that the DOC system was flawed.

Only those producers who give Albana their full attention—planting it on suitable sites (rather than simply where SANGIOVESE, Romagna's most important red wine grape, wouldn't ripen), drastically reducing yields, and harvesting it at full ripeness and aromatic development—overcome Albana's supposed neutral and tart character. Some producers are now making SKIN-FERMENTED versions, a style made popular by the NATURAL WINE scene.

With Albana in decline from 7,418 ha/18,330 acres in 1970 to just 818 ha in 2020, local research into Albana CLONES has helped to save the rarest ones from extinction while a greater focus on the selection of suitable sites has led to the production of several SINGLE-VINEYARD WINES, showing that the variety adapts equally well to the CALCAREOUS soils of the township of Bertinoro and the reddish CLAY soils of

Faenza. A system of subzones that would bring these differences into focus, analogous to that of ROMAGNA SANGIOVESE, is long overdue.

Albana can come in several versions: *secco* (dry), *amabile* (medium dry), *dolce* (sweet), and PASSITO, reaching its pinnacle in late-picked dry versions as well as BOTRYTIZED dessert wines. W.S.

www.consorziovinidiromagna.it

Romagna Sangiovese, quantitatively and increasingly qualitatively important DOC in EMILIA-ROMAGNA made from SANGIOVESE, the region's most widely cultivated red grape variety, with 6,235 ha/15,407 acres in 2020.

In the recent past the zone's reputation had been sullied by high YIELDS, mediocre wine quality, and the erroneous belief that the CLONES of Sangiovese in Romagna were inferior to those in Tuscany. Sangiovese di Romagna is part of the same Sangiovese Grosso group as, for example, BRUNELLO, but old BUSH VINES around Predappio in Romagna appear to be Sangiovese Lamole, which has a higher PHENOLIC content and produces smaller grapes resulting in higher EXTRACT in the final wines.

The DOC has 16 subzones, which can be broadly grouped into five macro zones. Faentino, the vineyard area around Faenza (with the subzones of Serra, Brisighella, Modigliana, Marzeno, and Oriolo), has a diverse array of soils, ranging from IRON-rich red CLAY at 250 m/820 ft in elevation around Marzeno to SANDSTONE in Modigliana, at 500 m on the edge of the Apennine Mountains separating Romagna from Tuscany. The Forlivese zone around Forlì (with the subzones Castrocaro-Terra del Sole, Predappio, Bertinoro, and Medola) is mostly at lower elevations with clay soils, except Predappio, an ancient winegrowing area giving some of the region's finest, long-lived Sangiovese from its many old vines and iron- and sandstone-rich soils at up to 450 m. Cesanese around Cesena (with the

subzones of Cesena, San Vicinio, and Longiano) has hillside vineyards rising to 200 m, CALCAREOUS clay soils, and a more moderate climate thanks to the proximity of the Adriatic coast. The Riminese zone includes Verruchio, Coriano, and San Clemente, and Imolese includes Imola. Thanks to the work of pioneers such as wine journalist Giorgio Melandri and oenologist Francesco Bordini, whose work in Modigliana has inspired a growing band of TERROIR-centric producers, stylistic differences based on subzones are beginning to become a reality.

W.S.

Masnaghetti, A., *Romagna Sangiovese* (2013).

www.consorziovinidiromagna.it

Romagna Trebbiano, DOC in EMILIA-ROMAGNA in central Italy for neutral dry whites made from TREBBIANO Romagnolo grapes. Permitted YIELDS of up to 14 tonnes/ha result in very ordinary wines. Wines of real interest can result if producers aim at quality, but most of its 14,170 ha/35,015 acres are tended by small grape-growers whose produce lands in the undiscerning vats of the huge CO-OPERATIVES here.

Romanée, Romanée-Conti, Romanée-St-Vivant, great red GRANDS CRUS, for more details of which see VOSNE-ROMANÉE. See also DOMAINE DE LA ROMANÉE-CONTI.

Romania is eastern Europe's quantitatively most important wine producer, fifth in the EU by area under vine and sixth by wine volume. In 2021 there were 180,345 ha/445,642 acres of vineyard, of which 97,043 ha were VITIS VINIFERA, according to data from Romania's National Office for Vine and Wine Products. In 2020 the harvest declined to 3.8 million hl due to difficult climatic conditions but returned to a more typical 4.5 million hl/118,877,427 gal in 2021.

Wine-growing regions

History

The beginning of Romanian viticulture may date to the Cucuteni-Trypillian culture from 5200–3500 BCE, though it's not clear if these people made wine. The region of Dobrogea claims to be the birthplace of the Thracian god DIONYSUS, and the Thracians were well-known wine drinkers. This region, on the Black Sea, was settled in the 7th century BCE by the ancient GREEKS, who may have brought vines of their own, while vineyard tools dating back 2,500 years have been found in Dobrogea and close to Iași. As Rome advanced into the Balkan peninsula, the resident Geto-Dacian tribes came together in opposition under King Burebista (82–44 BCE). It seems that Dacia had a well-established wine culture, but, in an attempt to put an end to repeated invasions, Burebista ordered the destruction of all vineyards. However, after the Roman Emperor Trajan had conquered Dacia (102 CE), coins were minted depicting a woman being offered grapes by two children, proof that not all the vineyards were uprooted.

After the Romans left, the area was overrun by successive waves of migration, leaving few records of wine. It was not until the 11th century that written records of wine reappear. Transylvania appears to have undergone a renaissance of winemaking in the 12th century with Saxon settlers from the Mosel and the Rhein, and by the 16th century wine was a major source of income in the region. The principalities of Moldavia and Wallachia evolved as part of the Eastern Orthodox world, and in the 16th century they became vassal states paying tribute to the Ottoman Empire, allowing them to avoid mass settlement by Muslims. Catholic-led Transylvania came under the Habsburg crown towards the end of 17th century. By 1812, Moldavia lost Bessarabia, its eastern territory, to Russia. In 1861 Wallachia and Moldavia unified, and in 1877 the newly named Romania declared independence from the Ottomans. Transylvania and Banat did not join Romania until 1918.

There is little detailed evidence of wine in the 19th century as many records were destroyed by the communists, though the arrival

of PHYLLOXERA in 1880 seems to have brought formal attention to the wine sector, with NURSERIES and research institutes set up as early as 1893 to restore viticulture with GRAFTED VINES and French grape varieties. However, poor rural growers preferred HYBRIDS over more expensive grafted vines. After the Second World War, the communist government began to confiscate private land, with full-scale collectivization launched in 1949. All wine was processed through state-owned Vinalcool plants, and vineyard area was expanded with an emphasis on MECHANIZATION and heavy use of FERTILIZERS. Vine material was also selected for quantity and FROST resistance rather than for quality. In 1967 the notorious dictator Nicolae Ceaușescu came to power, imposing a brutal and repressive regime until his death by firing squad in the revolution of December 1989. By that time vineyards covered 275,000 ha/679,540 acres.

Privatization after independence was slow and complex. Laws were changed multiple times, and lack of a land register is still causing disputes today. The country ended up with highly fragmented land holdings and dilapidated wineries. Improvements in wine quality remained difficult until the 2000s when a new wave of external investment began. From 2002 onwards, substantial EU funds have had a major impact on replanting and modernizing equipment.

Romania today has a strong domestic market, though official per capita consumption has fallen from a high of 30 l/8 gal in 2008 to 21.2 l/5.6 gal in 2020, not counting black-market homemade wines. White wine accounts for approximately 52.3% of official production, while reds and rosé make up 47.7%, a reflection of tastes moving away from semi-sweet styles towards drier styles and increasing red wine consumption. Romania remains a net wine importer, with imports in 2020 reaching 446,863 hl/9.8 million gal; exports in 2020 totalled 206,658 hl.

Of the country's 404 registered wineries, five producers (Cramele Recaş, Jidvei, Cotnari, Crama Ceptura, and Zarea) dominated the domestic market in 2020, with a 42% share between them. Fragmented land holdings remain a challenge: there were 843,866

registered grape-growers in 2021, with only 460 owning more than 20 ha/49 acres.

Geography and climate

Romania lies between 44 and 48° N and is dominated by mountains, especially the arc of the Carpathian range—half of this range lies in Romania, including the eastern and southern Carpathians (sometimes called the Transylvanian Alps). The Wallachian Plain stretches south to the River Danube and Bulgaria, while the Pannonian Plain lies between the hills and Hungary to the west. Romania's wine regions are widely dispersed throughout the country. Most of the country has a CONTINENTAL CLIMATE except by the Black Sea, which helps to moderate winter temperatures in Dobrogea. Severe winter temperatures below −20 °C/−4 °F occur four to five times per decade, and summer temperatures are increasingly likely to range from hot to very hot (>35 °C/95 °F), causing DROUGHT stress. Most vineyards are not irrigated, and access to IRRIGATION water or boreholes is restricted by the state, so even vine-growers who want to irrigate often cannot do so in practice. Average July temperature is 23.5 °C/74 °F, and average annual rainfall is 400–600 mm/16–21 in.

Viticulture

Vine-TRAINING SYSTEMS used here traditionally were mainly GOBELET, though from the late 1950s collectivization and the drive for quantity saw a switch to neatly wired rows using concrete posts and mainly GUYOT and CORDON training. In older vineyards, VINE DENSITY is typically low. MECHANIZATION of vineyard operations has become common, including MECHANICAL HARVESTING in bigger vineyards, a change forced by difficulties in finding LABOUR. EU funds have subsidized substantial replanting with higher-quality CLONES, especially commercial clones of local grapes such as FETEASCĂ Neagră, with VSP training (see VERTICAL TRELLIS) and much closer spacing (4,000–5,000 vines/ha).

Owing to both increasing extreme weather events resulting from CLIMATE CHANGE and winter cold, most vineyards are planted on gentle slopes (5–25%) and may be in valleys with MESOCLIMATES which offer some protection. Other viticultural hazards include both POWDERY MILDEW and DOWNY MILDEW, as well as GREY ROT, particularly in fragmented vineyards where vines may be left untreated due to the cost of SPRAYING. Another potential problem for grape-growers is theft of fruit, young vine plants, and even metal posts and wires, requiring larger operations to employ full-time security guards and dogs.

Winemaking

Winemaking in Romania has widely been updated to modern international standards with STAINLESS STEEL equipment, TEMPERATURE CONTROL, pneumatic PRESSES, and so on. Some traditional CONCRETE tanks, ROTARY fermenters, and large old Carpathian oak casks still exist, but these are gradually being replaced even if still preferred by some older winemakers. Today's winemaking is generally technically correct, and problems of lack of winery HYGIENE, OXIDATION, and excess VOLATILE ACIDITY have become much less prevalent. The use of OAK has become more sophisticated with premium wines often aged in BARRIQUES and sometimes fermented in oak. French oak is widespread, but Hungarian, American, and some Romanian COOPERAGES are now making high-quality barrels.

Vine varieties

Unusually in this part of Europe, it is INDIGENOUS VARIETIES that dominate Romania's vineyard. The country also has a significant area of HYBRIDS, which should have been uprooted by 2014 under the terms of EU accession agreements, but many of Romania's 800,000 or so vine-growers still grow these hybrids on small plots so there is no political will to change this. Industry data for 2021 showed that the most planted white varieties by far are the two white Feteascăs, Fetească Regală (12,289 ha) and Fetească Albă (12,076 ha), both of which can produce fresh, gently aromatic, dry white wines. Fetească Regală (now thought to be a CROSS of Fetească Albă and Frâncușă) has more BODY, with perceptible PHENOLICS in its pulp, and can be successfully BARREL FERMENTED, while the more delicate Fetească Albă is more typically vinified without oak and may be used in blends.

The third most planted white-wine variety is Riesling Italico, or WELSCHRIESLING, grown on 7,064 ha/17,456 acres but usually marketed locally simply as 'Riesling'. Note that genuine RIESLING was grown on only 442 ha and is labelled Riesling de Rhin. Sauvignon (5,697 ha), Aligoté (5,205 ha), then Muscat Ottonel (5,156 ha) are next. Other white varieties that have shown significant increases by area include Chardonnay (2,009 ha), Pinot Gris (1,471 ha, usually marketed as Pinot Grigio), and TĂMÂIOASĂ Românească (1,747 ha, the 'frankincense grape', a local CLONE of MUSCAT BLANC À PETITS GRAINS).

Merlot is the most planted red wine variety with 11,152 ha/27,557 acres, followed by Cabernet Sauvignon (5,423 ha). Local grapes Roşioară (Bulgaria's PAMID) planted on 2,653 ha and Băbească Neagră (2,569 ha, with its *gris* (i.e. pink-skinned) variant on a further 297 ha) are both losing ground and typically make light, ordinary reds. Of much greater interest is Fetească Neagră (the 'black maiden grape'), planted on 3,187 ha. This area is increasing rapidly because of its potential as Romania's flagship red grape. Pinot Noir is viewed in certain export markets as Romania's signature grape variety, and the area planted has increased from an estimated 500 ha in 2005 to

2,040 ha in 2021. The variety was imported into Romania around 1900, particularly for sparkling wine production. The variety long known as Burgund Mare ('big Burgundian') is Kékfrankos, or BLAUFRÄNKISCH, grown on 690 ha.

Other specifically Romanian varieties planted to a significant extent include the light-berried 'fat' GRASĂ and crisp Frâncușă, both grapes of COTNARI. Busuioacă de Bohotin (678 ha/1,675 acres) is a pink-skinned grape traditionally used for aromatic sweet and DEMI-SEC wines but increasingly appearing in quality, dry rosé wines and sparkling wines. It is named after the Romanian word for basil, *busuioc,* for its grapey, floral, red-fruit aromas, and it probably originates around Bohotin in the Moldovan Hills. Some research suggests this is a colour MUTATION of Muscat Blanc à Petits Grains, though this remains unproven. The Galbenă vine of Odobeşti makes light, crisp whites—384 ha are officially registered, with a further 58 ha under its synonym of Zghihară de Huşi—and the white Şarba (307 ha) is also found in this area. Other Romanian varieties planted include Crâmpoșie/Crâmpoșie Selecționată, Mustoasă de Măderat, Iordană, and Plavaie grown in Odobeşti. There is also some interest in reviving old INDIGENOUS VARIETIES and relatively new local CROSSES such as Negru de Drăgășani and Novac, both SAPERAVI crosses. Other crosses enthusiastically developed by Romanian viticultural stations include Columna, a Pinot Gris x Grasă CROSS, and the red-wine grape Codană.

Wine laws

Romanian wine law is fully compliant with EU regulations.

DOC (Denumire de Origine Controlată) is the recognized traditional term for PDO wines (i.e. high-quality wines grown and produced within a delimited area). It is supplemented by further classifications according to the grapes' maturity:

DOC-CMD: wines harvested at full maturity bearing a designation of origin

DOC-CT: LATE HARVEST wines

DOC-CIB: late-harvest/BOTRYTIZED sweet wines.

There are currently 33 PDO wines (38 are registered with the EU, some covering multiple wine styles), though they are produced in only seven of the eight major regions.

PGI wines are described as Vin cu Indicație Geografică (IG). There are 12 PGIs (Colinele Dobrogei, Dealurile Crişanei, Dealurile Moldovei, Dealurile Munteniei, Dealurile Olteniei, Dealurile Sătmarului, Dealurile Transilvaniei, Dealurile Vrancei, Dealurile Zarandului, Terasele Dunării, Viile Caraşului, Viile Timişului). Each has detailed specifications governing permitted grape varieties, maximum yields, vineyard density, minimum alcohol levels, and permitted winemaking. There has also been a category for VARIETAL wines since 2017. Other protected traditional terms include 'Rezervă', for wine matured for at least six months in oak and six months in bottle, and 'Vin de Vinotecă', for wine matured at least one year in oak and four years in bottle.

Wine regions

Romania's wine regions are divided into eight distinct zones (see map): Podișul Transilvaniei (Transylvanian Plateau); Dealurile Crișanei ai Maramureșului (Hills of Crişana and Maramureș); Dealurile Moldovei (Moldovan Hills) on the eastern slopes of the Carpathians; Dealurile Oltenei si Muntenei (Muntenia and Oltenia), the warm, central region in the southern Carpathians; Dealurile Banatului (Banat) towards the borders with Hungary and Serbia; Colinenele Dobrogei (the low hills of Dobrogea) between the Danube and the Black Sea; and the flatter Terasele Dunarii (Danube Terraces) and Nisipurile din Sudul Tarii (Southern sands), the last being relatively unimportant as a region for good-quality wine.

Transylvania is the high central region producing predominantly white wines, though recently good reds and sweet ice wines have appeared. The most important and oldest Transylvanian delimited wine region is Târnave, with its subregions Jidvei, Blaj, and Mediaş. Other DOC zones include Alba Iulia, Alba, Aiud, and Lechința to the north with Sebeş-Apold in the south-west. These are some of Romania's coolest vineyards at ELEVATIONS up to 500 m/1,800 ft. The mainly white wines typically have appealing fresh acidity and good aromatic expression. Evidence of the medieval immigration of Saxon settlers from the MOSEL Valley is still common in the architecture and in the wine styles. In addition to the common Fetească Regală and Fetească Albă, other varieties grown are Muscat Ottonel, Traminer, Sauvignon Blanc, and recently some successful Pinot Noir, Zweigelt, and Merlot. Apold's Iordană vine makes high-acid, low-alcohol wine used mainly for sparkling wines.

Crişana and Maramureș is slightly warmer than Transylvania though further north. Spring can be mild on the slopes facing south and south-west on the foothills of the Zarand Mountains, so BUDBREAK is usually earlier than in the rest of Romania. Annual rainfall is high, about 650 mm/23 in, and averages 365 mm during the growing season. Soils are typically low in humus but high in IRON, often over VOLCANIC or LIMESTONE bedrock, while vineyards can reach 500

m/1,640 ft in elevation. The region has two DOCs: Miniş in Arad County, influenced by the lake; and Crişana with the sub-denominations of Diosig, Biharia, and Simleu Silvaniei. Permitted white-wine varieties include Fetească Albă and Fetească Regală, Welschriesling, Muscat Ottonel, Traminer, Furmint (Miniş only), Pinot Gris, Sauvignon Blanc, and a traditional local white variety, Mustoasăde Măderat, which makes light, crisp wine. The more MEDITERRANEAN CLIMATE of Miniş gives long, warm autumns, so red wine grapes can ripen well, including Cabernet Franc, Cadarcă (KADARKA), Merlot, Burgund Mare (BLAUFRÄNKISCH), and Pinot Noir. The region was once famous for a sweet red made by the ASZÚ method from Cadarcă, popular with the Habsburg court.

Moldovan Hills, in eastern Romania, is part of the historic principality known as Moldavia (the eastern part is now the republic of MOLDOVA) and is home to possibly the country's oldest, and certainly most famous, wine region, COTNARI, whose golden nectar was at one time almost as sought after as those of TOKAJ and CONSTANTIA. The Moldovan Hills region lies north-east of the Carpathians, beginning at latitude 47° N and stretching southwards for several hundred kilometres. It is Romania's largest viticultural region, accounting for 39% of vineyards and 41% of wine volume in 2020. Vineyards in its north are typically on the slopes of amphitheatres facing south and south-west that protect the vines from the harsh north winds. Elevations vary from 200 to 500 m/656–1,640 ft. The region enjoys more than 2,000 hours of sunshine in an average year, and annual rainfall is only about 500 mm/20 in. Soil types include RENDZINA, chernozem (black, humus-rich soils overlying carbonate bedrock), and podzols (leached, well-drained, acidic soils usually low in fertility). GRASĂ is the variety responsible for most of the best sweet wines, supplemented by TĂMÂIOASĂ, together with Fetească Albă and Frâncușă, to produce dry and medium-dry lesser wines around Cotnari. Recently a few reds, especially from Fetească Neagră, and rosé from Busuioacă de Bohotin have appeared. DOC regions include Bohotin, Coteşti, Cotnari, Dealu Bujorului, Huşi, Iaşi, Iana, Nicoreşti, Odobeşti, and Panciu. Further south, Fetească Albă is

grown, mainly for light, everyday wines, together with Fetească Regală, Welschriesling, Aligoté, and Sauvignon Blanc. A range of red varieties are grown, including Merlot, Cabernet Sauvignon, Fetească Neagră, and BĂBEASCĂ NEAGRĂ. At Bohotin (and increasingly elsewhere in Romania), scented, pink-coloured wine is made from Busuioacă de Bohotin. Local Galbena de Odobeşti and its synonym Zghihară de Huşi both make pleasant if not complex young-drinking whites. Odobeşti is one of the largest and oldest viticultural centres in Romania and may well date from the Roman era. Şarba, a CROSS between Welschriesling and Muscat of Hamburg developed at the Odobeşti research station in 1972, has a grapey aroma and good acidity and is proving popular. The local grape Plavaie is also grown here for light, high-acid, low-alcohol, everyday wines. In Panciu, to the immediate north of Odobeşti, winters are colder, winds stronger, and HAIL more frequent, but some good still white and sparkling wines are made. Coteşti just south of Odobeşti, on the other hand, is distinctly warmer and can produce some deep-coloured reds; it is famous as the location of the 15th-century cellars of prince Ştefan cel Mare. Nicoreşti, east of Panciu, is another red-wine region, particularly well known for its Băbească. This region has seen some new investments but is generally focused on supplying local market demands.

The large area of Oltenia and Muntenia in the Carpathian foothills north of the capital Bucharest grows 25% of Romania's vines but produced 38% of the country's wine in 2020. DOC areas include Dealu Mare, Drăgăşani, Pietroasa, Ştefăneşti, Sămbureşti, Banu Mărăcine, Mehedinți, Cernăteşti-Podgoria, and Segarcea. Most famous is the historic and extensive Dealu Mare, meaning 'big hill', best known for its reds and the source of some of Romania's most exciting wines, especially those of the pioneering Davino and SERVE. Vineyards on iron-rich red soils are at ELEVATIONS of 130–550 m/430–1,800 ft, protected from WINTER FREEZE by high hills and forests. Annual rainfall averages around 640 mm/25 in. This is principally a red-wine district with Cabernet Sauvignon, Merlot, some Pinot Noir, recent plantings of Syrah, and considerable focus on Fetească

Neagră, both as a VARIETAL wine and in blends. An outcrop of CALCAREOUS soil in the Pietroasa district is known for its lusciously sweet, golden, LATE HARVEST wines, especially Tămâioasă from Pietroasele, which may be BOTRYTIZED. Archaeological finds in Ştefăneşti, an area noted for robust reds, suggest a long history of wine production, possibly dating back to Alexander the Great. Towards the south-west and the River Olt basin lie the historic vineyards of Drăgășani, which are said to date to the time of Dacian King Burebista, 82–44 BCE. The region stretches over 60 km/36 miles ranging from 200 to 500 m in elevation. Average rainfall is 640 mm, and hail is a frequent hazard. This is a dynamic region of small estates with its own growers' association. Whites show crisp acidity and good aromas, especially Fetească Regală, Tămâioasă (sweet and dry styles), Sauvignon Blanc, and the local Crâmpoşie Selecţionată. Local red specialities such as Negru de Drăgășani and Novac show promise, and there are some good Merlot and Cabernet Sauvignon too. Sâmbureşti is a much smaller wine region specializing in Cabernet Sauvignon. South-west of the university town of Craiova lies the DOC of Banu Mărăcine, with a small vineyard area based around the viticultural research station. About 20 km/12 miles south of Craiova is the DOC Segarcea, the site of the renovated former royal winery, with much new planting. Mehedinți DOC is the country's warmest zone, with soils of CLAY and LIMESTONE and IRON-rich outcrops. It has five subregions: Severin, Corcova, Golul Drincei, Vânju-Mare, and Orevița. This is the sunniest and warmest of the southern Carpathian wine regions and concentrates on red-wine production. In the far south-west, an outcrop of TERRA ROSSA around Oprișor produces some fine reds from Cabernet Sauvignon, Merlot, and Syrah. The climate here is temperate continental with a Mediterranean influence, with rainfall up to 800 mm/31 in per year. Many vineyards here were grubbed up in the 1980s and have only recently been replanted.

Banat grows just 2% of Romania's vines but produces 5% of the country's wine thanks to the presence of Cramele Recaş—in 2020 both the biggest exporter and number one in the domestic market.

There are also several smaller boutique estates in the region. Historically it was part of the Transylvanian province of the Austro-Hungarian Empire, and this influence is still clear in the varieties planted: Cadarcă (KADARKA), Italian Riesling (WELSCHRIESLING), Fetească Regală, Burgund (BLAUFRÄNKISCH), and Muscat Ottonel. Today, substantial new vineyards have been planted with selected clones of INTERNATIONAL VARIETIES as well as Fetească Neagră. Banat has a moderate, MEDITERRANEAN-influenced climate, cooler than much of the rest of Romania but warmer than most of Hungary. There are two DOC zones: Banat (with subregions of Moldova Nouă, Dealurile Tirolului, and Silagiu) and Recaş.

The Dobrogea region on the Black Sea coast comprised 8% of vineyards in 2020 but just 3% of wine. It is a warm region of low hills, as many as 300 days of sunshine annually and only 150–200 mm/6–8 in rainfall between April and October. There are four DOCs: Murfatlar (with subregions Medgidia and Cernavodă), Babadag, Adamclisi, and Sarica Niculiţel (with one subregion, Tulcea). Murfatlar was once best known for whites, including late-harvest wines, but today's emphasis is on richly flavoured reds, especially Merlot, Cabernet Sauvignon, Fetească Neagră, Syrah, and Băbească Neagră. The dry climate allows a few producers to farm ORGANICALLY.

The Danube Terraces region stretches along the lower banks of the Danube. Vineyards here are largely devoted to TABLE GRAPES. There are two DOCs: Oltina, on an outcrop of CLAY and LOESS at 200 m/656 ft and known to have been colonized by Romans; and Însurăţei, a newer DOC on red soils close to the Danube.

The Southern Sands region is a warm area with deep SANDY soils and 18,383 ha/45,425 acres of vines but produces only 2% of Romanian wine, none of notable quality.

Roman Muscat, synonym for MUSCAT OF ALEXANDRIA.

Rome, classical. '*Vita vinum est*' ('Wine is life'), exclaimed Trimalchio to his dinner guests (Petronius, *Satyricon* 34).

Wine was deeply embedded in Roman culture, as much a staple for the poor as for the wealthy. So the evidence is particularly rich, detailed, and varied—as rich as for any aspect of ancient society. There are the casual, but often illuminating, references in the poets, in letters, and even in the graffiti scratched on inn walls. All the AGRICULTURAL TREATISES, one of the largest bodies of technical literature to survive from antiquity, devote great space to detailed discussion of viticulture (see in particular CATO, *De agri cultura passim*, from the 2nd century BCE; VARRO, *De re rustica*, Book 1, from the end of the 1st century BCE; COLUMELLA, *De re rustica*, particularly Books 3–5, 12, and the separate work 'On trees' from the mid 1st century CE; and his contemporary PLINY, *Natural History*, Books 14, 17, and 23, as well as PALLADIUS from late antiquity). What these reveal is a lively debate about CLIMATE, VINE VARIETIES, PLANTING and PRUNING techniques, technological developments, and the economics of viticulture. A more surprising source of information is Roman law;

the sale of wine, particularly wholesale, raised considerable problems for the law of sale, when there was the question of what guarantee of quality the buyer might reasonably expect. The legal texts tell us much about the details of how wine was marketed. Equally interesting material comes from medical writers. Wine played an important role in medical treatment, and much of the information about the colour, quality, and effects of particular wines owes far less to the tasting books of Roman CONNOISSEURS than it does to the notes of the DOCTORS (see MEDICINE). Finally there is ARCHAEOLOGY, of which the most spectacular recent achievement, inspired by the underwater excavation of Roman wrecks, has been the identification of the types of AMPHORAE used to carry the wine and the recognition of the scale and pattern of the wine trade.

Both Pliny (*Natural History* 14. 21–39) and Columella (*De re rustica* 3. 2. 7–28) offer surveys of the main ANCIENT VINE VARIETIES. Columella's classification is the most revealing. His first class consists of the varieties used for the great Italian wines, most notably the types of Aminean. His second class is high-yielding vines, which nevertheless can produce wines which can be aged successfully. The final group is those prolific vine types used largely to produce *vin ordinaire*. This reveals that wine producers were aware of the great diversity in the markets for their wines and chose their vines accordingly.

'Classic wines can only be produced from vines grown on trees', was Pliny's verdict (*Natural History* 17. 199). Although this was disputed by some agricultural writers, the most striking fact about Roman viticulture was that the great wines—CAECUBAN, FALERNIAN, and so on—nearly all came from vineyards in which the vines were trained up trees, usually elms or poplars (see ARBOREAL VITICULTURE). However, all the normal forms of VINE TRAINING were also known and described by agricultural writers, from the low, free-standing BUSH VINE to elaborate TRELLIS SYSTEMS. As in every age, the literature abounds with references to extraordinary YIELDS (for example, over 300 hl/ha (17 tons/acre), high but not unknown in modern terms);

but Columella (*De re rustica* 3. 3) considers the economics of a vineyard on the basis of yields ranging from 21 to 63 hl/ha, a range which may look familiar to modern vine-growers concerned with wine quality.

'Be the first to dig the ground…but the last to harvest the grapes' was the advice in VIRGIL's poem of the countryside (*Georgics* 2. 410). This is just one of many clues which suggest that the Romans sought to make their white wines—and nearly all the great wines were white—sweet.

The treading of the grapes was usually, but not invariably, followed by their PRESSING. The MUST obtained from the treading was sometimes kept separate, but more frequently it was added to that from the pressing. The grape pulp could be subject to a second pressing—or even, after being soaked for a day, a third—to produce a thin drink for slaves (see PIQUETTE). From the press room the must was run off to ferment in large DOLIA, which were frequently sunk in the ground (like Georgia's QVEVRI). The wine could be racked off into amphorae at any stage from 30 days after being made to various points through the winter and into the next spring. Many white wines of note were probably left SUR LIE, with the possible consequent enhancement of flavour and COMPLEXITY. To those in the post-PASTEUR age of stainless-steel vats, Roman winemaking must seem somewhat slapdash and uncertain. However, the accumulated wisdom and experience conveyed in all the agricultural treatises demonstrate a commitment to care (for example, in stressing the need for cleanliness at all stages) and sophisticated observation (as in the siting of the press room and *dolia* yard with regard to the ambient TEMPERATURE during fermentation).

'We consider the best wine is one that can be aged without any preservative; nothing must be mixed with it which might obscure its natural taste. For the most excellent wine is one which has given pleasure by its own natural qualities.' Columella's statement (*De re rustica* 12. 19) reflected current opinion. However, it is made at the beginning of a long discussion of ADDITIVES for wine. Some of these are less objectionable to modern opinion than others. It was a normal

practice to add boiled must to wine either during fermentation or soon after to act both as a sweetener and, so it was thought, a preservative. LEAD-lined vessels were regularly used for the boiling of must because lead acetate is a sweetener. Such a practice is toxic, although ideas that it contributed to the fall of the Roman Empire are highly exaggerated. The addition of quantities of chalk or marble dust may be seen as attempts to modify the acidity of the wine (see DEACIDIFICATION). More surprising is the general advocacy of the addition of seawater or salt during fermentation. This was a distinctive Greek practice, taken over by the Romans. It was supposed both to 'enliven a wine's smoothness' (Pliny, *Natural History* 14. 120) (presumably increasing acidity) and to prevent a mouldy taste (Columella, *De re rustica* 12. 23. 2). RESINATED WINE was common. So were FLAVOURED WINES with all kinds of herbal and plant additives, of which the primary effect was to disguise the inferior nature of the basic wine.

For Roman connoisseurs, the key to a good wine was AGEING. In Roman law the distinction between 'new' wine and 'old' was that the old had been aged for at least one year. Of course, vast quantities of wine were drunk within the first year. However, a higher price could be expected if the producer could hold back even for as short a period as the summer following the vintage. As for the great wines, both white and red, their key characteristic was their capacity to be aged for considerable periods. Falernian was considered drinkable after a decade but at its best between 15 and 20 years; SURRENTINE, another white wine, came into its own after 25 years. It may be that being sealed in an amphora which had an impermeable coating of resin meant that the ageing process was slowed. On the other hand, CATO recommends that air space should be left when amphorae are filled, which must have led to OXIDATION on a level which would be unacceptable now. The frequent mention of the darkening of the colour of the great whites suggests that MADERIZATION was normal and, indeed, desired. The final curiosity of Roman wines was the widespread practice of storing them in lofts over hearths, where they were exposed to smoke and heat. This was seen as a means of

accelerating ageing, for which the nearest modern parallel may be the process of heating which MADEIRA is subjected to.

The heyday for Roman viticulture was the 1st century BCE and the first two centuries CE. This was the time for the recognition and development of great wines in central ITALY which could compete successfully with those from the Greek world (see GREECE). It was a period of considerable experimentation and innovation, not least in western areas such as GAUL and SPAIN, which saw the creation of their own vineyards, often by Italian settlers after the areas had become part of Rome's empire. There was clearly a massive increase in the market for wine throughout the empire. Rome itself, with a fluctuating population of a million or more, sucked in imports from Italy and the provinces, while the Romanization of the provinces included the stimulation of new markets for a commodity which was at the heart of Roman culture. The market for wine was a very diverse one, ranging from the elite's desire for great wine to the mass market for wines (for which the thousands of amphorae recovered from sites throughout the empire and beyond are ample testimony).

Romorantin, a white, eastern Loire grape variety that is fast fading from the French *vignoble*. Cour CHEVERNY is an appellation especially created in 1993 for the rather tart Romorantin grown just

west of Blois. DNA PROFILING has shown that this is yet another progeny of PINOT and GOUAIS BLANC.

ronco, north-east Italian term derived from the verb *roncare* (meaning 'to clear land', particularly land which is either wooded or overgrown with underbrush); the word has been used for over a century in a wide swathe of northern Italy to indicate a HILLSIDE VINEYARD. The first appearance on a wine label dates from the early 1970s, when it was used by Mario Pasolini in the province of Brescia in LOMBARDY for his Ronco di Mompiano, a legendary VINO DA TAVOLA from MARZEMINO and MERLOT grapes grown within the city walls of Brescia. More or less contemporary examples can also be found from the OLTREPÒ PAVESE, frequently with the diminutive form ronchetto. The widest current use is in FRIULI, often in plural as ronchi, and where the dialect form is *ronc*. Examples can also be found in ALTO ADIGE and in ROMAGNA.

See also COLLI.

Rondinella, Italian red grape variety grown in the VENETO, especially for Valpolicella. The vine yields profusely and is therefore extremely popular with growers, but its produce is rarely sufficiently flavoursome to please consumers. Rondinella is not as widely planted nor as respected as its parent CORVINA VERONESE, with which it is usually blended.

Rondo, once known as GM 6494–5, red-fleshed DISEASE-RESISTANT VARIETY grown to a limited extent in such northern European countries as DENMARK, ENGLAND, NETHERLANDS, SWEDEN, BELGIUM, and POLAND, where it is treasured for its combination of early ripening and depth of colour. It was bred using some VITIS AMURENSIS genes to withstand cold winters, has small berries, and makes light, fruity wines. It can occasionally suffer from POWDERY MILDEW, however. Despite its

parentage, it produces remarkably VITIS VINIFERA-like wine, so it has been registered as a *vinifera* variety. Consequently it may used in the production of PDO wines.

root, one of the three major organs of higher plants, the others being leaves and fruits/seeds. Roots' main functions are anchorage of the plant, storage of reserves of CARBOHYDRATES, absorption of WATER and MINERALS from the soil, and synthesis of specific compounds, such as reduced NITROGEN compounds and such hormones as CYTOKININS and ABSCISIC ACID.

The roots of a commercial vineyard originate from the roots that develop at the base of CUTTINGS, which are more divided than the tap-root style of a SEEDLING's root system. The position and number of the main framework roots, the 'spreaders' which extend out and down, are determined during the first three years. Although most vine roots occur in the top metre of soil (less if unfavourable soil horizons impede their penetration), there are many examples where roots have penetrated to 6 m/20 ft or more; often these examples are found in dry conditions such as the DOURO Valley. The root framework supports a large number of fibrous roots which, by their continuing growth, explore the soil for MINERALS and water. Root density is highest in friable soil with continuing supplies of minerals, water, and oxygen. MYCORRHIZAL fungi play an important role in increasing the surface area of the roots.

Vine roots are much less dense than those of many other crop plants. Different species of VITIS have different root distribution and habits, a difference that is deliberately used in the breeding of ROOTSTOCKS. B.G.C.

root growth, that part of the VINE GROWTH CYCLE which takes place below ground. In most fruit trees, the spring flush of root growth occurs at the same time as BUDBREAK, but for the vine it is delayed. There are two peaks of root growth during the growing season. The first takes place at FLOWERING of the shoots in early summer, and the second coincides with the normal HARVEST period in autumn. There is an important correlation between the size, health, and activity of the vine's root system and the growth of shoots and leaves above ground (see VIGOUR). This is because roots act as storage sites for the vine's crucial reserves of CARBOHYDRATES and NITROGEN compounds, and also as the site for the production of HORMONES such as CYTOKININS, GIBBERELLINS, and ABSCISIC ACID. Vines with restricted or unhealthy roots have low VIGOUR, and this is the basis of the principles of BALANCED PRUNING. Root growth also varies according to VINE AGE.

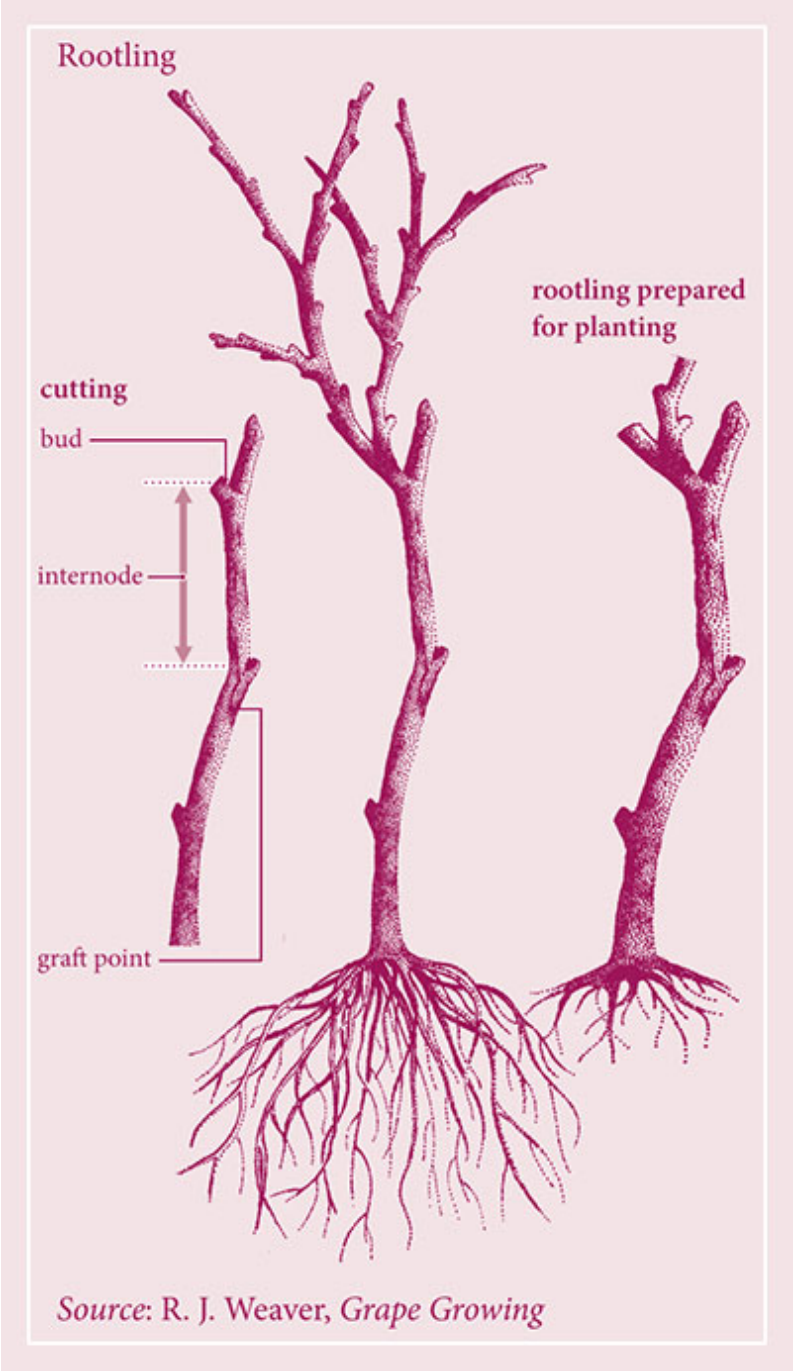
R.E.W. & R.E.S.

root-knot nematode. See NEMATODES.

root-lesion nematode. See NEMATODES.

rootling, a one-year-old vine grown in a NURSERY, the common material used for planting a vineyard. Typically it is a GRAFTED rootling, with the fruiting variety, or SCION, grafted on to a ROOTSTOCK. Most species of the vine genus VITIS, especially VITIS VINIFERA varieties, form roots readily on their CUTTINGS, but some rootstocks such as *Vitis berlandieri* and *Vitis champini* form roots poorly.

B.G.C.



rootstock, the plant forming the ROOT system of a grapevine to which a fruiting variety, or SCION, is grafted. In most vineyards in the world, European wine-producing VITIS VINIFERA vines are grafted on rootstocks which are, with few exceptions, either varieties of one AMERICAN VINE SPECIES or more commonly HYBRIDS of several. See VITIS

for details of the different species of this genus. Rootstocks are normally used to overcome soil pests or diseases but may also be used for special soil conditions such as SALINITY.

The use of rootstocks for grapevines became common around 1880 in France in order to combat the devastating root aphid PHYLLOXERA, which attacked the roots of the European grapevine *Vitis vinifera*, and the control of phylloxera remains a major, but by no means the only, reason rootstocks are used.

There are parts of the world where the choice of rootstock is more debated than the choice of the fruiting variety, since the latter might well be regulated by law or tradition. Even in traditional European viticultural regions, the choice of rootstock tends to change with time, helped by long-term experiments and commercial experience. By contrast, in some parts of the NEW WORLD the use of rootstocks is relatively new, or prior use has been restricted to only a few locally available rootstock varieties.

The rootstock AXR1 (alternatively ARG1 or Ganzin 1) had been found so adaptable in California it was described by A. J. WINKLER as 'the nearest approach to an all-purpose rootstock'; it was widely adopted, despite Winkler's qualifying phrase that 'resistance to phylloxera is not high', a viewpoint emphasised by many visiting European viticulturists. In the 1980s, AXR1 succumbed to what was described as a new BIOTYPE of phylloxera, necessitating extensive replantings and causing economic hardship for many. California now uses a wide range of rootstocks.

Sullivan, V., 'New rootstocks stop vineyard pest for now', *California Agriculture* 50/5 (1996), 7–8.

Choice of rootstock

Although at one time it was a common complaint that PRE-PHYLLOXERA wines in Europe were better than those since the invasion (perhaps partly because early rootstocks were not always ideally matched with SOIL TYPES), more recent experiments have shown that little effect on wine quality can be attributed directly to rootstock. Certainly rootstocks can influence VIGOUR, and the high-vigour rootstocks such as Rupestris St George can produce canopies so dense and SHADED that they affect wine quality (see CANOPY MANAGEMENT). Other studies indicate that the high-vigour rootstocks Harmony, Dog Ridge, Freedom, and Ramsey can result in high levels of POTASSIUM and PH in the resultant wine, but again this is very likely an indirect effect mediated through vigour and excessive canopy shade.

Any vigorous rootstock which stimulates vegetative growth late in the season will have a detrimental effect on fruit RIPENING and therefore on wine quality (see VINE PHYSIOLOGY). The use of rootstocks has also led to an increase in vine CHLOROSIS in those regions where LIMESTONE soils are common. Similarly, some rootstocks can induce MAGNESIUM deficiency, which, when severe, can inhibit PHOTOSYNTHESIS and ripening.

One of the earliest and perhaps most significant negative effects of rootstock use has been the impact of GRAFTING on the spread of VIRUS DISEASES, hidden by the fact that rootstock vines often do not show virus symptoms. LEAFROLL VIRUS, for example, delays ripening and can substantially reduce wine quality. Young grafted vines are also commonly infected by TRUNK DISEASE fungi, typically in the rootstock, causing some plants to die early and/or grow irregularly and turning others into a source of infection. Vine improvement has concentrated on avoiding the inadvertent spread of graft-transmitted virus diseases by sourcing virus-free plant material from certified MOTHER VINES of fruiting varieties and rootstocks. However,

transmission of trunk-disease fungi in CUTTINGS from infected mother vines is still common.

Rootstocks can have a dramatic effect on YIELD. In the absence of a rootstock, a vine grown on its own roots may not grow at all and die because of root damage from phylloxera or NEMATODES. Grafting on to a rootstock with resistance to soil pests and which is also suitable to LIME conditions or DROUGHT can, on the other hand, increase yield dramatically.

Rootstock selection for any particular vineyard may be guided by known soil pests or diseases (especially nematodes and phylloxera); by suitability to the soil environment (especially lime content, fertility, drought incidence, and waterlogging); or by the effect on the performance of the scion variety that is desired, such as lower vigour or earlier ripening.

Rootstocks also differ in characteristics that are important to nurseries. These include the ability of mother vines to produce plenty of wood, the ease with which cuttings root, and also the ease with which they can be grafted.

Rootstock characteristics

Phylloxera resistance The three most resistant AMERICAN VINE SPECIES are *V. riparia*, *V. rupestris*, and *V. berlandieri*, and the most susceptible species is the European VITIS VINIFERA (see VITIS). Interspecific HYBRIDS containing genes from any of the first three species will therefore have satisfactory resistance, and those hybrids including *V. vinifera* will have suspect resistance. Rootstocks of *V. vinifera* × *V. rupestris* (including AXR1, and Couderc rootstocks 1202 and 93–5) and *V. vinifera* × *V. riparia* parentage should be avoided because they do not have sufficient phylloxera tolerance. Interestingly, *V. vinifera* × *V. berlandieri* rootstocks such as 41 B and 333 EM generally have sufficient resistance. A few examples of rootstocks with high phylloxera resistance are Riparia Gloire, 101–14 Mgt, SO 4, and 5 BB.

Nematode resistance Two principal types of NEMATODES are present in vineyard soils. VITIS species having the most resistance to root-knot nematodes are *V. champini*, *V. longii*, and *V. cinerea*. Those having most resistance to the dagger nematode include *V. candicans*, *V. longii*, and *V. rufotomentosa.* Vines of the MUSCADINIA section of the *Vitis* genus are resistant to both types of nematodes, which explains the interest in this group of vines for rootstock breeding. As for phylloxera, *V. vinifera* is very susceptible to nematodes, so any one rootstock will not have resistance to all nematode species, nor indeed to all nematode races. Rootstocks commonly used for nematode tolerance include Ramsey, Dog Ridge, Harmony, 1613 C, 1616 C, SO 4, and Schwarzmann.

Lime tolerance Both *V. vinifera* and *V. berlandieri* contribute tolerance to the soils high in LIMESTONE common in Burgundy and Champagne. Rootstocks acknowledged to have the highest lime tolerance are 41 B, 333 EM, and the more recently bred Fercal.

Drought tolerance *Berlandieri–rupestris* hybrids are best able to tolerate drought, and these include 110 R and 140 Ru, followed by 1103 P and 99 R. *V. riparia* species and hybrids have low drought tolerance.

Salt tolerance The chloride component of salty soils can be toxic (see SALINITY). The *V. berlandieri* species is considered tolerant, but Australian research has found the *V. champini* rootstock Ramsey to be quite tolerant. *V. vinifera* is also tolerant.

Vigour The species *V. champini*, *V. berlandieri*, and *V. rupestris* and their hybrids give the most vigour, and *V. riparia* the least. Among the most vigorous rootstocks are therefore Ramsey, Dog Ridge, Rupestris St George, 99 R, and 110 R, while Riparia Gloire and 101–14 are among the least vigorous. Vigorous vines tend to delay fruit maturity and can substantially reduce red wine colour.

Some internationally important rootstocks

AXR1, otherwise called ARG1 in France, Australia, and New Zealand, is a *V. vinifera* × *V. rupestris* hybrid made by Ganzin in 1879. The rootstock was initially popular in France, but at the turn of the century it was found, there and in South Africa, to have insufficient phylloxera resistance. It is popular with growers because the vines are vigorous and yield well, and it is favoured by nurseries because it is easy to graft. It was found satisfactory in California until the 1980s, when it succumbed to phylloxera.

Dog Ridge is a seedling from the species *V. champini* which is suggested for use on light-textured soils with high nematode contents. It is only moderately tolerant of phylloxera. This rootstock is extremely vigorous, so it should not be used in fertile soils, and vines need to be pruned lightly to achieve BALANCE. The rootstock is not suggested for high-quality vineyards.

Fercal was bred at INRA Bordeaux in 1959 and developed especially for high-lime soils. It is a result of crossing Berlandieri-Colombard 2 (itself a *V. berlandieri* × Ugni Blanc hybrid) with 31 Richter. It is resistant to phylloxera and grafts readily. Fercal is of moderate vigour and is more tolerant of chlorosis and drought than 41 B.

Harmony is a hybrid of open-pollinated seedlings selected from *V. champini* and 1613 C. It was selected at Fresno, California, in 1966, and is quite tolerant of root-knot and dagger nematodes. Phylloxera tolerance is, however, low, and vigour moderate to high.

Riparia Gloire de Montpellier is one of the oldest rootstocks used against phylloxera in France, bred in 1880. Of the several *V. riparia* crosses brought in at the time of the phylloxera crisis, this proved the best. It confers excellent phylloxera resistance and is of low vigour, providing for lower yields of improved-quality fruit and early ripening. It is widely used throughout Europe for the production of good-quality wine.

Rupestris St George is sometimes called Rupestris du Lot or Rupestris-monticola. Bred in 1879, it was another early introduction to France to fight phylloxera, and it is said to be a selection of *V. rupestris* Scheele. This is an extremely vigorous variety with a long

growing season. It has excellent resistance to phylloxera, but vines grafted to it can easily overcrop or set poor crops because of extreme vigour. Because of high vigour, it is not used for high-quality vineyards.

Schwarzmann is a *V. riparia* × *V. rupestris* hybrid with high tolerance of phylloxera and nematodes but only moderate vigour. It is suited to deep, moist soils and is not as widely used as it might be.

SO 4, a *V. berlandieri* × *V. riparia* hybrid, is correctly known as Selection Oppenheim de Teleki No. 4, from the viticulture school at Oppenheim in Germany. This popular rootstock, used widely in France and Germany, shows excellent phylloxera resistance; it tends to favour FRUIT SET and slightly advanced maturity. Vigour is moderate, as is tolerance to nematodes. SO 4 is not, however, suited to dry conditions, and it is prone to MAGNESIUM deficiency.

5 BB Kober, sometimes called 5 BB Teleki, is a *V. berlandieri* × *V. riparia* hybrid. The seedling was raised by the Hungarian Sigmund Teleki from seeds produced by a French nurseryman. In 1904 some of the most interesting plants were sent to the Austrian Franz Kober, who selected 5 BB. This is quite a vigorous rootstock which is suited to more humid, clay soils. In many situations vigour is excessive. The rootstock 5 BB is widely used in Europe, especially in Germany and Switzerland.

5 C Teleki is a *V. berlandieri* × *V. riparia* hybrid selected in 1896 by Alexandre Teleki and Heinrich Birk. The rootstock is similar to SO 4 in aptitude and is mostly used in Germany.

41 B is an old rootstock obtained by Alexis Millardet and Charles de Grasset in 1882 at Bordeaux and is a hybrid between Chasselas and *V. berlandieri*. This rootstock has the advantage of being highly tolerant of lime, and so it is widely used in Cognac and Champagne. Its tolerance of phylloxera is sufficient but not absolute. This rootstock is moderately drought-tolerant.

99 Richter is a *V. berlandieri* × *V. rupestris* hybrid created by Franz Richter in 1902. This vigorous rootstock should not be used in cool regions because it can delay ripening. Phylloxera resistance is high and nematode resistance moderate.

101–14 Millardet et de Grasset is a lower-vigour and early-maturing rootstock used in some of the higher-quality vineyards in France. The vine is a *V. riparia* × *V. rupestris* hybrid made by Alexis Millardet and Charles de Grasset. It has high resistance to phylloxera but moderate nematode tolerance. The vine can tolerate only low lime content and has a shallow root system.

110 R, or 110 Richter, is a relatively old *V. berlandieri* × *V. rupestris* hybrid made by Franz Richter in 1902. This rootstock is noted for its high vigour and thus tends to delay maturity, especially if planted in fertile soils. 110 R has high phylloxera tolerance but low nematode tolerance. It is moderately lime-tolerant and quite drought-tolerant, and so it is widely used in MEDITERRANEAN CLIMATES. Initially it was not used extensively because of poor rooting in the nursery.

140 Ruggeri or 140 Ru is a hybrid produced in 1894 in Sicily by Antonino Ruggeri using *V. berlandieri* and *V. rupestris*. This vigorous rootstock is well suited to dry soils high in lime and to Mediterranean climates. This rootstock should not be planted on fertile, moist soils because of possible excess vigour.

161–49 Couderc is a *V. riparia* × *V. berlandieri* hybrid obtained in 1888 by Georges Couderc. This rootstock has high resistance to phylloxera but is susceptible to nematodes.

333 EM (École de Montpellier) is one of the few rootstocks used (with Fercal and 41 B) which has a *V. vinifera* parent. It was hybridized in 1883 by Gustave Foëx of MONTPELLIER by crossing Cabernet Sauvignon with *V. berlandieri*. Despite initial fears to the contrary, 333 EM has sufficient phylloxera tolerance. This rootstock is slightly more lime-tolerant than 41 B and is also drought-tolerant.

420 A Millardet et de Grasset is one of the oldest rootstocks, obtained in 1887 by Alexis Millardet and his assistant Charles de Grasset. It is a *V. berlandieri* × *V. riparia* hybrid and is highly regarded for good-quality vineyards, being a lower-vigour rootstock which hastens maturity. It is regarded as 'the *V. riparia* for chalky soils'. Phylloxera tolerance is high, but nematode tolerance is low to moderate.

1103 Paulsen was bred in 1896 by Federico Paulsen, the director of an American vine nursery in Sicily, by crossing *V. berlandieri* with *V. rupestris*. It is regarded as a drought-tolerant rootstock with high phylloxera tolerance and moderate nematode resistance. Lime tolerance is intermediate, and vigour moderate to high. It is welcomed by nurseries as being easy to graft and root.

1613 Couderc is a complex hybrid between Solonis (*V. riparia* × *V. rupestris* × *V. candicans*) and Othello (*V. labrusca* × *V. riparia* × *V. vinifera*) bred by Georges Couderc in 1881. Phylloxera resistance is low to moderate, but it finds favour because of moderate to high nematode resistance. It is well suited to fertile, SANDY, LOAM soils and is used mainly in California.

1616 Couderc is a *V. longii* × *V. riparia* cross bred in 1882 to produce a low-vigour rootstock with high nematode and phylloxera tolerance. It is best suited to more humid soils, and it advances maturity.

3309 Couderc is a *V. riparia* × *V. rupestris* cross made in 1881. Georges Couderc planted 18 seeds in a row of the nursery where he had added lime; of the five which did not show chlorosis, 3309 C became the most successful. Phylloxera tolerance is high and lime tolerance medium, and it is better suited to humid than drought-prone soils. Rooting and grafting are easy, and the use of this rootstock is widespread. R.E.S.

Roquebrun. See ST-CHINIAN.

Roriz. See TINTA RORIZ.

rosado is Spanish and Portuguese for ROSÉ; *rosato* is Italian. See also CLARETE.

Rosalia, internationally obscure former Austrian GROSSLAGE situated between LEITHABERG and MITTELBURGENLAND, promoted to DAC in 2018, covering BLAUFRÄNKISCH and ZWEIGELT (including rosé) from a vine surface of just 241 ha/596 acres. D.S.

Rosazzo, subzone of the FRIULI COLLI ORIENTALI DOC in north-east Italy for varietal RIBOLLA Gialla and PIGNOLO wines as well as a DOCG (2011) for a white blend based on FRIULANO, Sauvignon Blanc, and Pinot Bianco.

Rosé de Loire, general appellation created in 1974 for ROSÉ WINE made from any blend of the main dark-skinned grapes of the LOIRE, including Cabernet Franc, Cabernet Sauvignon, PINEAU D'AUNIS, Pinot Noir, Gamay, and Grolleau, with the notable exclusion of Côt (MALBEC). The wine may be produced anywhere within the ANJOU, SAUMUR, and TOURAINE zones and ranges in style from crisp and neutral to flavourful and assertive. Unlike Rosé d'Anjou and Cabernet d'Anjou (see ANJOU), it is always dry. P.Le.

Rosé des Riceys, rare, still, pink wine made in the commune of Riceys in the Aube *département*, the southern end of the CHAMPAGNE region. This dark, rose-coloured wine is made by careful SAIGNÉE of Pinot Noir grapes, by only a handful of producers. It can be one of France's more serious rosés.

Rosenmuskateller, German name for aromatic, pink-berried Moscato Rosa del Trentino, a minor but distinct grape variety particular to ALTO ADIGE and TRENTINO, northern Italy, where it is responsible mainly for rose-perfumed sweet wines. It is also planted to a very limited extent in Austria and Germany.

Rosette, very limited sweetish white-wine AOC just north-west of Bergerac in South West France. It includes some of the PÉCHARMANT zone. Made from Sauvignon, Sémillon, and MUSCADELLE, the wines have a MOELLEUX character that is ideal for APERITIFS, *foie gras*, and mushroom dishes.

Rosette is also the name of an old FRENCH HYBRID, also known as Siebel 1000, which once produced pale red wines in New York State.

rosé winemaking, production of wines whose colour falls somewhere in the spectrum between red and white.

Historically, rosé wines have been made by a number of different processes, but today two methods are in general use: direct PRESSING or short MACERATION. The preferred technique is a short maceration of the juice with the skins (see SKIN CONTACT) of dark-coloured grapes just after CRUSHING, in the PRESS or in a tank, for a period long enough to extract the required amount of colour or ANTHOCYANINS. The juice is then separated from the skins by DRAINING or pressing, and FERMENTATION proceeds as in WHITE WINEMAKING. With the red-skinned GRENACHE grape, traditionally much used for rosés partly because of its relative lack of anthocyanins, a maceration of eight to 12 hours is usually sufficient. Highly pigmented grape varieties may need much less contact time, while very lightly coloured grapes may need a day or two of maceration. See also SAIGNÉE and STABULATION.

Some basic rosés are made by blending a small amount of finished red wine into a finished white wine. While a pinkish colour can be achieved by this process, the hue and flavour of such a wine are quite different from those of a wine made by short-term maceration.

CHAMPAGNE is one of the few CONTROLLED APPELLATIONS in which the blending method of rosé winemaking is sanctioned—and in practice rosé champagne is more often made by blending than by maceration.

Pink wines may also be made by using CHARCOAL treatments to remove the colour from red wines which for some reason are not saleable as reds.

A VIN GRIS or BLUSH wine is made as above but with no maceration. Both tend to be even paler than most rosés. For a wine made pink by CO-FERMENTING red and white grapes, see SCHILLERWEIN. A.D.W.

rosé wines, increasingly popular wines in any shade of pink, from hardly perceptible to pale red (see COLOUR). For some reason they are rarely known as pink wines, although the English word BLUSH has been adopted for particularly pale rosés. There was also a FASHION in California, from the late 1980s, when wine had to be white to be popular, to label pale pink wines made from dark-skinned grapes 'White', as in WHITE ZINFANDEL. Global production of rosé wines tends to fluctuate between approximately 23 and 26 million hl (608–87 million gallons), usually about 8–10% of still-wine production.

In France, which is responsible for 27% of global production, rosés are particularly common in warmer, southern regions where there is local demand for a dry wine refreshing enough to be drunk on a hot summer's day but which still bears some relation to the red wine traditionally revered by the French. PROVENCE is the region most famous for its rosé, although in the greater southern RHÔNE (especially TAVEL), the LANGUEDOC, and ROUSSILLON rosés are at least as common as white wines. Grenache and Cinsaut are two of the grapes commonly used for rosé in the south of France. The Loire Valley also produces a high proportion of rosé wine of extremely varied quality and sweetness levels, particularly around ANJOU, whether lowbrow Rosé d'Anjou or highbrow Cabernet d'Anjou. (See also ROSÉ DE LOIRE.) VIN GRIS and SAIGNÉE are French terms for particular types of rosé. See also ŒIL-DE-PERDRIX.

Spain also takes pink wines seriously—so seriously that it has at least two names for them, depending on the intensity of the colour. A *rosado* is light pink, while darker pink (light red) wines are labelled *clarete*. Portugal's best-known pink wines are exported, for example MATEUS. Pink wines are not especially popular in Italy, where the term used is usually *rosato*, although *chiaretto*, meaning 'claret', is occasionally used for darker rosés. Official German terms for pink wines include WEISSHERBST, ROTLING, and, in WÜRTTEMBERG, SCHILLERWEIN.

The New World was long rather bemused by the concept of rosé, although this changed fast in the early 21st century. Chile was innovative. Australia makes some swashbuckling deep pinks, and South Africa (where red and white wines may be blended to produce a rosé) has a growing market, with Blanc de Noir (*sic*) a legal category for those produced solely from red grapes.

Roseworthy , town north of Adelaide in the state of SOUTH AUSTRALIA, close to the Barossa Valley, known in the wine world for Australia's first agricultural college, established in 1883. It trained a high proportion of winemakers and viticulturists in Australia and New Zealand and contributed greatly to the technical standing of the Australian wine industry (see AUSTRALIAN INFLUENCE) until 1991 when it was relocated to the Waite campus of the University of Adelaide, where the AWRI and CSIRO were already sited. For more details, see ADELAIDE.

Roşioară. See PAMID.

Rossese, name given to at least seven distinct north-west Italian grape varieties, making both red and white wines in Italy, where there were only 5 ha/12 acres of 'Rossese Bianco' (see GRILLO) and 164 ha/405 acres of 'Rossese Nero'. Rossese di Dolceaqua is the best known. This esteemed red grape variety produces distinctively

perfumed VARIETAL wines in LIGURIA. The variety has a long history in the region, and it has its own DOC in western Liguria. DNA PROFILING has shown it to be the same as Provence's TIBOUREN.

Rossignola, optional, tart ingredient in VALPOLICELLA.

Rosso Conero, Italian red wine DOC based on MONTEPULCIANO grapes whose full potential is yet to be realized. See MARCHE.

Rosso di signifies a red wine from the Italian zone whose name it precedes, often a declassified version of a long-lived, more serious wine such as BRUNELLO DI MONTALCINO or VINO NOBILE DI MONTEPULCIANO.

Rosso Piceno, or Piceno, Italian red wine consisting of 35–85% MONTEPULCIANO and a maximum of 50% SANGIOVESE. See MARCHE.

rot, loose term for the decay, with microbial interference, of any part of the vine. Rot is most commonly used as a synonym for BOTRYTIS BUNCH ROT, which is the most important sort of rot for wine quality. Other fruit rots include BLACK ROT, SOUR ROT, and WHITE ROT; rots of other vine parts include ARMILLARIA ROOT ROT and TEXAS ROOT ROT.

rotary drum vacuum filter (or RDV filter), form of depth FILTRATION designed to cope with liquids such as LEES that contain a high concentration of solids or particles that would rapidly block other filters.

RDV filtration relies on the constant regeneration of the filter medium, which is achieved by shaving off a fine layer of the filter medium through which the liquid passes. The filter comprises a slowly rotating drum covered in a fine stainless-steel mesh semi-

immersed in a trough into which liquid is introduced. An internal vacuum pump draws liquid from the trough through the drum surface. Initially, a slurry of filter media in water is processed to pre-coat the outside of the drum mesh with a filter cake, several centimetres thick. The juice or wine is then sucked through this cake, filtering it in the process. The surface of the cake is slowly shaved by a knife, removing filter cake that has been badly fouled by winemaking solids and exposing fresher filter cake. When the entire cake has been removed in this way, the filter is cleaned and prepared for another batch of juice or wine.

DIATOMACEOUS EARTH (DE) was typically used as the filter medium, but perlite, a processed volcanic rock, is now more common—because it is cheaper and due to safety concerns associated with the inhalation of DE—but it does not resolve issues surrounding the disposal of the filter medium. RDV filters are gradually being replaced by other technologies such as polymeric or ceramic cross-flow filters (see FILTRATION) with wider channels that can handle higher solids than standard wine cross-flow filters, enclosed spinning ceramic disc filters, and decanter CENTRIFUGATION. This transition will take time because this equipment is generally quite expensive, and some of these technologies are still not quite as adept as RDV filters at processing thick lees and not as suitable at handling different types of winery lees. S.N.

Rotbrenner, vine FUNGAL DISEASE found in most of Europe which can cause severe crop losses. Caused by the fungus *Pseudopezicula tracheiphila*, the disease is encouraged by prolonged rainfall and attacks leaves and young bunches. It can be controlled by FUNGICIDES applied early in the growing season. R.E.S.

Roter Traminer, German name for SAVAGNIN ROSE, non-aromatic relative of GEWÜRZTRAMINER.

Roter Veltliner, pink-skinned grape variety formerly widespread in Austria (once planted in California) for the production of TABLE GRAPES and powerful white wine, in 2021 grown on 188 ha/465 acres of Lower Austria. In warm years, if YIELDS are restricted, it can make intensely aromatic, concentrated wines with high EXTRACT, especially in Wagram. DNA PROFILING in Austria revealed in 1998 that Roter Veltliner is a parent of ROTGIPFLER, NEUBURGER, and FRÜHROTER VELTLINER.

Rotgipfler, the marginally less noble of the two white wine grape varieties traditionally associated with the dramatically full-bodied, long-lived, spicy white wine of Austria's THERMENREGION. (The other is ZIERFANDLER.) Plantings have remained fairly steady, at 112 ha/277 acres in 2022. It ripens late, but earlier than Zierfandler, and the wines are particularly high in EXTRACT, ALCOHOL, and BOUQUET. DNA PROFILING in Austria showed in 1998 that Rotgipfler is a natural CROSS of SAVAGNIN and ROTER VELTLINER.

Rothschilds and wine. The Rothschilds first entered the world of wine in 1853 when Baron Nathaniel (1812–70), grandson of Mayer Amschel and a member of the English branch of the family, bought Brane Mouton and renamed it Ch MOUTON ROTHSCHILD. This was common practice among more important CHÂTEAU owners. It was a buyer's market in Bordeaux vineyards then devastated by oidium, or POWDERY MILDEW, and the Rothschild purchase was viewed more as a property transaction than as the acquisition of a distinguished vineyard. When the important 1855 CLASSIFICATION placed Ch Mouton Rothschild top of the second growths, however, the Rothschilds were particularly exercised by what they regarded as its unfairly low placing.

Nathaniel was succeeded by his son Baron James (1844–81) and then Baron Henri (1872–1947), who was more interested in literature

than wine, and James's widow was responsible for Mouton until the arrival of Henri's younger son Philippe (1902–88) in 1922.

Baron Philippe de Rothschild was to prove one of the most influential forces in the wine business of Bordeaux and beyond. Not only did he acquire two neighbouring PAUILLAC fifth growth châteaux—Mouton d'Armailhacq (named at various stages Mouton-Baron-Philippe, Mouton-Baronne-Philippe, and, since the late 1980s, d'Armailhac) in 1933 and Clerc Milon in 1970—but he also established the importance of château BOTTLING, established MOUTON CADET as one of the world's most successful wine BRANDS and an important NÉGOCIANT business in the MÉDOC, astutely developed the concept (and value) of ARTISTS' LABELS, established the finest collection of wine-related works of art in the world, and in 1979 initiated Opus One, the world's first high-profile JOINT VENTURE, with Robert MONDAVI of California. In 1996 a joint venture with Concha y Toro of CHILE was created to produce the ambitiously priced Cabernet blend Almaviva, and Baron Philippe de Rothschild SA now has a substantial winery in Maipo Valley producing, inter alia, Mapu wines from Maule. Baron Philippe was succeeded at Mouton by his daughter Philippine (1933–2014). Under her leadership, Domaine de Baronarques, a red LIMOUX AOC, was bought with her two sons in 1998. At the same time, Baron Philippe de Rothschild S.A. diversified into VARIETAL wines from the LANGUEDOC.

Just next door to Mouton, Ch LAFITE was bought by Baron James of the French family in 1868 in the face of local competition. He died a few months later but is said to have visited the property briefly in the spring of that year. His son Edmond (1845–1934) was to sow, and indeed provide, the seeds for the establishment of the ISRAELI wine industry by making a vast donation in 1882. James's great-grandson Élie (1917–2007) was the family member who eventually took charge of Lafite, subsequently Lafite-Rothschild, until 1974 when his nephew Eric (1940–) became the château's head, handing over to his daughter Saskia in 2018. In 1962 the fourth growth PAUILLAC Ch Duhart-Milon was acquired. In 1984 the leading SAUTERNES property

Ch Rieussec was also purchased along with the Ch Paradis Casseuil in Entre-Deux-Mers, with L'Évangile in POMEROL being added in 1990. Joint ventures were established with Viña Los Vascos (Chile, 1988), Domaine d'Aussières (Languedoc, 1999), Bodegas CARO (Argentina, 1999), and Long Dai, in the Shandong region of China (2008), whose first vintage was 2017.

Since 2021, all of the estates in the Lafite stable, called Domaines Barons de Rothschild or DBR, have started the official path towards ORGANIC certification.

In 1973 Baron Edmond (1926–97), one of the family partners in Lafite but engaged in many other affairs, bought the semi-derelict Ch Clarke of LISTRAC, in 1977–8 building a very large new *cuvier* and CHAI. In 1979 he added Ch Malmaison in the adjoining commune of MOULIS, which was also treated to major renovation, as well as acquiring two more non-classified châteaux in the Médoc. Since 1998, this branch of the Rothschild family have had a joint venture with Anton Rupert of South Africa, Rupert & Rothschild. In 2002 Baron Edmond's son Baron Benjamin created a joint venture with Laurent Dassault in Mendoza, Argentina. In 2003 he bought Ch des Laurets, straddling Puisseguin- and Montagne-St-Émilion. In 2013 two new ventures were developed: one in Marlborough, New Zealand; and a Rioja joint venture, Macán, with VEGA SICILIA. A Central Otago winery, Akarua, was added in 2021.

In 1994 the English financier Lord (Jacob) Rothschild (1936–) opened a wine museum and cellar for the display and sale of Rothschild wines at Waddesdon Manor just north of London.

E.P.-R. & J.R.

Littlewood, J., *Milady Vine: The Autobiography of Philippe de Rothschild* (1984).

Rotling, category of German wines made from a mix of red and white grapes or MUST, comprising SCHILLERWEIN from Württemberg, BADEN's Badisch Rotgold, and SACHSEN's Schielerwein.

rotofermenter, or rotary fermenter, a horizontal FERMENTATION VESSEL arranged so that the contents can be mixed mechanically, either by rotating the vessel or by rotating an inner shaft fitted with vanes in a stationary vessel. Designed to eliminate the need for PUNCHING DOWN or PUMPING OVER, this equipment speeds the MACERATION phase of RED WINEMAKING. Some European wine producers, for example in Barolo, have invested in them, as have a number of NEW WORLD winemakers. Like most mechanical systems that promote skin–juice contact, they are expensive and require extensive and robust framing structures to mount and hold the horizontal tank. Rotofermenters are usually controlled by computers, with cycles of rotation chosen by the winemaker. P.J.W.

rotundone is a key aroma compound responsible for the distinctive 'spicy', 'peppery' aroma in some red wines, particularly SYRAH/Shiraz from cooler climates. It has also been found in Grüner Veltliner and many other varieties. In red wines it has a very low aroma detection threshold of 16 ng/l, but as many as one in five people cannot smell rotundone, even at very high concentrations. Rotundone is an oxygenated bicyclic sesquiterpenoid compound that was originally discovered in the tubers of *Cyperus rotundus*, a species of sedge. It is also present in black and white peppercorns and a number of herbs and fruits. When rotundone was added at sub-threshold levels to model beverages, it had significant enhancing effects on the overall fruity flavours. In wine, rotundone originates mainly from the GRAPE skins of some varieties and is extracted during alcoholic FERMENTATION. The concentrations of rotundone in Shiraz grapes have been shown to vary significantly between vineyards, between vintages for the same vineyard, and between grapevines within a vineyard, and its presence appears to be associated with variations in soil properties, TOPOGRAPHY, ambient TEMPERATURE, and vine water status (see SOIL WATER). Rouchalin, sometimes Rouchelin, occasional name for CHENIN BLANC in south-west France.

Rouchet, Italian red grape variety. See RUCHÈ.

Rouge du Pays, rare Swiss VALAIS red grape used to make deeply coloured red wines. Confusingly renamed Cornalin in 1972. The vine demands a fairly warm climate and restricted YIELDS to produce fresh wines with fine, silky tannins. DNA PROFILING at DAVIS showed that Rouge du Pays is the progeny of PETIT ROUGE and Mayolet, two varieties from the AOSTA Valley, and a parent of true CORNALIN, hence the confusion with the new name. J.V.

Rougeon, also known as Seibel 5898, FRENCH HYBRID red-wine variety grown in the north-eastern UNITED STATES. Very productive and winter-hardy, it produces deeply coloured wines with few hybrid aromas and sometimes has a meaty note, but it needs considerable attention because of its susceptibility to both DOWNY MILDEW and POWDERY MILDEW. D.F.

Roupeiro, the Alentejo name for the common Portuguese white grape variety SÍRIA.

Roussanne, sometimes erroneously spelt Rousanne, fashionable white Rhône grape which doubtless owes its name to the russet or *roux* colour of its skin. With MARSANNE, with which it is often blended, it is one of only two grape varieties allowed into the white versions of the northern Rhône's red-wine appellations HERMITAGE, CROZES-HERMITAGE, and ST-JOSEPH and into the exclusively white and often sparkling ST-PÉRAY. In each of these appellations, Marsanne is far more widely grown because the vine tends to be hardier and more productive. Roussanne's irregular YIELDS, tendency to POWDERY MILDEW and ROT, and poor wind resistance all but eradicated it from the northern Rhône until better CLONES were selected, and even today it is preferred there by a minority of producers such as Paul Jaboulet Aîné. Nevertheless, by 2019 French plantings had grown to 2,289 ha/5,656 acres, rather more than Marsanne with which a parent–offspring relationship has been revealed by DNA PROFILING.

Roussanne's chief attribute is its haunting aroma, something akin to a particularly refreshing herb tea, but it does need to reach full maturity in order to express itself elegantly and can OXIDIZE and age relatively easily. In the southern Rhône, Roussanne (but not Marsanne) is one of four grape varieties allowed into white CHÂTEAUNEUF-DU-PAPE, and Ch de Beaucastel here has demonstrated that their particular MASS SELECTION of Roussanne can respond well to OAK AGEING. The variety is also grown in Provence (although the more common pink-berried Roussanne du Var or Rousseli is a lesser, unrelated variety) and, increasingly, in the Languedoc and Roussillon, where Roussanne's tendency to ripen late is less problematic than in the northern Rhône and where results can be impressive. Although it is usually classified with Marsanne and Vermentino in appellation regulations, it can make a fine blending partner with the fuller-bodied Chardonnay, too. It can suffer in DROUGHT conditions, however.

The variety is also beguilingly fine and aromatic at Chignin in SAVOIE, where it is known as Bergeron, but should not be confused with ROUSSETTE. It is grown to a limited extent in Liguria and Tuscany, where it is a permitted ingredient in Italy's Montecarlo Bianco, and is grown for Clos d'Agon on the Catalan coast in Spain. Indeed, it has so much personality that many producers all around the wine world are experimenting with it on a small scale, both in aromatic, full-bodied white blends and as a VARIETAL. It is also found in Australia, even if Marsanne is much better established. Roussanne is decidedly more popular than Marsanne in California, where there were 330 acres/134 ha in 2020, particularly in the Central Coast.

Roussette, former name for the ALTESSE grape of SAVOIE now used for a number of wines made in eastern France.

Roussette de Savoie is the Savoie appellation for whites made exclusively from Altesse that age well in good vintages. With increasing plantings, this is fast becoming Savoie's most sought-after white-wine appellation. Four CRU names may be suffixed to the appellation: Frangy, Monterminod, Monthoux, and most notably Marestel, a steep south-facing slope in the village of JONGIEUX that yields exceptionally ripe fruit and is probably where the Altesse grape originated. Attractive Frangy wines tend to be drier and more herbal.

In the SEYSSEL appellation, the term 'Roussette de Seyssel' is no longer allowed, although growers have requested that it be reintroduced. In the nearby Ain *département*, Roussette du Bugey may be followed by the names of two crus, the rare Virieu-le-Grand and the more notable MONTAGNIEU, from steep vineyards on LIMESTONE scree overlooking the Rhône. W.L.

Roussillon has a distinct identity, both cultural and geographical, from that of the LANGUEDOC, the neighbouring region it was suffixed to until 2016. Its inhabitants are Catalan rather than French or Occitan, with a history rich in Spanish influence, particularly between the 13th and 17th centuries, when it was ruled first from Mallorca and then

from Aragón. It became part of France with the Treaty of the Pyrenees in 1659, and the Pyrenees link it rather than separate it from Spanish CATALUÑA. Today Roussillon equates to the *département* of the Pyrénées-Orientales, the eastern section of the mountain range that dominates the landscape, which reaches so high that much of it remains snow-covered throughout the summer. The geology is some of the most varied of any French wine region, with SCHIST, LIMESTONE, GNEISS, CLAY, and GRANITE. The climate is France's sunniest, with an average of 325 days of sunshine a year, often accompanied by strong WINDS—as many as eight different winds. Vines and olives are two of the rare agricultural crops that can thrive in the arid valleys of the Agly, Têt, and Tech, while the lower, flatter land by the coast is today an important source of cherries, plums, peaches, apricots, and nectarines.

Wine-wise, it is one of the rare regions to produce both fortified wine (VIN DOUX NATUREL, or VDN) and TABLE WINE (*vin sec*, as the locals call it).

Viticulture probably came to the region via the Greek establishment of Marseilles in the 7th century BCE and was developed by the Romans. It seems highly likely that the MUSCAT vine was the first to be introduced, in an effort to ape the popular sweet wines of the AEGEAN ISLANDS. In the early 13th century, ARNALDUS DE VILLANOVA is credited with inventing MUTAGE, a process thought to have been applied particularly to the region's whites made from MUSCAT BLANC, Malvoisie, and MACABEO. RIVESALTES had certainly earned an important reputation for its Muscat by the 14th century, which probably predated that of the Languedoc's FRONTIGNAN. Red fortified wines based on Grenache Noir followed so that Roussillon became the world's foremost producer of vins doux naturels, with BANYULS, MAURY, and Rivesaltes among the first appellations in 1936. A good 70 million bottles of Rivesaltes were sold each year in the mid 20th century.

But this specialization was to be its downfall in the second half of the 20th century, when strong, sweet wines became decidedly unfashionable and the many APERITIFS based on these wines, notably

the locally produced Byrrh, declined sharply in popularity. At the same time, more attention was paid to the *vins secs*, and two appellations were recognized in 1977: Côtes du Roussillon for all three colours and covering much of the *département*; and Côtes du Roussillon-Villages for red wine only, focused on the Agly Valley, with two named villages CARAMANY and LATOUR-DE-FRANCE. TAUTAVEL followed in 1996, LESQUERDE in 1997, and then Les Aspres in 2017. COLLIOURE Rouge came slightly earlier, in 1971, to be followed by Collioure Rosé and then Collioure Blanc, while Maury Sec was not recognized until 2011. The vineyard area of Roussillon totalled 19,900 ha/49,352 acres in 2019, registering a sharp decline from 38,000 ha in 2000 and 58,000 ha in 1979. Côtes du Roussillon represents 4,451 ha/11,038 acres, and Côtes du Roussillon-Villages, including the five villages, stands at 2,787 ha/6,911 acres. (See map under LANGUEDOC.)

The appellations are based on blends, with at least two, if not three, varieties among Grenache Noir, Carignan, Mourvèdre, and Syrah, with various limitations of precise percentages. Grenache's cousin LLEDONER PELUT is also allowed, while Cinsaut is relatively rare. The most planted varieties in Roussillon are, in descending order, Grenache Noir, Syrah, and Carignan. Next most planted are Muscat Blanc à Petits Grains and Muscat of Alexandria, grown traditionally for MUSCAT DE RIVESALTES but increasingly made as dry IGP wines. The principal grape varieties for the region's white wines are Grenache Blanc, Grenache Gris, and Macabeo, with TOURBAT, known locally as Malvoisie du Roussillon, enjoying a renewal of interest. Varietal wines, especially white wines, and also OLD VINE Carignan are sold either as IGP Côtes Catalanes or even VIN DE FRANCE. The best whites have an astonishing ACIDITY and MINERALITY that quite belies their warm origins.

INTERNATIONAL VARIETIES such as Chardonnay and Merlot are relatively unimportant here and generally not very suited to the growing conditions. These wines are usually labelled 'Pays d'Oc', while 'Côtes Catalanes' is used for the more authentically local

varieties. The IGP Côte Vermeille covers the four coastal villages of the appellations of Collioure and Banyuls.

CARBONIC MACERATION has been much employed in the past to counter Carignan's inherent astringency, but more traditional vinification techniques are increasingly used for the 'nobler' varieties. Wine-making has improved enormously, with experience, TEMPERATURE CONTROL, and better use of oak BARRELS; with larger foudres as well as barriques, and even AMPHORAE; and with a search for lower alcohol levels. Viticulture too has evolved with a growing awareness of the problems posed by CLIMATE CHANGE and low rainfall.

CO-OPERATIVES still dominate mass production but are declining in importance as numerous incomers from other French regions and other countries have invested in the potential of this still relatively under-appreciated region. They include an energetic band of producers of NATURAL WINE based on the village of Latour-de-France.

The winegrowers of Roussillon have been some of France's least content with the details of their appellation regulations, which continue to evolve. There can be considerable scepticism about a system devised as far away as Paris and administered from Brussels, especially among those who identify so closely with the inhabitants of Barcelona. It is not unusual to see 'Catalunya Nord' on a label.

Ponsich, P., 'Histoire de la vigne et du vin en Roussillon', in Éditions Montalba, *Les Vins du Roussillon* (1980).

row spacing, the space between rows of vines in the vineyard. See VINE DENSITY.

Royalty, also known as Royalty 1390, a complex HYBRID red-fleshed TEINTURIER bred in CALIFORNIA principally for its colour. It was released in 1958 along with the similar but much more successful RUBIRED.

There is little regal about this particular variety, which is difficult to grow, although a few hundred hectares persist, almost exclusively in the hot SAN JOAQUIN VALLEY.

RS, common abbreviation for RESIDUAL SUGAR.

Rubin, distinctively BULGARIAN cross of Nebbiolo and Syrah developed around 1944. It ripens in mid September and has 50% more ANTHOCYANINS than Cabernet Sauvignon, although interest is waning since the wines seem to age too fast. Confusingly, Rubin is also the name of a Slovakian CROSS and a Romanian HYBRID.

C.G. & J.V.

Rubired, California winemaker's secret weapon, a red-fleshed HYBRID released—along with the somewhat similar but much less successful ROYALTY—in 1958 and particularly popular at a time when depth of COLOUR became associated with QUALITY in wine. Its productivity and depth of colour made the variety so popular with blenders of wine, juice, and some food products that by 2003 there were more than 5,200 ha/13,000 acres in the state, making it California's sixth most popular red grape. Total acreage was still just over 10,000 acres in 2020. It is grown, without any major viticultural problems, mainly in the hot SAN JOAQUIN VALLEY and is never mentioned on a wine label.

ruby, style of FORTIFIED WINE. See PORT.

Ruby Cabernet, red Carignan × Cabernet Sauvignon CROSS bred in and for CALIFORNIA in 1936 and released in 1948. Dr H. P. Olmo of the University of California at DAVIS (see also EMERALD RIESLING, CARNELIAN) was attempting to combine Cabernet characteristics with Carignan productivity and heat tolerance. The slightly rustic Ruby Cabernet enjoyed a heyday in California in the 1960s and even in

2012 was still grown on more than 2,500 ha/6,000 acres, mainly in the southern SAN JOAQUIN VALLEY (though it is only half as popular as the red-fleshed hybrid RUBIRED). It is even more popular in South Africa, where it was grown in 2020 on a total of 1,943 ha, mainly in hotter inland wine regions, and has also been grown quite extensively in Australia's inland regions, appearing on Australian wine labels during the country's red wine shortage of the late 1990s. There were still 700 ha planted in Australia in 2022.

Ruchè, Ruché, Rouchet, or occasionally Roche, very rare but distinctive red grape variety of the PIEMONTE region in north-west Italy with its own varietal DOC around Castagnole Monferrato. Like NEBBIOLO, the wine is headily scented, and its TANNINS imbue it with an almost bitter aftertaste. There were about about 100 ha/247 acres in Italy in 2015.

Rueda, historic Spanish white-wine DOP named after the unprepossessing town which straddles the main road from Madrid to León in CASTILLA Y LEÓN (see map under SPAIN). In the Middle Ages, vineyards flourished on this bleak Castilian plateau, and cellars were hollowed out of the limestone under the town, but after PHYLLOXERA ravaged the zone Rueda went into rapid decline. The high-yielding PALOMINO FINO grape was used for replanting, a move that in this case was justified since the main local styles were FORTIFIED WINES in the image of SHERRY.

For much of the 20th century, the local VERDEJO grape was Rueda's sleeping beauty. It was awoken in the 1970s, when Bodegas Marqués de Riscal of RIOJA recognized the area's potential for dry white wine and sold a fresh Rueda white alongside its Rioja reds. A high plateau at 700–870 m/2,300–2,800 ft in elevation, Rueda was awarded DO status in 1980, and the local CONSEJO REGULADOR was so successful in relaunching the INDIGENOUS VARIETY that, by the mid 2000s, there was nearly three times as much Verdejo as Palomino. Rueda Dorado, a

fortified and OXIDATIVE wine aged for a minimum of two years, and Rueda Pálido, aged under FLOR, are now rare, and modern Rueda is mainly a light, fruity, dry white wine, although there are also richer styles made with BARREL FERMENTATION and LEES CONTACT. It may be made from a blend of Viura (MACABEO) and Verdejo, the latter accounting for at least 50% of the blend, or it may be 100% SAUVIGNON BLANC, a variety introduced by Marqués de Riscal in the early 1980s that overtook Viura in total hectarage by 2017. Rueda Superior must contain at least 85% Verdejo; Gran Vino de Rueda must come from vineyards more than 30 years old and with maximum yields of 6,500 kg/ha. Some sparkling versions are also made.

Red and rosé wines are allowed in the DOP, but only 3% of plantings are in red grapes, mainly TEMPRANILLO. V. de la S. & F.C.

www.dorueda.com

Rufete, late-ripening Portuguese vine variety, also known as Tinta Pinheira, capable of making fruity red wines in BEIRAS and DÃO as well lightish PORT further north. Portugal's plantings had fallen to 2,651 ha/6,551 acres by 2020. In Spain's Castilla-León, 529 ha were recorded in 2020. Grapes need to be fully ripe for their red-fruited wine to succeed.

Ruffiac, Ruffiat. See ARRUFIAC.

rugose wood, a complex of four VIRUS DISEASES which comprises Rupestris stem pitting (RSP), Kober stem grooving (grapevine vitivirus A or GVA), CORKY BARK (grapevine vitivirus B or GVB), and LN33 stem grooving (LNSG). Additionally, grapevine vitiviruses C and

D have been identified but have not yet been shown to cause disease in grapevines.

Although widespread, this complex of diseases is relatively unknown, as all but corky bark are generally symptomless on VITIS VINIFERA. Rugose wood induces graft incompatibility and can kill the vines, especially in the first years after planting. Typical symptoms are pitting or grooving of the wood. All four diseases can be identified by INDEXING. The effect on wine quality of these diseases is still to be evaluated.

Golino, D., et al., 'Laboratory testing for grapevine diseases', in L. J. Bettiga (ed.), *Grape Pest Management* (3rd edn, 2013), 61–8.

Ruländer is the more traditional German name for PINOT GRIS, which was propagated in the Rheinpfalz in the early years of the 18th century by wine merchant Johann Seger Ruland. Since the mid 1980s, the name has been reserved for sweeter—and increasingly unfashionable—styles of Pinot Gris, while the increasingly common dry wines are labelled GRAUBURGUNDER.

The name Ruländer is also used in Austria and for some of the Pinot Gris that is widely planted in ROMANIA.

Rully, rambling village in Burgundy's Côte CHALONNAISE providing about 70% white wine from Chardonnay. Grown on light and SANDY soil, the wines are attractive early and rarely age well. Rully is also a good source of sparkling CRÉMANT de Bourgogne. Twenty-three vineyards in the village, one-fifth of the total, are designated PREMIERS CRUS, with Grésigny, Rabourcé, and Cloux being the most frequently seen. J.T.C.M.

rupestris. See VITIS RUPESTRIS.

Russia . Only the most southern parts of the Russian Federation south of the Don River and north of the Caucasus between the Black and Caspian Seas are suitable for viticulture. The principal limiting factors are low temperatures and a short vegetation period.

History

South Dagestan is Russia's most important ancient viticultural area, although WILD VINES growing around the Caspian, Black, and Azov seas and the greater Caucasus were selected and cultivated long ago. There is evidence of viticultural co-operation between the native tribes living on the Black and Azov seas and the ancient Greeks who settled along the north-east coast of the Black Sea from the 5th century BCE.

The next important viticultural period was the time of the medieval Khazar Kaganate (Turks by language but Jews by faith), who may have brought INDIGENOUS VARIETIES from Dagestan to the banks of the Don and then—together with the Magyars—to Pannonia, modern HUNGARY.

After several centuries of viticultural oblivion, the first vineyards in the Novorossiysk zone of the Krasnodar region were established in 1870 and planted to Riesling and Portugieser. By 1914 the Russian vineyard area averaged 50,000 ha/123,500 acres, but this had halved by 1919, due mainly to the effects of the First World War and PROHIBITION. In 1940 vineyards occupied 42,000 ha of Russia. The great development of commercial vineyards came at the end of 1950, and throughout the Soviet era Russia had a highly efficient wine production and, especially, processing and bottling system until President GORBACHEV began an anti-alcoholism campaign in 1985. Just before then, in the mid 1970s, PHYLLOXERA reached the Taman Peninsula just east of the CRIMEA. Vineyards were abandoned or GRUBBED UP. (Only in a few regions, such as the Taman Peninsula, did it prove possible to retain them because the local authorities reported to Moscow that they were used predominantly to craft grape juice, not wine.) Land privatization during the transition to a market economy further shrivelled the Russian wine industry; by 2001, total vineyard area was 69,400 ha, less than half the area cultivated in the late 1980s, and the total grape harvest shrank to less than one-third of its previous level.

Vineyard acreage continued to fall until early 2014, when the annexation of the Crimea, long celebrated for its wines, added at least 25,000 ha to Russia's total vineyard area. It was then that the federal government announced plans to support the Russian wine industry by relaxing regulations and increasing vineyard plantings. As a result, in 2020 the total vineyard area, including Russian-occupied Crimea and Sevastopol, encompassed 94,250 ha, with a total yield of 490,900 tons of both wine and table grapes. On average, about 5,000 ha of new vines are planted annually, but the total vineyard area is reportedly growing by around 1,200 ha as a portion of the new vines replace uprooted plants.

Climate and geography

Most commercial vineyards of pre-2014 Russia (see CRIMEA for separate details) are in the North Caucasus where the climate is moderately CONTINENTAL and winters can be severe; all vines in the northern regions of Rostov Oblast and Stavropol Krai must be buried for WINTER PROTECTION. The most favourable soil and climate conditions are in the Krasnodar region and Dagestan, with active annual temperature summations of 3600–4000 °C (see CLIMATE CLASSIFICATION) and winters warm enough to permit non-protected viticulture thanks to the moderating influence of the Black Sea.

Krasnodar, the most important Russian wine region, is tentatively divided into five zones, of which the Anapa-and-Taman zone stretching along the ancient Kuban estuary is perhaps most promising for wine production, although its fertile soils can encourage excessive VIGOUR and call for disciplined PRUNING. No winter protection is required for vines here (apart from in the eastern zone where grapes are grown for brandy). The Black Sea zone is much more humid, but winters are less severe; thanks to the MARL and CALCAREOUS soils, still, sparkling, and dessert wines are produced here.

Dagestan with its extremely varied climate, some of it semi-desert, is Russia's second most important wine-producing region (and was its principal one in the late 1980s). The flat southern zone along the Caspian Sea between the capital city and AZERBAIJAN, with its strong tradition of viticulture, is one of the most propitious parts of the Russian Federation for wine and brandy production. Grape varieties grown include Pervenets Magaracha, Agadai, White Muscat, Asyl Kara, Red Tersky, Saperavi, Zálagyöngy, Premier, Codreanca, and Moldova.

About 10% of Russian wine is produced in the Stavropol region. Winter protection is essential as temperatures fall well below freezing (the median temperature in January is −5 °C/23 °F). Summers are cool and short, with a frost-free period typically lasting just 180–190 days. Precipitation is also low, at 300–500 mm/12–20 in per year. The

most common varieties are Levokumsky Ustoichivy (Stable), Sauvignon Blanc, Riesling, Rkatsiteli, and Aligoté.

Even smaller, but by no means less important for wine production, is the Rostov region with its dry, hot summers, sub-zero winters that demand winter protection of vines, and a plethora of INDIGENOUS VARIETIES, among them Krasnostop Zolotovsky, Tsimlansky Chorny, Sibirkovy, and Pukhliakovsky (Kecskecsecsű in Hungary). Chechnya now grows only TABLE GRAPES.

A new wine classification put in force in 2015 introduced the terms 'Protected Geographic Indication' (PGI) and 'Protected Appellation of Origin' (PAO). In 2021 the Russian government approved the breakdown of vinelands into vine-growing/winemaking zones (coinciding with the PGIs) and TERROIRS (coinciding with the PAOs). The list includes Dagestan, Don Valley, Terek Valley, Crimea (with Sevastopol), Kuban, North Ossetia–Alania, and Stavropol.

Industry organization

Most Russian vineyards and wineries have now been privatized. Only in Dagestan does the industry remain predominantly state-governed.

SPARKLING WINE comprises a significant proportion of wine consumption in Russia. In 2020, 550 million l/145.3 million gal of still wine and 178 million l of sparkling wine were sold in Russia, with official figures estimating that 55% of the market is domestically made wines and 45% is imported wines. Since 2015, the term 'domestically made' applies only to wines made from Russian-grown grapes instead of imported GRAPE CONCENTRATE and BULK WINE. The fashion for medium-sweet wines of all colours has also been on the wane, making up only 50% of sales by 2021.

A recent trend in Russian wine production has been the development of the so-called GARAGE WINES movement. In 2020 they were already playing a role on the southern Russian gourmet and tourist scene and at international tasting competitions.

Viticulture

Vine-TRAINING SYSTEMS changed enormously during the 20th century. Densely planted vineyards (5,000–10,000 vines per ha) with single-vine supports have given way to TRELLIS SYSTEMS in wider-spaced rows. The many vineyards that need winter protection are either trained with long and medium CANES left in one direction and covered with soil in winter by a vine-laying machine or left to be covered with a high mound of soil. The most widespread training systems for vineyards that do not need winter protection are tall-trunk bilateral CORDON and GUYOT.

In the Soviet era, the trunks of particularly vigorous vines were trained 1.2 m high with row spacing of 3–4 m/10–13 ft, the so-called broad-row training method. Such training systems are still seen in some older vineyards, but more frequently row and vine spacing is generally 2.5–3 m and 1.5–2 m respectively.

Vineyards on non-irrigated lands have medium- and high-TRUNKED forms with row and vine spacing at 2.5–3 m and 0.8–2 m respectively (or tighter for higher-end products.)

Three industrial-size NURSERIES located in Krasnodar Krai produce over 4.5 million GRAFTED VINES a year which ensures 80–85% of the demand; the rest are imported, mainly from Italy, Austria, France, and Serbia.

Vine varieties

The varietal assortment of Russia's vineyards is extremely diverse, with over 100 varieties allowed for commercial cultivation. Depending on the region, 70–85% of vineyards are planted to wine grapes, with TABLE GRAPES accounting for 15–30% of the total vineyard area. Among wine grapes cultivated in all viticultural regions of Russia, the most common, comprising almost half of all plantings, are Cabernet Sauvignon and the varieties typically grown for SPARKLING WINES—the Pinots, Chardonnay, Sauvignon Blanc, and Riesling. Also planted are Aligoté, Cebrener Franc, Muscats, Saperavi, and Merlot; the local red wine grapes Krasnostop Zolotovsky and Tsimlansky Chorny (Black); and the Soviet interspecific HYBRIDS Pervenets Magaracha, Dostoiny, and others.

NEW VARIETIES with improved resistance to FUNGAL DISEASES and FROST have been developed by the All-Russia Potapenko Research Institute for Viticulture and Ecology. Most notable among the wine grape varieties are SAPERAVI Severny (Severny means 'northern') and CABERNET SEVERNY. They and other new varieties such as Stepniak and Fioletovy Ranni occupy about 10,000 ha/25,000 acres on various Russian farms. Commercial cultivation of these new, specially bred varieties has allowed considerable expansion of non-protected viticulture.

In the early 1990s, there was a substantial expansion in the total area planted to new, high-yielding wine grape varieties such as Bianca, Pervenets Magaracha, Moldova, and 'all-purpose' varieties suitable for both wine and TABLE GRAPES such as Muscat Derbentsky and Zálagyöngy, as well as to INDIGENOUS VARIETIES such as Sibirkovy, Tsimlansky Chorny, Plechistik, Variushkin, Narma, and Güliabi Dagestansky. V.P.

Саркисян А. Авторский гид Российские вина 2021–2022 (2021).

Пукиш В. *Новый Старый Свет. Очерки по истории виноделия Кубани* (2015).

Russian River Valley, California AVA that stretches much of the width of Sonoma County along the Russian River. Its 6,070 ha/15,000 vineyard acres are particularly known for Chardonnay and a rich style of Pinot Noir. See SONOMA.

Rust, important wine town in Austria's Burgenland where the LEITHABERG foothills meet the NEUSIEDLERSEE, historically best known for RUSTER AUSBRUCH. Rust is home to the Austrian Wine Academy, the largest wine education centre in mainland Europe.

Ruster Ausbruch, sweet wine from shrivelled grapes grown in quintessentially picturesque RUST, on the western shore of eastern Austria's expansive but curiously shallow Neusiedlersee, which encourages the development of BOTRYTIS. Despite its diminutive size and thanks to the importance of its wine, in 1524 Rust was accorded the right to brand their casks with the initial 'R', and in 1681 it was granted the status of free city under the Hungarian Crown. Methods of production for Ruster Ausbruch evolved contemporaneously with those at the opposite end of the Hungarian Kingdom for TOKAJI Aszú, and with the same dominant grape, FURMINT. (*Ausbruch* and *aszú* are synonymous and signify the 'outbreak' of botrytis.)

While Rust remained an important wine-producing community throughout the 20th century, Furmint all but died out after the First World War (when the town became part of Austrian BURGENLAND), and production of sweet wine was not revived until the 1960s, tentatively and in response to the tastes of German tourists. In the late 1980s, winegrower Robert Wenzel re-introduced Furmint to Rust from Tokaj. In 1991 growers led by Heidi Schröck founded the Cercle Ruster Ausbruch, codifying the production of their community's famous elixir, then made from a wide variety of white (and occasionally black) grapes. In 2020 Ruster Ausbruch acquired the status of DAC, stipulating a minimum MUST WEIGHT of 30 °KMW (146 °Oechsle) and a minimum of 45 g RESIDUAL SUGAR. The grape varieties are restricted to

WELSCHRIESLING, WEISSBURGUNDER, CHARDONNAY, MUSKATELLER, and FURMINT. Sweet wines from Rust not meeting the conditions for Ruster Ausbruch are labelled by PRÄDIKAT and for their state of origin, Burgenland, while dry wines may seek approval as LEITHABERG DAC.

D.S.

Rutherford , important centre of wine production in California's NAPA Valley.

Rutherglen , historic wine region in NORTH EAST VICTORIA ZONE, famous for its FORTIFIED, sweet TOPAQUE AND MUSCAT from the likes of Morris and Campbell's.

Ruwer, German river, just 40 km/25 miles long but with viticultural significance well beyond its size, which rises in the Hunsrück Mountains and flows into the MOSEL, downstream from Trier. Ruwer wines long bore the designation Mosel-Saar-Ruwer, but since 2007 the region has been subsumed within MOSEL; as of 2019, wines may also specify Ruwer as subregion. Ruwer wines are similar in STRUCTURE to those of the SAAR but have a touch of earthiness to add individuality. See MOSEL.

S

Saale-Unstrut, small wine region in eastern GERMANY of terraced and sometimes isolated vineyards, starting to recover from the forlorn condition in which they were left by the former East German regime (see map under GERMANY). The main producers in the 798 ha/1,972 acres under vine as of 2019 are the cellars at Naumburg belonging to the state of Sachsen-Anhalt and the co-operative cellar at Freyburg. As in nearby SACHSEN, white wine grapes dominate: Müller-Thurgau (with 15% of vineyard area), Weissburgunder (14%), Riesling (9%), and Silvaner (7%), although both Dornfelder and traditional Portugieser also hold significant shares. Vineyards are predominantly underlain by fossiliferous LIMESTONE. These are continental Europe's northernmost significant vineyards, with a comparatively cool CONTINENTAL CLIMATE and considerable risk of FROSTS. D.S.

Saar, river which rises in the Vosges Mountains and joins the River Mosel at Konz, near Trier. Downstream from Serrig, RIESLING vines grow on SLATE, resulting in wines of long-standing renown. Since 2007, the Saar's vineyards are subsumed under the regional name MOSEL.

Sable de Camargue, IGP in the sand (*sable*) soils along the coast of the eastern Mediterranean best known for wines the colour of the flamingos that gather in the region's many lagoons. Gris and pink wines (94% of production) must be made from at least 70% Cabernets Sauvignon or Franc, Carignans and Grenaches Noir or Gris, Cinsaut, Merlot, or Syrah; red wines switch out the *gris* grapes and

Cinsaut for Marselan and Petit Verdot. The high sand content discourages PHYLLOXERA, so many vines remain UNGRAFTED.

Saccharomyces. See YEAST.

Sachsen, Saxony in English, and the third-smallest wine region in GERMANY. Formerly in East Germany, it is also known colloquially as the Elbtal and was home to the first German viticultural training institute (in Meissen) founded 1811–12. The region's 493 ha/1,218 acres of vines in 2018 follow the course of the river Elbe, from Pillnitz on the southern outskirts of Dresden to Diesbar-Seusslitz north of Meissen. Sachsen and SAALE-UNSTRUT are the most northerly wine regions in Germany (see map under GERMANY), featuring relatively cool CONTINENTAL climates and granite- and GNEISS-dominated soils. Yields are low, usually under half the national average, and local demand for an extremely limited supply guarantees prices that should make reviving Saxony's neglected terraces and its reputation for fine wine attractive. It was in Meissen, known for its porcelain factory, that viticulture in Sachsen was first documented in 1161.

White wine grapes that collectively dominate this region's almost entirely dry wines are Müller-Thurgau (14% of vineyard area), Riesling and Weissburgunder (each at 12.%), and Grauburgunder (Pinot Gris, 10%). Nearly 50% of the region's grapes are processed by the regional CO-OPERATIVE and state domaine (Schloss Wackerbarth), but Schloss Proschwitz, founded in 1990 and as such the region's oldest private wine estate, farms 14% of Sachsen vines.

D.S.

sack, name for a white FORTIFIED WINE, imported from Spain or the Canary islands, which was much in FASHION in England in the 16th and 17th centuries. Its most famous, fictional, consumer was Sir John Falstaff; in Shakespeare's *The Second Part of King Henry IV*, Act IV, sc. ii, he delivers his classic speech in its praise. The etymology of sack is disputed. The *Oxford English Dictionary* derives the word from

the French word *sec* meaning 'dry' but admits that it cannot produce a convincing explanation for the difference in vowels. Moreover, sack was probably sweet. It was matured in wood for up to two years, so it would have been like a cheap OLOROSO. Hence Julian Jeffs proposes another derivation: Spanish *sacar*, 'to draw out', from which *sacas* became exports of wine. Often the place of production was put before the noun, as in Canary sack (see LA PALMA), Malaga sack (see MÁLAGA), Sherris (or Sherry) sack. Sherris is JEREZ, hence the modern word SHERRY. From the end of the 17th century, 'sherry' began to replace 'sack' as the generic term, but 'sack' was still used in the 18th century.

Sack was popular in England, even more so when in 1587 Drake raided the Spanish fleet at Cádiz and captured 2,900 PIPES (not BUTTS at this stage) of sherry intended for the Armada, making drinking sack an act of patriotism. Undoubtedly the English colony did not welcome the second raid on Cádiz in 1595; yet sack continued to be exported to England. With the accession of James I in 1603, tension eased and the merchants flourished once more. Sack appears in the works of many of the major English writers of the 17th century, and, however much the Puritans disapproved of the theatre, they did drink sack: when Cromwell paid an official visit to Bristol he was presented with a pipe of sack. H.M.W.

Jeffs, J., *Sherry* (6th edn, 2019).

sacramental wine, saviour of some CALIFORNIA wineries during PROHIBITION. For more details of the sacramental nature of wine, see EUCHARIST.

Sacramento Valley, northern part of the vast CENTRAL VALLEY of CALIFORNIA from LODI northwards, including University of California at DAVIS, home to California's most famous VITICULTURE and OENOLOGY programme. It also includes the AVAs CLARKSBURG, Dunnigan Hills, and Capay Valley.

Sacy, white grape variety once widely grown in France's Yonne *département*. Its productivity is its chief attribute, its acidity the wine's most noticeable characteristic. This has been used to reasonable effect by the producers of sparkling wines, and the variety, also called Tressallier, is still (just) grown as an ingredient in the white wines of ST-POURÇAIN. See also PINOT.

SAFER stands for Société d'Aménagement Foncier et d'Etablissement Rural, meaning 'land development and rural settlement company'. These non-profit regional companies were set up in France from the 1960s to help restructure farms to be more economically viable and to support young people wanting to set up a rural enterprise. With the key aims of contributing to the sustainable development of rural areas, including viticulture and winegrowing, and to protect natural resources, they buy and allocate land and properties in accordance with the best local interests. See also PRICE, VINEYARD LAND PRICES.

www.safer.fr

Sagrantino, lively, tannic red-grape speciality of Montefalco in UMBRIA. Montefalco Sagrantino was elevated to DOCG status in the mid 1990s. Sagrantino has been used as the main ingredient in DRIED-GRAPE WINES but since the 1980s has shown promise as a carefully vinified dry red, as well as in blends with SANGIOVESE for Montefalco Rosso. It was the Arnaldo Caprai winery that created much interest in the variety in the 1990s, but the overall level of viticultural and oenological sophistication in the production zone still needs improvement. A total of 837 ha/2,068 acres were reported in 2020.

saignée, French term meaning 'bled' for a winemaking technique which results in a ROSÉ WINE made by running off, or 'bleeding', a

certain amount of FREE-RUN juice from just-crushed dark-skinned grapes after a short, pre-fermentation MACERATION. The aim of this may be primarily to produce a lightly pink wine or to increase the proportion of PHENOLICS and FLAVOUR COMPOUNDS to juice, thereby effecting a form of CONCENTRATION of the red wine which results from fermentation of the rest of the juice with the skins. The second operation was at one time often undertaken by ambitious producers of both red bordeaux and red burgundy but is now rare, unless the weather conditions have resulted in particularly big berries at harvest.

St-Amour, the most northerly of the BEAUJOLAIS crus, technically part of the MÂCONNAIS, and an area with some LIMESTONE, which supports both red wines as well as Beaujolais Blanc from the 315 ha/778 acres of vines. Unsurprisingly, there has often been a sense of conflicted identity here—spurred by diverse soils that also contain chert (a dense sedimentary rock of microcrystalline QUARTZ), SCHIST, and FLINT—and a sense of romance, given the name, which by various accounts comes from a Roman soldier who celebrated a narrow escape from death in Switzerland by converting to Christianity, along with other, earthier creation tales. The wines, in any case, show a delicacy more in line with the best Mâcon reds, without giving up their Beaujolais gusto. J.F.B.

St-Aubin, village in the Côte de Beaune district of Burgundy's CÔTE D'OR tucked out of the limelight between Meursault and Puligny-Montrachet. White wine production increased, justifiably, to 84% of the total by 2019, up from 39% in 1976. Two-thirds of the vineyard area is designated PREMIER CRU, notably Les Charmois, La Chatenière, En Remilly, and Les Murgers Dents de Chien, part of a swathe of mostly south-west–facing vineyards lying between the borders of Chassagne-Montrachet, Puligny-Montrachet, and the hamlet of Gamay, which is included in the St-Aubin appellation. The remaining vineyards have ideal south- and south-easterly ASPECT but are less favourably situated further up the cooler valley.

White St-Aubin is a fresh, energetic wine with some of the character of Puligny-Montrachet, especially in warmer vintages; the reds resemble a suppler version of red Chassagne-Montrachet.

See also CÔTE D'OR and BURGUNDY map. J.T.C.M.

St-Bris was granted full appellation status from the 2001 vintage for its crisp, cool-climate sauvignon (Gris is now allowed as well as Blanc), having been a VDQS since 1974. Total vineyard area in the communes of St-Bris-le-Vineux, Chitry, IRANCY, Quenne, and parts of Vincelottes south of AUXERRE and west of CHABLIS had grown to 161 ha/398 acres by 2018. The wine is too obscure to be made with anything other than artisan passion, but it lacks the breed and concentration of great LOIRE Sauvignon Blanc. Being technically Burgundian but made from a decidedly non-Burgundian grape, it is a curiosity. J.T.C.M.

St-Chinian, good-value, distinctive AOC in the LANGUEDOC in southern France with around 3,000 ha/7,400 acres that extend over spectacular, mountainous terrain in the foothills of the Cévennes between the MINERVOIS and FAUGÈRES appellations (see map under LANGUEDOC). Most wine is characterful red, but some fresh, dry rosé and a small volume of increasingly interesting whites are also made. The small town of St-Chinian itself is in the middle of the zone, which extends north and eastwards to Berlou and Roquebrun which earned their own appellations St-Chinian Berlou and St-Chinian Roquebrun for red wines in 2005. In this northern zone, vines at up to 400 m/1,312 ft in ELEVATION grow on arid SCHISTS and yield low quantities of extremely sharply etched wines with distinct MINERALITY. In the southern zone closer to St-Chinian itself, the (sometimes purple) CLAYS and LIMESTONE, typically at about 100 m, tend to result in fuller, softer wines. Syrah, Mourvèdre, and Grenache and quite frequently its doppelgänger LLEDONER PELUT form the backbone of the red blends, with Carignan and Cinsaut playing more minor roles. Whites

are based on Grenache Blanc, with Marsanne, Roussanne, and some Vermentino. Many producers here also grow other varieties with which to make some excellent IGP wines. M.S.

St-Christol, the easternmost red wine CRU within the LANGUEDOC AOC in southern France, named after a village on the eastern boundary of the Hérault *département* with Gard. Production of appellation wine is relatively low here and is chiefly in the hands of the village CO-OPERATIVE.

St-Drézéry , the smallest named red wine CRU within the LANGUEDOC AOC in southern France. Like neighbouring ST-CHRISTOL it is named after a village on the eastern boundary of the Hérault *département* with Gard, and such appellation production as there is is chiefly in the hands of the village CO-OPERATIVE, although Ch Puech-Haut makes fine reds and whites.

Ste-Croix-du-Mont, small 282-ha/697-acre sweet-white-wine appellation on the right bank of the GARONNE river in the Bordeaux region. At their best, especially on the steep, very chalky escarpments leading south down to the river, these mainly SÉMILLON wines can be excellent early-maturing answers to SAUTERNES and, in spite of their higher permitted yield, have a local reputation of being just as generous. Opposite the slope from the Église Ste-Croix-du-Mont, the cool Ciron river meets the warmer Garonne, creating more misty mornings than at LOUPIAC and therefore better BOTRYTIZATION, which, together with raisined grapes, must be hand-picked in several passes. Further inland, apart from a few GRAVEL outcrops, the soil is less noble and the exposures more varied than on the south-facing vineyards: as a result the sweet wines tend to be simpler, vinified and aged in tank rather than barrel, and these inland vineyards produce more dry and red wine. W.J.B.

Ste-Foy Côtes de Bordeaux, about 220 ha/543 acres of vineyards in the extreme east of the BORDEAUX region on the border with, and arguably more properly part of, BERGERAC. The appellation is named after its principal town, just 22 km/14 miles west of the town of Bergerac. Its red wines are very similar to red Bergerac and BORDEAUX AOC, while its much rarer white wines are often sweet and mostly undistinguished.

St-Émilion , important red-wine district in BORDEAUX producing more wine than any other RIGHT BANK appellation, and home of most of the extravagantly priced GARAGE WINES. A UNESCO World Heritage site, it takes its name from the prettiest town in the Bordeaux region, one of the few to attract tourists to whom wine is of no interest.

The town's historical importance is undisputed. In the 8th century it was a collection of caves hollowed out of the cliff on which a fortified medieval town was to be built. In the Middle Ages its port, Pierrefitte, played an important part in shipping wine down the DORDOGNE river, until it was overtaken by LIBOURNE a few miles downstream. It was on the pilgrim route to Santiago de Compostela, and even today its CONFRÉRIE the Jurade de St-Émilion prides itself on maintaining the district's reputation for hospitality. As outlined in BORDEAUX, history, St-Émilion was a wine region long before the MÉDOC on the left bank of the Gironde, even though for most of the 19th century it was less important commercially. In the early 20th century, the wines of St-Émilion were left to the merchants of Libourne to sell in northern France and northern Europe, while the BORDEAUX TRADE concentrated on selling LEFT BANK wines. The reputation of St-Émilion grew steadily throughout the second half of the 20th century, accelerating towards the end of the century, not least because of international interest in some of the *garagistes*. As a result, rivalry between the left and right banks intensified, with St-Émilion and the scores of wine shops lining its narrow cobbled streets being the focus of right-bank wine activity.

Whereas the Médoc is made up of large, grand estates, most of St-Émilion's 600 or so smallholders are essentially farmers, albeit dedicated to a single crop. That crop is dominated by the Merlot and Cabernet Franc (here called Bouchet) vine varieties, Merlot accounting for more than 60% of all vine plantings and imbuing the wines with their characteristic almost dried-fruit sweetness. A little Cabernet Sauvignon is grown, but it can be relied upon to ripen profitably only in favoured spots in the generally cooler soils and MACROCLIMATE of the right bank, and then only if a suitable CLONE has been planted and is grown with care.

In addition, starting with the 2019 vintage, all St-Émilion wines are required to have been farmed under certified SUSTAINABLE VITICULTURE methods, whether HVE, BIODYNAMIC, or ORGANIC VITICULTURE. Those that are not must be bottled under the generic BORDEAUX AOC.

Vine varieties apart, variation is the hallmark of this extensive region. The quality of its wines can range from light, fruity, serviceable CLARETS to fine FIRST GROWTHS capable of AGEING for a century or more. The diversity of soils in the district is such that Bordeaux's most diligent geographer, Henri Enjalbert, devoted his *tour de force* to the region.

Although conventionally the St-Émilion district has been divided into two general soil types—the *côtes* or hillsides below the town and the CLAY-rich CALCAREOUS soil on the LIMESTONE plateau to its east and west—there are myriad soil types (see detailed map in Johnson and Robinson). At its north-western limit is a distinctly GRAVELLY district around Chx Cheval Blanc and Figeac. Much of the appellation zone lies on the plain between the town and plateau and the river Dordogne. Wines made on this lower land, a mixture of gravel, SAND, and ALLUVIAL soils, tend to be lighter and less long lived than the wines produced on the plateau or the hillsides, and most, but not all, of them qualify for the most basic appellation, St-Émilion.

But the St-Émilion district also boasts a diversity of appellations and, uniquely in France, has a CLASSIFICATION of individual properties which is regularly updated and depends on tasting. This classification

was first drawn up in 1955 and is revised, often controversially, roughly every ten years, the most recent being that drawn up in 2022. Several hundred properties are accorded the misleadingly grand-seeming St-Émilion Grand Cru status. In 2020, for example, just 1,058 ha qualified for the simple St-Émilion appellation while 4,196 ha qualified as St-Émilion Grand Cru. But the classification's most significant task is to identify which properties rank as St-Émilion Grand Cru Classé and which few qualify as St-Émilion Premier Grand Cru Classé. See CLASSIFICATION for details of the 2022 classification, which rated 85 properties Grands Crus Classés, of which 14 are Premiers Grands Crus Classés and two, Chx Pavie and Figeac, have the 'A' status held by Chx CHEVAL BLANC, AUSONE, and ANGÉLUS before they withdrew from the classification. Most of the district's most highly ranked properties are either on the steep, clay-limestone hillsides immediately below the town or on the gravelly section of the plateau 5 km/3 miles west of the town and immediately adjacent to the POMEROL appellation.

Of traditionally famous St-Émilion properties, Ch Figeac—which predated and claims to rival Ch Cheval Blanc—is (unusually for the appellation) attached to Cabernet Sauvignon. Since most other St-Émilions lack this tannic ingredient, the district's wines in general mature much faster than their left-bank counterparts.

This is particularly true of the new wave of small properties which emerged in the 1990s, some of whose wines were offered (though did not necessarily sell) at prices in excess of the famous and established FIRST GROWTHS. See GARAGE WINES.

At the other extreme of value, the St-Émilion CO-OPERATIVE, l'Union des Producteurs de St-Émilion, is one of France's most ambitious, bottling one-quarter of St-Émilion's production. The whole region is characterized by a strong sense of local identity.

The satellite appellations

On the outskirts are the so-called St-Émilion satellites, LUSSAC-ST-ÉMILION, MONTAGNE-ST-ÉMILION, PUISSEGUIN-ST-ÉMILION, and ST-GEORGES-ST-ÉMILION. On this more rolling countryside north of the Barbanne (see LALANDE-DE-POMEROL), the vine is grown alongside other crops, and viticulture accounts for well over half of the total area, or 4,000 ha/9,884 acres. Co-operatives are important here, and Montagne- and Lussac-St-Émilion produce significantly more wine than either Puisseguin or, especially, St-Georges, which was for many years sold as Montagne-St-Émilion. The grape varieties planted are similar to those in St-Émilion proper, but the standard of winemaking is generally more rudimentary. There are, nevertheless, bargains to be sought out. J.R. & J.L.

Penning-Rowsell, E., *The Wines of Bordeaux* (6th edn, 1989).

The vine variety

St-Émilion is also a synonym for the widely planted white grape variety called UGNI BLANC in France and TREBBIANO Toscano in Italy. The name is used particularly in Cognac in south-west France, where it is widely planted.

St-Estèphe, the northernmost of the four important communal appellations in the HAUT-MÉDOC district of BORDEAUX. St-Estèphe is separated from the vineyards of Pauillac's Ch LAFITE only by a stream —indeed, Ch Lafite owns some land in the commune of St-Estèphe itself. To the immediate north of St-Estèphe, across a stretch of polder, lies the Bas-MÉDOC, the lower, lesser portion of this most famous region.

The soils of St-Estèphe contain their fair share of GRAVEL, but often on a CLAY base. Less well drained and cooler than that of their counterparts further south in the Médoc, the soils can delay ripening, leaving St-Estèphe grapes higher in acidity. In Bordeaux's low-rainfall vintages, the water-retaining clays of St-Estèphe have an advantage.

A high proportion of grapes grown on St-Estèphe's area of just over 1,200 ha/2,960 acres of vines used to find their way into the vats of the village's CO-OPERATIVE, which often uses the name Marquis de St-Estèphe. The village may boast fewer famous names and CLASSED GROWTHS than MARGAUX, PAUILLAC, or ST-JULIEN, but its wines have a distinctive style that is deep-coloured, full of extract, perhaps a little austere in youth, but very long lived. This style was perceptibly softened during the 1980s as higher proportions of Merlot grapes blurred the edges of the Cabernet, and winemaking techniques, particularly CONCENTRATION, have been harnessed to make the wines seem softer and fuller.

The stars of St-Estèphe are its two second growths, Chx Montrose and Cos d'Estournel, whose fortunes and reputations have alternated throughout the village's relatively recent history as a fine wine producer. Cos (pronounced 'koss') d'Estournel has the Médoc's most

eye-catching architecture, in a façade of pure oriental folly beside the main road through the Médoc's wine villages. Its wines are the commune's most ambitious, styled to age for many decades to come. Ch Montrose produces much more traditionally STRUCTURED, almost Ch LATOUR–like wines, confirming this while implementing an ambitious SUSTAINABILITY programme, including conversion to ORGANIC VITICULTURE.

St-Estèphe's other classed growths are the increasingly dramatic third growth Ch Calon-Ségur, the reliable fourth growth Ch Lafon-Rochet, well sited between Ch Lafite and Cos, and the distinctly modest fifth growth Ch Cos-Labory. Some of the village's most conscientiously made wines, however, are such unclassified estates as the exotic Chx Haut-Marbuzet, Meyney, de Pez, and Haut-Beauséjour (both owned by ROEDERER), Les-Ormes-de-Pez (the latter run in tandem with Pauillac's Ch Lynch-Bages), and Ch Phélan-Ségur.

For more information, see MÉDOC and map of BORDEAUX.

Ste-Victoire, DÉNOMINATION GÉOGRAPHIQUE COMPLÉMENTAIRE within Côtes de PROVENCE.

St-Georges d'Orques , named CRU within the LANGUEDOC AOC just west of Montpellier.

St-Georges-St-Émilion, satellite appellation of ST-ÉMILION in Bordeaux on around 200 ha/500 acres of vines in 2020.

St-Guilhem-le-Désert , small IGP covering vineyards in the foothills of the Cevennes in the north-east of the Hérault *département* of France. The IGP can be used for wines that fall outside of PIC-ST-LOUP and allows a great many grape varieties, including ASSYRTIKO, AGIORGITIKO, and SAPERAVI, among others that might thrive in the region's LIMESTONE soils and MEDITERRANEAN CLIMATE. Two more precise geographic indications may be appended to the IGP: Val de Montferrand, and Cité d'Aniane for wines from the commune made famous by the wines of Mas de Daumas-Gassac.

St-Jean-de-la-Porte , CRU on warm, south-facing slopes east of Chambéry whose name can be added to the eastern French appellation SAVOIE. Use of the name is restricted to wines from the local MONDEUSE grape, from which floral and structured reds are made. W.L.

St-Jean-de-Minervois , small mountain village in the far north-east of the MINERVOIS region that gives its name to the Languedoc's most delicate and refreshing VIN DOUX NATUREL, Muscat de St-Jean-de-Minervois. It is made from MUSCAT BLANC À PETITS GRAINS, to which alcohol is added during fermentation to produce a wine with at least 15% alcohol and 125 g/l RESIDUAL SUGAR. St-Jean's vineyards are hacked out of the stony LIMESTONE and *garrigue* at 250 m/825 ft above sea level. The ELEVATION and cooler CONTINENTAL CLIMATE allows the grapes to ripen a good three to four weeks later than other Muscats grown closer to the Mediterranean, with higher ACIDITY levels and YIELDS that rarely reach the permitted maximum of 30 hl/ha.
M.S.

St-Joseph, the second largest AOC in the Northern RHÔNE, producing wine from 1,370 ha/3,385 acres in 2020. A thin sliver of an appellation, stretching 60 km/37 miles from Chavanay in the north to Guilherand-Granges in the south, it is effectively an umbrella

appellation that gathers together the succession of dramatic slopes facing south, south-east, and east that have largely been created by tributaries of the Rhône that flow in from the west, cutting through the eastern edge of the Massif Central. When the appellation was created in 1956 it included just six communes, all bunched around its southern pole just across the Rhône River from HERMITAGE: Glun, Mauves, Tournon, Lemps, St-Jean-de-Muzols, and Vion. Another 20 were added in 1969. There is no village of St-Joseph here: the appellation takes its name from an outstanding LIEU-DIT in the commune of Mauves. Most of the appellation is based on GRANITE, with small outcrops of GNEISS in the north, LIMESTONE in the south, and some recent ALLUVIAL deposits and pockets of LOESS throughout.

White wines make up just 13% of production, the full-bodied dry whites based on MARSANNE and/or ROUSSANNE. Red wines depend entirely on SYRAH, those from the southern end of the appellation tending to be slightly more concentrated and STRUCTURED than those from its cooler northern extension. The wines tend to cost less than those from the more prestigious neighbouring appellations of CÔTE RÔTIE, Hermitage, and CORNAS, despite some of the steep, terraced vineyards being just as difficult to work. Wines by producers such as Domaine Jean-Louis Chave, CHAPOUTIER, and Domaine Gonon show, however, that these wines can be exceptionally fine, the reds wines able to age for 20 years or more, but more generally speaking red St-Josephs are best drunk younger, up to eight years. M.C.W.

St-Julien, one of the most homogeneous, reliable, and underrated village appellations in the Haut-Médoc district of Bordeaux. St-Julien may suffer in popular esteem because, unlike PAUILLAC to its immediate north and MARGAUX a few miles to the south, it has no FIRST GROWTH properties. Instead, however, it can boast five superb second growths, two excellent third growths, four well-maintained fourth growths, and, from the 1980s at least, an unrivalled consistency in winemaking skill. St-Julien has been the commune for

wine connoisseurs who seek subtlety, balance, and TRADITION in their red bordeaux. The wines may lack the vivid, sometimes almost pastiche, concentration of a Pauillac, the austerity of a classic ST-ESTÈPHE, or the immediate charm of a stereotypical (if all too rare) Margaux, but they embody all the virtues of fine, long-lived blends of Cabernet and Merlot grapes, being deep coloured, dry, digestible, appetizing, persistent, intriguing, and rewarding.

The appellation, the smallest of the Médoc's most famous four, has for years encompassed about 900 ha/2,220 acres of vineyard within the communes of St-Julien and Beychevelle to its immediate south. Both GRAVELLY soils and subsoils with CLAY and LIMESTONE and hardpan here are relatively homogeneous, broken only by a narrow strip of river bank on either side of the *jalle* that bisects the zone and flows into the GIRONDE north of Ch Ducru-Beaucaillou. South of St-Julien is a considerable extent of land classified merely as Haut-Médoc, but to the north the appellation is contiguous with the southern border of Pauillac, and Ch Léoville-Las-Cases in the extreme north of St-Julien shares many characteristics with some fine Pauillac wines, notably Ch LATOUR, which is well within sight.

The Léoville estate, as PENNING-ROWSELL points out, must have been the largest in the entire Médoc in the 18th century, before it was divided into the three second growths known today as the châteaux Léoville-Las-Cases, Léoville-Poyferré, and Léoville-Barton. Léoville-Poyferré, which includes the original château building, enjoyed a heyday in terms of its reputation in the 1920s but also demonstrated something of a return to form in the 1980s. Best value, and perhaps most representative of the appellation, is Léoville-Barton, run from Ch Langoa-Barton, a fine third growth that is, unusually for the Médoc, the home of its owners, the BARTON family. Chx Gruaud-Larose and Ducru-Beaucaillou are the other two St-Julien second growths and produce two of the Médoc's finest wines in most vintages. The third growth Ch Lagrange was much improved in the 1980s by investment from SUNTORY of JAPAN, while fourth growth châteaux St Pierre, Talbot, Branaire-Ducru, and Beychevelle are generally well run. St-Julien's classed growths account for over three-

quarters of the appellation's total production, and even such unclassified properties as chx Gloria, Hortevie, and Le Petit Ducru (ex-Lalande-Borie) do not believe in underpricing their admittedly admirable produce.

For more information, see MÉDOC and map of BORDEAUX.

J.R. & J.L.

Brook, S., *The Complete Bordeaux* (4th edn, 2022).

Penning-Rowsell, E., *The Wines of Bordeaux* (6th edn, 1989).

St-Laurent, as well as being one of the few villages of any size in the MÉDOC, is the name of a black grape variety today most commonly encountered in AUSTRIA, where it is known as Sankt Laurent. DNA PROFILING has confirmed that the variety is a progeny of PINOT. The other parent remains unknown; SAVAGNIN has been suggested but can be ruled out by DNA profiling. It is capable of producing deeply coloured, velvety reds with sufficient concentration—provided yields are limited—to merit ageing in oak and then bottle. Thanks to the German red-wine boom of the 1990s, total German plantings had reached almost 700 ha/1,730 acres by 2012 but had declined to just over 600 ha by 2020, mainly in the Pfalz and Rheinhessen. In Austria its 621 ha in 2021 puts it on an equal footing with the viticulturally more demanding Blauburgunder (PINOT NOIR). Certainly it has had several centuries to adapt itself to conditions in the Thermenregion and Burgenland, where its viticultural disadvantages—dangerously early budding, tendency to drop its flowers, and susceptibility to COULURE and ROT—are less problematic than in Alsace, for example. St-Laurent wine can resemble a powerful Pinot Noir. It is even more important in CZECHIA and SLOVAKIA, where it is once again known respectively as Svatovavřinecké and Svätovavrinecké, having been robbed of its sainthood during the communist regime when it was called simply Vavřinecké. There were 1,012 ha planted in Czechia in 2019, tied with Frankovka (BLAUFRÄNKISCH) as the country's most planted red wine grape. Slovakia had 785 ha planted in 2021, making

it the country's second most planted red variety. It is also grown in Slovenia, where it is called Šentlovrenka.

St-Macaire , town in the BORDEAUX region across the river GARONNE from Langon in the GRAVES district. It lends its name to Côtes de Bordeaux St-Macaire, an appellation of just 35 ha/86 acres for mostly sweet white wines from SÉMILLON and MUSCADELLE.

St-Mont , AOC in southern GASCONY dominated by the dynamic Plaimont CO-OPERATIVE which has worked hard to identify and revive INDIGENOUS varieties. The 1,200-ha/2,965-acre zone is effectively an extension of the MADIRAN area with much the same grape varieties planted, although yields are generally higher. Reds make up just under 60% of production, and rosé one-quarter, both based on TANNAT, with FER Servadou and Cabernet Sauvignon the usual blending partners. For whites, GROS MANSENG must make up at least 40% of the blend, with ARRUFIAC and PETIT COURBU the preferred other ingredients, thereby differentiating this wine from PACHERENC DU VIC-BILH and JURANÇON to the south. Quality is increasing with every vintage, as is the price differential between it and the local IGP Côtes de Gascogne. P.S.

St-Péray, a small appellation straddling the communes of St-Péray and Toulaud in the far south of the Northern RHÔNE dedicated to white wine made from MARSANNE and/or ROUSSANNE. It was best known for TRADITIONAL METHOD sparkling wines throughout the late 19th and 20th centuries, but now dry still wines are much more common. Comprising just 103 ha/255 acres of vines in 2020, the CRU is suited to white wines thanks to a large outcrop of LIMESTONE rising to nearly 400 m/1,312 ft. The other main soil type is GRANITE. Wines are full-bodied with fairly low acidity. M.C.W.

St-Pourçain, small appellation along the Sioule and Allier rivers in the greater LOIRE region in the cereal- and OAK-producing ALLIER *département* almost precisely in the centre of France. (See map under FRANCE.) It was an important site in Roman times, near RIVER transport and offering suitable HILLSIDE VINEYARDS. White St-Pourçain was one of the most respected wines in France in the Middle Ages (see LOIRE, history, and MEDIEVAL LITERATURE) but is today more of a cool-climate curiosity. Now its 600 ha/1,483 acres of vineyard on soils of CLAY, SAND, LIMESTONE, GRANITE, and GNEISS produce a range of wines, all typically dry, light in BODY, and relatively high in acidity.

The traditional vine variety was SACY, but today the whites must be 50–80% Chardonnay with Sacy the blending partner. Rosés must be GAMAY, which also makes up 40–75% of the region's light red, blended with PINOT NOIR. Sparkling wines are labelled Vin MOUSSEUX de Qualité. The CO-OPERATIVE in the town of St-Pourçain-sur-Sioule itself dominates production.

St-Romain, exquisitely pretty village perched on top of a cliff in the Côte de Beaune district of Burgundy producing red wines from Pinot Noir and white wines from Chardonnay. There are no PREMIERS CRUS in the appellation, which was granted only in 1947 and applies to just 135 ha/334 acres, of which two-thirds produce lively white wine.

The vineyards of St-Romain are situated behind those of AUXEY-DURESSES and at higher ELEVATION, 300–400 m/985–1,310 ft, than is usual in the Côte d'Or. In lesser vintages, the grapes do not ripen as well as elsewhere, but in warmer years the wines can be excellent value. St-Romain is also home to one of the region's best-known COOPERS, François Frères.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

St-Sardos, small wine region on the left bank of the GARONNE near Montauban in SOUTH WEST FRANCE dedicated to red and rosé wines. The main grape variety is Syrah, with some TANNAT and a little Merlot and Cabernet Franc.

St-Saturnin, one of the more exciting red wine CRUS in France's LANGUEDOC, named after the eponymous village. Like Montpeyroux, it falls within the TERRASSES DU LARZAC, in high, rugged country where little other than vines will grow. The St-Saturnin CO-OPERATIVE is particularly dynamic.

Saintsbury, Professor George (1845–1933). Though a distinguished man of letters in his day, Saintsbury is now principally remembered for *Notes on a Cellar-Book*, a seminal work on wine which was an immediate success and has run to many editions.

He was born in Southampton, where his father was superintendent of the docks. The family moved to London in 1850, and Saintsbury attended King's College School, where he acquired his deep love of literature. Aged 17 he won a Postmastership to Merton College, Oxford, but to his everlasting regret he failed to win a Fellowship. For ten years, from the age of 21, he was a schoolmaster, but eventually he settled in London and for a time was assistant editor of the *Saturday Review*.

The actual cellar book was a simple exercise book in which Saintsbury listed the contents of just two cellars, the first in his London house in West Kensington, the second in Edinburgh, where from 1895 to 1915 he held the Regius Chair of Rhetoric and English Literature at Edinburgh University.

In June 1915 he retired from the Chair in Edinburgh, having some ten years previously developed gout, which prevented him from drinking red wine. He eventually retired to Bath, where he published 13 volumes, including *Notes on a Cellar-Book*, which first appeared in July 1920, as well as innumerable articles and pamphlets.

A London DINING club, the Saintsbury Club, was founded in his honour in 1931; although nominated as president, the professor, due to ill health, never attended a meeting. The all-male membership, limited to 50, has always comprised men of letters, wine lovers both professional and amateur, and a good sprinkling of DOCTORS and lawyers. The Club meets in Vintners' Hall twice a year, ideally on his birthday 23 October and on his name day 23 April, St George's Day. He also inspired the name of a California winery, in CARNEROS. See also LITERATURE OF WINE. J.M.B.

Saintsbury, G., *Notes on a Cellar-Book* (16th edn, ed. T. Pinney, 2008).

St-Véran, appellation created in 1971 for white wines from the Chardonnay grape in southern Burgundy, between Mâconnais and Beaujolais, to include much of the wine once sold as Beaujolais Blanc. St-Véran encompasses seven communes: Davayé, Solutré-Pouilly, and Prissé on classic LIMESTONE soil adjacent to POUILLY-FUISSÉ and Châne, Chasselas, Leynes, and St-Vérand, where the sandy red soil of Beaujolais is mixed with limestone. In 2018, 743 ha/1,836 acres were declared under vine. The wines frequently have more body and ageing ability than a typical MÂCON-VILLAGES without rivalling the power and persistence of the wines of Pouilly-Fuissé, which forms an enclave within St-Véran. J.T.C.M.

salary, wine as. The practice of paying workers in wine is an old one (and certainly older than the payments in salt from which the word 'salary' is derived). In ancient PERSIA, for example, wine rations were strictly ordered and were often far in excess of any individual's possible personal consumption.

In the more recent past, but no longer, labourers, and in particular grape-pickers on the bigger BORDEAUX estates would have expected to receive some quantity of wine (rarely of great quality and often lowly PIQUETTE) in addition to wages.

The most notorious, and now outlawed, instance of paying workers with deliberately stupefying quantities of wine was the so-called *dop* system once prevalent in SOUTH AFRICA.

See also LABOUR.

Salice Salentino , DOC for robust red wine made mainly from NEGROAMARO grapes in PUGLIA in south-east Italy. The DOC Salice Salentino Bianco was created for Chardonnay-based whites, although the variety has no history nor much adaptability here. W.S.

salinity, the concentration of salts (mainly sodium chloride) in soils or irrigation water. Grapevines are relatively sensitive to salt injury. Salts in the rootzone affect grapevines in two ways: first, it is harder for the vines to extract water from the soil, and they may suffer from drought; and second, salts can be toxic at high concentrations in the vine's tissues. When vines are irrigated by sprinklers with water containing excessive salt, or are grown on excessively saline soils, leaves may be burnt, and in severe cases this leads to defoliation. Similar effects can occasionally be found in coastal vineyards affected by wind-borne salts. MERLOT vines are particularly susceptible. Saline soils are typically found in hot and dry climates where IRRIGATION has been introduced. For example, salinity is seen as a potential problem for the inland irrigated vineyards of Australia, along the Murray–Darling river systems, and also in PADTHAWAY. The problem is also found in southern France, where there are 10,000 ha/24,700 acres or more of vineyards planted on ancient marine deposits. Salinity in the soil may be monitored by measuring the electrical conductivity of the soil. Rootzone salinity can be overcome by applying slightly more irrigation water than the vines require, so as to leach the salts. Some vine varieties such as COLOMBARD are tolerant of salt, and there are ROOTSTOCKS such as Dog Ridge, Schwarzmann, 140 Ruggeri, and Ramsey which show salt tolerance through salt exclusion in the roots. Grape juice and hence wine may contain elevated sodium and

chloride concentrations. The EU limit on sodium and chloride in wine is 394 mg and 606 mg per litre. R.E.S. & R.E.W.

Nicholas, P., *Soil, Irrigation and Nutrition* (2004).

White, R. E., *Understanding Vineyard Soils* (2015).

salt can affect vines. See SALINITY and ROOTSTOCKS. Some, although relatively few, wines may taste slightly salty (see TASTING).

Salvagnin, light red blend of Pinot Noir and Gamay (possibly with some GAMARET and GARANOIR), the first appellation created in SWITZERLAND in 1960. It accounts for about half of all wine produced in the canton of Vaud.

Salvagnin (Noir), sometimes Savagnin Noir, is a Jura name for PINOT NOIR, disconcertingly similar to the name of one of the Jura's own vine varieties, SAVAGNIN BLANC.

Sämling 88, common AUSTRIAN synonym for the SCHEUREBE vine variety, of which 307 ha/759 acres were planted in the southern Austrian wine regions of Burgenland and Styria in 2021.

Samos . See GREECE.

sampling, important part of a continuum of wine quality-control procedures which begin in the vineyard and may end when consumers pick a bottle out of a CASE in their CELLAR.

A very small proportion of a vineyard's fruit may be sampled to assess its chemical composition to help predict the HARVEST date, as well as to indicate likely quality and eventual wine style. Grape sampling might simply consist of selecting some berries randomly

from the vineyard and expressing juice into a REFRACTOMETER to measure sugar content (see MUST WEIGHT; see also RIPENESS). A more rigorous approach may involve larger samples of either berries or bunches and more elaborate winery laboratory analysis. Even for a uniform vineyard site, berry composition (on a single vine or even within one bunch) will vary greatly due to different times of FRUIT SET and subsequent development. See RIPENESS.

Vineyard sampling has become far more focused since the turn of the century, thanks to PRECISION VITICULTURE and to research into GRAPE COMPOSITION AND WINE QUALITY. Both approaches make it much easier to keep together batches of fruit that have similar quality potential, sometimes referred to as streaming when the fruit is fermented together in large vats. However, some vineyards are harvested without a fruit sample being taken, particularly in more traditional regions where tasting the berries is considered sufficient to judge the time to pick.

Typically the sample is crushed or pressed in the winery to obtain juice, which is then analysed for sugar and typically also ACIDITY and PH. Some modern laboratories use spectrophotometry or near infrared spectroscopy (NIRS) to analyse the concentration of extractable ANTHOCYANINS and the total PHENOLIC compounds in the grapes. See also GRAPE QUALITY ASSESSMENT.

A second sampling is frequently made when a load of grapes is delivered to the winery, particularly if the grapes have been bought by contract, since grape PRICES are often based on grape composition, typically on sugar levels.

During FERMENTATION samples are taken at least daily to verify the regular conversion of sugars to ALCOHOL. Later, during ÉLEVAGE, regular sampling provides the winemaker with valuable guidance. Finally, shortly before BOTTLING, samples are taken for detailed analysis to ensure that the wine meets all regulations and is free of FAULTS and CONTAMINANTS.

An important part of selling wine EN PRIMEUR is the release of cask samples drawn from the containers in which the wine is still being matured, typically a BARREL, on which wine merchants and wine writers can base their assessments. Such raw wines, often roughly drawn off into small sample bottles, have not undergone STABILIZATION and can suffer OXIDATION and other faults after only a week or two. The best way to judge a young wine still in cask is sampling in the cellar or winery itself, from a range of different barrels. However, some producers, particularly in Burgundy, are concerned that repeated sampling from a barrel and subsequent TOPPING UP is not likely to benefit the wine. J.H. & R.E.S.

Samsó , Catalan name for CARIGNAN.

Samtrot, German synonym for Pinot Meunier. See MÜLLERREBE.

San Antonio , cool wine valley within the Aconcagua region of CHILE, close to the Pacific Ocean, excelling at white wines and reds of Pinot Noir and Syrah.

San Benito, small CALIFORNIA county 32 km/20 miles inland from MONTEREY Bay that has been continuously planted with grapes since 1849. Geologically distinguished by LIMESTONE-rich soils and fault-driven topography, the region hosted some of the state's earliest plantings of Pinot Noir in what is now the Cienega Valley AVA and, later, some of its most famous plantings of the grape on Mount Harlan AVA, site of the celebrated Calera winery. Wines from the county's two other sub-AVAs, Lime Kiln Valley and Paicines, are rarely seen.

Cienega Valley AVA

Frenchman Theophile Vache began planting vines in the Cienega Valley in 1849 and built a colonial-style adobe building in San Juan Batista that would become known as the Vache Wine Depot to sell his wares. His enterprise would not survive PROHIBITION, but the vines did. Now some of the oldest continuously producing plots in California are owned by the sole producer of note in the region, Eden Rift. The San Andreas fault bisects the AVA, its activity mixing the valley's intensely CALCAREOUS soils with deeper dolomitic and GRANITE-based sandy LOAMS.

Mount Harlan AVA

A one-man, one-vineyard, one-winery AVA established in 1974 by Pinot Noir pioneer Josh Jensen after assisting with the 1970 and 1971 harvests in BURGUNDY and coming away convinced of the virtues of limestone. He located a suitable concentration on Mount Harlan, where he proceeded to establish one of California's iconic wineries, named after the Spanish term for the old lime kiln on the property. Calera's ageworthy single-vineyard Pinot Noirs set a standard for what the grape could do in the late 1970s and early 1980s, when few believed the variety had a future in the state. Calera was sold to Duckhorn Wine Company in 2016. A.Y.

Sancerre, dramatically situated hilltop town on the left bank of the upper LOIRE which lends its name to one of the Loire's most famous wines: racy, pungent, dry white wines made from Sauvignon Blanc. The town's situation on such a navigable RIVER, and the favourable DRAINAGE and TOPOGRAPHY of the rolling countryside around it, assured Sancerre's long history as a wine producer; the suitability of the site for viticulture was obvious from Roman times. Pre-PHYLLOXERA, the region had been largely planted with Pinot Noir. Sancerre's piercing and distinctive Sauvignons, characterized by flavours of gooseberries and nettles, were initially introduced into the bistros of Paris as a sort of white-wine equivalent of BEAUJOLAIS, but, by the late 1970s and early 1980s, Sancerre was regarded as the quintessential white wine for restaurants around the world.

Sauvignon has adapted well to many of the varied TERROIRS around Sancerre, where, in 14 communes, vines are cultivated, particularly on the south-facing slopes of hills that average 200–400 m/655–1,310 ft in ELEVATION. There are three distinct soil types: Kimmeridgian MARL, known as *terres blanches*, found on the westernmost hills, particularly around the hamlets of Chavignol and Amigny, known for powerful, long-lived wines; pebbly LIMESTONE soils, known as *caillottes*, found throughout the appellation, said to

produce delicate wines; and FLINTY soils known as *silex* in the eastern part of the appellation, which yield long-living, particularly perfumed wines. Comparisons with POUILLY-FUMÉ, made just a few miles upstream on the opposite bank, are inevitable. The total area given over to the Sancerre appellation, which had declined to about 700 ha/1,730 acres in the 1960s, had reached 3,000 ha/7,413 acres by 2019.

The climate here is distinctly CONTINENTAL, and the vineyards are easily subject to spring FROSTS, but the river to the east and the forests to the west moderate low temperatures. Vines are generally CORDON or single GUYOT trained.

Sancerre's popularity has brought with it the inevitable increase in the proportion of mediocre wine produced (or over-produced) within the zone. In particularly cool years, even the best producers must work hard to avoid excessive VIGOUR, resulting in unpleasantly HERBACEOUS aromas and a lack of fruity substance, but techniques such as grassing, de-budding, and leaf plucking result in healthier grapes and more concentrated wines. TRUNK DISEASES such as ESCA have been a constant presence since 2010, with a 5% loss each year typical in many vineyards.

Many Sancerre *blancs* are ready for drinking almost as soon as they are bottled, but the best certainly keep. Vintages such as 1996, 2002, and 2008 are prized for their flavours of white truffle that emerge with age, and both 2014 and 2017 have produced wines worthy of laying down.

Historically, producers featured the names of villages such as Chavignol more prominently on labels than the appellation itself. And today there is an increasing drive to express the distinctive terroirs found in the appellation. Many growers make SINGLE-VINEYARD WINES such as Les Monts Damnés in Chavignol and Le Chêne Marchand in Bué, with particularly good examples coming from producers such as François Cotat and Vincent Pinard. While there is no official hierarchy, these vineyards command consistently higher prices and offer greater COMPLEXITY and AGEING potential than traditional Sancerre. As in

Pouilly-Fumé, some have mastered the art of matching Sauvignon with OAK, which can bring complexity and STRUCTURE to the wines.

Sancerre also exists in light, often beguiling, red and rosé versions, made from Pinot Noir grapes and representing approximately 10% and 6% of total production respectively. These wines enjoy a certain following, mainly in France, but need low YIELDS, very high standards of winemaking, and good weather to imbue them with a good core of fruit. CLIMATE CHANGE is helping, and the reds are becoming far more interesting.

The region is also famous for its goat's-milk cheese, Crottin de Chavignol, which, unsurprisingly, is an excellent match for the region's wines.

Friedrich, J., *Earthly Delights from the Garden of France, Wines of the Loire*, Vol 1: *The Kingdom of Sauvignon Blanc* (2011).

sand, description of sediment or soil which is made up of relatively large particles (bigger than SILT and much bigger than CLAY). See SOIL TEXTURE and GEOLOGY for more details of this particular form of soil classification. Sandy soils can be difficult to cultivate because of their poor ability to store water and nutrients, but they are notable in viticulture for providing a good measure of protection from PHYLLOXERA. Vineyards dominated by sand include those of COLARES in Portugal, the Camargue in the south of France, the Great Plain of HUNGARY, and Maipo Valley in CHILE.

San Diego County , warm area south of Los Angeles, CALIFORNIA, where wine grapes were first planted in 1769 by Franciscan MISSIONARIES. Today most of its vineyards are contained within the South Coast AVA. In 2021, 160 wineries were active, including a number of URBAN WINERIES. Cabernet Sauvignon, Syrah, and Sangiovese dominate the region's 276 ha/682 acres of vines. M.D.K.

sandstone, a sedimentary rock composed of SAND-size particles, most commonly QUARTZ. The grains are held together by natural cement formed by chemical precipitation in the pores. Typically this consists of silica but may be another material such as calcium carbonate, forming a CALCAREOUS sandstone. Most sandstone soils are poorly fertile, slightly acid, and well drained; famously, they offer some resistance to PHYLLOXERA. Sandstone soils are widespread: examples are the Courthézon area of CHÂTEAUNEUF-DU-PAPE, Ballard Canyon (SANTA BARBARA) and the Great Plain of HUNGARY. A.J.M.

San Francisco Bay , commercially expedient, geographically extensive AVA that includes CONTRA COSTA COUNTY, Lamorinda, SANTA CLARA VALLEY, and the much larger LIVERMORE VALLEY. The Bay Area is also home to many an URBAN WINERY, which source grapes from throughout the state.

Sangiovese, qualitatively variable red grape variety that is Italy's most planted wine vine and is particularly common in central Italy. In 1990 almost 10% of all Italian vineyards, or more than 100,000 ha/247,000 acres, were planted with some form of Sangiovese, although this had fallen to 68,428 ha/169,089 acres by 2015. In its various CLONAL variations and names (Brunello, Prugnolo Gentile, Morellino, NIELLUCCIU), Sangiovese is the principal vine variety for fine red wine in TUSCANY, the sole grape permitted for BRUNELLO DI MONTALCINO, and the base of the blend for CHIANTI, VINO NOBILE DI MONTEPULCIANO, and the vast majority of SUPERTUSCANS. It is, in addition, the workhorse red grape of all of central Italy, widely planted in UMBRIA (where it gives its best results in the wines of TORGIANO and Montefalco), in the MARCHE (where it is an important component of Rosso Piceno), and in LAZIO. Sangiovese can be found as far afield as Lombardy and Valpolicella to the north and Campania to the south.

Sangiovese is widely thought to be of ancient origin, as the literal translation of its name ('blood of Jove') suggests, and it has been postulated that it was even known to the ETRUSCANS, although its origins are still debatable.

In 2004 researchers Vouillamoz and Grando at SAN MICHELE ALL'ADIGE proposed the following parents of Sangiovese: the Tuscan 'cherry grape' CILIEGIOLO and Calabrese di Montenuovo, an obscure variety found in Campania though probably originating from Calabria. In 2012 Ciliegiolo and Negrodolce, an old and obscure Puglian variety, were suggested as putative parents of Sangiovese. These two parentages were recently invalidated using another type of DNA marker, showing that Ciliegiolo is in fact the progeny of Sangiovese and Muscat Rouge de Madère (or Moscato Violetto) and that Negrodolce and Calabrese di Montenuovo are also progenies of Sangiovese, whose parents remain unknown. Additional progenies of Sangiovese were also discovered, including numerous varieties from southern Italy such as FRAPPATO, SUSUMANIELLO, GAGLIOPPO, NERELLO MASCALESE, and PERRICONE, showing Sangiovese's significant historical importance in the south. In 1590 Giovanvettorio Soderini mentioned the variety Sangiogheto. This is commonly accepted as the first historical mention of Sangiovese, but there is no evidence that Sangiogheto actually was Sangiovese. Indeed, when Soderini writes about the ways to make a very good wine, he cautions readers to 'beware of the Sangiogheto, who thinks to make wine from it will make vinegar'. This is confirmed in 1738 by Cosimo Trinci, who observed that wines made solely from Sangiovese were somewhat hard and acid, though they were excellent when blended with other varieties, a judgement echoed by Giovanni Cosimo Villifranchi in 1883 Bettino RICASOLI found a way to tame Sangiovese's asperity—a substantial addition of sweetening and softening CANAIOLO—which became the basis of all modern Chianti and of Vino Nobile di Montepulciano (although Ciliegiolo, MAMMOLO, and COLORINO as well as the white grapes Malvasia and, especially, Trebbiano were subsequently added to the authorized blend). The use of small oak

barrels, begun in the 1970s, may have softened Sangiovese's tannins but was primarily a response to changing FASHIONS.

Conventional ampelographical descriptions of Sangiovese, based on the pioneering work of G. Molon in 1906, divide the variety into two families: the Sangiovese Grosso, to which Brunello, Prugnolo Gentile, and the Sangiovese di Lamole (of Greve in Chianti) belong, and the Sangiovese Piccolo of other zones of Tuscany, with the implicit identification of a superior quality in the former. Current thinking is that this classification is too simplistic, that there is a large number of clones populating the region's vineyards, and that no specific qualitative judgements can be based on the size of either the berries or the bunches. Significant efforts are at last being made to identify and propagate superior clones; MASS SELECTION in the past sought principally to identify high-yielding clones without any regard for wine quality. The variety adapts well to a wide variety of soils, although the presence of LIMESTONE seems to exalt the elegant and forceful aromas that are perhaps the most attractive quality of the grape.

Sangiovese's principal characteristic in the vineyard is its slow and late ripening—harvests traditionally began after 29 September and even today can easily be protracted until or even beyond mid October—which gives rich, alcoholic, and long-lived wine in hot years and creates problems of high ACIDITY and hard TANNINS in cool years. Over-production tends to accentuate the wine's acidity and lighten its colour, which can OXIDIZE and start to brown at a relatively young age. The grape's rather thin skin creates a certain susceptibility to ROT in cool and damp years, which is a serious disadvantage in a region where rain in October is a frequent occurrence. In the past, Sangiovese was planted with scant attention to ASPECT and ELEVATION in Tuscany, where the vine is often cultivated at up to or even above 500 m/1,640 ft. A good part of late 20th century vinicultural research in Tuscany—which has involved increased VINE DENSITY, lower YIELDS per vine, better clones, more appropriate ROOTSTOCKS, lower vine-TRAINING SYSTEMS, more suitable supplementary varieties for blending,

different temperatures and lengths of FERMENTATION, variations in the use of OAK—was dedicated to putting more meat on Sangiovese's bones as well as increasing its international appeal.

Throughout modern Tuscany, Sangiovese has often been blended with a certain proportion of the Bordeaux grape CABERNET SAUVIGNON, whether for Chianti (up to 15% of the total) or Chianti Classico (up to 20%) or a highly priced VINO DA TAVOLA. Even in this commercially successful blend, sanctioned by the DOC authorities in CARMIGNANO, Cabernet can overwhelm the Sangiovese.

In UMBRIA, the variety dominates most of the region's best red wine, as in the Torgiano of the producer Lungarotti. In terms of quantity, Sangiovese is more important in Romagna but is also increasingly significant in terms of quality, as explained in ROMAGNA SANGIOVESE. Two of the best clones currently being used to repopulate Tuscan vineyards, R24 and T19, are from Romagna. Some Sangiovese is grown in the south of Italy, where it is usually used for blending with local grapes, and the success of Supertuscans has inevitably led to a certain amount of experimentation with the variety to the north of Tuscany too.

Outside Italy

Like other Italian grape varieties, particularly red ones, Sangiovese was taken west, to both North and South America, by Italian emigrants. In South America it is best known in Argentina, where there were 1,390 ha/3,435 acres in 2020, mainly in Mendoza province, producing wine that few Tuscan tasters would recognize as Sangiovese.

In California, however, international recognition for the quality of Supertuscans brought a sudden increase in Sangiovese's popularity in the late 1980s and 1990s. By 2003 the area had increased to more than 1,200 ha/3,000 acres, but this had fallen to 587 ha/1,451 acres by 2020, perhaps partly because California Sangiovese, typically more FRUIT-DRIVEN than the prototype, failed to establish a strong identity. ANTINORI, unsurprisingly, persists with the variety at their Antica winery on Atlas Peak above the Napa Valley.

The grape also seems to be losing favour in Washington State where plantings had fallen to below 54 ha/134 acres by 2017. In Australia, however, it has the allure of being classified an ALTERNATIVE VARIETY, and total area was 433 ha/1,070 acres by 2022 even if renditions varied considerably in style and quality. It is a minor feature in South Africa and Chile.

Sangiovese di Romagna. See ROMAGNA SANGIOVESE.

sangría, a mixture of red wine, lemonade, sugar, and, sometimes, spirits and fresh fruit, served with particular gusto in Spain's tourist resorts. In 2014 the EU ruled that bottled beverages using the name should be restricted to the produce of Spain and Portugal.

sanitation. See HYGIENE.

San Joaquin Valley, southern half of the vast Central Valley in CALIFORNIA, stretching almost 354 km/220 miles from Stockton to Bakersfield. With 61,000 ha/151,000 acres under vine, it produces 50% of the state's total wine grapes, much going to BULK WINE. It includes the AVAs Madera, Salado Creek, Tracy Hills, River Junction, Diablo Hills, and LODI.

San Juan , wine-producing province in ARGENTINA especially celebrated for Syrah.

Sanlúcar de Barrameda , one of the three main Spanish towns in which SHERRY is made and matured. MANZANILLA is a delicate, pale, dry sherry matured in Sanlúcar.

San Luis Obispo , wine-producing county in the CENTRAL COAST AVA of CALIFORNIA midway between Los Angeles and San Francisco, best understood in terms of its AVAs rather than as a larger whole thanks to stark contrasts among its MESOCLIMATES. Unrelenting summer sun beats down on the high, sheltered plain that is the PASO ROBLES AVA, while only 20 miles/32 km west fogs hang over the narrow, cool coastal shelf of the SLO Coast AVA, which encompasses the AVAs of Edna Valley and Arroyo Grande Valley.

San Luis Obispo (SLO) Coast AVA

Approved in 2022, this 97-km/60-mile-long, 15-mile-wide, 408,585-acre AVA carves out a slice of the county's coast from the redwood forests of Big Sur south to the border with SANTA BARBARA. Its 50 resident wineries grow more than 1,619 ha/4,000 acres of primarily PINOT NOIR and CHARDONNAY, mostly planted within 10 km/6 miles of the ocean, some of which are the coldest vineyard sites in the state.

Edna Valley AVA

Directly south of the coastal town of San Luis Obispo, Edna Valley won quick fame for its Chardonnays, beginning in the mid 1970s. Edna Valley Vineyards, now part of E. & J. GALLO, was the pioneer, and the principal wine company is Niven Family Wine Estates (the Nivens founded Edna Valley Vineyards), producer of Baileyana, Tangent, Zocker, and other labels. The AVA also claims Alban Vineyards, established in 1989 by RHÔNE RANGER John Alban, whose finest Syrahs, Grenaches, and Viogniers are the region's most expensive and are sold strictly via mailing list. Low hills on three sides give the small valley a soup-tureen shape, allowing it to collect moisture-laden air from the Pacific, making FUNGAL DISEASES a frequent threat despite low rainfall. Cool, even temperatures and fog cover result in a very long growing season, often 50% longer than Burgundy. Soils are largely marine SHALES and SAND mixed with richer LOAMS. Planted acreage stood at 1,077 ha/2,661 acres in 2018 but has fallen since as more profitable citrus groves replace vineyards.

Arroyo Grande Valley AVA

A long range of hills sloping towards Pismo Beach at the southern edge of San Luis Obispo County, Arroyo Grande was viticulturally distinguished in the 1980s only by the painstaking decision to plant 350 ha/865 acres of it for Maison Deutz, the California arm of Champagne house Deutz. It was later sold, morphing into Laetitia winery. With 838 acres under vine in 2018, the region continues to produce high-quality CHARDONNAY and PINOT NOIR for Laetitia as well as labels such as Talley Vineyards and Au Bon Climat. While best known for its cool coastal plantings, the sunnier inland hills behind Lake Lopez host 140-year-old ZINFANDEL vines, bottled by Saucelito Canyon, as well as more recent plantings of SYRAH and CABERNET SAUVIGNON.

www.slocoastwine.com

San Marino , tiny republic within Italy between EMILIA-ROMAGNA and the MARCHE. Its elusive wines, from 120 ha/296 acres of vineyards, are based on SANGIOVESE for its red, Ribolla di San Marino (which is in fact Umbria's GRECHETTO) and Biancale for its whites.

www.consorziovinisanmarino.com

San Michele all'Adige, Istituto Agrario di, or strictly, since being renamed in 2008, the Edmund Mach Foundation, one of Italy's best-known viti-agricultural schools and centres of ACADEME. It was founded in 1874 in what was then the Austrian South Tyrol and is now the province of Trento in the far north of the country. Its aim is to promote cultural and socioeconomic growth in the agricultural

sector and to develop SUSTAINABLE forestry and agriculture. Its first director Edmund Mach set up the institute to include an experimental station and a farm alongside the school. Today a wide range of agricultural and viticultural training and research is undertaken, including the genomics of INDIGENOUS VARIETIES in collaboration with international research institutes, and oenological concerns include the analysis of flavour and PHENOLICS, microbiology, and sensory analysis (see TASTING). The institute hosts the most important AMPELOGRAPHIC collection in Italy, with varieties from Italy and all over the world, and it produces a range of wines under the San Michele all'Adige label.

Santa Barbara , southern CALIFORNIA city and county which gives its name to the southernmost in a string of three heavily planted wine counties on California's CENTRAL COAST (see also MONTEREY and SAN LUIS OBISPO). Though just 160 km/100 miles from Los Angeles, it is home to some of the coolest wine appellations in the state, as the county's northern valleys open directly on to the Pacific Ocean due to the Transverse Ranges that run east to west. The small but cosmopolitan city enjoys a dreamy, dry climate and is awash in Spanish Colonial architecture. Missionaries first planted vines in the late 1700s (see CALIFORNIA, history), and vineyards were common until PROHIBITION. Just offshore, Santa Cruz Island was one of the largest commercial vineyards in California at the turn of the 20th century. Modern commercial winemaking dates back to 1964, with an initial emphasis on CHARDONNAY in the Santa Maria Valley. The planting of Sanford & Benedict Vineyard in 1971 proved that PINOT NOIR could grow in the western reaches of the Santa Ynez Valley, located north of the mountains that frame Santa Barbara's beaches. By 2021 there were more than 6,070 ha/15,000 acres of vines planted. As Chardonnay and Pinot Noir became the region's prized varieties, the latter fueled by the award-winning film SIDEWAYS, winegrowers also created a series of appellations to explore the varying Santa Ynez Valley's many MESOCLIMATES, in which more than 40 grape varieties are grown. From the cooler west to the warmer east, they are the

Sta. Rita Hills (focused primarily on BURGUNDY varieties, Ballard Canyon (RHÔNE varieties), Los Olivos District (a mix), and Happy Canyon of Santa Barbara (BORDEAUX varieties). Between the Santa Maria and Santa Ynez valleys near the town of Los Alamos is the Alisos Canyon AVA, created in 2020.

Santa Maria Valley AVA

Located just south of San Luis Obispo County, the west-to-east–oriented Santa Maria Valley opens wide on to the Pacific Ocean, which contributes morning fog and afternoon breezes. Vineyards grow on the flat parts of the floodplain, which is also home to extensive strawberry, broccoli, and other row crops, as well as along the BENCHES and up into the canyons on the north and south sides of the valley. Commercial viticulture started in 1964, with Chardonnay grown mostly for the North Coast, but local winemakers such as Jim CLENDENEN of Au Bon Climat were successful with Chardonnay and Pinot Noir by the mid 1980s. Cool-climate Syrah is also a star, thanks to Qupé, founded in 1982 by Bob Lindquist. Though about 3,000 acres are planted, only a handful of wineries operate in the appellation, including Cambria (owned by KENDALL-JACKSON), Foxen, Presqu'ile, and Rancho Sisquoc, which released its first wines in 1972. That same year, the Miller family planted Bien Nacido Vineyard, whose nearly 1,000 acres of premium grapes are sold to wineries around the country. The GALLO family owns part of the historic Sierra Madre Vineyard (planted 1971) as well as the newer Rancho Real. Most of the region's grapes are sold to wineries in the greater Santa Barbara area or much further away.

Santa Ynez Valley and sub-AVAs

Due to the east–west orientation of the Transverse Range, the Santa Ynez Valley, which was granted AVA status in 1983, is one of the only valleys on the west coast to open directly on to the Pacific Ocean. That guarantees extremely MARITIME conditions of thick fog and persistent wind on the valley's western side, with much warmer and drier daytime conditions towards the east. The valley's TOPOGRAPHY is also tumultuous, with mountains to the south and east as well as a mix of hills, canyons, and ALLUVIAL fans elsewhere. As such, a diverse range of grape varieties achieve ripeness here, and a series of sub-AVAs have been developed since the early 2000s to explore those MESOCLIMATES.

On the western side, the STA. RITA HILLS AVA is dominated by Chardonnay and Pinot Noir, with growing amounts of Rhône varieties. To the east, the Ballard Canyon AVA (223 ha/550 acres planted) runs between Solvang, Buellton, and Los Olivos and is believed to be the first US appellation dedicated to Rhône varieties; a bottle designed specifically for Syrah, which makes up more than half its plantings, may be used for ESTATE WINES. Further east is Los Olivos District AVA (2016), which covers an alluvial fan that runs from Figueroa Mountain down to the Santa Ynez River and is planted in many varieties. Furthest east is Happy Canyon of Santa Barbara (2009), where warmer weather and VOLCANIC soils shift the focus to Bordeaux varieties. The seventh AVA, Alisos Canyon, is slightly north of Santa Ynez Valley proper and home to primarily Rhône varieties. M.D.K.

sbcountywines.com

Santa Clara Valley, California wine region and AVA south of San Francisco. Its colloquial name, Silicon Valley, derives from its status in the computer high-tech industry. Despite a long vinous history,

factories, shopping malls, and homes began to supplant most of its vineyards in the 1950s. By the 1970s the transformation was nearly complete, and the final chapters were being written for once-important winery names such as Almadén and Paul Masson. Mirassou remains today but is now owned by E. & J. GALLO, the wines sourced from throughout California and its vineyards in the Salinas Valley in MONTEREY. A few acres of Santa Clara vines persist to the west in the SANTA CRUZ MOUNTAINS and at its southern end in the Hecker Pass district, but the area's luxury homes for computer programmers make all these vineyards more of a toy than a viable agricultural investment. Twenty small wineries exist, largely for the benefit of TOURISTS. The embedded San Ysidro District AVA east of Gilroy is a single grower, owned by a New York winery. L.M. & A.Y.

Santa Cruz Mountains, diverse 141,700-ha/350,000-acre CALIFORNIA wine region and AVA immediately south of San Francisco explicitly carved out of and separate from the SAN FRANCISCO BAY and CENTRAL COAST AVAs which would otherwise seem to enclose it. This region covers the hillsides and ridgetops of the Coast Range from Highway 92 in San Mateo County in the north down to the town of Interlaken in the south. One of the few AVAs in California defined by ELEVATION rather than watersheds or political boundaries, its western edges begin in the fog-laden foothills facing the Pacific at 122 m/400 ft in elevation, the eastern edges at 240 m, and it rises to nearly 1,000 m/3,280 ft. These mountains are geologically the youngest in the state, having been formed a mere million years ago by tectonic forces still at work along the San Andreas Fault, which runs the length of the region. The crenellated, steep, heavily forested slopes and ridges offer a dizzying array of ASPECTS, MESOCLIMATES, and sedimentary soil types, to the point of preventing generalizations about the region. That said, it is among the coolest of California wine regions, though a warmer pocket on the south-eastern flanks of the mountains, as well as the inland edge of its uppermost summit ridge

can ripen BORDEAUX varieties, as RIDGE VINEYARDS has so ably proved with its Monte Bello CABERNET SAUVIGNON.

While Cabernet may be responsible for the region's greatest fame, PINOT NOIR and CHARDONNAY have a longer and arguably more storied history in the region, thanks to BURGUNDIAN émigré Paul Masson, who arrived in 1901 and quickly built a reputation for still and sparkling wines. Masson's protégé, Martin Ray would go on to make some of California's first VARIETAL bottlings of Pinot and Chardonnay, paving the way for later winemaking luminaries such as David Bruce as well as Richard Graf and Merry Edwards at Mount Eden Vineyards (the current name of Masson's original estate). Started in the counterculture woods behind UC Santa Cruz, Bonny Doon and its RHÔNE RANGER founder Randall GRAHM brought more attention to the region in the 1990s, despite sourcing grapes primarily from the CENTRAL COAST. Producers such as Kathryn Kennedy, Bargetto, Storrs, and Thomas Fogarty have joined Ridge, Bruce, and Mount Eden in producing consistently high-quality wines over the years. North Coast producers are increasingly sourcing grapes from the region, albeit in limited quantities. Plantings in the AVA amount to a mere 618 ha/1,526 acres in 2021, with most vineyards 5–25 ha/2–10 acres in size, spread among hundreds of independent growers. The region also has one sub-AVA, the granitic ridge of the Ben Lomond Mountain AVA, which sits north-west of the town of Santa Cruz but rarely appears on labels. Though unofficial, producers often refer to several 'neighbourhoods' of this diverse AVA, including the coolest and most southerly Corralitos, the northernmost Skyline area, the Heart of the Mountains and Summit areas on the ridgeline of the AVA, and the warmer, easterly Saratoga region, sometimes known as Over the Hill.

Santa Lucia Highlands, California wine region and AVA. See MONTEREY.

Santa Maddalena, known as St Magdalener by the many German speakers who make and drink it, was historically the most famous wine of ALTO ADIGE in north-east Italy. (In an Italian government classification of 1941, it was for political purposes ranked after Barolo and Barbaresco as the country's most significant wine, a rating which would be unlikely to be repeated today.) An official subzone, and therefore suffix, of the enormous Alto Adige DOC, it takes its name from the hill of Santa Maddalena north-east of the city of Bolzano (Bozen), long considered particularly suitable for the cultivation of the SCHIAVA (Vernatsch) grape from which the wine is made. Since the late 20th century this light red wine has become so unfashionable that its total vineyard area has shrunk from 456 ha in 1978 to 200 ha/494 acres in 2019, with an average yield of 76.2 hl/ha—much lower than the near 90 hl/ha allowed by law. The production regulations decree a minimum 85% Schiava; about 5% LAGREIN is routinely blended in to deepen its pale colour.

Like other Italian DOCs, when Santa Maddalena sold well its production zone was significantly enlarged from the original nucleus (now called Santa Maddalena CLASSICO) of the communes of Santa Maddalena, Retsch, Justina, Leitach, and St Peter. The zone now stretches to Settequerce (Siebeneich) in the Val d'Adige to the west and to Cornedo (Karneid) in the Val d'Isarco to the east. These latter zones give Schiava of good quality but with less personality than that of Santa Maddalena; fortunately over 85% of current production of Santa Maddalena is Santa Maddalena Classico. The subzone Bozener Leiten partially overlaps with Santa Maddalena but is rarely seen on labels. W.S.

Santa Maria Valley, California wine region and AVA. See SANTA BARBARA.

Sta. Rita Hills In 1971 Richard Sanford and Michael Benedict turned a former bean farm on the western side of the SANTA YNEZ VALLEY into the Sanford & Benedict Vineyard, proving that PINOT NOIR could thrive in this foggy, windswept region that extends from Lompoc to Buellton. Dozens of vineyards followed, prompting the creation of the Santa Rita Hills AVA in 2001. (The name was later abbreviated per an agreement with Viña Santa Rita in CHILE.) In 2021 about 60 vineyards grow 2,700 acres of mostly Pinot Noir and Chardonnay, with increasing interest in Rhône varieties and other cool-climate grapes. M.D.K.

Santa Ynez Valley, California wine region and AVA. See SANTA BARBARA.

Santenay , somewhat forgotten village and spa in the Côte de Beaune district of Burgundy producing red wines from Pinot Noir and occasional whites. The soils in Santenay are a little richer in MARL than most of the Côte d'Or, producing red wines tending to the rustic. This is largely the fault of a poor selection of Pinot Noir vines whose vigour can fortunately be tamed by the CORDON DE ROYAT training system in place of the usual GUYOT.

Most of the best vineyards—the PREMIERS CRUS La Comme, Clos de Tavannes, and Les Gravières—form an extension from Chassagne-Montrachet. Also reputed are La Maladière, situated behind the main village, and Clos Rousseau on the far border of Santenay, beyond the casino and thermal waters of the higher village.

Santorini, Cycladic island known in classical times as Thíra, and the most famous wine region in GREECE.

History

The island is a part of the core of an ancient volcano, which erupted *c.*1640–1620 BCE (perhaps a century earlier), destroying the Minoan civilizations of Thíra and, it is thought, neighbouring Crete. A large part of Thíra became submerged and has remained so to this day.

In antiquity the island was not especially famous for its wine, but this was to change in the Middle Ages. It belonged to the Byzantine empire until the Crusaders sacked Constantinople in 1203–4 and Santorini was given to one of the Venetian conquerors, remaining in his family until 1336. It then became part of the duchy of Naxos, but VENICE retained a strong influence; 1479–89 was another period of direct Venetian rule. It was Venetian enterprise that made Santorini an important wine producer. The wine it exported was made from a mixture of grape varieties, chiefly the white ATHIRI and red MANDILARIA, and it was prized for its sweetness and high alcohol which enabled it to withstand the six-month sea voyage, via Venice, to western Europe. Santorini was conquered by the Ottoman Turks in 1579, but the Turks did not discourage the production of the only cash crop that the island's volcanic soil could sustain.

Loanwords from Italian still in use in Santorini today testify to Venice's importance in its winemaking past. For example, the local dialect word for the vintage is *vendemma* from Italian *vendemmia.*

See GREECE. H.M.W.

Santorini today Modern times have been equally kind to the wines of Santorini. Since at least 2005, Santorini has been the champion of modern Greek wine, at least in terms of visibility, media coverage, and prices commanded, with several producers enjoying superstar status, even in export markets. The fact that Santorini is one of the most beautiful islands in the Mediterranean, with millions of tourists every year, helped popularity but condemned long-term viability via ever increasing real-estate prices.

Santorini is one of the most surreal TERROIRS for viticulture. The WINDS are extreme and the land largely devoid of trees, offering little respite from the fierce gales, so in most places vines have to be trained in a low basket shape (*koloura* or *kladeftiko;* see TRAINING SYSTEMS) for protection. Recent trials with conventional TRELLIS SYSTEMS in some sheltered areas have been successful but highly controversial in the eyes of traditionalists. The island is very sunny and arid, with only morning fog to sustain any form of agriculture. The soils are VOLCANIC and not just free of PHYLLOXERA but immune to it. As a result, vines are UNGRAFTED, that portion below ground being up to 400 years old. YIELDS are seldom more than 15 hl/ha (0.8 tons/acre), which means that Santorini wine may eventually become a thing of the past.

The PDO Santorini allows for dry wines as well as sweet wines made from sun-dried grapes, all based on ASSYRTIKO, with smaller amounts of ATHIRI and AÏDANI. The dry wines are, more often than not, pure Assyrtiko and generally present an outstanding combination of MINERALITY, high alcohol, and high acidity, often resulting in PH levels below 3. Those vinified entirely in stainless steel can be fiercely austere. Nykteri versions, dry but harvested late into the growing season and traditionally at night (*nykta* in Greek), are richer, at least 13.5% alcohol and aged for at least three months in oak barrels. The traditional Nykteri style is for wines made with a short SKIN CONTACT and aged in partly filled old oak casks to initiate deliberate OXIDATION. As strong as 16% alcohol, these are not for the faint-hearted but are some of the world's most impressive and individual white wines, capable of long AGEING.

The Santorini PDO also includes sweet wines called Vinsanto, a term wrongly assumed to be a loanword from the Italian VIN SANTO. However, 'Visanto', the Vino of Santorini, was exported, mainly for religious purposes, to Russia well before Italians initiated the style. Vinsanto is made from sun-dried grapes, mainly Assyrtiko (at least 51%), and oak-aged for several years if not decades. The wines are intensely sweet, with as much as 300 g/l RESIDUAL SUGAR, but are

balanced by high acidity, and the best can age for a century or longer.

A small percentage of Santorini's vineyards are planted to red grapes, once popular for use in sweet wines. The MAVROTRAGANO variety is the most esteemed, today used to produce deeply coloured, TANNIC dry reds. The most common is MANDILARIA, used primarily in sun-dried sweet wines. No red wines are (yet) included in the appellation framework. K.L.

Saperavi, ancient and distinctive south-west GEORGIAN grape variety notable for its deep COLOUR (Saperavi means 'dye'), its ACIDITY, firm TANNINS, full BODY, and dark fruit. It is Georgia's signature and most planted red wine grape, representing more than 90% of the vineyard area dedicated to red grapes in Kakheti. As a VARIETAL wine, it is capable, not to say demanding, of long AGEING and finds its finest expression in PDO wines such as Mukuzani, Napareuli, and Kindzmarauli. Its strong personality also makes it very useful in blends. The flesh of this dark-skinned grape is deep pink, and it produces wines that command attention if not always devotion. It ripens late, is relatively productive, and is quite well adapted to cold winters, but not so well that the Russian Potapenko viticultural research institute has been discouraged from producing a Saperavi Severny, a hybrid of SEVERNY and Saperavi which was released in 1947 and incorporates not just Saperavi's VITIS VINIFERA genes but also those of the cold-hardy VITIS *amurensis*.

Traditional Saperavi is planted throughout almost all of the wine regions of the former Soviet republics. It is an important variety in RUSSIA, UKRAINE, MOLDOVA, BULGARIA, ARMENIA, and AZERBAIJAN, as well as in its native GEORGIA, although in cooler areas the acidity may be too marked for any purpose other than blending, despite its relatively high sugar levels. It was also used extensively for VINE BREEDING at MAGARACH, the Crimean wine research centre.

Sardinia, Sardegna in Italian, is an island in the middle of the Mediterranean with a history of winegrowing dating back at least 3,000 years according to archaeologists from the University of Caligari, who discovered 15,000 wine-grape seeds at Sa Osa, near Oristano. Because of its strategic geographical position, Sardinia had been ruled by Phoenicians, Carthaginians, Romans, Arabs, Aragon, Genovese, and Pisans before becoming an integral part of ITALY in 1726, when it was ceded to the House of Savoy. Each of these groups left a mark on the island's history, culture, and language as well as its wine industry, which, by the end of the 1900s, boasted 80,000 ha/197,684 acres of vines.

History

In the last 200 years, Sardinia's wine economy has had its ups and downs: PHYLLOXERA arrived in 1883 to decimate the vineyards; they did not recover until after the Second World War, when low-yielding BUSH VINES were widely replaced with high-yielding TENDONE and wire-trained vineyards aided by lavish subsidies from both Rome and the regional government. However, as the subsidies dried up, so did interest in grape-growing. By 2010 only 19,000 ha/47,000 acres remained.

Since then a new generation has taken up winemaking, their efforts boosted by the growing interest in oeno-TOURISM. By 2020 vines covered 27,217 ha/67,255 acres, and wine grew from just 6% to 17% of the agricultural economy, much of which is dedicated to the grazing of animals—sheep in particular—for milk, cheese, and meat.

The focus has moved from quantity to quality as well: in 2020 Sardinia produced 630,000 hl/16,642,839 gal of wine, only a small percentage of which was basic BULK WINE.

Vine varieties

Five grapes represent 70% of the surface under vine: VERMENTINO, Cannonau (GARNACHA), MONICA, NURAGUS, and Carignano (CARIGNAN, also called Bovale Grande in Sardinia). The red variety GRACIANO is also a rising star. It goes by several names here, such as Bovale Sardo, Bovaleddu, and Muristellu, or, in the village of Usini in the north-west, Cagnulari. For whites, there is Semidano, an INDIGENOUS VARIETY that thrives in the VOLCANIC soil of Mogoro in the province of Oristano; TORBATO, which Sella e Mosca has been instrumental in reviving; and Granazza (or Granatza), grown in the village of Mamoiada in the north-east of the island.

Geography and climate

With an area of 24,106 sq km/9,305 sq miles, Sardinia is the second largest island in the Mediterranean. Overall, the climate is hot and dry, with most rain falling in the winter months, although differences in LATITUDE, ELEVATION, and proximity to the sea result in a diversity of MESOCLIMATES. The island boasts one DOCG, 17 DOCs and 15 IGPs.

The DOC production areas of the most popular varieties, Cannonau, Vermentino, Monica, and Moscato (MUSCAT), have been extended to include the entire surface of the island. Three smaller subzones have been created for Cannonau: Capo Ferrato, Oliena, and Jerzu (the smallest). Cannonau CLASSICO must come from the provinces of Nuoro and Ogliastra and be at least 95% Cannonau, compared to 85% in the other subzones.

Vermentino, the island's signature white wine grape, claims Sardinia's only DOCG, Vermentino di Gallura, located in the north of the island. SUPERIORE limits yields to 9 tonnes/ha in contrast to 10 tonnes/ha for the basic DOCG. While most Vermentino wines are picked on the early side to retain refreshing acidity, a rich LATE HARVEST style known as Vendemmia Tardiva has been popularized by producers such as Capichera, Cantina del Vermentino, Cantina Gallura, Depperu, and Tondini. PASSITO and sparkling versions are also made.

Sweet wines are made all over the island, with the most prominent DOCs being Moscato di Sorso Sennori, Nasco di Cagliari, Malvasia di Cagliari, and Girò di Cagliari. There are also sweet sparkling muscats made in Gallura, especially in the high elevations around Mount Limbara, where the wines can be labelled Moscato di Tempio.

Less known but worth seeking out are Vernaccia di Oristano, from Sardinia's western coast, and Malvasia di Bosa, from a tiny DOC within the Oristano province where Cantina Giovanni Battista Columbu is one of the last producers. Both wine styles are aged under FLOR in an oxidized style similar to SHERRY but unfortified.

An occasional good bottle of Nuragus di Cagliari, a white wine from the higher elevations of Cagliari (minimum 500 m/1,640 ft), only underlines the absurdity of the region's high allowed yields (16 tonnes/ha). Some of the island's best reds come from Carignano del Sulcis, a coastal region at the island's south-east end where the SANDY soils allow for UNGRAFTED VINES.

As wine holdings tend to be small across the island (less than a hectare per owner), CO-OPERATIVES play an important part in Sardinia's wine economy. However, the real custodians of Sardinia's original wine styles and cultivation methods are several small producers who, by following ORGANIC or BIODYNAMIC methods while tending to old BUSH VINES, produce wines that truly reflect their origin. Prime examples include Dettori in Sennori, Panevino in Nurri, Sedilesu and Paddeu in Mamoiada, Pusole in Lotzorai, Altea in Serdiana, and Nero Miniera in Carbonia. W.S. & C.O.

Sárga Muskotály, or Sárgamuskotály, occasional Hungarian name for the 'yellow Muscat' of TOKAJ (MUSCAT BLANC À PETITS GRAINS).

Sassicaia, trail-blazing Tuscan wine, made largely from CABERNET SAUVIGNON, originally as a house wine by Mario Incisa della Rochetta at the Tenuta San Guido near BOLGHERI. It was one of the first Italian reds made in the image of fine red BORDEAUX and was the first serious wine to emerge from the MAREMMA. The first small commercial quantities were released in the mid 1970s, the wine labelled as a VINO DA TAVOLA. In 1994 Sassicaia was granted its own DOC as an official subzone of Bolgheri (Bolgheri-Sassicaia DOC), the only wine from a single estate in Italy to enjoy this privilege. It is relatively reserved in youth, in contrast to its neighbour Ornellaia (see FRESCOBALDI).

Fini, M., *Sassicaia—The Original Super Tuscan* (2000).

Saumur , town in the LOIRE just upriver from the ANJOU district giving its name to an extensive wine district and several appellations. Lodged between TOURAINE and ANJOU, it shares with the former its geology while it is climatically and politically linked to the latter. Developed first by religious orders and aristocrats—as illustrated by the 'Très Riches Heures du Duc de Berry' painting *c.*1412–16—then by the DUTCH WINE TRADE, Saumur production shifted over time from sweet and dry white wines to sparkling and red, with the PHYLLOXERA crisis as an accelerating factor. The protection of the Mauges hills and the tempering effect of the Thouet and Dive rivers create a favorable MESOCLIMATE for a large diversity of styles, with the exception of heavily BOTRYTIZED wines. Like its direct neighbours CHINON and ANJOU, CHENIN BLANC and CABERNET FRANC are the historic primary grapes, but CHARDONNAY, SAUVIGNON, GAMAY, PINOT NOIR, PINEAU D'AUNIS, CABERNET SAUVIGNON, and GROLLEAU are authorized as minority blending partners. The largest production is white or rosé Saumur MOUSSEUX, whose vineyards extend beyond the limits of the still wine area. TRADITIONAL METHOD sparkling wine has been present in Saumur since the early 19th century when the Ackerman-Laurance house, today still a prominent actor, actively developed it. As the Turonian TUFFEAU was excavated to provide building material for local constructions and royal castles in the Loire and abroad, it left extensive underground, well-tempered cellars perfect for AGEING sparkling wines (and growing button mushrooms, the other major local crop). Based on the high-acid Chenin Blanc, these wines rapidly gained commercial success. The tradition is carried on today by larger houses with superb caves such as Gratien & Meyer, Langlois Chateau (owned by Champagne BOLLINGER), and Bouvet Ladubay, as well as the dominant local CO-OPERATIVE Robert and Marcel in St-Cyr-en-Bourg. CRÉMANT de Loire is also produced, but the criteria are more rigorous: YIELDS of 50 rather than 60 hl/ha, 12 rather than nine months' TIRAGE, and mandatory hand-harvesting.

Historically a famous white-wine area—the strip of vineyards from Saumur to Montsoreau now part of the Saumur-Champigny sector

used to be known as the *Côte des blancs*—Saumur Blanc is undergoing a revival after being decades of neglect. SINGLE-VINEYARD WINES from the CHALKY hill of Brézé are leading the pack, confirming the potential of dry white wines whose subtle profiles are sometimes more comparable to BURGUNDY than to the firmer ANJOU Blanc or SAVENNIÈRES from SCHIST.

Saumur Rouge is a much more recent success story, owing its promotion to local mogul Antoine Cristal in the late 19th century, who believed the wines could rival the best BORDEAUX. First vinified as off-dry rosé (under the now-abandoned Cabernet de Saumur AOC), CABERNET FRANC owns its success as a dry red to the Saumur-Champigny AOC, where the St-Cyr-en-Bourg co-operative in particular encouraged the planting of Cabernet Franc in the 1970s and 1980s. Created in 1957, the appellation spreads its 1,500 ha/3,700 acres of sandy soils on tuffeau bedrock close to the Loire. Most of its reds are relatively light and fruity, yet the most serious examples can age for decades.

In 2018 another AOC, Saumur Puy-Notre-Dame, was made official, with stricter production requirements. Situated in the south-west of the region, its higher ELEVATION, more CONTINENTAL CLIMATE, and Turonian subsoils enriched with IRON, CLAY, and FLINT produce Saumur's most STRUCTURED red wines. A small amount of dry rosé is made under the Saumur Rosé AOC (2016), while Coteaux de Saumur, a testimony to the sweet-wine history of the area, is made in minute quantities from Chenin Blanc.

See also LOIRE, including map. P.Le.

Saussignac, small (33 ha/72 acres) sweet-white-wine appellation in SOUTH WEST FRANCE. It lies within the BERGERAC district, adjacent to MONBAZILLAC, producing similar but perhaps slightly lighter wines from the same grape varieties. Since the mid 1990s, the appellation has become an enclave of great SWEET WINEMAKING, now led by domaines Richard and Miaudoux. There are 15 or so independent growers

(many ORGANIC) and no CO-OPERATIVE. In 2004 appellation laws were strengthened to insist on manual picking and completely natural sweetness, generally due to BOTRYTIS. P.S.

Sauterne, occasionally found on labels of GENERIC sweet white wine. Real SAUTERNES always ends in *s*.

Sauternes. The special distinction of this appellation of 1,930 ha/4,342 acres (including BARSAC), located in the extreme south-east of the Bordeaux region, is that it is dedicated, in a way unmatched by any other large wine region, to the production of sweet white wine. In Germany or Alsace, say, such wines are the exception rather than the rule and are made from vines that more usually produce drier wines.

In Sauternes the situation is quite different: the appellation is entirely reserved for SWEET WINES, and any dry production must be declared as straight Bordeaux. They must come from five communes: Preignac in the lower, flatter reaches, with lighter, more filtering soils; Fargues, Bommes, and of course Sauternes higher up, all planted on hilly terrain of GRAVEL over CLAY; and the fifth, Barsac, on completely different soil, fine red LOAM over LIMESTONE, entitled also to its own appellation. They must all adhere to the INAO regulations stipulating specific vineyard and cellar practices that ensure Sauternes' particular style of sweetness.

The origins of these special wines are shrouded in the mists of time. Sauternes produced red wines ('claret') under the English rule of Aquitaine of the 12th–15th centuries, then dry or semi-sweet white wines under the influence of the DUTCH WINE TRADE in the 15th–17th centuries. During these two periods, there are occasional records of BOTRYTIZED wines, probably produced by accident and only becoming the norm when, in the 1770s, Françoise-Josephine de Lur Saluces of YQUEM mastered the art of harvesting botrytized grapes in successive *tries*, or passes, which were instantly recognized as vastly superior

and for which her customers would pay handsomely. Sauternes took off, first in the Paris *salons*, then (following the enthusiasm of Thomas JEFFERSON) in the young United States, then with the Tsar in Russia, finally becoming one of the most coveted wines in all markets.

At the height of this glorious period took place the CLASSIFICATION at the 1855 Universal Paris Fair. Twenty-seven estates were classified, including 15 second growths, 11 firsts, and one 'premier cru exceptionnel' (Yquem), an astounding achievement and a token of Sauternes' extraordinary reputation. Today 48% of the production is controlled by the CRUS CLASSÉS.

Only four grape varieties may be used. SÉMILLON accounts for roughly 80% of plantings because of its susceptibility to NOBLE ROT and its capacity to provide more complex aromas when affected by its onset; SAUVIGNON BLANC attracts noble rot earlier and as a result is currently favoured because of the drier, hotter Septembers of the 21st century (see CLIMATE CHANGE)—and also because it adds freshness of flavour to balance Sémillon's richer, broader style; then come two very aromatic minor grapes, both in decline: MUSCADELLE, because of its fragility, and SAUVIGNON GRIS, providing a more obvious form of Sauvignon aromatics and higher sugar but at the expense of finesse.

Sauternes is the product of a specific MESOCLIMATE located close to the confluence of the cool spring-fed Ciron river with the warmer GARONNE, creating morning mists that envelop the vineyards until the sun burns them away, a perfect medium for the development of *Botrytis cinerea*, or noble rot, a fungus that attacks the already concentrated grapes and causes them to transform their molecular constitution, engendering all the complexity and purity of aromas that make the wines of Sauternes so special. At this stage, if the weather turns from damp to dry (which nowadays it often does in October), the making of great Sauternes becomes possible as the grapes dehydrate and pass from *pourri plein* stage (15–16° POTENTIAL ALCOHOL) to *rôti* stage (upwards of 20°), concentrating not only their

sugars but also their aromatic complexity. Until the recent past, when bad weather at this stage often reduced the potential for ultimate concentration, growers strove for as much sweetness as possible—and often didn't get it, then hastily proceeded to harvest what they could save; today, with climate change making sweetness easier to achieve, they often have the luxury of being able to strive for balance, finesse, and harmony rather than for the sheer concentration of sugars that could sometimes make the wines seem heavy, especially if they had been chaptalized (see CHAPTALIZATION), a practice still allowed today in small proportions but hardly ever used, the sugars being naturally so high.

The turning point that pulled Sauternes out of its very difficult period of the 1960s and 1970s was the 1983 vintage. Prices rose, and wise proprietors could at last put money towards long overdue investments, the most important of which was the gradual conversion from tank fermentation (and sometimes ageing too) to BARREL FERMENTATION, allowing for more detailed precision by separating the various 'lots' that could then be progressively and carefully married together during ageing. The trio of 1988, 1989, and 1990 vintages confirmed this very positive trend, culminating in a succession of vintages from 1996 to 2021 when as many as 11 were great, 12 very good, and only two deficient, a series never seen before, even in the mid 1800s.

Today Sauternes is again showing the quality of which it is capable. It combines all the power and voluptuousness of sweetness with a newfound finesse and purity of aroma. It can be enjoyed young or old and can evolve and improve for up to 50 years or more. Given the risks and costs involved in its intricate production, it remains underpriced in relation to the pleasure it brings to those growing numbers of wine lovers who not only pair it with the traditional accompaniments of desserts, blue cheese, and foie gras but are also now finding it an excellent match with Asian and Indian cuisine, seafood, fish, poultry, and more generally anything spicy or salty. W.J.B.

Brook, S., *Sauternes, and Other Sweet Wines of Bordeaux* (1995).

Olney, R., *Yquem* (1986).

Sauvignonasse, old Bordeaux white grape hardly encountered there today but also known as Sauvignon Vert and, in Friuli, as FRIULANO (once Tocai Friulano). Recent and as-yet unpublished DNA PROFILING at INRAE suggests that Sauvignonasse gave birth to CHENIN BLANC through a natural cross with SAVAGNIN. It is quite distinct from the more famous SAUVIGNON BLANC, but the two were long confused in Chile, where there are now 469 ha/1,159 acres of Sauvignon Vert. In general the wines produced from Sauvignonasse are much less crisp and aromatic than those of Sauvignon Blanc, and this vine is much more sensitive to DOWNY MILDEW and ROT. According to official statistics, Argentina has a little less of this variety than Chile. In Slovenia the variety is now known as Zeleni Sauvignon.

Sauvignon Blanc is the hugely popular vine variety solely responsible for some of the world's most distinctively aromatic dry white wines: SANCERRE, POUILLY-FUMÉ, and a tidal wave of Sauvignon Blanc and Fumé Blanc from outside France, most notably NEW ZEALAND. The direct, obvious, easy-to-appreciate nature of VARIETAL Sauvignon Blanc seems to answer a need in modern wine consumers who are perhaps more interested in immediate fruit than in subtlety and AGEING ability—which is not to deny that in many great white wines, both dry and sweet, it does also add nerve and zest to its most common blending partner SÉMILLON. It has always shared a certain aromatic similarity with the great red wine grape Cabernet Sauvignon (something approaching HERBACEOUSNESS), and in 1997 Sauvignon Blanc's standing in the world of wine rose when DNA PROFILING established that, with Cabernet Franc, Sauvignon Blanc was a parent of Cabernet Sauvignon, the result of a spontaneous field crossing, probably in the 18th century, in Bordeaux. Further DNA studies have suggested that the variety's origins are probably in the Loire; that it has a parent–offspring relationship with the historic

SAVAGNIN Blanc (and is therefore probably its progeny); that it is probably a sibling of the CHENIN BLANC of the Loire; and that it seems genetically close to Sémillon. It is certainly well-connected.

Sauvignon Blanc's most recognizable characteristic is its piercing, instantly recognizable aroma. Descriptions typically include 'grassy, herbaceous, musky, green fruits' (especially gooseberries), 'nettles', and even 'tomcats'. Research into FLAVOUR COMPOUNDS suggests that METHOXYPYRAZINES play an important role in Sauvignon's aroma. Over-productive Sauvignon vines planted on heavy soils can produce wines only vaguely suggestive of this, but Sauvignon cautiously cultivated in the central vineyards of the Loire, unmasked by oak, can reach the dry white apogee of Sauvignon fruit with some of the purest, most refreshingly zesty wines in the world. The best Sancerres and Pouilly-Fumés served as a model for early exponents of New World Sauvignon Blanc, although by the 1980s it was the Loire vignerons, and winemakers all round the world, who were more likely to copy their counterparts in New Zealand in experimenting with fermentation and maturation in oak and picking the grapes at different levels of RIPENESS to add nuance and pungency to the aroma and weight to the palate.

Oak-aged examples usually need an additional year or two to show their best, but almost all dry, unblended Sauvignon is designed to be drunk young, although there are both Loire and Bordeaux examples that can demonstrate durability, if rarely evolution, with up to 15 years in bottle (see POUILLY-FUMÉ and Pavillon Blanc de Ch MARGAUX, for example). As an ingredient in the great sweet white wines of SAUTERNES, on the other hand, Sauvignon plays a minor but important part in one of the world's longest-living wines.

The vine is particularly vigorous, and if the vine's vegetation gets out of hand then the grapes fail to reach full maturity, resulting in wines that are aggressively herbaceous. (And underripe Sémillon can exhibit very similar characteristics—just as underripe Cabernet Sauvignon can smell like Cabernet Franc, which their genetic relatedness may help to explain.) A low-vigour ROOTSTOCK and CANOPY

MANAGEMENT can help combat this problem. Sauvignon buds after but flowers before Sémillon, with which it is typically blended in Bordeaux and, increasingly, elsewhere. Until suitable clones such as 297 and 316 were identified, and sprays to combat Sauvignon's susceptibility to POWDERY MILDEW and BLACK ROT were developed, yields were uneconomically irregular and the variety was not popular with growers. In 1968, for example, Sauvignon was France's 13th most planted white grape variety, but within 20 years it had risen to fourth place, and by 2019 its French total of 31,773 ha/78,513 acres put it behind only Ugni Blanc and Chardonnay in France.

In Bordeaux it was not until the late 1980s that Sauvignon overtook Ugni Blanc as second most planted white grape variety after Sémillon, which in 2019 still outnumbered Sauvignon but not by that much—and the newer CLONES of Sauvignon are much more productive than the important but rapidly declining Sémillon. The Gironde's Sauvignon is concentrated in the Entre-Deux-Mers, Graves, and the sweet-wine-producing districts in and around Sauternes. In each of these areas, it is dominated by and usually blended with Sémillon, particularly in Sauternes, where the typical blend incorporates 80% of the more NOBLE ROT–prone Sémillon together with a little Muscadelle, although with the rise and rise of New Zealand Sauvingon Blanc more varietal Sauvignons have appeared in Bordeaux. BORDEAUX Blanc owes much to Entre-Deux-Mers Sauvignon although low YIELDS and, often, expensive OAK AGEING—as in the best dry white PESSAC-LÉOGNAN, GRAVES, and the handful of expensive Médoc whites (sold as BORDEAUX AOC)—are prerequisites for a memorable performance from Sauvignon in Bordeaux.

As with red wines, the satellite areas of SOUTH WEST FRANCE reflect Bordeaux's spread of vine varieties, and Sauvignon is often an easily perceptible ingredient in the dry whites of such areas as BERGERAC, Côtes du MARMANDAIS, and Côtes de DURAS.

It is in the Loire that Sauvignon is encountered in its purest, most unadulterated form. In the often LIMESTONE vineyards of SANCERRE, POUILLY-FUMÉ, and their eastern satellites QUINCY, REUILLY, and

MENETOU-SALON, it can demonstrate one of the most eloquent arguments for marrying variety with suitable TERROIR, although CLIMATE CHANGE is making it more difficult to achieve this style. The variety is often called Blanc Fumé here and has happily replaced most of the lesser varieties once common, notably much of the CHASSELAS in Pouilly-sur-Loire. The best examples need a few years in bottle to show their best. From this concentration of vineyards, Sauvignon's influence radiates outwards: north-east towards Chablis in ST-BRIS, south to ST-POURÇAIN-sur-Sioule, and north and west to Coteaux du GIENNOIS and CHEVERNY, as well as to a substantial quantity of well-priced eastern Loire wines, typically labelled TOURAINE. Such Sauvignons tend to be light, racy, and, of course, aromatic. With Chardonnay, it has also been allowed into the vineyards of Anjou, where it is sometimes blended with the indigenous CHENIN BLANC.

Elsewhere in France, Sauvignon Blanc has been an obvious, though not invariably successful, choice for those seeking to make internationally saleable varietal wine. In the Languedoc and Roussillon, its total plantings of 8,785 ha/21,708 acres in 2019 made it the region's second most planted white wine grape, a long way behind Chardonnay, even if yields are often too high to extract quite enough varietal character. Small plantings of Sauvignon can also be found in some of the Provençal appellations.

Across the Alps, Sauvignon's most successful Italian region is the far north-east in FRIULI, with some ALTO ADIGE and COLLIO examples exhibiting particularly fine fruit and purity of flavour. Many of the better bottles from the north-east are made from the extremely pungent and recognizable R3 clone of the Rauscedo vine NURSERY. Attempts to transfer Sauvignon to central Italy have been notably less successful. In the 1980s Italy's plantings of Sauvignon doubled to nearly 3,000 ha/7,410 acres, but by 2010 growth had slowed, leaving a total 3,935 ha in 2019. Overall it is a relatively minor grape in Italy.

The Primorska region across the SLOVENIAN border from here is known as a source of BARREL AGED and site-specific Sauvignon Blanc,

with delicate styles more typical of Podravje. In Vipava and Brda districts, both barrel-aged and unoaked styles are produced. The variety conspicuously thrives in Styria in AUSTRIA, where it is capable of expressing the local TERROIR, stylishly combining fruit with aroma, texture, and greater age-worthiness than in many other wine regions. Austria had more than 1,648 ha/4,072 acres of Sauvignon Blanc in 2021, while Germany had a rising total of 1,661 ha in 2020, almost half in the Pfalz and around one-third in Rheinhessen. Parts of SERBIA, especially the Fruška Gora district, and some of CZECHIA, where it is widely planted, clearly have potential for racy Sauvignon. ROMANIA had even more Sauvignon Blanc planted than Cabernet Sauvignon—5,697 ha/14,078 acres in 2021—and neighbouring MOLDOVA also had sizeable plantings of the variety.

Sauvignon Blanc plantings in Spain have increased rapidly this century, reaching 6,933 ha/1,7132 acres in 2020, mainly in Castilla-La Mancha, where varietals can lack definition. It has also been particularly popular with growers in RUEDA. Certainly Portugal and north-western Spain have no shortage of INDIGENOUS VARIETIES (see MINHO and GALICIA) capable of reproducing vaguely similar wine styles. There is a tendency for Sauvignon Blanc to taste oily when reared in too warm a climate, as it sometimes does in Israel and other Mediterranean vineyards where those with an eye to the export market put it through its paces.

This was clearly perceptible in many of Australia's earlier attempts with the variety, although by the early 1990s there was even keener appreciation of the need to reserve it for the country's cooler sites (see AUSTRALIA for more on the wines produced); plantings soared, reaching nearly 7,000 ha by 2012, not least because of the extraordinary popularity of New Zealand examples of the varietal on the Australian market. Several of the best-selling whites in Australia were Marlborough Sauvignons by the start of the second decade of the 21st century—something that would have been unthinkable in the previous century. But plantings had fallen back to just 6,445 ha by 2022 and are outnumbered more than three to one by Chardonnay.

New Zealand has built its wine industry and reputation on the particularly distinctive style of Marlborough Sauvignon Blanc. This is the variety that introduced New Zealand wine to the world, and it did so by developing its own pungent style: intensely perfumed, more obviously fruity than the Loire prototype, with just a hint of both gas and sweetness and, occasionally, gooseberries or asparagus. This style of Sauvignon can now be found in Chile, South Africa, the cooler areas of North America, and virtually all parts of France where Sauvignon is grown. The area planted with Sauvignon Blanc had risen to 26,559 ha/65,629 acres by 2022, representing more than 60% of New Zealand's vines and a far greater area of Sauvignon than anywhere else. The great majority of the country's Sauvignon is grown in the rapidly expanded Marlborough region, although it is also found in all other regions. So popular has Kiwi Sauvignon become that Chardonnay is, unfortunately, relatively ignored in New Zealand.

Chardonnay overtook Sauvignon Blanc in Chile early this century, but the trend has been reversed. According to official statistics, total Chilean plantings of Sauvignon Blanc rose rapidly to 15,224 ha/37,619 acres in 2020 (compared with Chardonnay's 10,920 ha), fuelled especially by the expansion of cooler, often coastal, wine regions from which some remarkably successful examples of true Sauvignon Blanc, in which yields are limited, are emerging. High yields help depress the keynote aromas of Sauvignon Blanc in most other South American wines labelled Sauvignon, although some of the higher-elevation offerings from Argentina, where total plantings of Sauvignon Blanc were 1,489 ha in 2020, are improving.

Thanks to Robert MONDAVI, who renamed it FUMÉ BLANC, Sauvignon Blanc enjoyed enormous success in California in the 1980s, and since the late 1990s a second great wave of popularity for California Sauvignon Blanc has boosted plantings to almost 16,000 acres/6,500 ha by 2020. See CALIFORNIA for more on the wines, which are very occasionally sweet and even BOTRYTIZED, a sort of Sémillon-free Sauternes. There has also been an increase, as elsewhere in the NEW WORLD, in blending in some Sémillon to dry white Sauvignon to add weight and fruit to Sauvignon's aroma and acidity. Like California,

WASHINGTON State makes both Sauvignon Blanc and Fumé Blanc, harvesting 8,320 tonnes in 2021, much less than Riesling but slightly more than Pinot Gris. Elsewhere in North America it is not especially notable, although fine white BORDEAUX blends have been made in British Columbia. But perhaps Sauvignon's real success in the New World, New Zealand excepted, has been in SOUTH AFRICA, where local wine drinkers fell upon the Cape's more successful early Sauvignons as a fashionable, internationally recognized wine style. By 1990 there were 3,300 ha of Sauvignon Blanc to South Africa's barely 2,400 ha of Cabernet Sauvignon. By 2020 there were 9,831 ha/24,293 acres and the area was still growing, if more slowly. Cape Sauvignon Blanc, particularly from the cooler vineyards of Cape Point, Elgin, Darling, and Cape Agulhas, shows intense capsicum and peapod flavours and reasonable ageing potential.

Sauvignon Blanc is often simply called Sauvignon, especially on wine labels, but it has mutated into variants with darker-coloured berries, notably SAUVIGNON GRIS and Sauvignon Rouge, also grown to a limited extent in the Loire. SAUVIGNON VERT is genetically distinct.

Bowers, J. E., and Meredith, C. P., 'The parentage of a classic wine grape, Cabernet Sauvignon', *Nature Genetics*, 16/1 (1997), 84–7.

Sauvignon Gris, also known as Sauvignon Rose, has discernibly pink skins and is a colour mutation of SAUVIGNON BLANC, with which it is sometimes blended. As a VARIETAL, it can produce more substantial wines than many a Sauvignon Blanc, and it is increasingly specified as an authorized grape variety in AOC regulations, notably in Bordeaux and the Loire. It is also planted in Chile, Argentina, Uruguay, and New Zealand. See also FIÉ.

Sauvignon Vert, synonym for SAUVIGNONASSE, except in California, where the variety called Sauvignon Vert is MUSCADELLE.

Savagnin is a very old, genetically important vine variety which has a ramified and fascinating genealogy and whose origins lie in north-east France. Like PINOT, with which it has a parent–offspring relationship, it is so old as to exist in many different mutations, including GEWÜRZTRAMINER, TRAMINER, and HEIDA (Païen), all with the same genetic fingerprint even if they display some clonal variation. DNA PROFILING has further shown that Savagnin is a parent of dozens of varieties, including Chenin Blanc, Grüner Veltiner, Sauvignon Blanc, Silvaner, Trousseau, and Petit Manseng; even more surprisingly, it probably has a parent–offspring relationship with Verdelho.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Savagnin Blanc is the white-berried, non-aromatic SAVAGNIN best known as the characteristic white wine grape of the JURA in eastern France. Both this pale-skinned clone and a pink-skinned one may be called Traminer, the latter also Roter Traminer, while GEWÜRZTRAMINER is the aromatic, pink-skinned form.

Savagnin Blanc, often called simply Savagnin, is a fine but curious vine variety with a typically light crop of small, round, pale berries. France's vineyard census of 2019 found a grand total of 596 ha/1,473 acres of this variety cultivated almost exclusively in the Jura, where it makes increasingly varied wines alongside the nutty, sherry-like VIN JAUNE, a winemaking oddity. In addition to *vin jaune* and other OXIDATIVE dry white wines, including blends with Chardonnay, there has been a significant rise this century in the number of fresh, unoxidized *ouillé* (TOPPED-UP) Savagnin wines made in unoaked, oaked, and even SKIN-FERMENTED styles. Exuberant floral and citrus aromas are often evident, and, whatever the style, Savagnin is always a firm, long-lasting wine high in EXTRACT and, usually, acidity. The vine is well adapted to the ancient, west-facing MARL slopes of the Jura, but for oxidative styles many believe it is at its finest in the steep vineyards of CHÂTEAU-CHALON.

In Switzerland, Savagnin plantings are growing steadily, and it is now the sixth most planted white variety, with a total vineyard area of 219 ha/541 acres in 2020, 95% of this in the Valais, where it is called Heida or Païen and made in a dry and richly flavoured style.

Official statistics showed that in 2015 Australia had 60 ha/148 acres of Savagnin, virtually all planted in the early years of this century by growers who thought they had been supplied ALBARIÑO by CSIRO, the result of a mis-labelling of cuttings imported from Spain via France. (The 'true' Albariño has since been imported.) Australian Savagnin mostly disappears into blends, but there are some fine fresh examples and a handful of Jura-style oxidative wines. As part of a move to planting 'Alpine' varieties, a little is grown in California.

J.H. & W.L.

Savagnin Noir is a Jura name for PINOT NOIR.

Savagnin Rose, the pink-berried SAVAGNIN and non-aromatic version of GEWÜRZTRAMINER, also known in Germany as Clevner and Roter Traminer and in Alsace as KLEVENER DE HEILIGENSTEIN.

Savatiano, sometimes spelt Savvatiano, Greece's most common wine grape, widely planted on 10,263 ha/25,360 acres in 2021 throughout Attica and central Greece. DNA PROFILING has shown it to be a parent of RODITIS. This light-berried vine, with its exceptionally good DROUGHT resistance, is the most common ingredient in RETSINA, although Roditis and ASSYRTIKO are often added to compensate for Savatiano's naturally low acidity. On particularly suitable sites, Savatiano can produce well-balanced, herbal-scented dry white wines.

Savennières, idiosyncratic and celebrated white-wine appellation in the Anjou region, just south-west of the town of Angers on the north bank of the LOIRE. The AOC stretches 6 km/4 miles over five

main south-facing, more or less steep hills of SCHIST and VOLCANIC soils that produce CHENIN BLANC with a unique balance of nerve, concentration, and longevity, while the vineyards on the sandier plateaus produce bottlings more giving in their youth. Historically famous as a sweet wine and part of the original zone of ANJOU-Coteaux de la Loire, Savennières fostered the production of dry wines as a way to survive a commercial crisis when it obtained its AOC in 1952. Sweeter versions labelled DEMI-SEC, MOELLEUX, or DOUX are still authorized but rarely seen. The 1980s marked a turning point for the region as winegrowers from LAYON arrived, bringing selective picking techniques to soften the austere style. The revitalization has continued, with plantings rebounding from 46 ha in 1977 to 135 ha/334 acres in 2021. Within the area, two appellations were recognized in 2011: Savennières-Coulée de Serrant, a single estate of just 6 ha/15 acres run by the Joly family on BIODYNAMIC lines, and the 19 ha/47 acres of Savennières-Roche-aux-Moines, bottled by nine estates (as of 2021). Both appellations are bidding to become the Loire's next GRAND CRU after QUARTS DE CHAUME.

See also LOIRE, including map. P. Le.

Savigny-lès-Beaune , small town in BURGUNDY near Beaune, as *lès* (Old French for near) implies, with its own appellation for red wine and a little white. The reds are rival those of BEAUNE itself but lack the depth and character of wines from villages such as Pommard or Volnay more prominently sited on the LIMESTONE escarpment.

The village is divided by the river Rhoin. Those vineyards on the southern side, including PREMIERS CRUS Les Peuillets, Les Narbantons, Les Rouvrettes, and Les Marconnets, are on sandy soil and produce wines similar to those of Beaune, although lighter. Those on the other side, towards Pernand-Vergelesses, including Les Lavières and Les Vergelesses, are on stonier soil.

An engraving dating from 1703 at the Château de Savigny describes the wines as '*nourrissants, théologiques et morbifuges*'—nourishing, theological, and disease-defying. A little white wine is

produced from Chardonnay, at its best on the plateau behind and above the village. Domaines Chandon de Briailles and Simon Bize have been the leading producers based here.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

Savoie, eastern French alpine region on the border with both Switzerland and Italy, historically Anglicized to Savoy, comprising the two *départements* Savoie and Haute-Savoie together with small parts of neighbouring Ain and Isère. The dramatic countryside is so popular with visitors for both winter sports and summer relaxation that the wines found a ready market, and it was rare for them to leave the region. However, 21st-century interest in lighter wines and INDIGENOUS VARIETIES has encouraged exports.

Savoie became part of France only in 1860 and grows a highly distinctive group of vine varieties that seem to be unrelated even to those of nearby AOSTA. Most Savoie wine is sold under the much-ramified appellation Vin de Savoie or increasingly, simply Savoie, although there are individual appellations for ROUSSETTE de Savoie (for wines from ALTESSE), CRÉMANT de Savoie, and SEYSSEL. The Savoie vineyards tend to be clustered on the slopes of the LIMESTONE-based pre-Alpine and Jura foothills at ELEVATIONS of 250–500 m/820–1,640 ft. Owing to the mountainous terrain they are widely dispersed, with varying climate and soil characteristics, justifying the 16 CRUS which can append their names to the Savoie appellation. Some vineyards are high above the banks of the River RHÔNE as it flows from Lake Geneva towards the wine region known as the Rhône Valley. Seyssel is here as well as the CHAUTAGNE and JONGIEUX cru vineyards.

South of here, close to the town of Chambéry that was once famous for its VERMOUTH, is a cluster of CRUS including ABYMES and APREMONT, below the imposing Mont Granier; and ARBIN, CHIGNIN, CRUET, and SAINT-JEAN-DE-LA-PORTE in the Combe de Savoie. These sectors produce two-thirds of Savoie wine.

Further north, in Haute-Savoie, the CHASSELAS grape predominates in a cluster of vineyards on the south-eastern shores of Lake Geneva and makes a range of light, dry, almost appley wines in the crus CRÉPY, MARIGNAN, Marin, and RIPAILLE. Towards Chamonix, the isolated cru of AYSE makes sought-after still and sparkling wine from the obscure GRINGET variety.

Total vineyard area for the Savoie appellation increased from about 1,650 ha/4,075 acres in 1990 to around 2,100 ha/5,190 in 2020. Over two-thirds of production is white: crisp, delicate, lightly scented, and essentially alpine. The most widely planted variety is JACQUÈRE, popular with growers because of its productivity. The finest white varieties are Altesse, with its own appellation ROUSSETTE de Savoie, and ROUSSANNE, known locally as Bergeron, responsible for the cru CHIGNIN-BERGERON. While Chardonnay is declining, rare indigenous varieties such as MONDEUSE BLANCHE are increasing.

Most of Savoie's wines are VARIETAL; among reds, Gamay and Pinot Noir can be perfectly respectable, if relatively light. Most inspiring is the late-ripening MONDEUSE NOIRE (usually labelled simply Mondeuse) with its deep colour, peppery flavour, and occasionally rustic tannins. Arbin has a particular reputation for Mondeuse with notable STRUCTURE and AGEING ability at alcohol levels rarely above 12%. The historic PERSAN variety is enjoying a revival, too, giving plummy, potentially long-lived reds. W.L.

Lorch, W., *Wines of the French Alps: Savoie, Bugey and Beyond* (2019).

scale, types of insects which attack grapevines, comprising at least 13 different species. Scale insects feed by sucking sap, and heavy infestations can weaken vine VIGOUR. Some scale insects excrete honeydew, which can spoil any bunches because a black, sooty mould usually grows on the honeydew. If many bunches are affected, this may taint the resultant wine. Scale insects can spread VIRUS DISEASES. R.E.S.

Schaumwein, German for SPARKLING WINE. *Qualitätsschaumwein* is an alternative term for SEKT.

Scheurebe is the one early 20th century GERMAN CROSS that deserves attention from any connoisseur, and the only one named after the prolific vine breeder Georg Scheu, the original director of the viticultural institute at Alzey in Rheinhessen. Sometimes called simply Scheu, it was developed with specific sandy, Rheinhessen soils around Dienheim in mind but has achieved its greatest popularity in the PFALZ. DNA PROFILING in 2012 showed that it is a cross of RIESLING and BUKETTRAUBE, a white-berried SILVANER × SCHIAVA Grossa cross. It is much more than a riper, more productive replica of Riesling. Provided it reaches full maturity (like other such German crosses as BACCHUS and ORTEGA, it is distinctly unappetizing if picked too early), Scheurebe wines have their own exuberant, racy flavours of blackcurrants or even rich grapefruit. It is one of the few varietal parvenus countenanced by quality-conscious German wine producers, not just because it can easily reach high PRÄDIKAT levels of ripeness but because these are so delicately counterbalanced with the nerve of acidity—perhaps not quite so much as in an equivalent Riesling but enough to preserve the wine for many years in bottle. Furthermore, for all its inherent aromatic exuberance, Scheurebe also follows its parent Riesling in reflecting soil and MESOCLIMATE, generating some striking and site-typical variations not just in the Pfalz but in Franken, in rare instances along the Nahe, and around Boppart in the Mittelrhein.

Despite its distinct virtues and distinctive flavours, Scheurebe has been in steady decline in Germany over recent decades, slipping to 1,437 ha/3,551 acres by 2020, of which almost half were in Rheinhessen. This may be because it is associated with sweet wine, which is unfashionable in Germany, but such prejudice seems unwarranted. Estates such as Müller-Catoir, Pfeffingen, and Lingenfelder in the Pfalz and Wirsching in Franken have for many more years vinified impressive, full-bodied dry Scheurebe. (Brüder Dr

Becker even makes a respectable sparkling version in Scheurebe's home base in Dienheim.)

The variety is also grown in southern Austria, where it is known as SÄMLING 88 and can make fine sweet wines such as those of Kracher. It is also planted to a very limited extent elsewhere, in Canada and Switzerland, for example.

Schiava, Italian name for several distinct and generally undistinguished dark-skinned grape varieties known as Vernatsch by the German speakers of Alto Adige, or Südtirol as they would call it, and as TROLLINGER in the German region of Württemberg, where they are widely grown. The name Schiava, meaning 'slave', is thought by some to indicate Slavic origins.

The Schiava group is most planted in TRENTINO-ALTO ADIGE in northern Italy, with 204 ha/504 acres in Trentino in 2020 and 635 ha in Alto Adige. The most common is Schiava Grossa (Grossvernatsch), which was used to breed many GERMAN CROSSES including KERNER and HELFENSTEINER and has been shown to be a parent of MUSCAT OF HAMBURG. It is extremely productive and until recently has been associated with soft, pale wines without any real character or concentration. However, a renaissance has begun throughout the region with producers around Girlan and from Merano to Bolzano choosing to curb yields and make elegant, complex wines, often from PERGOLA-trained OLD VINES including several different CLONES. Schiava Grossa is also found in Japan and, as the TABLE GRAPE Black Hamburg, in one ancient vine at Hampton Court Palace in England. Schiava Gentile (Edelvernatsch) produces better-quality, aromatic soft wines from smaller grapes. The most celebrated and least productive clone is Tschaggele. Schiava Grigia and Schiava Lombarda are even less important. Light Schiava-based wines have become much less fashionable than in the late 20th century, when they enjoyed much popularity in Switzerland, Austria, and southern Germany. Plantings are in decline as Schiava has been substantially replaced by

INTERNATIONAL VARIETIES, although Schiava grapes are still found in most of the non-varietal light red wines of Trentino-Alto Adige.

Schiefer. See SLATE and SCHIST.

Schilcher, rosé wine found mainly in Western Styria in AUSTRIA that is light, acid, fruity, and made from the ancient BLAUER WILDBACHER vine variety.

Schilfwein, literally 'reed wine', name used in Austria's NEUSIEDLERSEE for STRAW WINE, because in this area grapes for such concentrated sweet wines were traditionally dried on mats made from the reeds that grow round the lake.

Schillerwein, pink wine speciality made by CO-FERMENTING red and white grapes or MUST in the WÜRTTEMBERG region in Germany. The term is also used in German SWITZERLAND, but there the grapes must be grown and processed together.

Schioppettino, perfumed red grape variety native to the FRIULI region of north-east Italy often confused with but distinct from Ribolla Nera and a likely offspring of the old, no-longer-cultivated Vulpea. In spite of official attempts to encourage its replanting, Schioppettino was substantially neglected after the PHYLLOXERA epidemic of the late 19th century in favour of the new imports from France: Merlot, Cabernet Franc, and Cabernet Sauvignon. It seemed destined to disappear until an EU decree of 1978 authorized its cultivation in the province of Udine (see also PIGNOLO). The wine is deeply coloured and medium-bodied, with an attractively aromatic richness hinting at violets combined with a certain peppery quality reminiscent of the RHÔNE. Although vine plantings and therefore wine production are still limited, being concentrated in FRIULI COLLI

ORIENTALI, the potential is notable. Prepotto close to Slovenia, where, as Pokalca, it has virtually disappeared, is considered its elective home, but quite good quality has also come from the Buttrio-Manzano area. In 2015 total plantings were 87 ha/215 acres.

schist, a metamorphic rock with a distinct planar aspect due chiefly to the parallel alignment of some of its constituent MINERALS, best shown by mica and amphibole (see GEOLOGY). It has developed a coarser grain-size than SLATE, having been subjected to greater burial temperatures and pressures, and as a result splits less cleanly. The transition between slate and schist is therefore gradual, and the distinction rather subjective. The rocks of PRIORAT, for example, are described by some as slate and by others as schist. (To add to the confusion, the German word *Schiefer* is commonly used for both rocks, as is the French word *schiste*, which is also sometimes extended to include SHALE.)

The planes in schist can have any orientation but are commonly close to vertical—ideal for vine roots to penetrate and for rainwater to percolate through. This is probably why in the DOURO vineyards sited on schist perform better than those on the region's massive, relatively impenetrable GRANITE. Schist is also important in parts of the Languedoc—such as BANYULS, FAUGÈRES, parts of ST-CHINIAN, and CORBIÈRES—and in NEW ZEALAND's Central Otago. A.J.M.

Schloss Johannisberg, German wine estate in the RHEINGAU with a history closely interlinked with that of the entire region. First planted by Benedictine monks around 1100, it served in the 18th century under the prince-abbot of Fulda as a model for viticultural success with Riesling. Legend has it that Schloss Johannisberg played an important role in the discovery of BOTRYTIZED wines. Grapes affected by NOBLE ROT were allegedly first harvested at Johannisberg unwittingly, giving rise to the AUSLESE, BEERENAUSLESE, and TROCKENBEERENAUSLESE styles in which, among German growing

regions, the Rheingau took the lead. In 1802 Johannisberg became secularized and the property of the prince of Orange. It was won four years later by Napoleon, who presented it to Marshal Kellerman, duke of Valmy, who owned it until 1813. From 1813 to 1815, the property was administered by the allies Russia, Prussia, and Austria; it was then given to the Habsburg Emperor Francis I of Austria at the Vienna Congress. In 1816 he presented it to his chancellor, prince of Metternich Winneburg, whose descendants sold their majority share in the property only in the 1970s. The property today belongs to the Oetker family, whose vast network of businesses includes the sparkling wine producer HENKELL FREIXENET. The historic prestige of the estate resulted in the name Johannisberg Riesling being a synonym for German RIESLING.

See also GERMAN HISTORY. D.S.

Schönburger, pink-berried 1939 GERMAN CROSS with Pinot Noir, Chasselas Rose, and Muscat of Hamburg among its antecedents. It has been more useful to the wine industry of ENGLAND than to its native Germany, where it is hardly grown, although English plantings have been declining. Its wines are white, low in acid, and relatively full-bodied.

Schoonmaker, Frank (1905–76), influential American wine writer and wine merchant. Born in South Dakota, he first became interested in wine when researching travel books in Europe in the late 1920s. Immediately after the Repeal of PROHIBITION, he wrote a series of wine articles for the *New Yorker* which were published as *The Complete Wine Book* in 1934. Soon afterwards he founded an eponymous wine import company and travelled extensively, becoming noted for his abilities as a judge of young wines, his espousal of DOMAINE BOTTLING in Burgundy, and his expertise in German wines. An early advocate of American wines, he was highly critical of the habitual GENERIC naming of them. In the 1940s, he was hired as consultant to the large California producer Almaden, for whom he

created the best-selling VARIETAL Grenache Rosé, having been inspired by the French wine TAVEL. Schoonmaker employed Alexis LICHINE, who was to occupy a very similar post immediately before the Second World War, and the two men were to publish the first editions of their respective wine encyclopedias in 1964 and 1967. He published five wine books and numerous shorter works on wine.

Schwarzriesling, a German synonym for Pinot Meunier. See MÜLLERREBE.

Sciaccarellu (sometimes written Sciaccarello and Sciacarellu) is a speciality of the French island of CORSICA, where plantings totalled 885 ha/2,187 acres in 2015. DNA PROFILING has established that both Sciaccarellu and the Corsican variety known as Malvasia Montanaccio are in fact the genetically important MAMMOLO of Tuscany. The grape variety is capable of producing red fruit-flavoured if not necessarily deep-coloured reds and fine rosés that can smell of the island's herby scrubland. The vine has good disease resistance and thrives particularly successfully on the GRANITIC soils in the south-west around Ajaccio and Sartène. It buds and ripens late and is less important than NIELLUCCIU.

science. It was long maintained that WINEMAKING was an art, but the proportion of the world's wine made by individuals with little appreciation of science, even in the OLD WORLD, has shrunk substantially in the last century. Now most people practising OEONOLOGY and VITICULTURE are scientifically trained, often to a tertiary level. Even by the late 1980s, it had become difficult to discuss wine with many of those who grow and make it without being conversant with a wide range of scientific terms and concepts, including a host of measurements such as PH, TA, RS, GA (GALLIC ACID), and IPT (*indice des polyphénols totaux*). The dramatically improved overall quality of wine since ACADEME took a role in teaching and researching wine-

related subjects is eloquent testimony to the beneficial effect of the increasingly scientific approach of all those involved with wine. As in all fields, however, the best scientists are often those who seek to explain rather than dominate; in Old World regions whose wines have been admired for centuries, the best results are often obtained by those who combine scientific knowledge with a respect for TRADITION. For specific applications of science, see, for example, AI, DNA PROFILING, GLOBAL NAVIGATION SATELLITE SYSTEMS, INFRARED SPECTROSCOPY, and PRECISION VITICULTURE.

scion, in viticulture, is the piece of the fruiting vine that is grafted on to the quite separate ROOTSTOCK. When grown, such a plant will have the leaves and desired fruit of one VINE VARIETY (Cabernet Sauvignon, for example) but the roots of the other (rootstock) variety (110 Richter, for example). GRAFTING is very widely used in viticulture since rootstocks are needed to combat soil-borne pests or diseases such as PHYLLOXERA and NEMATODES. B.G.C.

scoring individual wines, and many aspects of their production, became an increasingly popular pursuit with professionals and amateurs alike in the late 20th century.

Scoring vineyards

Vineyards may be scored to assess their suitability for producing good-quality wine grapes. The most famous system is that used in the DOURO Valley of northern Portugal for PORT production. Vineyards are allocated points, from plus 1,680 for the most promising to minus 3,340 for the least favoured, taking into account YIELD, SOIL TYPE, MESOCLIMATE, vineyard maintenance, GRAPE COMPOSITION, ENCÉPAGEMENT, and VINE AGE. Highly classified vineyards are entitled to produce as much wine as they are able each year, while production from lower classifications can be restricted to meet demand. The CHAMPAGNE region of north-east France has a similar, if considerably less precise, system whereby whole COMMUNES are given a percentage rating, between 80 and 100.

Vineyards may also be scored for their adherence to organic growing principles as part of their accreditation (see ORGANIC VITICULTURE).

R.E.S.

Smart, R. E., and Robinson, M., *Sunlight into Wine: A Handbook for Winegrape Canopy Management* (1991).

Scoring wines

Wine drinkers are, happily, presented with more choice than ever before. Unhappily, we all seem to have less and less time to make decisions. A score which can be interpreted at a glance is one obvious way of solving both those problems, and it was perhaps understandable that in the late 20th century many wine consumers and, particularly, retailers leaned heavily on scores as a means of buying and selling wine respectively. Some of the various scoring systems and their wider context are discussed in NUMBERS AND WINE. The prototype is that used by the American writer Robert PARKER, who did much to promote the controversial but highly influential practice of awarding points out of 100 between 50 and 100, modelled on the American high-school system. Effectively, wines of interest to readers of his and the many other WINE WRITERS who adopted a similar scoring system were originally those scoring more than 85, but grade inflation has tended to increase this lower limit to 90. Serious COLLECTORS and INVESTORS tend to concentrate on those which score more than 95, so-called TROPHY WINES. Other tasters use other scales, often in Europe points out of 20, but the 100-point scale is more popular with retailers.

These scores have had an extraordinary effect on the wine market. They enable potential INVESTORS, especially wine FUNDS and even FINE WINE traders, to take a position and affect the market without necessarily knowing anything whatsoever about wine. They empower new wine drinkers to make decisions independently of wine traders. And because, unlike TASTING NOTES, they can be understood universally, they can guide potential wine buyers all over the world, thus opening up the wine market in general and the fine-wine market in particular to countries without an established wine culture. Scores undoubtedly played a part in ASIA's dramatic and inflationary entry into the fine-wine market in the mid 1990s, for example, just as they have since encouraged interest from new wine buyers not just in established markets but in expanding markets such as South America

and Russia. The implications of extending the market so widely for a commodity as finite as fine wine, especially trophy wines, are obvious, and the price gap between the trophy wines and the rest has continued to widen.

Quite apart from price and demand, however, scoring affected the wines themselves. Because scores are invariably arrived at as a result of a comparative TASTING of many different samples of the same sort of wine, it is inevitable that some of the more subtle wines are overlooked and, particularly with red wines, the deeper-coloured, stronger, more concentrated wines were likely to make a more immediate, and often favourable, impression in Parker's era. Of course this varies with the taster(s), but overall it is undeniable that in the late 20th century wines became more alcoholic, more concentrated, smoother-textured, and less acid—all as an indirect result of comparative tasting in general, and possibly what has become known as 'Parkerization' in particular, although the early 21st century saw a backlash resulting in a FASHION for fresh, much paler reds.

There has been another, more obviously beneficial, effect of the prevalence of scoring individual wines. New wine producers can make a name for themselves and their wines very much faster than has ever been the case. A sample judiciously sent to influential wine CRITICS can ensure immediate commercial success and direct communication with potential consumers. The downside for wine drinkers, of course, is that prices will inevitably rise steeply.

Wine scores, as those who award them try vainly to point out, can never substitute for description, however. Even if in the 1990s the market seemed much more interested in numbers than words, the 21st century has seen—perhaps as a reaction to over-reliance on scores in the US market and as a way for the army of new American recruits to wine drinking to distinguish themselves—an increased reliance on personal TASTE and on the stories behind wines rather than the numbers in front of them.

For more detail of the practicalities and weaknesses of wine scoring, see NUMBERS AND WINE. J.R.

Scotland . While Scotland has a long and proud history of wine importation and wine bottling—the foundation of the Auld Alliance it built with FRANCE—its attempts at viticulture have been less successful. A few small-scale vineyards have tested the water with what one might term 'hardy varieties', but the low average temperatures, high rainfall, and wind exposure have proved too much. In 2021 a 1.5-ha/3.7-acre experimental vineyard was planted overlooking Loch Striven, west of Glasgow, using early-ripening VITIS VINIFERA and modern HYBRIDS, and the results are eagerly awaited.

S.S.

Kay, B., and Maclean, C., *Knee Deep in Claret* (1983).

Scott Henry , a vine-TRAINING SYSTEM whereby the CANOPY is divided vertically and the shoots are separated and trained in two curtains, upwards and downwards (see diagram). The canopy is about 2 m/6.5 ft tall, and the shoots and leaves are held in place by foliage wires. The system was developed by an Oregon vine-grower of the same name in the early 1980s when his vines were so vigorous that both yield and quality were reduced. The system was originally developed for CANE PRUNING; a later spur-pruned version has now generally been superseded by the SMART-DYSON system.

The Scott Henry system is suited to moderate-vigour vineyards with row spacing of about 2.5 m or more. It became widely used in many New World countries in the 1990s because of its suitability for MECHANICAL HARVESTING and potential for improving wine quality and yield. A New Zealand company (Delegat) has the world's largest vineyards using this system, around 2,000 ha/4,950 acres in 2021 in Hawke's Bay and Marlborough.

R.E.S.

Smart, R. E., and Robinson, M., *Sunlight into Wine: A Handbook for Winegrape Canopy Management* (1991).

screwcaps, sometimes known as ROTEs (roll-on, tamper-evident) and often by the brand name Stelvin, have emerged as a leading competitor to cork in terms of performance and usage. They are cheaper than top-quality corks, and no capsules are needed, but the cost of new bottling equipment and bottles can deter smaller producers.

Screwcaps as an alternative to cork for bottling wine were first used in 1959, when a French company introduced the Stelcap-vin, which had already proved successful for a range of spirits and liqueurs. The rights to manufacture this closure were acquired by Australian Consolidated Industries Ltd (ACI) in 1970, and it was renamed Stelvin® for the Australian market. ACI trials of four closures (three screwcaps with different wadding materials and a

cork for comparison) on three red and three white wines, first reported in 1976, concluded that screwcaps were ideal for sealing wine bottles but only if they had the right wadding material and a satisfactory seal between bottle and cap. An industry push towards screwcaps at that time lost momentum, partly through lack of consumer acceptance and partly because awareness of the shortcomings of cork were not very widespread.

As dissatisfaction with cork gradually increased in the 1990s, there were sporadic attempts to introduce screwcaps to the marketplace. In 2000 winemakers in Australia's Clare Valley, famous for its Rieslings, banded together to take a stand on the issue. The Clare winemakers, many of whose wines are made in a style that shows any cork-related faults particularly transparently (see CORK TAINT and PREMATURE OXIDATION), had to overcome a significant logistical obstacle: at the time, no Australian supplier could offer bottles and caps of the required style and quality. As a result, they had to gather together enough like-minded producers willing to adopt screwcaps to generate the threshold order of 250,000 bottles from Pechiney in France. Their effort made the headlines, and momentum increased so that by the 2004 vintage some 200 million wine bottles were sealed with screwcaps in Australia. This Clare initiative prompted New Zealand winemakers to form the New Zealand Screwcap Initiative in 2001. By 2004 an estimated 70% of New Zealand's wines were sealed under screwcap, up from just 1% three years earlier. Ten years later, in 2014, an estimated 95% of New Zealand wines and 80% of Australian wines were screwcap-sealed. Recent (2021) data in the US showed that the proportion of wineries using screwcaps has now exceeded 50%, suggesting a watershed moment in their usage, which had remained at around 40% for a decade.

Screwcaps consist of two components: the aluminium alloy cap, which comes attached to the sleeve; and the liner, which is made of an expanded polyethylene wadding. The liner typically contains a layer that acts as a barrier to gas exchange, overlain by a PVDC (Saranex) film that provides an inert surface in contact with the wine. In production, the screwcap is not screwed on but is held down tight

over the end of the bottle, and a set of rollers moulds the sleeve of the cap over the ridges on the outside of the top portion of the neck. This holds the whole closure firmly in place. The cap itself is joined to the sleeve by a series of small metal bridges, which are broken when the cap is twisted. To obtain a tight seal it is especially important that the lip of the bottle be free of defects and that the application be executed correctly. The technology for applying screwcaps is thus much more complex than that required for the insertion of corks or similar closures.

Although they are often considered as a single closure type, not all screwcaps are alike. The most significant difference is in the nature of the liner. In some caps the seal is a tin-foil layer; if applied properly, this closure has a very low OXYGEN TRANSMISSION RATE. This transfer of oxygen into the bottle is much less than natural cork (*c.* 2%) and yields a very different wine after some years of AGEING. Whether this is desirable or not depends on the style of the wine. Careful testing is therefore required before switching from a closure with what might be referred to as a 'normal' OTR (normal being defined by history: a natural cork in a glass bottle at around 13 °C/55 °F). Other liners are designed to mimic the nominal OTR of natural cork. The large OTR discrepancy between screwcap liner types makes it impossible for consumers to know how any one wine sealed with a screwcap is likely to age or whether a wine sealed under screwcap is suitable for long ageing. The same is true of other closure types, which means that, unless a wine is bought for immediate consumption, wine lovers need more information about the OTR of a wine's packaging.

A deluxe version of the screwcap also exists, one in which the thread is not visible on the outside of the sleeve, more closely mimicking a standard CAPSULE and appeasing those who object to screwcaps on aesthetic grounds. J.A.G., T.M.S. & A.L.W.

Taber, G., *To Cork or Not to Cork* (2007).

Scuppernong, the best-known of the vine varieties belonging to the *Vitis rotundifolia* species of the MUSCADINIA genus planted in the south-east of the United States and in Mexico. Like other Muscadines, the grapes (in this case bronze-skinned) are very distinctively flavoured. Some well-structured, sweet, dark gold wines are made which taste markedly different from the much more widely known product of VINIFERA varieties. Scuppernong has been substantially replaced in the southern states by Muscadines specially bred for wine production.

sec is French for DRY while secco is Italian, seco is Spanish and Portuguese, and TROCKEN is German for 'dry'. See SWEETNESS, and DOSAGE for official EU sugar levels.

secateurs, handheld scissors used for winter PRUNING of vines. Two-handled secateurs are used for cutting larger-diameter and older wood of the vine. Pruning can be faster, more effective, and less tiring with pneumatic or electric secateurs (see MECHANICAL PRUNING).

R.E.S.

secbutyl-methoxypyrazine (SBMP). See METHOXYPYRAZINES.

sécheresse, French for DROUGHT and occasionally used to refer to WATER STRESS although the latter is more often referred to as *stress hydrique*. When the stress is mild, this is a recognized contributor to wine quality and then the term *déficit hydrique* is preferred.

second crop is one that may form after the main one but on LATERAL SHOOTS. Second-crop bunches are most abundant on strong laterals. In some varieties, a lateral-borne second crop is rare, but on others, such as PINOT NOIR and many MUSCAT varieties, this crop can be large. Usually the existence of a second crop is a negative factor for wine quality since its development runs six to eight weeks behind

the main crop and it competes for nutrients, as well as complicating the development and control of VINE PESTS and VINE DISEASES. Worse, it adds a proportion of immature fruit to the HARVEST (especially where MECHANICAL HARVESTERS are used), which usually adversely affects the quality of the resulting wine. A second lateral-borne crop is anatomically different from bunches that develop on so-called 'secondary buds' after the primary BUD has been damaged or killed by FROST, for example. B.G.C. & R.E.S.

Keller, M., *The Science of Grapevines* (3rd edn, 2020).

second fermentation, a fermentation that occurs after the completion of the normal alcoholic FERMENTATION. This may be a requisite step in the process of SPARKLING WINEMAKING or simply a restarting in the winery of an alcoholic fermentation of a wine that still contains fermentable SUGARS. This can happen if, for example, there is a rise in TEMPERATURE or a more powerful YEAST is introduced. The GOVERNO winemaking process associated with TUSCANY in central Italy is another example of deliberate provocation of a second fermentation. MALOLACTIC CONVERSION is sometimes referred to as the second fermentation.

See also FERMENTATION IN BOTTLE.

second growth. See the CLASSIFICATION of Bordeaux.

second wines are wines made from batches of wine or parcels of vines considered not good enough for the principal product, or *grand vin*, made at an estate. The phenomenon was born in BORDEAUX in the 18th century and was revived in the early 20th century at Ch LAFITE, but it was hardly developed commercially until the 1980s, when increased competition forced ever more rigorous selection at the ASSEMBLAGE stage. Some of the more famous second wines are Ch LATOUR's Les Forts de Latour, supplied by vineyards specifically

designated for this purpose, and Ch MARGAUX's Pavillon Rouge. So important has the quality and reputation of second wines become that both these first growths also sell a third wine. The branded wine MOUTON CADET began life as the second wine of Ch MOUTON ROTHSCHILD, which much more recently created Le Petit Mouton as its modern second wine. Second wines are likely to contain the produce of young vines together with the least satisfactory lots. In particularly unsuccessful VINTAGES, some properties make no *grand vin* at all so that the second wine, or *second vin*, is the only wine produced that year. In general, a second wine from a poor vintage (when a *grand vin* was also bottled) is rarely an exciting drink, but a second wine from a quality-conscious producer in a good vintage can represent excellent value and typically matures faster than the *grand vin*.

sediment, the solid material which settles to the bottom of any wine container, whether it be a bottle or a vat, tank, cask, or barrel. This sediment is a very heterogeneous mixture which in winemaking consists mainly of dead yeast cells and bacteria (the gross LEES), the insoluble fragments of grape pulp and skin. At subsequent stages it consists also of TARTRATES and, from red wines, PHENOLIC polymers, as well as any insoluble materials added to assist CLARIFICATION or to facilitate FILTRATION.

Sediments in bottled wines are relatively rare and usually signal a fine wine that has already spent some years in bottle. So unaccustomed have modern wine consumers become to sediment that many (erroneously) view it as a fault. Many winemakers therefore take great pains to ensure, through clarification, STABILIZATION, FINING, and filtration that the great majority of wines made today, and virtually all of those designed to be drunk within their first few years, will remain free of sediment for at least a few years. Wines designed for long periods of AGEING, on the other hand, frequently deposit crystals of tartrates, white in white wines and dyed red or black in red wines. Red wines, in addition, deposit some PIGMENTED TANNINS that are the result of phenolic polymerization. The

heavy deposits in bottles of vintage port are a particularly dramatic example of this phenomenon. A bottle of wine containing sediment needs special care before SERVING.

Environmentally responsible disposal of sediment from wine production presents a challenge: skins, stems, seeds, and pulp residues can be processed for the recovery of small amounts of sugar, tartaric acid, colouring agents (see OENOCYANIN), and grapeseed oil. Alcohol can also be obtained by a distillery from the skins and stems. However, in most wine regions the costs of recovery greatly exceed the market value of the recovered substances. The solid sediments are frequently returned to the vineyard and worked into the soil instead. See also WINERY WASTE.

See also the quite different phenomenon of BOTTLE DEPOSIT.

A.D.W.

seedling, the young plant that develops when a seed germinates. Grape seeds have tiny embryos which develop rapidly as the seed germinates, growing a freely branching tap-root and a shoot. The growth of seedlings is important in VINE BREEDING, though not otherwise in commercial viticulture as vines are propagated from cuttings (see VEGETATIVE PROPAGATION).

B.G.C.

seeds. For details of grape seeds, see GRAPE.

For details of the historical evidence provided by finds of ancient grape seeds (and other parts of the grape), see PALAEOETHNOBOTANY.

Ségalin, 1959 INRA cross of Jurançon Noir × PORTUGAIS Bleu which has good colour, structure, and flavour and is authorized in SOUTH WEST FRANCE. (See also CALADOC, CHASAN, and PORTAN.)

Ségurs, important family in the history of the BORDEAUX wine region, originally from the village of PAUILLAC. In 1670 Jacques de Ségur, a notary who was a councillor of the legal Parlement of

Bordeaux, became the second husband of Jeanne de Gasq, daughter of another Parlement councillor. As a dowry she brought with her the *seigneurie* of LAFITE, to add to others he had, including Calon in ST-ESTÈPHE, and an estate of about 1,000 ha/2,470 acres to the north of Pauillac. Their son Alexandre de Ségur was born in 1674. His father died in 1691, but in 1695 he married Marie-Thérèse de Clausel, the heiress of LATOUR, which gave him all the southern part of Pauillac and another very large estate. Their son, the future Marquis Nicolas-Alexandre de Ségur, was born in Bordeaux in 1697, and when his father died in 1716 he took over the very large domaine, which then included the farm of MOUTON before it passed in the 1730s to the Marquis de Branne. The marquis, a vice-president of the Bordeaux Parlement, was said to have been called 'le prince des vignes' by Louis XV. He is reputed to have said, 'I make wine at Lafite and Latour, but my heart is at Calon', and on the label of Ch Calon Ségur there is today a large heart. He had four daughters, and their descendants owned Ch Latour until 1962. E.P.-R.

Penning-Rowsell, E., *The Wines of Bordeaux* (6th edn, 1989).

Seibel, common name for many of the FRENCH HYBRID vine varieties bred by Albert Seibel of the Ardèche in the late 19th and early 20th centuries, most of them identified by number and many of them given a more colloquially appealing name. Seibel 5455 is more often called PLANTET, for example, while Seibel 4986 is Rayon d'Or and Seibel 9549 is DE CHAUNAC. The variety once known simply as Seibel in France is Seibel 7053, which is known as CHANCELLOR in New York State.

Sekt, word used in German-speaking countries for SPARKLING WINE. Long governed in Germany by manufacturing rather than wine law, most Sekt there is inexpensive and produced in bulk, often from imported wine. The name Deutscher Sekt designates Sekt from German fruit. A growing minority of German Sekt issues from family

wineries, CO-OPERATIVES, and houses specializing in the genre and frequently focused on vineyard-designated BOTTLE FERMENTED wine, especially from RIESLING or SPÄTBURGUNDER (Pinot Noir). In 2020 the VDP introduced the Sekt Statute, making bottle-fermentation obligatory for the VDP Sekt label; the vintage version must age at least 24 months on the LEES, and 36 months for those labelled Prestige.

In AUSTRIA, which has an even longer, stronger Sekt tradition than Germany but a similar dominance of bulk production, federal legislation in 2015 introduced a Sekt Austria PDO. All Sekt bearing the PDO must be made from Austrian grapes; wines labelled Reserve or Grosse Reserve must be bottle fermented and mature for a minimum of 18 or 30 months respectively on the lees. D.S.

selection, increasingly important practice in maximizing wine quality whereby only the finest grapes or lots of wine are allowed in the final blend. See GRAPE SORTING and ASSEMBLAGE. See also SELECTIVE HARVESTING.

Selection was introduced into German wine law in 2000 as a class of hand-harvested, estate bottled, dry-tasting wine subject to the unusual stipulation that the vineyard surface to be utilized had to be declared by 1 May before the harvest, ostensibly to permit greater administrative oversight. To say that this category failed to catch on appears to be an understatement. D.S.

sélection clonale is French for CLONAL SELECTION, while sélection massale is French for MASS SELECTION.

Sélection de Grains Nobles, the richest, most sumptuous ripeness category of ALSACE wines, applied to wines made mainly from grapes affected by BOTRYTIS with minimum sugar levels of 276 g/l for

RIESLING and MUSCAT, and 306 g/l for GEWU¨RZTRAMINER and PINOT GRIS. The term is also used in the Loire AOCs Coteaux de AUBANCE and Coteaux du LAYON for botrytized wines reaching at least 323 g/l sugar, and in MONBAZILLAC in South West France for wines reaching at least 255 g/l.

sélection parcellaire, French term meaning 'parcel selection', generally used to refer to a wine made from a clearly defined and particularly good plot of vines or vineyard PARCEL.

selective harvesting is a key application of PRECISION VITICULTURE and the major management strategy employed in ZONAL VITICULTURE. It involves the separate picking of different parts of a vineyard according to different yield/quality criteria in order to exploit the variation observed within a vineyard and to maximize the uniformity of individual fruit parcels delivered to the winery. These fruit parcels may then be selected for different wines—perhaps for different styles or at different PRICE POINTS. Typically, different parts of the same vineyard block are harvested into separate bins, either during a single operation or at different times. Early adoption of this strategy was predominantly by small-scale producers or by large companies with the equipment to process small lots. However, selective harvesting may also be profitable even when production is geared to large fermentation volumes. For example, a block of Cabernet Sauvignon might be mechanically harvested into either of two bins, depending on location within the block, in order to maximize the volume produced of a high-value VARIETAL wine by allocating fruit from areas producing lower-value material to a lower-value blended wine. Under conventional uniform management, only the latter would have been produced from the block. R.G.V.B.

Bramley, R. G. V., et al., 'Selective harvesting is a feasible and profitable strategy even when grape and wine production is geared

towards large fermentation volumes', *Australian Journal of Grape and Wine Research*, 17/3 (2011), 298–305.

Bramley, R. G. V., et al., 'Patterns of within-vineyard spatial variation in the "pepper" compound rotundone are temporally stable from year to year', *Australian Journal of Grape and Wine Research*, 23/1 (2017), 42–7.

Bramley, R. G. V., et al., 'Generating benefits from precision viticulture through selective harvesting', in J. Stafford (ed.), *Proceedings of the 5th European Conference on Precision Agriculture* (2005).

Selektion, term without legal status or specific parameters but often used by growers in AUSTRIA to signify a wine with high quality pretensions or in some way unusual. The term is used, for example, by some growers in the WACHAU to designate wines that fail to qualify for the category SMARAGD because they have too high a level of RESIDUAL SUGAR; and by certain growers in STYRIA to highlight SINGLE-VINEYARD WINES as opposed to lighter KLASSIK bottlings. Not to be confused with SELECTION, a specific category of German wine. D.S.

selfling, or selfed vine, a plant created by one VINE VARIETY crossed to itself. This is not a very successful breeding strategy, since most varieties carry deleterious recessive genes, and there is consequently a strong inbreeding depression. This is avoided by crossing unrelated vines, which is a feature of successful VINE BREEDING. See also NEW VARIETIES. R.E.S.

semi-carbonic maceration, red winemaking process which involves a short or partial CARBONIC MACERATION phase followed by a normal alcoholic FERMENTATION. Whole bunches of grapes are placed in a fermentation vessel. The weight of the grapes breaks open those grapes at the bottom of the vessel, and the MUST begins to ferment

and produce CARBON DIOXIDE due to the action of AMBIENT YEASTS, derived either from the grapes or from the winemaking equipment or environment. Immediately above this there are whole grapes that are surrounded by juice; above this, whole grapes in an atmosphere of carbon dioxide. This upper layer will undergo true carbonic maceration. The grapes in the middle layer will undergo similar intracellular transformations but at a much slower rate. Thus, alcoholic fermentation and carbonic maceration processes proceed simultaneously. The grapes are then crushed and pressed, and the yeast completes the fermentation off the skins. The great majority of Beaujolais NOUVEAU and most other PRIMEUR wines are made in this fashion. Such wines have a very distinct aroma reminiscent of bananas or kirsch, arising from the distinctive by-products of the intracellular fermentation occurring within the whole berries and without yeast, during the first phase. Variations of the technique include completing the alcoholic fermentation on the skins in order to increase EXTRACTION and AGEING capacity. G.C.

Sémillon, often written plain Semillon in non-francophone countries, is a golden grape variety from south-west France and is one of the unsung heroes of white-wine production. Blended with its traditional partner SAUVIGNON BLANC, to which it seems to be vaguely related (underripe Sémillon can taste remarkably like Sauvignon), this golden- or sometimes copper-berried vine variety is the key ingredient in SAUTERNES, arguably the world's longest-living unfortified wine, as it is in most of the great dry whites of Graves (see PESSAC-LÉOGNAN). Unblended, in Australia's Hunter Valley, it is responsible for one of the most idiosyncratic and historic wine types exclusive to the NEW WORLD, but overall it is not fashionable and has been declining in importance.

Outside Sauternes, Sémillon seems destined to play a supplementary role. The wines it produces tend to fatness and, although capable of AGEING, have little aroma in youth. Sauvignon Blanc, with its internationally recognized name, strong aroma, high

acidity, but slight lack of substance, fills in all obvious gaps. In the early 1990s, in a world desperate for Chardonnay, Sémillon found itself the passive ingredient in commercially motivated blends—most notably but not exclusively in Australia. Sémillon's weight and high YIELD make it a useful base for commercial blends.

As a vine, Sémillon is easy to cultivate. It is almost as vigorous as Sauvignon Blanc, with particularly deep-green leaves, but flowers slightly later and is not particularly susceptible to COULURE. Nor is it a victim of disease, apart from rot, which, in favourable conditions, is the blessed NOBLE ROT rather than the destructive GREY ROT.

Its greatest concentration is still in Bordeaux, where, although Sauvignon Blanc has been catching up fast particularly for dry white BORDEAUX AOC wines in the Entre-Deux-Mers district, there were still 5,979 ha/14,774 acres in 2020 (down from 9,256 ha in 2000). On the left bank of the Garonne, in the Graves, Sauternes, and its enclave BARSAC, Sémillon still outnumbers Sauvignon in almost exactly the traditional proportions of four to one. Sauvignon and Sémillon fight for dominance in the great, long-lived dry whites of Graves and Pessac-Léognan. In Sauternes, Sémillon's great attribute is its proneness to noble rot, which is the key to wines such as Ch d'YQUEM that may continue to evolve for centuries. Again, oak ageing deepens Sémillon's already relatively deep gold (really ripe grapes may almost look pink). Similar but usually less exciting sweet whites, the most ordinary made simply by stopping fermentation or adding sweet grape MUST, are made in the nearby appellations of CADILLAC CÔTES DE BORDEAUX, CÉRONS, LOUPIAC, and STE-CROIX-DU-MONT.

Like Sauvignon Blanc, Sémillon is allowed in many other appellations for dry and sweet whites of SOUTH WEST FRANCE but is perhaps most notable in qualitative terms in MONBAZILLAC. Thanks to its (declining) importance throughout BERGERAC, Sémillon is the most planted white wine variety in the Dordogne by far, although its 3,528 ha/8,718 acres in 2019 had been overtaken by Merlot. It is technically allowed in most appellations of PROVENCE but has made

little impact on the vineyards of the Midi, where acidity is at a premium.

Sémillon's other great sphere of influence has been South America in general and, in particular, Chile, although total plantings there had fallen to 700 ha/1,730 acres by 2020 and Sauvignon is very much more common. Argentina has pockets of prized old-vine Sémillon, but total plantings in 2020, mainly in the Mendoza region, were just 639 ha.

In North America, Sémillon is generally rather scorned, lacking the image of Sauvignon Blanc, although a significant number of producers use the former to add interest to the latter. Total area planted in California stood at 226 ha/559 acres in 2020. A few producers have tried using it to produce BOTRYTIZED wines in the image of Sauternes, and it also adds weight to Sauvignon in white MERITAGE blends. Historically LIVERMORE VALLEY has produced some of the best fruit. Sémillon was once nearly as important in Washington State as Sauvignon Blanc, and the likes of L'Ecole 41 still make a fine dry VARIETAL version, but plantings had fallen to 235 acres by 2017.

It is quite widespread, without being particularly important, throughout eastern Europe, but it is in both SOUTH AFRICA and AUSTRALIA where Sémillon had a particularly glorious past. In 1822, 93% of South Africa's vineyard was planted with this variety, imported from Bordeaux. So common was it then that it was simply called Wyndruif, or 'wine grape'. It was subsequently called Green Grape, a reference to its abnormally green foliage, but has been declining in importance so that in 2020 it was planted on just 990 ha/2,446 acres—although growth in Sauvignon Blanc plantings in South Africa has brought an increase in sophisticated white BORDEAUX BLENDS, often oak aged.

While all the Australian pale grape focus was on the growth of Chardonnay (and the decline of Riesling) from the early 1990s, plantings of Semillon (typically without the accent) stealthily grew from 2,526 ha/6,242 acres in 1990 to 6,310 ha in 2002, although this had fallen to 3,719 ha by 2022. Its role in the Hunter Valley is well known: to produce, from early-picked grapes, low-alcohol (10.5–

11%) wines with unmatched cellaring potential. It has also enjoyed success as a wooded style, blended with Sauvignon Blanc, in the Adelaide Hills, and the blend is a popular speciality in Margaret River. See AUSTRALIA for more details.

In New Zealand it has been completely swamped by Sauvignon-mania, and only 28 ha, mainly in Hawke's Bay, remained in 2022.

semi-sparkling wine. See FIZZINESS.

Senegal is home to Domaine du Clos des Baobabs, the only vineyard in West Africa, planted in January 2013. In 2021 it extended over 3 ha/7 acres, mainly Grenache with experimental plantings of Cabernet Sauvignon, Cinsault, Grenache, Sangiovese, and Syrah at a density of 5,000 vines per hectare. The vineyard is in the Petite Côte region, 15 km/9 miles from the sea, where temperatures never drop below 14 °C/57 °F, and there are two distinct seasons: a dry season November–May, requiring vineyard IRRIGATION; and a rainy season June–October. Nearly 2,000 bottles of red wine are produced annually, with the first commercial release in 2019. J.-B.A.

sensitivity, an important factor in TASTING. We all vary in our sensitivities to different compounds, sometimes a thousandfold or more in terms of tasting thresholds. Some of the most obvious examples are dramatic differences between tasters in sensitivities to the effects of BRETTANOMYCES, CORK TAINT, MOUSINESS, and ROTUNDONE.

sequence of wines to be served. See ORDER.

Serbia, officially the Republic of Serbia and independent since 2006, is a landlocked nation in the central Balkans and includes the autonomous province of Vojvodina. Archaeological digs at Vinča near Belgrade found grape remains and AMPHORAE dating back to Neolithic

times, but it was probably during the ROMAN era that grape-growing became well established in this region. Sirmium, the present-day city of Sremski Mitrovica, was declared one of the four capitals of the Roman Empire in 294, and Emperor Probus is credited with ordering the first vines to be planted on the slopes of Fruška Gora. The Serbian state developed in the Middle Ages during the Nemanjić dynasty, and the wine industry was encouraged by conversion to Christianity. Ottoman rule brought destruction to much of the wine industry, although some Serbians fled north to Srem and Banat taking vines with them. In 1699 the Karlovac Peace Agreement saw Srem and Banat join the Habsburg Empire, which encouraged wine production. As in the rest of the Balkan region, PHYLLOXERA was devastating, and the early 20th century saw the development of growers' CO-OPERATIVES. After the Second World War the industry was collectivized as part of YUGOSLAVIA, and vineyard area rose to 135,000 ha/333,592 acres by 1955. The brutal wars of independence after the break-up of Yugoslavia seriously affected wine production, although the 21st century has seen considerable change. The former state wineries have largely disappeared through bankruptcy, and the number of small to mid-sized, quality-focused estates with vineyards and modern equipment is increasing, undoubtedly helped by significant government subsidies.

Serbia's vineyard register showed 20,501 ha/50,659 acres under vine by 2019, though only 6,827 ha for commercial wine production. An estimated 13% of households own vineyards, though over 90% are smaller than 0.5 ha. There were 353 wineries and 3,997 registered growers by 2019. Wine production averaged 330,000–370,000 hl from 2016 to 2018. The country has been divided into three wine-growing units (Vojvodina, Central Serbia, and KOSOVO), 22 wine regions, and 77 subregions. Most wine is produced without any quality designation, though work is in progress to develop this sector and add further PDO classifications. PGI wines are described as Geografska Indikacija (GI); PDO wines are either Kontrolisano Poreklo i Kvalitet (KPK) or Kontrolisano i Garantovano Poreklo i Kvalitet

(KGPK). Serbia imports twice as much wine as it exports (126,000 hl in 2019, largely to Russia and Balkan neighbours).

Vineyards, varieties, and regions

Serbia's largely CONTINENTAL CLIMATE is moderated by mountains such as Fruška Gora and by rivers, especially the Danube, Velika Morava, and Timok. There are as many as 200 varieties grown in the country, with around 30 local grapes. INTERNATIONAL VARIETIES including Cabernet Sauvignon, Merlot, and Pinot Noir arrived with Aleksandar I around the 1920s and can perform well, but more exciting is the rediscovery of PROKUPAC. A century ago, this was the most planted grapevine on Serbian territory. It is naturally vigorous and capable of huge crops, though with low YIELDS, and can make elegant, refined wines. Local varieties such as Morava, Neoplanta, Probus, Seduša, and Začinak are also gaining attention, though there is still a lack of high-quality NURSERY material or CLONAL SELECTION.

The Fruška Gora region, on the hills north of Belgrade, is now Serbia's most dynamic wine region with numerous young winemakers experimenting with NATURAL, BIODYNAMIC, ORGANIC, and AMPHORA wines. The town of Smederevo south of Belgrade gives its name to the white SMEDEREVKA grape (aka Bulgaria's Dimyat). WELSCHRIESLING is important here, often labelled with its historic local name of Grašac. The oldest written mention of Grašac and preserved herbarium specimens dating to the late 18th century have recently been found here.

The northern province of Vojvodina belongs to the Pannonian plain that extends into Hungary and includes the regions of Srem, Šubotica, Bačka, Telečka, Potisje, Banat, and South Banat. The Srem region is close to the Danube on the lower slopes of the Fruška Gora Mountains. The Danube influence moderates winter cold and aids earlier ripening in the summer, while an ELEVATION of around 200–300 m/660–980 ft helps keep freshness in the resulting wines. This is regarded as the heartland of Grašac, while international white-wine grapes including Chardonnay can thrive. Some Gamay and Portugieser (historically grown for vermouth-like Bermet) are present too. The sandy soils of Subotica are of Pannonian origin so it is no

surprise there is some overlap with Hungarian varieties such as EZERJÓ, FURMINT, KÖVEDINKA, and KADARKA (including vines dating to 1880), although the area is best known for white wines from Graševina (WELSCHRIESLING) and Riesling. The Banat region lies on the western end of the Carpathians where the hills meet the plain. The rare Serbian white-wine grape KREACA is believed to originate here and is also found over the border in Romania as Creață.

In Central Serbia, there are 13 regions (Beograd, Pocerje-Valjevo, Čačak-Kraljevo, Toplica, Vranje, Niš, Leskovac, Nišava, Knjaževac, Mlava, Negotinska Krajina, Tri Morave, and Šumadija). The most important of these is Tri Morave to the south of Belgrade, especially its subregions Župa and Trstenik. The Župa area, with its mild continental climate moderated by surrounding mountains and rivers, has long been famous for wine production, with records of grape supply to monasteries dating to the 12th century. Today it boasts a group of pioneering new estates and is the heartland of the Prokupac revival. North of Tri Morave, the moderate continental region of Šumadija is arguably the centre of the revival of quality winemaking. It has four subregions—Krnjevo, Oplenac, Rača, and Kragujevac—of which Oplenac includes some of Serbia's best producers. It is also where King Aleksandar built his royal cellar in 1931. It is perhaps most famous for whites made to an old royal recipe, but some of the country's top Cabernet Sauvignon can be found here too. C.G.

Sercial, Portuguese white grape variety probably originally from BUCELAS, where most is to be found today. It was once quite commonly planted on the island of Madeira, but only about 25 ha/62

acres grew there in 2018. The name came to be used to denote the lightest, most acid, latest-maturing style of MADEIRA rather than the grape variety from which it was made. On the Portuguese mainland it is also known as ESGANA CÃO and is notable for its late ripening and high acidity. It should not be confused with CERCEAL Branco.

Serine, or Sérine, old synonym for SYRAH used in the northern Rhône and in the Isère *département* to distinguish a revered and ancient BIOTYPE of this variety that is sometimes mentioned on labels. Variant spellings include Sereine, Sérène, and Serinne.

service of wine. See SERVING WINE and SOMMELIER.

serving wine involves a number of fairly obvious steps, but mastering each of them can maximize the pleasure given by any individual wine. See OPENING THE BOTTLE, BREATHING, DECANTING, GLASSES, FOOD-AND-WINE MATCHING, ORDER OF WINES TO BE SERVED, and LEFTOVER WINE for details of these particular aspects of serving wine.

Perhaps the least obvious requirement of anyone serving wine is that they appear superficially mean, by filling glasses no more than two-thirds, and preferably less than half, full. This allows energetic agitation of the glass if necessary and enables the all-important AROMA to collect in the upper part of the bowl (see TASTING).

The factor which probably has the single greatest effect on how a wine tastes, however, is temperature, and this is one aspect which can be controlled by whoever is serving. Because of the well-known general rule that white (and rosé) wines should be chilled while red wines should be served at something called room temperature (see CHAMBRÉ), and because many refrigerators are set at relatively low temperatures, in practice many white wines are served too cool and many red wines dangerously warm. See TEMPERATURE for some guidance on specific recommended serving temperatures for certain styles of wine. Few wine drinkers have wine thermometers, however,

so a certain amount of experimentation with ways of modifying serving temperatures is advisable.

Cooling wine in a refrigerator is much slower than cooling wine in a container holding water and ice (two hours rather than 30 minutes to cool an average bottle from 22 to 10 °C/72 to 50 °F). (Note that a container full of ice cubes but no water is not a very effective cooler as it provides relatively little contact between the bottle and the cooling medium.)

A freezer or ice box would do the job faster but has the serious disadvantage that the bottle will be cooled right down to icebox temperature if left there. This may well freeze the wine and push the cork out. Some refrigerators are, furthermore, set at such low temperatures that wines may emerge simply too cool.

It is a happy coincidence that the ideal cellar temperature, around 13 °C/55 °F, is also ideal for serving a wide range of wines, such as complex dry white wines and light-bodied red wines, and is not so low that it takes impossibly long to warm tannic red wines to a suitable serving temperature.

In cool climates, wine drinkers may have difficulty in warming bottles of red wine to suitably high temperatures for serving, however. Direct heat should not be applied to a bottle, and even contact with a radiator can heat wine to such a dangerously high temperature that some of the more volatile FLAVOUR COMPOUNDS are lost and the ALCOHOL can dominate so that the wine tastes unbalanced.

One of the most effective ways of warming wine, whether intentionally or not, is to pour it out into glasses in a relatively warm environment or, even faster, to pour the wine into a decanter or glasses which previously held hot water. This effect is accentuated if the glasses are cupped in human hands. For this reason, it is usually wise to serve wines slightly cooler than the ideal temperature at which they are best appreciated. Warming wine in microwave ovens can be effective if the oven is big enough and if great care is taken not to overheat the wine—and to remove the FOIL if it is metallic.

Ambient temperature can affect how a wine tastes: crisp, light wines taste either delightfully refreshing or disappointingly meagre when the taster is hot or cold respectively. On the other hand, in tropical climates, where both temperature and HUMIDITY are high, it can be almost impossible to find suitable conditions in which to serve even the finest red wine as, without air conditioning, drinks heat up so rapidly that a red wine has either to be served well chilled or run the risk of being almost MULLED. Light red wines with marked ACIDITY such as BEAUJOLAIS and reds from cooler climates such as the LOIRE, ENGLAND, NEW ZEALAND, TASMANIA, NEW YORK, and CANADA can taste more appetizing in hot climates than CLASSED GROWTH red bordeaux or fine burgundy.

One final aspect of serving wine, about which the Latin poet HORACE wrote extensively, is matching wine to guest and occasion. Part of what might generally be called CONNOISSEURSHIP, this is a pleasure associated with wine which can be almost as great as drinking it.

See also TASTING for the special conditions of serving wine for this particular purpose, a very different one from actually drinking it.

set. See FRUIT SET.

settling, the winemaking operation of holding GRAPE JUICE, MUST, or wine in a vessel for 12–24 hours so that suspended solids sink to the bottom. It is most commonly used to begin the CLARIFICATION of freshly drained and pressed white juice before FERMENTATION and is one of the most important stages in white winemaking. The addition of a small quantity of SULFUR DIOXIDE during this stage reduces the risk of OXIDATION and slows down any activity of yeasts and bacteria. For the same reasons, the juice is often cooled to below 15 °C/60 ºF. Settling of particularly viscous grape juice can also be encouraged by the addition of ENZYMES designed to break chains of PECTINS. For white

wines, there is another period of settling after fermentation or after BARREL AGEING.

Red wines, whose skins are included in the fermentation vessel, are settled after fermentation and MACERATION. The purpose is to remove not just grape debris but also dead yeast cells and bacteria, or LEES.

Settling is governed by such factors as the size of the solid particles, the difference in their DENSITY from that of the liquid, and the extent to which the liquid moves within the settling vessel. Because must and cloudy grape juice are so much denser than wine, they are much more difficult to settle. Solids as large and dense as seeds and stem fragments settle rapidly. Finely divided pulp debris and dead yeast cells and bacteria which are very small settle more slowly and are easily resuspended by currents within the settling vessel. COLLOIDS, which have dimensions of large molecular size, are very slow to settle because their movement is influenced by the smallest liquid movement within the vessel. The settling of colloids can be greatly assisted by the addition of clarifying or FINING agents such as BENTONITE, albumin (see EGG WHITES), GELATIN or CASEIN, which adsorb them and grow them into complexes large enough to settle.

V.L.

Setúbal , port on the Sado estuary south of Lisbon, the capital of PORTUGAL, is also the name of a Portuguese FORTIFIED WINE with its own DOC region (see map under PORTUGAL). It is made predominantly from Moscatel (MUSCAT) grapes, and the region was officially demarcated in 1907 for Moscatel de Setúbal. The finest examples grow on LIMESTONE soils on the cool, north-facing slopes of the Arrábida hills. Grapes are also grown on the plain around the town of Palmela. The principal type of Moscatel is MUSCAT OF ALEXANDRIA; a tiny but growing amount (around 50 ha/123.6 acres) of pink-skinned, much earlier-ripening Moscatel Roxo is bottled separately and is generally slightly drier and more complex. Initially Setúbal is made in much the same way as a VIN DOUX NATUREL. After vinification, however, pungent Muscat grape skins are left to macerate in the wine

for five or six months, which imparts a taste of fresh grapes and gives Setúbal its intense aroma and flavour. As for MADEIRA's *canteiro* wines, wood-aged wines are aged above ground in warm to hot conditions to concentrate them. The minimum ageing requirement for Moscatel is 18 months and for Moscatel Roxo, 36 months. Most Setúbal is sold at two to five years of age. Basic examples are unoaked, but those aged in wood—traditionally large oak vats (although other formats are used)—develop an amber-orange colour and spicy candied citrus and raisin flavours. Small quantities are bottled (typically for NON-VINTAGE blends) after 20 years or more in cask, by which time the wine is deep brown and has a rich, grapey intensity and RANCIO character. Leading producer José Maria da FONSECA occasionally bottles and sells stocks dating back to the mid 19th century. Bottles labelled Moscatel Torna-Viagem crossed the equator twice by ship en route to and from the tropics and are considered the finest; multiple experiments by José Maria da Fonseca reportedly bear this out. For details of the unfortified wines made on the Setúbal peninsula, see PENÍNSULA DE SETÚBAL. R.J.M. & S.A.

Mayson, R. J., *The Wines of Portugal* (2020).

Severny, Russian vine variety developed at the All-Russia Potapenko Institute from a Précoce de Malingre seedling with a member of the famously cold-hardy VITIS AMURENSIS vine species native to Mongolia. Severny means 'northern' and is a suffix of several crosses such as SAPERAVI Severny and CABERNET SEVERNY specifically bred for harsh winter climates.

sexual propagation, reproduction by seed involving the union of male and female sex cells (POLLEN and ovule respectively). The important feature of this type of propagation is that the parent plants are genetically different, so the seedling is in turn genetically different from either parent. Throughout the world of nature, this is how genetic diversity is continued, permitting selection of those progeny

best suited to survive. In commercial viticulture, this process has been circumvented by propagating selected, desirable individuals and propagating them vegetatively (see VEGETATIVE PROPAGATION). Originally sexual seedlings, all grape varieties have been propagated asexually for many years, decades, or centuries with substantially the same genetic constitution. Sexual propagation is used for VINE BREEDING throughout the world to produce NEW VARIETIES. Success depends on selecting suitable parents, now helped by marker-assisted selection techniques and many years of painstaking evaluation. J.V.

Seyssel , the oldest appellation within the eastern French region of SAVOIE, producing light, dry, and off-dry white still and sparkling wines from vineyards concentrated on the steep slopes of the upper Rhône Valley about 40 km/25 miles downriver of Geneva. Historically, sparkling Seyssel (especially the Royal Seyssel brand) was one of the few Savoie wines to escape the region itself, but it suffered a decline with less than 70 ha/173 acres of vines remaining in the appellation by 2020, about one-quarter used for sparkling wine. ALTESSE (sometimes referred to as Roussette) is the dominant grape variety here, although the local MOLETTE is also grown. Since the CRÉMANT de Savoie AOC was created in 2014, Seyssel sparkling wines are supposed to contain at least 70% Molette, but local growers are fighting to reduce this proportion to allow more Altesse (10% minimum is required). The sparkling wines need to be BOTTLE FERMENTED in the region. They are light and refreshing, and the best can develop in bottle. Still whites (mostly VARIETAL Altesse, while others are Molette) may be floral and crisp, but many are flattened by RESIDUAL SUGAR. W.L.

Seyssuel, commune in the Isère *département*, to the north of CÔTE RÔTIE, on the opposite bank of the RHÔNE. Currently within the IGP Collines Rhodaniennes growing area, Seyssuel was once known for

the quality of its wines, but it wasn't replanted after PHYLLOXERA. Three local winegrowers, Pierre Gaillard, François Villard, and Yves Cuilleron, started replanting here in 1996, and they have since been joined by many more as the potential for quality has been confirmed. Neighbouring communes Chasse-sur-Rhône and Vienne have also seen plantings, and local producers hope that these three communes will be collectively promoted to CRU status, likely under the name Seyssuel. The main grapes used are SYRAH for red wine and VIOGNIER for white. M.C.W.

Seyval Blanc, complex, light-skinned FRENCH HYBRID, the most widely planted SEYVE-VILLARD hybrid, number 5276, the result of crossing two SEIBEL hybrids. It is productive, ripens early, and is well suited to relatively cool climates such as that of ENGLAND, where it was the single most planted vine variety in the late 20th century but has been superseded by the popularity of the Champagne grapes and by BACCHUS. It is also popular in NOVA SCOTIA and, to a lesser extent, in the eastern United States, notably in NEW YORK State. Its crisp white wines have no hint of FOXY flavour and can even benefit from BARREL AGEING. In the UK it is mainly used for blending and is particularly successful for sparkling-wine production. As a sparkling wine, it can (somewhat unexpectedly in view of its hybrid origins) be labelled as Quality Sparkling Wine.

Seyve-Villard, series of about 100 FRENCH HYBRIDS developed by hybridizer Bertille Seyve and his partner and father-in-law Victor Villard, much planted in France in the mid 20th century. Perhaps the most famous, however, is SEYVAL BLANC.

Sezão, dark-skinned Portuguese variety of which there were just 23 ha/57 acres in Portugal in 2023, mostly in the Douro Valley. Originally known as SOUSÃO, which is also the Douro synonym for Vinhão, it was

renamed in 2012 when DNA PROFILING showed it to be a distinct variety.

Sforzato, or Sfursat, a dry red DRIED-GRAPE WINE made in the VALTELLINA zone in the far north of Italy from Nebbiolo, which is known locally as Chiavennasca.

SGN. See SÉLECTION DE GRAINS NOBLES.

shade, the absence of sunlight, for example in a vine CANOPY. This is due to leaves blocking out sunlight, as the transmission of light through one leaf is less than 10% of sunlight. Generally, shade is due to vigorous vines being trained to a restrictive vine-TRAINING SYSTEM.

Sunlight levels in the centre of dense canopies with many leaf layers can be as little as 1% of the levels above the canopy. At this very low level of light, PHOTOSYNTHESIS is zero or negative, and in time the leaves turn yellow and then fall off. Leaves deep in the canopy also experience filtered sunlight with altered spectral composition, in that red light is reduced and far-red light relatively enriched. The ratio of red to far-red light can act as a signal system for the vine and other plants and may play a role in the vine's response to shade. Similarly, ULTRAVIOLET RADIATION (UV) is filtered in the canopy, which can have a significant impact on PHENOLICS. Since the vine evolved in forests, it has tendrils for avoiding shade by climbing towards the sunlight.

Shade can reduce vine YIELD dramatically by reducing bud INITIATION, BUDBREAK, FRUIT SET, and hence berry number, as well as BERRY SIZE. Yields may increase up to threefold where shade has been removed by altering the training system and allowing the sunlight to penetrate.

Shade can also alter grape chemical composition and reduce grape quality. Studies around the world, for a range of vine varieties in a range of climates, have demonstrated that shade decreases levels of

SUGARS, ANTHOCYANINS, PHENOLICS, TARTARIC ACID, monoterpene FLAVOUR COMPOUNDS, and apparent varietal character. Other negative effects of shade on wine quality are increases in MALIC ACID, PH, POTASSIUM, and the so-called HERBACEOUS characters. Shaded fruit is also more susceptible to BOTRYTIS BUNCH ROT and POWDERY MILDEW. CANOPY MANAGEMENT can reduce shade in the canopy and, in high-vigour vineyards, will improve yield and quality simultaneously.

With CLIMATE CHANGE and warmer air temperatures, berry SUNBURN has become an issue. It can be addressed by avoiding excessive exposure for bunches facing the mid-afternoon sun. For this reason, east–west row orientation is preferred in hot regions. R.E.S.

Smart, R.E., et al., 'Canopy management to improve grape yield and wine quality: principles and practices', *South African Journal of Enology and Viticulture*, 11/1 (1990), 3–17.

shale, a very fine-grained sedimentary rock, usually dark-coloured, which is weak and easily split because of the way the clayey sediment has settled, so that shale always breaks roughly parallel to the stratification of the sedimentary rock, unlike some metamorphic rocks (see SLATE and, especially, SCHIST). The splintered fragments are flaky and irregular (unlike cleaved slate). Shale weathers easily, to give CLAY-rich soils, often poorly drained. See also GEOLOGY. A.J.M.

shanking. See BUNCHSTEM NECROSIS.

sharpshooters, insects which feed on vine foliage and can carry important vine diseases. See LEAFHOPPERS.

shatter. See FRUIT SET.

Shaulis, Nelson (1913–2000). Born in Pennsylvania, Nelson Shaulis was destined to have a greater impact on world viticultural practice than most of his scientific contemporaries. His eastern US origin was appropriate, as this was the region of his greatest influence, though he began his career at the Agricultural Experiment Station, Geneva (see CORNELL UNIVERSITY), in 1948 and retired as Professor of Viticulture there in 1978.

Shaulis can be considered the father of CANOPY MANAGEMENT, although the term was not coined by him. In his early experiments with CONCORD grapevines, he realized that limits to YIELD and RIPENESS were a consequence of SHADE within the grapevine CANOPY. The solution was simple enough in hindsight but revolutionary for the time. By dividing a dense canopy into two less dense canopies, shade could be reduced, and suddenly yield and ripeness could be dramatically increased. The new TRELLIS design, first published in the mid 1960s, was called the GENEVA DOUBLE CURTAIN. As an important extension to this work, Shaulis and colleagues developed the world's first MECHANICAL HARVESTER of grapes and subsequently undertook important primary research on MECHANICAL PRUNING.

The impact of Shaulis's research has been felt throughout the wine world, but the NEW WORLD, free of yield limits, has benefited most. Shaulis influenced many younger researchers who made canopy management an accepted practice globally, including Carbonneau from Bordeaux (see LYRE), Intrieri and Cargnello from Italy, Kliewer from California, and Smart in Australia and New Zealand. R.E.S.

Shenandoah Valley of California is an AVA in the SIERRA FOOTHILLS. There is also a Shenandoah Valley in VIRGINIA.

sherry, seriously undervalued but slowly reawakening wine from the region around the city of Jerez de la Frontera in ANDALUCÍA, south-west Spain. 'Sherry' was used as a generic term for a wide range of FORTIFIED WINES made from white grapes, but in the mid 1990s the

sherry trade successfully campaigned to have the name restricted—at least within the EU—to the produce of the Jerez DOP. (For details of other once-prominent producers of similar wine styles, see CYPRUS, SOUTH AFRICA, and BRITISH WINE.) 'Sherry' is still used as a generic for the traditional and frequently fortified wines of Andalucía, therefore including wines from MONTILLA-MORILES, MÁLAGA, CONDADO DE HUELVA, and other lesser known places; in fact, for the sake of brevity, the word 'sherry' is sometimes used in this book as a synonym for 'traditional wines of Andalucía'.

Despite renewed interest in high-quality sherry, overall production has dropped continuously for a quarter-century and was down to 400,000 hl/10.5 million gal a year by 2021. Apart from Spain, the two most important markets for sherry have been the Netherlands and Great Britain.

'Sherry' is the English corruption of the word 'Jerez', while *Xérès* is its French counterpart and is also the French name for sherry. The words 'Jerez-Xérès-Sherry' appear on all bottles of sherry, on paper seals granted by the CONSEJO REGULADOR to guarantee the origin of the wine.

There are two principal types of sherry: *fino* (or, in Sanlúcar de Barrameda, *manzanilla*), which ages biologically (i.e. under the influence of the film-forming yeast FLOR); and *oloroso*, which ages oxidatively, without the protection of flor. All sherry styles found on labels (Manzanilla, Fino, Amontillado, Oloroso, Pale Cream, Cream, etc., in generally ascending order of BODY) are derived from these two main types. Palo Cortado is a naturally resulting intermediate type between Amontillado and Oloroso. PEDRO XIMÉNEZ is an intensely sweet wine, usually for blending, made from the grape variety of the same name often grown outside the sherry region.

History

Jerez is one of the oldest wine-producing towns in Spain. It may well have been established by the PHOENICIANS who founded the nearby port of Cádiz in 1110 BCE. The Phoenicians were followed by the CARTHAGINIANS, who were in turn succeeded by the ROMANS. Iberian viticulture advanced rapidly under Roman rule, and Jerez has been identified as the Roman city of Ceritium. The local Hispano-Romans lost control around 400 CE, when southern Iberia was overrun by successive kingdoms of Vandals and Visigoths, who were in turn defeated by the Moors after the battle of Guadalete in 711 (see ISLAM). The Moors held sway over different parts of Andalucía for up to seven centuries, and their influence is still evident in the architecture in towns such as Seville, Cordoba, and Granada. Under Moorish domination, Jerez grew in size and stature. The name of the town changed from Ceret to Seris and later to Jerez de la Frontera, when it stood on the frontier of the two warring kingdoms during Christian reconquest in the 13th century.

Viticulture, which continued despite Moorish occupation, was revitalized by the Christians. Exports began and, despite periodic setbacks, trade with England and France was well established by the 1490s, when it was declared that wines shipped abroad would be free from local tax. In 1492 the Jews were expelled from Spain, their vineyards were confiscated, and foreigners, many of them English, took their place as merchants. Certain basic quality controls were established, including the capacity of the sherry cask or BUTT, which has not changed to this day.

At the end of the 15th century, after Christopher Columbus had reached America from his base in Andalucía, the sherry town of Sanlúcar de Barrameda became an important port for the new transatlantic trade, and in the 16th century large quantities of wine were shipped to the Americas from Jerez. In his book *Sherry,* Julian Jeffs speculates that Vino de Jerez (sherry) was almost certainly the first wine to enter North America.

Relations between England and Spain began to deteriorate in the 16th century; although trade continued, the colony of English merchants trading from Sanlúcar began to suffer privations. In 1585, after a number of predatory raids by Sir Francis Drake and his fleet, English merchants were arrested and their possessions seized. Exports ceased. Two years later, in a failed attack on Cádiz, Drake stole '2,900 pipes' of wine. This plunder helped to establish sherry as a popular drink in Elizabethan England.

After the death of Elizabeth I, trade became easier and 'sacke', or SACK, returned to royal circles. The English colony re-established itself and prospered, often by shipping poor-quality wines.

By the 17th century, 'sherris-sack' was well established in England and was drunk by Samuel Pepys, who in 1662 records that he mixed sherry and MÁLAGA. Pepys visited the English colony in Sanlúcar de Barrameda in 1683. At that time, until the construction of a railway in the mid 19th century, most of the sherry bodegas were located on the coast at Sanlúcar and Puerto de Santa María for easy export.

The sherry industry suffered many setbacks at the beginning of the 18th century, when England and Spain became embroiled in a series of conflicts beginning in 1702 with the War of the Spanish Succession. The METHUEN TREATY (1703) diverted trade to Portugal, and a series of restrictive measures imposed by the Gremio or Wine Growers Guild of Jerez sent merchants to Málaga in search of wine. However, the latter half of the century was an era of increasing prosperity stimulated by the arrival of a number of French and British merchants. The firms of Osborne, Duff Gordon, and Garvey date from this period.

The Peninsular Wars (1808–14) devastated Jerez. Andalucía became a battleground, occupied for a time by the French, who pillaged the sherry bodegas and forced a number of families to flee to the relative safety of the Cádiz garrison. With the defeat of the French, merchants set about rebuilding their businesses with spectacular success. Pedro Domecq took over the firm of Juan Haurie in 1822, and Manuel María González Angel, founder of GONZÁLEZ BYASS, began trading in 1835. Sherry exports rose steadily from about

8,000 butts in the early years of the century to over 70,000 butts in 1873, a figure not exceeded again until the 1950s. In the 1850s, the sherry industry was greatly helped by the construction of a RAILWAY linking Jerez and Puerto de Santa María, and a number of merchants left their quayside bodegas. Many new producers took advantage of the sherry boom only to be wiped out by PHYLLOXERA and economic depression a few years later.

By the end of the 19th century, the sherry industry was on the brink of collapse. The boom gave rise to numerous spurious 'sherries' from South Africa, Australia, and France—and from Germany, where a sherry-style potion was made from potato spirit. A spiral of price-cutting began, and sherry was stretched with poor-quality wine imported from other parts of Spain. Demand fell as Victorian society refused sherry, alarmed by scare stories that the wine was detrimental to health. The predations of phylloxera from 1894 helped to stabilize the market, and the shippers who survived the depression held large stocks of unsold wine to tide them through the lean years when all the vineyards were replanted.

In 1910 the leading traders united to form the Sherry Shippers Association, which campaigned vigorously to restore the fortunes of the beleaguered industry. After the First World War exports returned to their late 19th century levels. In 1933 a CONSEJO REGULADOR was formed to protect and control the sherry industry, and in 1935, a year before the outbreak of the Spanish Civil War, Jerez established its own DOP region. The Civil War (1936–9) had little effect on sherry exports, but trade collapsed during the Second World War.

The most dramatic episode in the recent history of sherry began in 1944 when Don Zoilo Ruiz-Mateos y Camacho, mayor of the town of Rota, bought out a small sherry stockholder whose business had suffered badly during the war. In the late 1950s, his son, the now legendary José María Ruiz-Mateos, secured a 99-year contract to supply the important BRAND owners Harveys of Bristol with all their sherry requirements. With help from the banks, he began buying up other bodegas and in 1961 established the Rumasa empire. In the 1970s, Ruiz-Mateos acquired substantial wine interests outside Jerez

(see RIOJA), as well as in banking, construction, retailing, tourism, chemicals, and textiles. The group is said to have bought three banks in a single day. Although Ruiz-Mateos contributed greatly to the modernization of the Spanish wine industry, Rumasa initiated a price-cutting spiral which continued to blight the long-term interests of sherry well into the 1990s. Ruiz-Mateos's empire-building abruptly ended in 1983 when, fearing imminent collapse, the government nationalized Rumasa, which at that point controlled about one-third of the sherry industry. Rumasa's component parts were subsequently returned to the private sector.

Since the mid 1980s, the sherry industry has been facing decline. The total vineyard area is less than one-third of what it was at the end of the 1970s. Plots of sunflowers and cereals are now commonplace among the vines. In the early 1990s, with a worldwide market estimated to be around 1.09 million hl/28.7 million gal, stocks were drastically reduced as the sherry industry attempted to bring supply and demand back into balance. By 2012 a new phenomenon surfaced as the supply of grapes from the dramatically smaller vineyard area dropped for the first time below demand. Ruiz-Mateos briefly resurfaced in the early 21st century before his group again went under amid charges of assorted fiscal misdeeds. A few new names have appeared on the Jerez landscape, such as Tradición, Rey Fernando de Castilla, Dios Baco, and El Maestro Sierra. They have typically acquired older soleras from bodegas which either disappeared or were taken over by others.

Another leading actor has been the Estévez group, once led by the idiosyncratic José Estévez, the inventor of a controversial system to remove HISTAMINE from sherries. This group now includes Marqués del Real Tesoro, Tío Mateo, Hijos de Rainera Pérez Marín-La Guita, and Valdespino. Also showing signs of dynamism have been the Sanlúcar de Barrameda bodegas, from the giant Barbadillo to smaller ones such as Hidalgo-La Gitana and Pedro Romero. Equipo Navazos, formed by wine writer and criminologist Jesús Barquín and Estévez group winemaker Eduardo Ojeda, has successfully contributed to the rebirth of interest in sherry worldwide by acquiring exceptional old

butts from various bodegas and releasing small bottlings under the brand 'La Bota de…'.

Amid calls to rejuvenate the concept of sherry, including the promotion of a larger number of vintage-dated wines (a concept adopted by González Byass for some top-end Olorosos, Amontillados, and Palos Cortados), the Consejo Regulador responded in 2000 by creating two new categories of high-quality sherry: VOS (Very Old Sherry or *Vinum Optimum Signatum*), for wines with an average age surpassing 20 years; and VORS (Very Old and Rare Sherry or *Vinum Optimum Rare Signatum*), for wines over 30; with four subcategories of both, Oloroso, Palo Cortado, Amontillado and Pedro Ximénez. Such methods as carbon dating were introduced to ascertain the age of the wines submitted by bodegas, and demanding blind tastings were instituted to accept or reject samples. This elite category has stirred up fresh interest in sherry, but it is a minor presence on the market as most of the brands release just a few hundred bottles of their prized elixirs every year.

There is also increasing interest in the EN RAMA sherries that are perceived as more authentic and less manipulated than the regular versions.

The most important development, however, may be the return of non-fortified wines produced under flor, as they would have been 200 years ago, a movement pioneered by Equipo Navazos with their wines Navazos Niepoort (since vintage 2008) and Florpower (since vintage 2010). These delicate, lower-alcohol wines are classified either as generic table wine (VINO) or under the IGP Vino de la Tierra de Cádiz (as are the many compelling red wines from the variety TINTILLA DE ROTA). The success of these non-fortified white wines has inspired the Ministry of Agriculture to drop the fortification requirement for sherry, a change that was awaiting approval by the European Commission in 2023.

Geography and climate

The climate of the Jerez region is strongly influenced by its proximity to the Atlantic. Sea breezes from the gulf of Cádiz alleviate extremes. The oceanic influence is strongest in the coastal towns of Sanlúcar de Barrameda and Puerto de Santa María, where temperatures in July and August may be 10 °C/18 °F lower than in Jerez, 20 km/12 miles inland. Winters are mild and damp with most of the region's annual average rainfall of 650 mm/25 in falling between late autumn and spring. Summer temperatures often reach 30 °C inland, occasionally rising to 40 °C with the levante, a dry, dusty WIND from the south-east.

The vines are sustained during the dry summer months by the porous, white ALBARIZA soils that are at the heart of the Jerez DOP. The roughly triangular demarcated region extends from the town of Chiclana de Frontera in the south-east to the river Guadalquivir in the north-west, tapering inland. However, the best albariza soils cover a stretch of rolling country north of the river Guadalete between Jerez and Sanlúcar de Barrameda. These outcrops of albariza are known collectively as Jerez Superior, and most of these vineyards are within the municipality of Jerez de la Frontera, with secondary pockets around Sanlúcar de Barrameda, Trebujena, Puerto de Santa María, Chiclana, Chipiona, and Rota.

The albariza zone is divided into subdistricts. Those with the deepest, but not necessarily the most CALCAREOUS, albariza soils—like the famous Balbaina, Macharnudo, Carrascal, and Añina districts—produce the most delicate wines for the finest Finos and Manzanillas (see Winemaking below). The most calcareous soils, known as *tajón*, are generally unsatisfactory for viticulture because of potential CHLOROSIS. The finest albarizas include a proportion of SAND and CLAY and tend to vary with depth, with a LIMESTONE content of 25% or more on the surface rising to 60% in the rooting zone 80–100 cm/31–39 in below the surface. In between the hills of albariza, *barro* soils have more clay and would produce fuller, coarser wines and slightly higher yields if they were planted. On the sandy soils known

as *arenas*, yields are twice as great as on the albariza, but the quality of the wine is poor. Arena soils were popular with growers at the end of the 19th century as PHYLLOXERA could not survive in it. They are still popular for Moscatel (Muscat of Alexandria). However, viticulture is increasingly concentrated on the albariza soils, and over 80% of the region's vineyards are situated in Jerez Superior.

Viticulture and vine varieties

In the 19th century, many vine varieties were planted around Jerez but, after phylloxera wiped out most of the vineyards in the 1890s, many varieties were never replanted. Only three varieties have been authorized for new vineyards in Jerez: PALOMINO, PEDRO XIMÉNEZ, and MUSCAT OF ALEXANDRIA. Of these, Palomino is the most important and accounts for around 95% of the total vineyard area. There are in fact two types of Palomino: Palomino Basto (also known as the Palomino de Jerez) and Palomino Fino. Palomino Basto has largely been supplanted by Palomino Fino, which provides better YIELDS and is more resistant to disease. Palomino Fino has proved to be a particularly versatile grape and is used for most types of sherry.

Moscatel Gordo Blanco (Muscat of Alexandria) represents about 3% of the Jerez vineyard and is planted principally in the sandy soils on the coast around Chipiona. It is mainly used for sweetening although some producers make VARIETAL Moscatel wines, including one of near-mythical proportions, Valdespino's Toneles.

Pedro Ximénez (known for short as PX) has given ground to Palomino and currently represents less than 100 ha/250 acres of vineyard since Palomino Fino is easier to cultivate. Most sweet wine is now made from Palomino although some smaller producers still maintain small PX SOLERAS which they bottle as a VARIETAL wine.

In late 2022 some of the traditional varieties that almost disappeared after phylloxera, namely Beba, PERRUNO, and Vejeriega, were also authorized. Their presence in the region's vineyards is minimal today, hence we should not expect an explosion of the volume of wine made with these grapes in the foreseeable future.

Since phylloxera swept through Jerez, all vines have been grafted on to American ROOTSTOCKS which are selected according to the soil's LIME content. In the past vines were planted in a hexagonal pattern known as *tresbolillo*, but, with increasing MECHANIZATION, vineyards are planted in orderly rows at a maximum VINE DENSITY of 4,100 vines per ha (1,660 per acre). Yields from the Palomino are high, although

the maximum permitted yield for the entire DOP has been set at 80 hl/ha (4.5 tons/acre).

With the onset of mechanization, modern vineyards are trained on WIRES, while the traditional PRUNING method, called *vara y pulgar* and similar to the GUYOT system, is being abandoned. A *vara* (meaning 'stick' or 'branch') with seven or eight BUDS produces the current year's crop. The *pulgar* (meaning 'thumb') is a short SHOOT with one bud which will produce the following year's *vara*.

Winemaking

The HARVEST begins when the Palomino has reached a MUST WEIGHT of at least 11 °BAUMÉ. It was traditionally on 8 September, but in recent decades it tends to start close to mid-August in the inland vineyards. It lasts for about a month.

Grapes are loaded into plastic crates and transported to large, automated wineries, where they are destalked and pressed. Most bodegas use horizontal plate or pneumatic PRESSES to control the EXTRACTION rate, which may not legally exceed 72.5 l/19 gal of juice from 100 kg/220 lb of grapes (16% higher than the extraction rate permitted for CHAMPAGNE, for instance). Others, especially the CO-OPERATIVES, use continuous de-juicers which tend to produce coarser wines with more solids and PHENOLICS. Today acid levels are adjusted with the addition of TARTARIC ACID prior to fermentation, and cold STABILIZATION before bottling is usually essential.

After SETTLING or CENTRIFUGATION, fermentation generally takes place in temperature-controlled, stainless-steel tanks, although a few shippers continue to ferment a small proportion of their wine in butts, mainly to impregnate and season new casks of American oak that are to be used for maturation. (New BARRELS are not valued in Jerez.)

The modernization of the sherry industry which began in the 1960s has removed much of the mysticism that once surrounded the production of sherry. The modern winemaker can predetermine which of the two initial sherry types—*fino* and *oloroso*—each lot of grapes becomes.

The first selection takes place in the vineyard. Wines for the best *finos* are sourced from older vines growing on the best albariza soils, while *olorosos* are made from grapes grown on the heavier clays. Elegance is crucial to *finos*, also made from the best FREE-RUN juice, which has fewer impurities than the slightly coarser and more astringent juices from the press; those are set aside for *olorosos* or inferior *rayas*, particularly coarse *olorosos*. Wine destined for *fino*

tends to be fermented at a lower temperature than that made for *oloroso*.

The second selection takes place soon after the end of fermentation. Palomino-based wine has a natural alcohol content of 11–12%. Depending on the style of the wine, sherry may be fortified with grape spirit to 15–17.5% alcohol. The appearance of FLOR, the veil of yeast that forms on the surface of the wine and distinguishes *fino* from other styles of sherry, is determined by the degree of alcohol: growth is inhibited by an ALCOHOLIC STRENGTH much above 16%. Wines destined to develop into *finos* are therefore fortified to 15–15.5%. *Olorosos*, which mature without flor, are fortified to a higher strength.

The sherry bodegas are teeming with the flor YEAST strains. This beneficial FILM-FORMING YEAST grows naturally on the surface of the wine, although some houses now choose to cultivate their own flor culture. Butts used for *fino* are filled only to around five-sixths of their 600-l/160-gal capacity because flor, which both protects the wine from OXIDATION and changes its character, feeds off OXYGEN as well as alcohol, glycerine, and ACETIC ACID.

Flor is also extremely sensitive to heat, and in the warm and dry summer months it tends to die. In Montilla, for example, flor is reduced to a scum-like film in July and August, while it tends to grow more thickly and evenly in the cooler, more humid coastal towns of Sanlúcar de Barrameda and Puerto de Santa María (although this can depend on the architecture, orientation, and management of each building). This accounts for some of the subtle differences in style between *finos* from Jerez and El Puerto and from Manzanilla outlined below.

Left to its own devices, flor would feed on the nutrients in the wine and die before having a profound influence on the wine's character. However, flor is kept alive in casks of *fino* for six years or more by continually topping up the butt with younger wine, which replenishes the yeast nutrients. This is the basis of the SOLERA system, a method of fractional blending which, apart from nurturing flor in *fino*, also maintains a predictable style.

A sherry solera comprises several groups of butts, each of which is known as a criadera. Wine is typically withdrawn from the group containing the oldest wine, which is itself called the solera. This is replenished from the butts that form the first criadera, which is in turn replenished by wine from the second criadera, a process known as 'running the scales'. Simple soleras are fed by three or four criaderas, while more complex systems run to as many as 14. The whole system is fed with new wine from the most recent harvest. Up to 33% of the wine in a solera may be withdrawn in any one year. *Fino* soleras need to be refreshed the most frequently, and by running the scales at regular intervals (usually two or three times a year) flor may be kept alive for eight to ten years, more if the task is carefully done.

Styles of sherry

The diagram on this page shows how commercial styles of sherry are derived.

The lightest, driest styles are *fino* sherries. These wines are aged under a protective layer of flor and filtered before bottling at a minimum of 15% alcohol. A Manzanilla sherry is a *fino* style aged in SANLÚCAR DE BARRAMEDA, where the flor layer grows thicker; it tends to be lighter, higher in acidity, and lower in alcohol than a *fino*.

Finos which lose their covering of flor become *amontillados*, turning amber in colour and changing in character due to greater contact with the air. *Amontillados* evolve naturally if the flor has exhausted its supply of nutrients, or the style may be induced if the flor is killed off by fortification to 17% alcohol or more. A *fino* beginning to take on the characteristic of an *amontillado* used to be able to be labelled as a *fino amontillado*, but no longer; however, a *fino* from Sanlúcar de Barrameda can be labelled as Manzanilla Pasada. True *amontillados* are completely dry and the finest examples age for many years in their own soleras. (see AMONTILLADO).

Olorosos, on the other hand, are fortified to 18–22% alcohol, inhibiting the development of flor. They age in greater contact with the air, turning brown and gaining in concentration with age. The alcoholic content increases with slow EVAPORATION such that the strength of an old *oloroso* may approach 24%. *Olorosos* are dry, although old wines may taste full and concentrated. *Rayas* (inferior *olorosos* used in blending) may be aged in the open air. Sweet styles may no longer be labelled as OLOROSO; instead they are typically called Cream.

A Palo Cortado is a wine that was chosen to become a *fino* but never developed a full covering of flor and so aged in an oxidative, oloroso way, the final result falling somewhere between the two in delicacy and flavour.

Sweet sherries, most of them styled Cream or Medium, can be made in several ways. Today Palomino grapes are frequently dried to raisins under plastic tunnels, pressed, and fortified before

fermentation to make a MISTELA. This is never as sweet or as powerfully concentrated as PX, but the method is widely used for more commercial sherries. Some commercial Cream sherries may be very ordinary blends to which sweetening and colouring wines have been added.

The darkest sherries may be adjusted with ARROPE or *vino de color*, a dark, sweet syrup that has been prepared by boiling down fresh grape must. Pale Cream sherry, typically a blend of *fino* and sweet wine, is normally adjusted with GRAPE CONCENTRATE and fresh, vacuum-concentrated Palomino must. A few bodegas sweeten their wines with fortified Moscatel, but this tends to produce a rather obvious, aromatic, grapey style of sherry.

In the early 2000s, two designations were introduced for particularly old sherries: VOS, Very Old Sherry or *Vinum Optimum Signatum*, for blends at least 20 years old; and VORS, *Vinum Optimum Rare Signatum* or Very Old and Rare Sherry, for blends at least 30 years old. Wines may also be labelled 12, 15, 20, and 30 Years Old.

Organization of the trade

Most properties are small, averaging little over a hectare. Growers typically sell their grapes either directly to a shipper or to one of seven CO-OPERATIVES. Some co-ops maintain their own soleras, but most sell the wine to one of the sherry bodegas.

There is a distinction between types of bodegas that has lost relevance in the last decade: *Bodegas de Crianza y Almacenado* are firms which mature and keep stocks of wine or ALMACENISTAS. They may sell young or aged wines in bulk to the *Bodegas de Crianza y Expedición*, firms which both mature and sell wine for consumption. The Bodegas de Expedición used to be required by law to maintain a significantly higher stock of wine than that of the almacenistas, but that changed in 2013 (now they each have to meet a minimum of 250 hl/6,600 gal., i.e. 50 sherry casks), so it is now a matter of choice by each producer.

Another major change is underway: the disappearance of the historical distinction between *zona de producción* (the entire territory of the DOP) and the *zona de crianza* (the three main towns that form the Sherry triangle). Historically, only wines matured within the towns of JEREZ DE LA FRONTERA, SANLÚCAR DE BARRAMEDA, and PUERTO DE SANTA MARÍA were permitted to use the term 'sherry'. A new regulation published in October 2022 permits the use of the term 'sherry' for wines aged and bottled in any of nine towns in the Sherry DOP.

shipping. See TRANSPORT OF WINE.

Shiraz, the Australian name for the SYRAH grape, widely used elsewhere, and therefore a name better known by many consumers than its Rhône original. Because Australian Shiraz was so successful in European markets, the word 'Shiraz' has been used on wine labels for Syrah grown all over the world, notably SOUTH AFRICA, although the word 'Syrah' is also used there to denote a lighter, fresher northern RHÔNE style of wine rather than a typically concentrated, FRUIT-DRIVEN, potent Australian-style Shiraz. The variety was probably taken to Australia, possibly from Montpellier, in 1832 by James BUSBY. It flourished so obviously that it was rapidly adopted by New South Wales and spread from there. From that time onwards, Shiraz (variously called Scyras, Syrah, or Hermitage) was the dominant red variety in Australia and still is, with a total vineyard area of 43,192 ha/106,730 acres in 2022. When the concurrent red-wine and export booms began in the second half of the 1980s, plantings in all regions, very cool to very warm, increased substantially. The result has been a range of styles from elegant, cool-grown Rhône styles (often with a dash of Viognier—see CO-FERMENTATION) through half a dozen important and regionally distinctive richer, riper styles, some traditional (Barossa Valley), some newer (Heathcote). Blends of Shiraz and Cabernet have been an Australian speciality for decades. For more detail, see AUSTRALIA.

The grape variety shares a name, but little else, with the medieval capital of PERSIA, although the (white) wine of Shiraz has been enthusiastically documented.

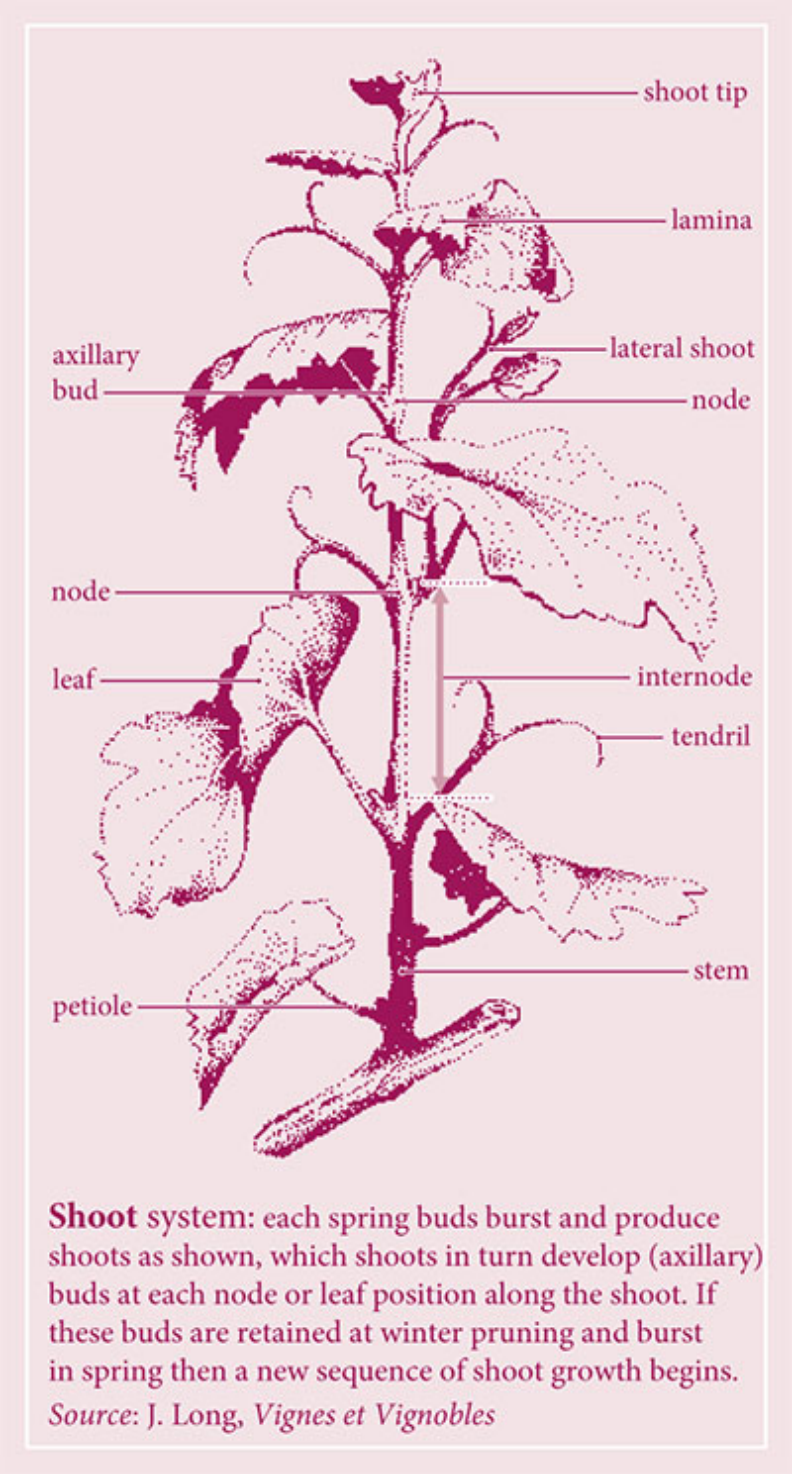
Shoalhaven Coast, warm, humid region on the NEW SOUTH WALES coast south of Sydney producing noteworthy SÉMILLON and CHAMBOURCIN, favoured for its MILDEW resistance.

shoestring root rot, vine disease. See ARMILLARIA ROOT ROT.

shoot, new growth in a vine plant that develops from a bud and consists of a stem with leaves and tendrils or INFLORESCENCES; these last become bunches of grapes. Collectively, the shoots and leaves of a vine form its CANOPY. The BUDS of a grapevine burst in spring to begin a new shoot (see BUDBREAK). Shoot growth gradually accelerates to a maximum rate before FLOWERING, then may slow to a stop at about VERAISON, common in unirrigated vineyards in a MEDITERRANEAN CLIMATE. When vines are well-supplied with water, shoots can continue to grow after veraison, which compromises fruit RIPENING; see WATER STRESS.

VIGOUR, which effectively means shoot growth rate, varies hugely between and within vines. A vigorous shoot is evident by its long INTERNODES, large leaves, strong LATERAL SHOOTS, and long tip tendrils well before flowering; weak shoots are the opposite. Despite these differences in growth rate and length at full bloom, shoots, whether weak or vigorous, have 17–20 visible internodes. Later in summer the stem of the shoot changes from green to brown (lignifies) and thus becomes a CANE (see CANE RIPENING).



Shoot system: each spring buds burst and produce shoots as shown, which shoots in turn develop (axillary) buds at each node or leaf position along the shoot. If these buds are retained at winter pruning and burst in spring then a new sequence of shoot growth begins.

B.G.C. & R.E.S.

shoot-positioned, general term used to describe some vine-TRAINING SYSTEMS created using a TRELLIS SYSTEM and SHOOT POSITIONING.

shoot positioning, spring and summertime viticultural practice of placing vine SHOOTS in the desired position on a TRELLIS to assist in TRIMMING, LEAF REMOVAL, and HARVEST operations and to facilitate the control of VINE DISEASES and VINE PESTS.

The practice is by no means universal but is more common in wet and humid climates with moderate to high vineyard VIGOUR and a high risk of FUNGAL DISEASES, for example in Germany, Alsace, and New Zealand. Some important examples of non-shoot-positioned CANOPIES are found in drier climates, such as the GOBELET-trained vines of the Mediterranean and also the 'drooping' canopies of vigorous vines in California and Australia.

Typically the shoots are positioned upwards and are held between two pairs of foliage or catch wires, and sometimes the foliage wires themselves are moved to catch the shoots. Generally the operation is carried out manually, but a VINE FOLIAGE LIFTER may also be used. Shoots are then trimmed to resemble a neat hedge so that the shoots do not fall down the sides and cause SHADE. This then facilitates other vineyard operations such as SPRAYING and general cultivation, enabling mechanical operations such as leaf removal. For some training systems, such as GENEVA DOUBLE CURTAIN, shoots are positioned downwards, or upwards and downwards, as in the SCOTT HENRY and SMART-DYSON systems. R.E.S.

Smart, R. E., and Robinson, M., *Sunlight into Wine: A Handbook for Winegrape Canopy Management* (1991).

shoot thinning, vineyard operation normally carried out by hand in the early spring which consists of breaking off unwanted shoots arising from the vine's HEAD or CORDON. Sometimes these shoots have

no bunches and are called WATER SHOOTS. The shoot-thinning operation can be done most quickly when the shoots are 20–40 cm/8–15 in long and the bunches are quite visible, which allows discrimination between fruitful and non-fruitful shoots. The aim of shoot thinning is to reduce the density of the CANOPY and to avoid leaf congestion later in the season. This can help improve wine quality (see CANOPY MANAGEMENT) but is common only in regions with plentiful and relatively inexpensive LABOUR. Shoot thinning by machine is possible but not common. See also DESUCKERING. R.E.S.

shoot tip, the 1 cm/0.4 in of shoot furthest from the vine's original bud, also known as the shoot apex. This small piece of tissue competes very effectively with the grapes for food produced by the mature leaves, and so a vigorously growing vine may slow fruit RIPENING. These nutrients may be temporarily diverted to the grapes by TIPPING the shoots but only until the LATERAL SHOOTS regrow.

The balance between shoot growth and fruit growth has important effects on grape RIPENING and wine quality (see BALANCE, LEAF TO FRUIT RATIO, and VINE PHYSIOLOGY). Shoot-tip growth is being increasingly used to monitor vine growth as a guide to vine management. For example, IRRIGATION should be regulated so that shoot growth stops by the time of VERAISON, and Californian, Australian, and French studies have related shoot-tip appearance to measurements of vine WATER STRESS. Also, a vine which is in balance and has been pruned appropriately will not have excessive numbers of shoot tips from the main and lateral shoots. B.G.C. & R.E.S.

short, tasting term for a wine whose impact on the PALATE is not persistent; the opposite of LONG.

shot berry, small, immature, usually seedless berry resulting from insufficient pollination. See MILLERANDAGE.

shows, wine. Now a universal phenomenon, wine shows have occupied a particularly important place in Australia's wine culture, taking place in each AUSTRALIAN state's capital (originally offshoots of general agricultural shows), with some uniquely Australian features. Each class, established by variety and vintage(s), is judged by a panel of three judges, one being panel chair, and three associate judges. To be invited to act as a judge or even an associate judge is regarded as an honour. Judges usually wear white coats, work in silence, and may be expected to evaluate as many as 200 wines a day. If one or more of the judges has given gold-medal points to a wine, it will automatically be retasted and discussed, and the show chair may well be called in. The more experienced judges officiate at up to ten regional and capital city shows a year, know each other well, and have mutual respect for each other. While the discussion—in best Australian fashion—may be robust, it seldom, if ever, becomes ill-tempered. The most important part of the discussion usually turns on style issues.

The trophies and medals awarded to the more successful exhibitors are used extensively in marketing and promotion, being accepted as reliable indicators of quality by retailers and consumers alike. But the greater long-term benefit has been for the winemaker judges, drawn from the leading wineries and schooled by chairs in the tradition of Len EVANS. J.H.

shutdown, vine. Some growers use this imprecise term for a cessation of the ripening process caused by WATER STRESS and/or temperatures over 35 °C/86 °F, which cause STOMATA to close and PHOTOSYNTHESIS and TRANSPIRATION to stop.

Sicily (known as Sicilia in Italian), large and viticulturally important island off the toe of ITALY (see map under ITALY).

Ancient history

Sicily was famed throughout classical antiquity for its agricultural produce, not least its wines. The recent find of a Copper Age (*c.* 3000 BCE) pot with traces of tartaric residue may take the production of wine in Sicily back to prehistory. However, the settlement of colonies of Greeks around the island in the 8th century BCE was an undoubted spur to the growth of viticulture. The local production of western Greek wine AMPHORAE from the 6th century on confirms this development. Flourishing vineyards are testified for the 5th century at the later Greek settlement Akragas (Agrigento). Sicily may have played a key role in the development of viticulture on the Italian peninsula (see ITALY, ancient history). Vines from Morgantina and Tauromenium were transplanted to POMPEII around Vesuvius, the Colli ALBANI, and southern Etruria, where they were well established by the 2nd century BCE (Pliny, *Natural History* 14. 25, 35, and 38). The most notable characteristic of Sicilian wines was their sweetness. The most famous were Mamertine, a sweet, light wine from the north-east of the island around Messina, and a very similar wine from Tauromenium (Taormina); but there is evidence for wine production right down the east coast. Inland there was the Murgentina vine from Morgantina (Serra Orlando). Inscriptions on amphorae testify to a so-called 'Mesopotamian' wine from the south coast near Gela. Sicilian wines were certainly exported (references to Tauromenian, for example, appear on amphorae). J.J.P.

Wilson, R. J. A., *Sicilia under the Roman Empire* (1990).

Medieval history

Throughout the Middle Ages, Sicily's main export product was grain. It also produced olives, citrus fruits, and wine, but wheat has the advantage of being far less capital intensive: whereas olive trees, citrus fruit trees, and vines take years to come into full bearing, wheat can be harvested months after it has been sown. Medieval Sicily owed its wealth to grain.

Under the Normans, who governed Sicily from 1130 to 1194, smallholders owned most of the land, and they made their living mainly by growing wheat or, in the mountainous parts of the island, keeping livestock. They grew vines as well, but the wine made was usually for domestic consumption. In the 14th century, demand for high-quality wine rose, and vineyards spread through Sicily. Many of these vineyards, which produced wine for well-to-do Sicilians or for export, were owned by members of the feudal aristocracy or the local nobility. The principal winemaking towns were strung along the north-eastern and eastern coasts: Cefalù, Patti, Aci, Catania, Augusta, and Syracuse. These not only produced large surpluses of wine but were also able to ship their wine safely to Messina, from where it was taken to Africa and the Levant. From Patti, wine was carried to Constantinople, and Syracuse traded with nearby MALTA. Messina also imported wines from CALABRIA, which it then shipped to northern Italy; Messina and Palermo also carried Sicilian wines to the towns of northern Italy.

Palermo was Sicily's largest and most important city. In the early 14th century, it had 100,000 inhabitants, as did NAPLES; in the whole of Europe only VENICE and Milan, with populations of 200,000, were larger. Because of its size, Palermo and its surrounding countryside could never make enough wine for the city's needs, and so it imported wine from Naples and Calabria, which was cheaper than transporting wine overland from eastern Sicily. This provoked the wrath of the citizens of Catania. Palermo exported wine as well.

From the late 14th century onwards, more and more vineyards around Palermo, Messina, and Catania came to be owned by

members of the upper classes; so, after 1400, did taverns. In the 15th century, most of the wine continued to be made in areas near ports: Aci, Catania, Messina, Taormina, and, in the west, Trapani. But further inland, Noto and Randazzo were also important. By far the biggest exporter was Messina, but Francavilla, Patti, Trapani, and Palermo handled a lot of the foreign trade in wine, too.

The wines that Sicily exported were mostly strong, sweet wines capable of surviving the sea voyage, such as VERNACCIA and Muscatello. Other names of wines mentioned in documents are Mantonico (also called Mantonicato), which could be red or white; a white wine named Cuctumini; and finally Mamertino, which shares its name with the classical Mamertinum, which PLINY tells us was grown in Messina (*Natural History* 14. 66). Matthew, D., *The Norman Kingdom of Sicily* (1992).

Modern wines and other vine products

While Sicily had been Italy's second most important wine region after the Veneto in 2013, it was in fifth place by 2020, its total vineyard area having fallen to 98,355 ha/243,040 acres (down from 114,290 ha in 2011). Of the 3.6 million hl of wine it produced in 2020, two-thirds were DOC and IGT wines, a clear sign Sicily has firmly set course on quality rather than quantity.

The earlier concentration on quantity over quality, systematically encouraged between 1960 and 1987 by the regional government's subsidies for the transformation of traditional BUSH VINES into more productive WIRE-trained or TENDONE systems, led to a chronic cycle of over-production, with the EU's compulsory DISTILLATION regime encouraging CO-OPERATIVES to produce wine they knew would be distilled and GRAPE CONCENTRATE used for ENRICHMENT.

Sicily's BULK WINE production has steadily declined since, but it is still used, legally or not, to beef up weaker wines and vintages throughout Italy as well as in France and Germany. Nevertheless, Sicily produces much more white than red wine, notably from the island's 30,227 ha/74,693 acres of white wine grape CATARRATTO; the second most planted variety is the red NERO D'AVOLA, with 14,749 ha/36,446 acres. While Sicily was quick to adapt to demand for INTERNATIONAL VARIETIES such as Syrah, Chardonnay, and Merlot, they play an increasingly shrinking role in the vineyards, while PINOT GRIGIO has increased to 2,749 ha/6,793 acres, up from 1,197 ha in 2010.

In terms of climate and geology Sicily is often, rightfully, considered a continent itself. Its diverse MESOCLIMATES range from distinctly alpine on Mount Etna, where vineyards rise up to 1,000 m/3,280 ft in ELEVATION, to the subtropical on the island of PANTELLERIA, which is closer to Tunisia than it is to the province of Trapani to which it administratively belongs. The island's centre can be hot and dry, although at higher elevations there can be favourable DIURNAL TEMPERATURE RANGE, while many regions are close enough to

the coast to benefit from such constant WINDS that FUNGAL DISEASES are a rarity except in the wettest of years.

The drive for quality began at the end of the 1980s when producers such as Planeta and Tasca d'Almerita began producing smartly packaged international varietals that seemed to copy wines from the New World. This drew the attention of large producers from Italy's north, who, attracted by low land PRICES and the virtual absence of a stringent DOC system, created large, fully mechanized estates, typically in the island's centre, which had traditionally been devoted to grain. While capitalizing on the Sicily brand name and image, these wines, unsubjected to practically any quality control and often bottled in Italy's north, did nothing to elevate Sicily's reputation. To curb these unregulated practices, several of Sicily's key producers put their weight behind the creation of a DOC covering the entire island in 2011. YIELD controls and the instigation of mandatory laboratory ANALYSIS and a subsequent panel tasting have had a direct effect on quality. In another effort to eliminate low-quality wines while protecting two of Sicily's most important INDIGENOUS VARIETIES, the white GRILLO and the red NERO D'AVOLA may no longer be mentioned on labels for non-DOC wines.

Several ancient wine regions have been rescued from the brink of extinction. From the island's eastern tip near Messina to Catania and the slopes of Etna, the distinct red NERELLO MASCALESE, in tandem with NERELLO CAPPUCCIO and Nocera, dominate the vineyards. Etna especially has seen an enormous rise in popularity resulting in huge investments and an influx of newcomers. (See ETNA for more detail.) The Faro DOC had been largely abandoned until the 1990s when the Palari estate began producing fine reds from its steep terraces. Between Messina and Milazzo, the DOC Mamertino, a wine region already appreciated by the Romans, declined quickly after the introduction of international varieties and a controversial mandatory addition of Nero d'Avola to the elegant, local, crisp Nocera, but Planeta's investment in the region has triggered a renaissance.

CERASUOLO DI VITTORIA, situated near the town of the same name near Ragusa on the south-eastern coast, is Sicily's only DOCG so far. Several producers, notably COS, which ferments some of its wine in AMPHORAE, and Arianna Occhipinti, who espouses BIODYNAMICS, are producing high-quality examples of the classic Nero d'Avola–FRAPPATO blend, while in the south-east the Eloro DOC with the subzone Pachino is Nero d'Avola's place of birth. The success of this accommodating variety is such that it has been planted in every corner of the island, regularly at the cost of other local varieties. The wines used to be made in a commercial straitjacket of rich concentration and oak, completely disguising their origin, but recent examples are fresher and more elegant. Producers Tasca d'Almerita and Centopassi are also beginning to coax out the potential of PERRICONE, an ancient red variety which is as tannic and as fickle to handle as NEBBIOLO.

Sicily's ancient sweet wine traditions can be found on the island of Lipari, where LATE HARVEST or DRIED-GRAPE examples of MALVASIA are turned into Malvasia delle Lipari, while Passito di PANTELLERIA is the greatest expression of ZIBIBBO, or Muscat of Alexandria. Many ALBERELLO vineyards can be found in Sicily's extreme west between Erice and Trapani, but their future seems uncertain now that so many have been GRUBBED UP thanks to EU subsidies. Meanwhile MARSALA, once western Sicily's raison d'être and one of the world's famous FORTIFIED WINES, has long languished on the margins but now is experiencing renewed interest triggered by a handful of stalwarts and a new, energetic generation. www.consorziodocsicilia.it

Sideritis, Greek pink-skinned vine variety found to a limited extent near Patras in the northern Peloponnese. Originally grown mainly for TABLE GRAPES, it can also make steely, peppery whites.

Sideways, a 2004 film by Alexander Payne of the eponymous book by Rex Pickett about a wine enthusiast's adventures in the CENTRAL COAST. One of its themes was the superiority of Pinot Noir over the then-popular Merlot. It had an immediate effect on demand for varietal Pinot Noir, particularly in the US—to such an extent that it resulted in a global shortage of BULK Pinot. One Languedoc supplier managed to sell GALLO vast quantities of a Grenache blend masquerading as varietal Pinot Noir until being found guilty of ADULTERATION AND FRAUD. An earlier edition of this book figured prominently in the book but not the film. See also FILMS ABOUT WINE.

Siegerrebe, modern GERMAN CROSS grown principally, like certain giant vegetables, by exhibitionists, *Sieger* meaning 'champion'. In Germany it can break, indeed has broken, records for its ripeness levels, but the flabby white wine it produces is so rich and oppressively musky that it is usually a chore to drink. It was bred from SAVAGNIN ROSE and MADELEINE ANGEVINE and has been known to reach *double* the Oechsle reading required for a TROCKENBEERENAUSLESE. Total German plantings had blessedly dwindled by 2020 to 60 ha/148 acres in the Pfalz and Rheinhessen. The variety has also been used to bolster some blends in England, Switzerland, Washington State, and British Columbia.

Sierra de Gredos, mountain range 80 km/50 miles west of Madrid in SPAIN in which are parts of three DOPs in three political regions: Vinos de MADRID, MÉNTRIDA in Castilla-La Mancha, and

CEBREROS in Castilla y León. They form a specific viticultural area which one day may have its own appellation. Small vineyards in the mountains are planted with old GARNACHA and ALBILLO Real vines with some Garnacha Blanca on GRANITE and SLATE soils. A group of young growers began revitalizing the region in the early years of this century. V. de la S. & F.C.

Sierra de Salamanca, VINO DE CALIDAD in the south of Salamanca province in western SPAIN. The Sierra de Francia mountain range has some 300 ha/750 acres of vineyards on acid, GRANITE soils differing from the usual LIMESTONE of Spain's high plateaus. Ten wineries led by the ambitious Viñedos del Cámbrico and La Zorra vinify the mainly TEMPRANILLO and local RUFETE grapes. In 2020 Rufete Serrano Blanco (a variety distinct from Rufete) was authorized as an accepted variety, with promising results. V. de la S. & F.C.

Sierra Foothills, wine region in GOLD RUSH country in CALIFORNIA and an AVA covering the foothills on the western edge of the Sierra Nevada, the snowy mountains which separate California from the rest of the US. Thousands flocked here after 1849 and, miners being notoriously thirsty, the region's vineyards go back almost that far. The Sierra Foothills AVA encompasses the vineyards in El Dorado, Amador, and Calaveras counties while taking in a few others in the flanking Nevada and Mariposa counties. California Shenandoah Valley and Fiddletown are AVAs within Amador County; El Dorado AVA and the sub-AVA Fair Play take in the vineyards in that county. North Yuba AVA is in Yuba County.

El Dorado County and Fair Play AVA

In 1870 El Dorado was California's third most productive region, with 2,000 acres under vine. Despite dwindling to nearly none during PROHIBITION and staying that way until the late 1960s, the county again hosts around 809 ha/2,000 acres of vines and nearly 50 wineries. El Dorado's vineyards are much higher than those of Amador, starting close to 1,500 ft and ranging up above 1,160 m/3,600 ft on wooded hillsides over GRANITIC or VOLCANIC soils. Predictably, conditions are cooler, and the choice of varieties leans towards Cabernet Sauvignon, Merlot, Chardonnay, and Riesling, with Syrah, Petite Sirah, and Zinfandel. El Dorado was one of the few places growing the desired varieties when RHÔNE RANGERS such as Steve Edmunds of Edmunds St. John winery went looking for grapes in the 1980s. His wines prove the possibilities of Syrah in the county's higher ELEVATIONS; Grenache also can be superb.

The subdistrict Fair Play AVA is south of the El Dorado vineyards, which cluster around Placerville (known as Hangtown during the Gold Rush), about halfway to Amador County, but not along the aptly named main road, Highway 49. Thus Fair Play is mildly isolated, but its gaggle of small wineries has a justly deserved reputation for good times and for good-value wines.

Amador County

The heart of the county's wine production is its two AVAs, Fiddletown and California Shenandoah Valley (see below), where pre-PROHIBITION Zinfandel vines thrive and old-school BARBERA has found new life. Modernity also exists here, in Ann Kraemer's Shake Ridge Ranch, near the hamlet of Sutter Creek. Kraemer, an established Napa Valley viticulturist, has applied Napa vineyard expertise to Zinfandel, Syrah, Barbera, Tempranillo, and other varieties now highly sought after by producers looking for authenticity over commercial appeal. Typical ELEVATIONS are 240–360 m/800–1,200 ft.

Fiddletown AVA

Amador County's Fiddletown AVA adjoins the upper, eastern end of California Shenandoah Valley in the foothills east of the town of Plymouth. Amid rolling meadows and patchy pine forest at elevations ranging up to 2,500 feet, Fiddletown grows some of the state's oldest ZINFANDEL in a region now most famous for that grape. Soils are often granitic in origin, somewhat acidic, and well drained. There are few wineries in this AVA, but many elsewhere in Amador County purchase Fiddletown grapes.

California Shenandoah Valley AVA

Not to be confused with the Shenandoah Valley AVA in VIRGINIA, the California version is a mesa between two rivers east of the town of Plymouth. It became famous for hearty Zinfandels before the turn of the century and, after a long slumber, has regained some of its old momentum, again with Zinfandel and also Rhône varieties. More than a score of wineries share a modest acreage that also includes Sauvignon Blanc, Sangiovese, Syrah, and Petite Sirah.

North Yuba AVA

Sitting at the farthest northern extent of the Sierra Foothills AVA, the tiny North Yuba AVA was established in 1985 through the efforts of the only winery in the area, Renaissance Vineyard, which was founded by a controversial religious society known as the Fellowship of Friends. The AVA would not be worth noting but for the efforts of Gideon Bienstock, who made extraordinary wines for Renaissance from 1993 to 2006 and continues to do so at his own winery Clos Saron. L.M. & A.Y.

www.eldoradowines.org

www.amadorwine.com

Sierras de Málaga, Spanish DOP created in the early 21st century as effectively a subappellation of MÁLAGA to include a number of relatively new vineyards producing dry, unfortified wines, some in a subzone known as Serranía de Ronda around the inland town of Ronda. Powerful reds made from Syrah and Petit Verdot, and refreshing dry whites made from MUSCAT, are the region's key wines. The unfortified sweet Muscat wines from Axarquía, a style revitalized by Telmo Rodriguez and Jorge Ordoñez, merit mention, too. F.C.

silica gel and silica sol, amorphous forms of silicon dioxide in which there is no crystalline structure, used in white winemaking and rosé winemaking as FINING agents. In white wines it is also used in conjunction with GELATIN, and it may be used after fining with BENTONITE to improve SETTLING. It has also been suggested that its use reduces the risk of overfining.

silt, description of particles of intermediate size between CLAY and SAND. See SOIL TEXTURE and GEOLOGY for more details of this particular form of soil classification. Grains of silt dominate LOESS and are often predominant in ALLUVIAL soils. Silt is a major component of many of the soils in California's NAPA Valley.

Silvaner, called Grüner Silvaner in Germany, is an early-budding white grape variety grown mainly in Germany and central Europe (see SYLVANER for an account of it in France). Its very name suggests romantic woodland origins (*silva* means 'forest' in Latin), and certainly it has a long history over much of Eastern Europe, where it may indeed first have been identified growing wild. DNA PROFILING in Austria established that Silvaner is the progeny of SAVAGNIN (Traminer) and Österreichisch Weiss, a variety often mistaken for Silvaner and yet another progeny of GOUAIS BLANC. The cross probably took place in what is now Austria (although hardly any true Silvaner is grown there today), and it certainly came to Germany from the banks of the Danube. A vine known as Silvaner was widely grown throughout the extensive vineyards of medieval Germany. Its arrival from Austria at Castell in FRANKEN in 1659 is well documented, and it is the most planted variety in Franken, where distinctive CLAY and LIMESTONE soils seem to play a defining role in making full-bodied, firm, if aromatically discreet wines. Silvaner enjoyed its greatest popularity in the first half of the 20th century, when it overtook ELBLING to become Germany's most planted vine variety and established a dominant position in Rheinhessen. At 4,581 ha/11,320 acres in 2020, the variety is a distant third among white wine grapes to the even more productive MÜLLER-THURGAU, which rapidly surpassed it in area after the Second World War. GRAUBURGUNDER (Pinot Gris) has been catching up rapidly, however.

This vigorous vine buds a few days before Germany's quintessential RIESLING and can suffer spring FROST DAMAGE. It is not notable for its disease resistance, but it is productive. The chief

characteristic of the wine produced is its high natural acid, generally lower than Riesling's in fact but emphasized by Silvaner's lack of BODY and STRUCTURE. Provided YIELDS are not too high, it can offer a suitable neutral canvas on which to display more geographically based flavour characteristics (see TERROIR). Most of Germany's finest Silvaners come from Franken, where Riesling is difficult to ripen and Silvaner has remained popular. Occasional and encouraging examples are made elsewhere, however—such as in certain CALCAREOUS, SANDSTONE, or porphyry sites in RHEINHESSEN—where talented growers have achieved transparency of flavour and distinctively earthy character while avoiding the curse of a coarse, thick mid palate. Silvaner is certainly more than capable of producing versatile, workhorse white wine, and the winegrowers of Rheinhessen, where more Silvaner is grown than anywhere else, have been at pains since the early 1990s to generate consumer awareness and a better image for this grape. It is particularly recommended with white asparagus.

Blauer Silvaner is a local, dark-berried MUTATION that is a speciality of WÜRTTEMBERG.

Outside Germany, Silvaner is relatively important, as Sylvánské Zelené, in CZECHIA, is still grown in SLOVENIA as Zeleni Silvanec, and is grown in Croatia, Ukraine, and Moldova. It is also planted in ALTO ADIGE, where it makes light, piercing wines for youthful consumption. In SWITZERLAND it is the fourth most planted white wine grape. Also called Johannisberg, it can seem positively luscious in comparison with French Switzerland's ubiquitous CHASSELAS. Sylvaner is the second most planted white grape variety in the Valais, where it was once called Rhin, or Gros Rhin (as opposed to Petit Rhin, the local synonym for RIESLING). The variety ripens later than Chasselas and, in villages as warm as Chamoson, Leytron, and Saillon, can result in wines with more body, character, and race.

Despite its useful acidity levels, Silvaner is not widely grown outside of Europe, although California and New Zealand grow it to a strictly limited extent.

Simon, André Louis (1877–1970). Simon was the charismatic leader of the English wine trade for almost all of the first half of the 20th century and the grand old man of literate CONNOISSEURSHIP for a further 20 years. In 66 years of authorship, he wrote 104 books. For 33 years he was one of London's leading champagne shippers; for another 33 years, the active president of the Wine & Food Society. Although he lived in England from the age of 25, he always remained a French citizen. He was both Officier de la Légion d'Honneur and holder of the Order of the British Empire.

Simon was born in St-Germain-des-Prés, between the Brasserie Lipp and the Deux Magots (the street has since been demolished), the second of five sons of a landscape painter who died (of sunstroke, in Egypt) while they were still young.

From the first his ambition was to be a journalist. At 17 he was sent to Southampton to learn English and met Edith Symons, whose ambition was to live in France. They married in 1902 and remained happy together for 63 years in England. Simon was a man of judgement, single-mindedness, and devotion all his life.

He was also a man of powerful charm, the very model of his own description of the perfect champagne shipper, who 'must be a good mixer rather than a good salesman; neither a teetotaller nor a boozer, but able to drink champagne every day without letting it become a bore or a craving'.

He became a champagne shipper, the London agent of the leading house of Pommery, through his father's friendship with the Polignac family. It gave him a base in the centre of the City's wine trade, at 24 Mark Lane, for 30 years. From it he not only sold champagne; he also soon made his voice heard as journalist, scholar, and teacher.

Within four years of his installation in London he was writing his first book, *The History of the Champagne Trade in England*, in instalments for the *Wine Trade Review*. A. S. Gardiner, its editor, can be credited with forming Simon's English prose style: unmistakably charming, stately, and faintly whimsical at once. He spoke English as he wrote it, with a fondness for imagery, even for little parables—but

with an ineradicable French accent that was as much part of his persona as his burly frame and curly hair.

His first *History* was rapidly followed by a remarkable sequel: *The History of the Wine Trade in England from Roman Times to the End of the 17th Century*, in three volumes in 1906, 1907, and 1909—the best and most original of his total of over 100 books. None, let alone a young man working in a language not his own, had read, thought, and written so deeply on the subject before. It singled him out at once as a natural spokesperson for wine, a role he pursued with maximum energy, combining with friends to found (in 1908) the Wine Trade Club, where for six years he organized tastings and gave technical lectures of a kind not heard before; this was the forerunner by 45 years of the Institute of MASTERS OF WINE. In 1919 he published *Bibliotheca vinaria*, a catalogue of the books he had collected for the Club. It ran to 340 pages.

The First World War ended this busy and congenial life, full of dinners, lectures, book-collecting, and amateur theatricals. Before war was declared, Simon was in France as a volunteer, serving the full four years in the French Artillery, where as 'un homme de lettres' he was made regimental postman, before being moved on to liaison with the British in Flanders and on the Somme. It was in Flanders that the irrepressible scribbler wrote his bestseller, *Laurie's Elementary Russian Grammar*, printed in huge numbers by the War Office in the pious hope of teaching Tommy, the British soldier, Russian.

In 1919 Simon bought the two homes he was to occupy for the rest of his life: 6 Evelyn Mansions, near Westminster Cathedral (where he attended mass daily); and Little Hedgecourt, a cottage with 28 acres beside a lake at Felbridge in Surrey. Gardening these acres, making a cricket pitch and an open-air theatre, and enlarging the cottage into a rambling country house for his family of five children were interspersed with travels all over Africa and South America to sell Pommery, until suddenly, in 1933, caught in the violent fluctuations of the franc–pound exchange rate when Britain came off the gold standard, he could no longer pay for his

champagne stocks, and Pommery, without compunction, ended their 33-year association.

Simon began a second life at 55: that of spokesperson of wine and food in harmonious association. Already, with friends, he had founded the Saintsbury Club in memory of the crusty old author of *Notes on a Cellar-Book*. With A. J. A. Symons he founded the Wine & Food Society (now INTERNATIONAL WINE & FOOD SOCIETY). Its first (Alsace) lunch at the Café Royal in London in the midst of the Depression (and for 10*s*. 6*d*.) caused a sensation. But its assured success came from the ending of PROHIBITION in America. Sponsored by the French government, Simon travelled repeatedly to the US, founding its first Wine & Food Society branch in Boston in December 1934 and its second in San Francisco in January 1935.

Meanwhile, while working briefly for the advertising agency Mather & Crowther, he conceived the idea of *A Concise Encyclopedia of Gastronomy* to be published in instalments. It sold an unprecedented 100,000 copies. Research, writing, and editing (and finding paper to print) the *Encyclopedia* and the Society's *Quarterly* occupied him throughout the Second World War. His daughter Jeanne and her family moved into Little Hedgecourt for the war and thereafter. His son André was a wine merchant. His two other daughters and a son all retired from the world into religious communities.

Simon was a better teacher than businessman. He was repeatedly helped out of difficulties by adoring friends. Thus the National Magazine Company gave him an office in Grosvenor Gardens in 1941, to be followed by the publisher George Rainbird, still in central London at Marble Arch. In 1962 his friend Harry Yoxall suggested that, at 85, daily responsibility for the Society and its magazine was too burdensome and bought the title from him for Condé Nast Publications. But in his 90s, Simon was still exceptional company at dinner and gave little picnics for friends beside his woodland lake.

His final book, *In the Twilight*, written in his last winter, 1969, recast the memoirs he had published as *By Request* in 1957. On what would have been his hundredth birthday, 28 February 1977, 400

guests at the Savoy Hotel in London drank to his memory in CLARET he had left for the occasion: Ch LATOUR 1945. H.J.

Singapore makes no grape wine of its own, but the South East Asian island-country is a serious contender for becoming Asia's wine hub in the 2020s, a role played by HONG KONG since 2008. While the DUTY on wine may be considered a deterrent, there are plenty of positives. Located at a crossroads of several key markets, Singapore is the busiest trans-shipment port in the world. The highly affluent population is becoming only more so, a trend that has encouraged a proliferation of wine bars and shops, including a branch of the London wine club 67 Pall Mall, which offers the largest wine collection in South East Asia, including 1,000 wines by the glass. There is also an abundance of secure, competitively priced, temperature-controlled storage facilities, including South East Asia's largest, The Singapore Wine Vault. Singapore also hosts a vast array of food and wine events and trade fairs, including, from 2023, Prowein, the world's largest wine-trade fair, after more than two decades in Hong Kong. A.L.S.

single-vineyard wines, wines made from the produce of one vineyard, and sometimes a single block within a vineyard, are becoming increasingly common throughout the world of wine. Arguably most of the better wines of GERMANY, AUSTRIA, and the Côte d'Or in BURGUNDY were the prototypes. (Many Bordeaux CHÂTEAUX are made up of several non-contiguous plots.)

Sirah is the name by which some PETITE SIRAH is known in South America. It should not be confused with the true SYRAH of the northern Rhône.

Síria , old, light-berried vine variety with many synonyms grown on a declining 4,726 ha/11,672 acres all over Portugal, where it was the fourth most planted white wine grape in 2020. Wines are aromatic

but often age rapidly. It is known as Crato Branco in the Algarve, Roupeiro and Alva in Alentejo, and Códega in the Douro (distinct from CÓDEGA DE LARINHO). Known in Spain in the 16th century, it was planted on 1,947 ha in 2020, mainly in Castilla y León but also in Galicia. It is often known as Doña Blanca, as Cigüente in Extremadura, and as Malvasía Castellana in Toro.

site climate, the climate of a specified site, for instance a vineyard or part of a vineyard. The scale of definition usually falls within that of MESOCLIMATE.

site selection. See VINEYARD SITE SELECTION.

Sizzano , tiny but slowly growing DOC of 9 ha/22 acres in 2019 in the Novara hills in the PIEMONTE region of north-west Italy for seriously ageworthy reds made from SPANNA, the local name for Nebbiolo.

skin, grape. For details of grape skins, see GRAPE.

skin contact, *macération pelliculaire* in French, winemaking operation with the aim of extracting FLAVOUR COMPOUNDS, FLAVOUR PRECURSORS, and ANTHOCYANINS from grape skins into grape juice. In its widest sense it is identical to MACERATION, and some form of skin contact is usually essential to ROSÉ WINEMAKING, but the term is generally used exclusively for the maceration of white grapes before PRESSING and FERMENTATION with the aim of increasing the extraction of constituents that contribute to the aroma of white wines. It typically lasts four to eight hours, but since skin contact tends to reduce must acidity and increase PH the duration depends in part of the evolution of the pH. Destemmed and moderately crushed grapes are put into a vat and covered with INERT GAS and cooled down, if

necessary, to a temperature of less than 15 °C/59 °F. At the end of the process, the FREE-RUN juice is collected and the MARC is pressed. Skin contact can also take place directly in airtight pneumatic PRESSES. Skin contact also increases the concentration of AMINO ACIDS, leading to a better rate of fermentation. Vine varieties frequently processed with skin contact are Sémillon, Sauvignon Blanc, Gros Manseng, Muscat, and Riesling. Grapes must be healthy, be fully ripe, and have sufficient acidity and low tannin content. Denis DUBOURDIEU and his team have been responsible for its application to white bordeaux since the late 1980s. It is important to arrest skin contact before excessive amounts of PHENOLICS (which may also darken colour) are extracted. In some vintages and in some regions, especially when the skin is rich in TANNINS due to a hot, dry climate, the technique simply does not work as too much undesirable material is extracted with the minimum amount of additional flavour compounds.

Ribéreau-Gayon, P., et al., *Traité d'Œnologie* 1: *Microbiologie du vin: Vinifications* (7th edn, 1998), translated by J. Towey, as *Handbook of Enology* 1: *The Microbiology of Wine and Vinifications* (3rd edn, 2021).

skin-fermented. All red wines are fermented in contact with the skins of the grapes (see RED WINEMAKING and MACERATION). Many wines are pink because the juice was briefly in contact with the skins of red wine grapes (see ROSÉ WINEMAKING). Most white wines are made by separating the juice from the grape skins before fermentation (see WHITE WINEMAKING). However, a small but increasing proportion of white wines are fermented in contact with grape skins, often described as fermented on the skins: *maischevergoren* in German, *vino brisado* in Spanish, *vi brisat* in Catalan, *vini bianchi macerati* in Italian, and *vin blanc de macération* or *vin blanc macéré* in French. 'Skin-fermented white wine', or 'skin-macerated white wine', is therefore a more technically descriptive synonym for ORANGE WINE and

is so far regulated only in ONTARIO, South Africa, and Cataluña's Terra Alta DO. Not to be confused with SKIN CONTACT.

Lorteau, S., 'A comparative legal analysis of skin-contact wine definitions in Ontario and South Africa', *Journal of Wine Research*, 29 (2018), 265–77.

slashing, vineyard operation of mowing or cutting a COVER CROP, or cutting vine shoots in summer (see TRIMMING).

slate, a moderately hard, very fine-grained metamorphic rock (see GEOLOGY), the result of the burial of pre-existing rocks such as mudstone, SHALE, and volcanic TUFF, with a marked propensity to cleave into thin sheets. With increased metamorphism, slate becomes SCHIST.

Slate is found, for example, in the Cederberg Mountains, SOUTH AFRICA, and the CLARE VALLEY, South Australia. It is particularly celebrated in Germany's MOSEL and RHINE regions, where it makes famously stony slopes and is thought to hold moisture and heat and radiate warmth at night. A.J.M.

slip-skin. See AMERICAN VINE SPECIES.

SLO Coast, short for San Luis Obispo Coast, a coastal California wine region and AVA. See SAN LUIS OBISPO.

slope, or incline, an important characteristic of any vineyard site that is not completely flat. For more details, see TOPOGRAPHY.

Slovakia is regaining the vibrant wine scene it had before splitting from CZECHIA in 1992. Since then, total vineyard area has fallen from

around 25,000 ha/62,000 acres to around 7,000 ha in 2021, and yields are lower than the EU average. This shortfall may be explained by a combination of climatic and political conditions, FROST, poorer VITICULTURE practices, small-scale undeclared private production, and the complexity of legally restoring vineyards post-communism. New wine laws combining the principles of both French and German wine law came into force in 2009, defining six wine-growing regions, authorized grape varieties, and details such as minimum ripeness levels. Since then, interesting wines have been emerging, drier and more TERROIR-focused than 20th-century styles.

Despite a decidedly CONTINENTAL CLIMATE, Slovakia has many MESOCLIMATES suitable for winegrowing. Plantings are predominantly VITIS VINIFERA, although VINE BREEDERS, notably Dorota Pospíšilová, have produced a host of new Slovak CROSSES such as Devín, Dunaj, and Hron, all designed to reach high sugar levels rapidly.

The most resonant wine-growing area is in the west of the country, in the Malé Karpaty (Small Carpathians), where predominantly white wine is made from such grapes as SILVANER, VELTLINER, WELSCHRIESLING, RIESLING, Chardonnay, and various MUSCATS. Another key area is along the southern border, where the warmer climate favours red wine production from the likes of Cabernet Sauvignon and Frankovka (BLAUFRÄNKISCH). Tekov, in the Nitra wine-making region east of the Malé Karpaty, features VOLCANIC soils, remnants of the Sitno volcano, and a tradition of growing FETEASCĂ Regală (called Pesecka Lenka in Slovakia). In the far east, the Slovak portion of the TOKAJ region produces wines much like those across the border in HUNGARY, from FURMINT, MUSCAT BLANC À PETITS GRAINS, HÁRSLEVELŰ, and ZÉTA, their sweetness expressed in *putňový,* although a handful of winemakers are also starting to produce dry-style wines and even sparkling Furmint.

Slovakia consumes virtually all the wine it produces, with the noteworthy exceptions of the fine Rieslings of Kastiel Béla and the production of a growing number of wineries focused on NATURAL WINE such as Strekov 1075 and Slobodné vinárstvo. These winemakers

export most of their production to major cities all around the world, helping to confirm Slovakia's potential to produce high-quality wines.

V.K.R.

Slovenia , small and dynamic wine country in Central Europe that typically produces a little over half a million hl of wine annually from 14,900 ha/36,800 acres of vineyard. The country boasts one of the highest per capita wine consumption rates in the world, at about 36 l/7.9 gal a year, which means that little Slovenian wine leaves the country: only around 10% is exported. More than 27,000 winegrowers and 2,500 bottlers are registered, resulting in a highly fragmented vine-growing and winemaking scene. In Maribor, the capital of Štajerska Slovenija, is the 400-year-old *Stara trta* ŽAMETOVKA vine, which is officially the oldest on the planet and still producing grapes.

History

CELTS and Illyrian tribes were making wine here before the ROMANS. In the Middle Ages, wine production was an important economic activity undertaken by MONKS AND MONASTERIES. In 1880, when the country was part of the Austro-Hungarian empire, PHYLLOXERA arrived and literally halved the winegrowing area, extinguishing many INDIGENOUS VARIETIES. By 1935 the region saw its first defined wine zones, including recommended vine varieties, in Drava Banate, a province of what was then YUGOSLAVIA. After the Second World War, production was limited to CO-OPERATIVES, where quantity ruled over quality. However, some outstanding, long-lived whites were produced in those times, especially in the Podravje region, and some are still available from cellar archives. Commercially important private-sector wine businesses started to emerge in the 1970s. In 1967 the PSVVS (Business Association for Viticulture and Wine Production), now Vinska družba, was founded and introduced a seal of approval for Slovenian wines. In 1991 Slovenia established its independence, and in 2004 joined the EU. It was the first of the ex-Yugoslav countries to build a successful wine industry with fully implemented and well-policed wine laws and a thriving private sector.

Geography and climate Slovenia, laying between latitudes 45 and 47° N, is geographically very diverse, with many MESOCLIMATES. The country is divided into three wine regions, each further divided into nine districts. Podravje in the north-east and Posavje in the south-east both benefit from a moderate-to-cool CONTINENTAL CLIMATE influenced by the cooling effect of the Alps and warming effect of the Pannonian Plain. To the west, Primorska features a moderate-to-warm MEDITERRANEAN CLIMATE.

Annual rainfall averages 800–1,500 mm/31.5–59 in and DRY FARMING is standard. Spring FROST, summer HAIL, and occasional DROUGHT may be experienced in most wine districts.

Primorska With a steady 6,300 ha/15,600 acres of vines, this region has made great progress in quality since early 1990s and is today the most praised Slovenian wine region in certain quarters, having become an epicentre of NATURAL and ORANGE WINE production. Primorska is divided into four districts (PDOs). Goriška Brda, bordering Italy's COLLIO DOC and influenced by its Italian neighbours, is currently Slovenia's most esteemed wine district and PGI, having begun the quest for quality as early as the late 1980s. Rebula (RIBOLLA) is the flagship variety. Many of the best wines are oak-aged white and red blends based on Rebula/Chardonnay and Merlot/Cabernet Sauvignon/Cabernet Franc respectively. The dynamic Vipavska Dolina (Vipava Valley) district is proud of its native light, aromatic Zelen and flashier Pinela. Merlot and Pinot Noir show some class as well. Kras (Carso), a plateau above Trieste, is the home of Teran, a distinctive, highly acidic dark red made from Refošk (REFOSCO) grapes. Slovenska Istra on the coast is the warmest district in the country. Refošk and white Malvazija (MALVAZIJA ISTARSKA) prevail. Primorska also boasts some great sweet wines made in PASSITO style; Verduc (VERDUZZO) and Pikolit (PICOLIT) are specialities of Brda. Also grown in Primorska are Rumeni Muškat, Beli Pinot, LAŠKI RIZLING, VITOVSKA Grganja, Klarnica, Glera, Viognier, Barbera, Syrah, Cipro (possibly MAVRO), Pokalca (SCHIOPPETTINO), and Maločrn.

Podravje With 6,100 ha/15,000 acres of vines, this is the second largest wine region in Slovenia and also a PGI, divided into two districts (also PDOs). The extensive Štajerska Slovenija (Styrian Slovenia) district with its beautiful rolling hills is slowly regaining its former status, while the rather warmer Prekmurje district, a continuation of the Pannonian Plain in the far north-east of the country, is of minor significance. In 1852 Slovenia's first sparkling wine (*penina*) produced by the TRADITIONAL METHOD was made in Gornja Radgona.

White wines dominate in Podravje, making up 92% of production in 2020. The dominant grape variety is LAŠKI RIZLING, usually used for

inexpensive blends, but the region's reputation is based on aromatic whites typically produced in STAINLESS STEEL and bottled under SCREWCAPS. The increasingly popular Sauvignon Blanc (which also thrives across the border in STYRIA) has enjoyed some export success, as has Šipon (FURMINT), the traditional grape of the region. Renski Rizling (RIESLING), Chardonnay, Sivi Pinot (PINOT GRIS), Beli Pinot (PINOT BLANC), Dišeči Traminec (GEWÜRZTRAMINER), and Modri Pinot (Pinot Noir) are common for high-quality VARIETAL wines. Most of these varieties were introduced to the region by the Austrian Archduke Johann in 1822. Modri Pinot is the most planted dark-skinned variety, and Modra Frankinja (BLAUFRÄNKISCH) shows much promise.

Podravje and, to a lesser extent, Posavje (see below) are also where the country's best BOTRYTIZED wines are made, mainly from Šipon, Laški Rizling, and Renski Rizling and labelled in German fashion according to sugar level: *pozna trgatev* (SPÄTLESE), *izbor* (AUSLESE), *jagodni izbor* (BEERENAUSLESE), *ledeno vino* (EISWEIN), and *suhi jagodni izbor* (TROCKENBEERENAUSLESE).

Other grape varieties planted in Podravje are the Ranina (BOUVIER), Ranfol, Muškat Ottonel (MUSCAT OTTONEL), Zeleni Silvanec (SYLVANER), Rizvanec (MÜLLER-THURGAU), KERNER, Portugalka (PORTUGIESER), Kraljevina, Rdeča and Bela Žlahtnina (Red and White CHASSELAS), GAMAY, and ZWEIGELT.

Posavje With 2,400 ha/5,900 acres of vines, Posavje is the smallest and historically least important wine region and PGI in Slovenia, producing slightly more reds than whites. Production is widely dispersed and BULK WINE prevails. It has three PDOs: Bizeljsko Sremič is known for the indigenous Modra Frankinja (BLAUFRÄNKISCH), sparkling wine (sometimes from the highly acidic local white Rumeni Plavec), and traditional white and red blends called Bizeljčan. Bela Krajina, the warmest wine district, can produce some good Modra Frankinja and the best Rumeni Muškat (MUSCAT BLANC À PETITS GRAINS) in the country. It is home to the light red PDO blend Metliška Črnina and white PDO wine Belokranjec. Dolenjska, the coolest Slovenian district, has recently developed a strength in sparkling wine, although traditionally it is home to the highly popular Cviček, a light, pale ruby, highly acidic blend of red and white grapes (usually Žametovka and Kraljevina). Other grapes grown here are Sauvignon Blanc, Chardonnay, Beli Pinot, Sivi Pinot, Renski Rizling, Traminec, Šipon, Ranina, NEUBURGER, Modri Pinot, Šentlovrenka (ST-LAURENT), Gamay, Zweigelt, and Rdeča Žlahtnina.

Viticulture and winemaking Over 60% of Slovenia's vineyards are planted on slopes with more than 15% incline, many of them TERRACED. Handpicking is a norm, though MECHANICAL HARVESTING is on the increase. The high-yield PERGOLA training system (*latnik)* and *casarsa* (similar to GENEVA DOUBLE CURTAIN), once common in Primorska, are being replaced with double or single GUYOT, now the most common training system.

White wines dominate, a fact reflected in the top five grape varieties planted: Welschriesling, Refosco, Chardonnay, Sauvignon Blanc, and Malvasia Istarska. Pinot Gris also excels.

Reds, notably Pinot Noir, have improved considerably since the early 1990s. However, Slovenia is still trying to find its place on the international market with varieties such as Rebula, Šipon, Refošk, and local blends.

Wines were traditionally vinified in large, old wooden casks of Slovenian or Slavonian oak. Modern practice includes the use of stainless steel and BARREL AGEING in Slovenian or French oak of varying sizes. Recently, QVEVRI and CONCRETE eggs have become popular, particularly in Primorska. These are most often connected with SKIN-FERMENTED and so-called ORANGE WINES. MALOLACTIC CONVERSION for whites is common in Primorska but often suppressed in Podravje and Posavje. As in most former Austro-Hungarian Empire countries, the best wines have tended to be VARIETAL, while blends are reserved for entry-level wines and, since the turn of the century, for flagship wines in Primorska. Large, often well-equipped wineries, either CO-OPERATIVES or now privately owned, still represent a significant part of the market, but smaller family estates are in FASHION, their wines often commanding premium prices.

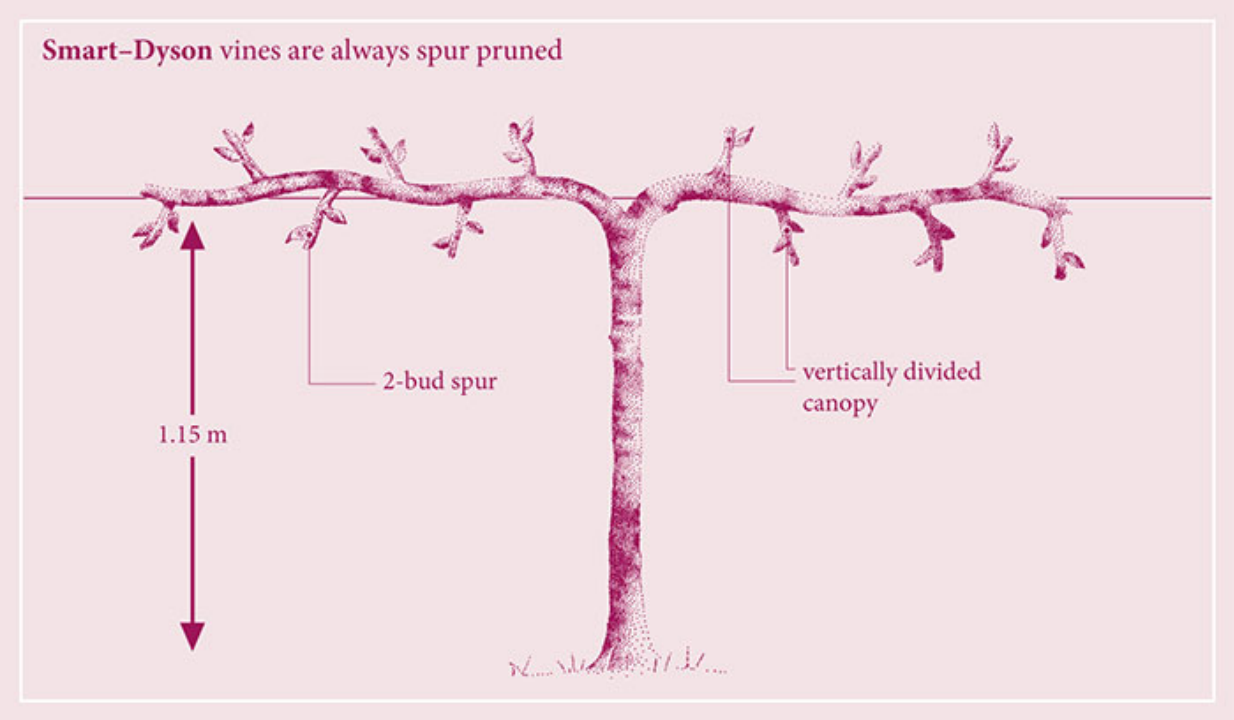
Wine law By law all wines must be analysed, tasted, and scored to determine their quality level before going to market. Zaščitena Označba Porekla (ZOP) is the PDO equivalent, while Zaščitena Geografska Označba (ZGO) corresponds to PGI but is hardly used. Traditional designations still widely in use are: *namizno vino* (table wine); *deželno vino PGO* ('Vins de Pays' coming from a single region); and *kakovostno vino ZGP* (quality wine) and *vrhunsko vino ZGP* (premium quality wine), both of which come from single district.

Priznano Tradicionalno Poimenovanje (PTP) is similar to Austria's DAC. According to the RESIDUAL SUGAR level, all wines in Slovenia are designated as either *suho* (dry), *polsuho* (medium-dry), *polsladko* (medium-sweet), or *sladko* (sweet). R.F.G.

Smaragd, category of white wines made from the ripest grapes in the WACHAU in Austria. Alcohol levels in the unchaptalized Grüner Veltliners and Rieslings that qualify must be more than 12.5% and are commonly 13–14.5%. The category is named after the green lizard that basks in the sun on the Wachau's steep stone terraces above the Danube. See also STEINFEDER and FEDERSPIEL.

Smart-Dyson, vine TRAINING SYSTEM developed in the early 1980s in California and by the end of the 2000s adopted in new plantings in Spain, South Africa, and New Zealand in particular. In South Africa, adoption was encouraged by the experience of companies such as DISTELL, which showed an increase in both yield and quality.

The system was devised by Richard Smart of Australia and John Dyson of New York, and it was initially trialled on Dyson's ranch in Gilroy, California, in 1992 with Merlot vines. It is a vertically divided training system like SCOTT HENRY, but the vine is CORDON-trained and there are upwards- and downwards-pointing SPURS giving rise to the two canopies. It is compatible with MECHANICAL PRUNING, unlike the Scott Henry system, and it can be MECHANICALLY HARVESTED as readily, as can Scott Henry.



R.E.S.

Smederevka, white grape variety commonly planted in SERBIA and NORTH MACEDONIA, the name presumably being inspired by the town of Smederevo south of Belgrade. Often blended with other varieties, notably LAŠKI RIZLING, its wine is generally unremarkable. It is the same as Bulgaria's DIMYAT.

smell. The smell of a wine is probably its single most important attribute and may be called its AROMA, BOUQUET, odour or off-odour if it is positively unattractive, or even FLAVOUR.

The sense of smell is the most acute human tasting instrument (a blocked nose robs food and drink of any flavour), but, since it is so closely related to what we call the sense of taste, it is considered in detail under TASTING. Those who lose their sense of smell, either temporarily or permanently, are said to be anosmic.

smoke taint in grapes and wine has become an increasing problem as the incidence and intensity of bushfires or WILDFIRES

escalates in many wine regions that are experiencing hotter and drier periods due to CLIMATE CHANGE.

Grape berries can absorb gaseous volatile phenol compounds generated by pyrolysis of woody lignin material in a fire. The uptake of volatile phenols can occur as early as FRUIT SET when the berries are small and green (2–4 mm). Depending on the stage of grapevine development and the level and duration of smoke exposure, smoke-tainted wines can display an array of different sensorial attributes, variously described as 'burnt', 'smoky', 'charry', 'ashtray', 'smoked meat', 'vinyl/plastic', 'disinfectant', 'leather', and 'medicinal/Band-Aid'.

Research since 2003 by the AWRI related the exposure of grapevines to atmospheric smoke to the development of smoke-related flavour and aroma characteristics in the resultant wine. The compounds primarily responsible for the sensory perception of smoke-taint characters include, but are not restricted to, a number of phenols including guaiacols, cresols, and syringols. These phenols can also exist in grapes and wine as GLYCOSIDE FLAVOUR PRECURSORS, which can be broken down during processing, alcoholic FERMENTATION, and MALOLACTIC CONVERSION and through a chemical process during AGEING. Glycoside flavour precursors can also be broken down in the mouth when wine is tasted or consumed, resulting in perceptible smoke characters. These can become more evident during maturation and after bottling. Recent research at Oregon State University suggests that thiophenols (sulphur-containing equivalents of known taint compounds) may also contribute to the sensory attributes of smoke-tainted wine.

All grape varieties are sensitive to smoke taint. The volatile phenol compounds appear to be concentrated near the berry skin, so vineyard and winery practices that reduce skin contact or damage can minimize, but not necessarily remove, the effects of the smoke. Techniques such as hand harvesting, WHOLE-BUNCH PRESSING, lower processing temperatures, less time on skins (before, during, and after fermentation), and separation of press fractions (see PRESS WINE) can reduce the extraction of smoke compounds into wine. The style and

STRUCTURE of the wine can also have a significant impact. For example, smoke-taint characters in a full-bodied Shiraz/Syrah may be less obvious than in a lighter-bodied Pinot Noir. The use of certain FINING agents made from activated carbon (see CHARCOAL) has proven to be somewhat effective at removing both the volatile phenol fractions (from wine) and the glycoside precursors (from juice). However, the non-selective nature of activated carbon may also result in the removal of desirable flavour compounds and TEXTURE attributes. REVERSE OSMOSIS has been used successfully to remove the free volatile phenol fraction, but this method is not effective at removing smoke glycosides. Careful leaf removal is also important since leaves may contribute smoke-taint compounds to the ferment.

These compounds can also occur naturally at very low concentrations in grapes and wine which have not been exposed to smoke, especially in varieties such as Shiraz/Syrah, so comparing results with natural background levels is a key to assessing the potential risk prior to harvest if grapes have been exposed to smoke. Risk assessment following smoke exposure includes analysis of volatile phenols and their associated glycosides in grapes and conducting a mini-ferment and sensory assessment of the resultant wine to determine potential effects. M.P.K. & C.A.S.

Krstic, M., et al., 'Review of smoke taint in wine: smoke-derived volatile phenols and their glycosidic metabolites in grapes and vines as biomarkers for smoke exposure and their role in the sensory perception of smoke taint', *Australian Journal of Grape and Wine Research*, 21/51 (2015), 537–53.

Simos, C., et al., 'I can smell smoke—now what?', *Australian & New Zealand Grapegrower & Winemaker*, 672 (2020), 28–31. Tomasino, E., et al., 'A combination of thiophenols and volatile phenols cause the ashy flavor of smoke taint in wine', *Food Chemistry Advances*, 2 (2023).

smudge pot, small burner, usually fuelled with oil, once popular as a means of FROST PROTECTION and still used in some European vineyards.

snails, vine pests of which at least two types can be of economic significance to wine production: the white Italian snail, *Theba pisana*, and the brown or English snail, *Helix aspersa*. They are mainly a problem in early spring and can strip vines of young foliage if they are in large numbers, which happens particularly in wet conditions. They will contaminate fruit and wine if they are present at HARVEST time. Clean TILLAGE is an important preventive measure, and sprays or baits used early can also control snails. Copper-based FUNGICIDES used on vines also affect snails by repelling and killing them. Ducks and geese feed on snails, and their presence in vineyards will keep numbers down. M.J.E.

Soave, white wine from the VENETO region of north-east Italy, mostly dry but on rare occasions sweet and/or sparkling. Like the neighbouring VALPOLICELLA zone, the Soave zone was expanded enormously with the creation of the Soave DOC in 1968. At the time, both regions were enjoying an export boom, so production flowed off the small hilly zone on to the alluvial plain of the Adige River.

The central CLASSICO zone of HILLSIDE VINEYARDS, first defined and delimited in 1927, is the source of superior Soave. It, together with the north-eastern part of the Colli Scaligero subzone, which includes all hillside vineyards outside the Classico zone, are planted on decomposed VOLCANIC rock and produce steelier wines than those from the western part of Soave, where the higher percentage of LIMESTONE in the soil and the warmer afternoon sun gives fuller, more forward wines.

in 2020 there were 2,800 ha/6,918 acres of vineyards on the plain (compared with 1,500 ha in the Classico zone), and these are responsible for the bulk of ordinary Soave, which has developed a

reputation for being insipid. The culprit is excessive YIELDS, sometimes more than 15 tonnes/ha. It was hoped that the introduction of the DOCG in 2002 would correct this situation, but instead of restricting the DOCG to the Classico hills a general Superiore category was created, a half-baked compromise that included most of the produce of the local CO-OPERATIVE. Maximum permitted yields for Soave Superiore DOCG are still high but are reduced to 10 tonnes/ha, and the minimum natural alcohol level is 12%.

In an effort to elevate Soave's reputation, in 2020 the region introduced 33 UGAs (*unità geografica aggiuntive*) which may appear on labels. Regionally referred to as 'crus', these areas (some as large as 1,600 ha) are practically all hillside sites, the majority being in the Classico area, some are unreasonably joined such as Calvarino and Monte Crocetta.

Another potential improvement is the exclusion of TREBBIANO Toscano from DOC and DOCG Soaves. This interloper was introduced to the area in the 1960s, when high yields were the driving force, and it soon displaced the local Trebbiano di Soave (which is, in fact, VERDICCHIO). Today Soave must be at least 70% GARGANEGA and up to 30% Trebbiano di Soave, Chardonnay, Pinot Bianco, and/or the Sauvignon Blanc that has been used to add interest and body to wines from over-productive vines. When yields are controlled, Garganega can give wines of real class. A late-ripening variety, it has a thick skin that helps protect it against the autumn mists rising from the northern part of the Po Valley. Producers such as Pieropan, Gini, Pra, and Ca' Rugate have illustrated the potential not only of Garganega but also of the Soave zone.

Garganega is also the mainstay of the sweet RECIOTO di Soave DOCG, a PASSITO made from raisined Garganega grapes. It can also be sparkling, though examples are rare. W.S.

Lorenzoni, A. (ed.), *Soave Terroir: Le 33 Unità Geografiche Aggiuntive del Soave* (2020).

www.ilsoave.com

social media refers to the use of mobile and web-based technologies for communicating and networking between individuals and organizations. Such networking shares, creates, discusses, and proliferates information in both textual and visual form. Social media have dramatically changed how information about wine is disseminated. Traditional media outlets still share information but have greatly decreased in number, leading to fewer permanent wine columns and paid WINE WRITING positions. Increasingly, wine experts and consumers alike share wine information and opinion via social-media channels such as TikTok, Twitter, Instagram, and Facebook. Although blogs (see INFORMATION TECHNOLOGY) helped create the importance of social media to wine, they waned as mobile applications (apps) proliferated.

Social media were initially differentiated from traditional media as being essentially consumer-generated, whereas traditional media were generated for consumers by experts selected to create such content, but the distinction is becoming increasingly blurred as wine producers and retailers are using social media to establish direct contact with consumers. One of the effects of social media on wine criticism has been a general democratizing of authority, dispersing it broadly across online networks. Consumers increasingly turn to social media for information, thus relying less on expert authority and more on crowd-sourced information. Prior to social media, influential information was concentrated around industrial media sources and established WINE WRITERS. But within social media, specific wine-focused communities have arisen, especially via apps. Nielsen studies have shown that internet users spend significantly more time on social-media sites than anywhere else online.

Social media have also led to a change in both wine publishing and wine marketing. Because of the dynamic nature of social media, the influence of any particular person or media source can change

much more rapidly than in the past, and individuals who are charismatic but not necessarily expert can achieve prominence, even influence (see INFLUENCERS). Another consequence of social media is that traditional wine experts can now be in direct contact with their readers, who can publish their reactions to them. Communication is very much a two-way process today.

The impact of traditional marketing approaches such as ad campaigns simply seeking circulation numbers has been eroded, and many wineries implement social-media marketing techniques instead. Such processes can integrate social media with information technology that tracks social media users' mentions of wine in general and specific wines, as well as their wine-based travel. Producers can thereby respond directly to consumers who mention their wines.

The proliferation of information online has also increased general discussion about even small-production and relatively obscure wines among consumers. Thus the democratization of wine information via social media has also encouraged consumers to experiment with a wider range of wines. E.C.B.

sodium, element that is not a required nutrient for vine growth (see VINE NUTRITION). Sodium chloride (common SALT) is, however, a major hazard for vine-growers, particularly in hot, irrigated areas where ground waters are saline or where salty irrigation water is applied to the leaves (see SALINITY). Sodium has an unfavourable effect on soil fertility because it reduces water infiltration due to its tendency to disperse clay particles. This can be overcome by addition of CALCIUM to the soil, normally as gypsum. See also SALINITY. R.E.S.

Sogrape, Portugal's largest wine producer, owned by the Oporto-based Guedes family, whose success is founded on MATEUS Rosé. Since the 1980s, it has invested in new wine regions, acquiring Portuguese winemaking facilities and vineyards in the MINHO, DÃO, BAIRRADA, ALENTEJO, and DOURO (it owns port shippers FERREIRA,

SANDEMAN, and Offley, as well as more than 500 ha/1,235 acres of vineyard in the valley). Its Portuguese table-wine brands include Douro icon Casa Ferreirinha's Barca Velha, Legado, Gazela, Quinta de Azevedo, Quinta dos Carvalhais, and Herdade do Peso. Global acquisitions include Finca Flichman (Argentina), Framingham (New Zealand), Los Boldos (Chile), RIOJA-based Bodegas Lan, and UK importer Liberty Wines.

soil, mineral material at the Earth's surface formed by weathering of underlying bedrock (see GEOLOGY), or transported sediments, which form the parent material of the soil. The main distinction between soil and parent material is that a soil is enriched with plant and animal remains that undergo decomposition to form soil ORGANIC MATTER. Because soil formation is an ongoing process, dependent on geology, CLIMATE, vegetation, TOPOGRAPHY, and time, the boundary between a soil and its parent material is usually indistinct. Over very long periods, episodes of erosion and deposition followed by soil formation have led to layered soils, common in old weathered landscapes such as in Australia and southern Africa. However, where soils have formed on one parent material *in situ*, such as in north-west Europe and North America during the 11,000 years since the last Ice Age (see CLIMATE CHANGE, historical and contemporary climate changes), distinctive zones called horizons can form in a vertical array, which is called a SOIL PROFILE. These horizons can be differentiated by their organic matter, colour, thickness, texture, structure, and stoniness. In addition to organic matter, soils are distinguished from rock materials by their structure (see SOIL STRUCTURE), which influences the rate of water infiltration (from RAINFALL or IRRIGATION), resistance to SOIL EROSION, and ease of root penetration. The combined effect of SOIL TEXTURE and structure determines a soil's water-holding capacity, aeration, and DRAINAGE and hence the soil's suitability for healthy ROOT GROWTH and vine performance.

In Australia, where there is a pronounced and relatively abrupt increase in soil clay content between a surface A horizon (topsoil)

and a subsoil B horizon, the soil is called duplex. This kind of profile is commonly found in soils referred to as podzolic in many other vineyard regions around the world. Duplex soils may develop impermeable subsoils when the exchangeable sodium content (see CLAY) exceeds a certain threshold. The presence of high magnesium in many Australian subsoils results in this threshold being lower than in North American soils.

See GEOLOGY, STONES AND ROCKS, SUBSOIL, TERROIR, TOPOGRAPHY, and other entries prefaced by SOIL, most importantly SOIL AND WINE QUALITY. R.E.W.

White, R. E., *Understanding Vineyard Soils* (2nd edn, 2015).

soil acidity, or low soil PH, occurs where hydrogen cations (H+) predominate relative to those of the alkali cations CALCIUM, POTASSIUM, SODIUM, and MAGNESIUM adsorbed on the surfaces of CLAY and ORGANIC MATTER. Acidity is found mainly where the alkali mineral elements have been leached out of the SOIL PROFILE under heavy rainfall over extended periods, and their place on the soil's CATION EXCHANGE CAPACITY has been taken by hydrogen ions. Soils developed on coarse-textured sediments (GRAVEL, GRANITE) are prone to be acidic, while soils developed on CALCAREOUS sediments are never acidic.

In soils of less than pH 5, described as highly acid, exchangeable aluminium is released by slow decomposition of the clay and can inhibit grapevine root growth. Such soils are best avoided for viticulture; if this is not possible, then LIME should be applied. The soil acidity of the MÉDOC in Bordeaux, for example, promotes COPPER availability and consequent toxicity, wherever there has been a build-up of copper in the topsoil from spraying vines with BORDEAUX MIXTURE.

In neutral to alkaline soils rich in organic matter, ready decomposition may release mineral NITROGEN, which predisposes to excess VIGOUR, whereas the release of nitrogen in soils of lower pH is

limited. Problems of soil acidity are to be expected in most viticultural regions with high rainfall, affecting parts of Europe and some highly weathered soils in south-east Australia and South Africa.

Soil acidity should be contrasted with SOIL ALKALINITY, which is more common in arid areas. It does not follow that soil acidity bears any relation to wine ACIDITY. R.E.S., C.v.L. & R.E.W.

soil alkalinity. A soil is said to be alkaline when the measured PH is above about 7. A pH above about 8.5 usually implies a content of free LIME or CHALK (usually described as CALCAREOUS soil; see also LIMESTONE) or too high a content of soluble salts (including common salt, sodium chloride). In the latter case, such soils are described as SALINE. When these soils are leached, their pH can increase to 9 or more due to the hydrolysis of SODIUM ions (see CATION EXCHANGE) and the ORGANIC MATTER can disperse, forming a black alkali soil. Saline and black alkali soils should definitely be avoided for viticulture. However, some of the best vineyard soils in cool climates are associated with limestone or chalk.

High lime and pH can induce deficiencies of IRON, ZINC, and MANGANESE or BORON in the vines. Lime-induced iron deficiency can cause CHLOROSIS. These deficiencies can usually be controlled by leaf sprays or the selection of particularly well-adapted varieties of ROOTSTOCK.

Soils high in free lime can sometimes create nutritional difficulties through the reduced availability of POTASSIUM.

J.G., C.v.L. & R.E.W.

soil amelioration, a viticultural practice for improving soils by the addition of so-called soil amendments. These can include FERTILIZERS to overcome mineral nutrient deficiencies (such as superphosphate to add phosphorus); LIME, which will overcome SOIL ACIDITY; and gypsum and ORGANIC MATTER, which will improve SOIL STRUCTURE. These ameliorants are spread on the soil surface and occasionally turned in by TILLAGE. Where there is a need for deep placement, as in liming or

the application of rock phosphate (see FERTILIZERS), then RIPPING implements drawn by powerful bulldozers are used before planting. When the lime and gypsum are finely ground, special applicators allow these normally insoluble products to be added through DRIP IRRIGATION systems, but the drippers easily become blocked.

soil and wine quality. The SOIL has many attributes that can influence the vine grown in it and thence the composition of grapes and the quality and character of wine. Quite how influential these attributes are remains a matter of debate, with a fairly marked but fast-decreasing divergence between the OLD WORLD and NEW WORLD, if not of opinion then of interpretation.

Old World and New World

Opinions in Europe, especially in France, have strongly emphasized soil effects on vines, grapes, and wines at a vineyard level, particularly in relation to vine water status. These are fundamental to the concept of TERROIR which underlies the official French AOC system, although the influence of soil is generally regarded as less significant than that of climate. In Germany, for example, large local differences in climate associated with TOPOGRAPHY are often considered to override soil effects (see MESOCLIMATE and CLIMATE AND WINE QUALITY), although soils are still regarded as an important factor affecting wine quality.

Until a few decades ago, New World opinion tended to minimize the role of soil and instead to stress major differences in regional climate, or MACROCLIMATE. Amerine and Winkler's 1944 CLIMATE CLASSIFICATION of California into five temperature regions epitomized this view. Much of the divergence in approach can be ascribed to differences in historical, geographical, and commercial background. Traditional European vineyards were small, with the identities of their wines often uniquely established over many generations. It was observed that certain sites consistently produced different and/or better wines than others, apparently regardless of VINE MANAGEMENT and WINEMAKING practices and sometimes in the absence of discernible differences in mesoclimate. One general observation, especially marked in Bordeaux, was that the best sites stood out most clearly in poor VINTAGE YEARS. These sites maintained a relative consistency of high quality, whereas others, superficially similar and often very close, suffered greatly diminished quality. The only possible reason seemed to lie in unalterable (and perhaps invisible) properties of the soil.

New World viticulture has generally lacked this experience. Individual vineyards were often much larger, and until fairly recently grapes from individual plots were rarely fermented separately (see SINGLE-VINEYARD WINES). Moreover, the dominant commercial

organizations tended to employ extensive BLENDING of wines from different soils and regions, so that any individualities were often masked or lost.

Differences in agricultural history have also influenced the choice of soils for planting vines. In Europe, all the fertile land was needed for cereal production or grazing to provide sufficient food for the people. Since vines would grow almost anywhere, they were often planted on the poorest soils to optimize land use. In the New World, there was generally no shortage of land so that viticulture developed on a wide range of soils, from infertile to fertile, with irrigation a common, and in many cases necessary, practice.

Nevertheless, the absolute need for quality (and, in particular, wine individuality) in a highly competitive world market means that winegrowers in all parts of the wine-growing world have increasingly emphasized the importance of soil as contributing to a site's terroir. This has become especially evident with advances in SOIL MAPPING as part of VINEYARD DESIGN and in PRECISION VITICULTURE, notably in North America and Australia. This approach is now a prerequisite to the design of a new vineyard and particularly any IRRIGATION system. It also makes it possible to identify different plots by soil attributes and to manage and harvest them separately, even in extensive vineyard developments. The results obtained support European experience, as reported by Smart. However, the effect of soil on wine quality is reduced in warmer climates, which is why the influence of terroir is so much more marked in marginal climates such as that of Chablis or England.

Winegrowers and scientists in all parts of the wine world investigate the reasons some soils can give better wines than others. The work of the late Bordeaux researcher Professor Gérard Seguin laid important foundations for such studies and forms a background to the discussion below, which distinguishes between chemical and physical soil attributes.

Physical soil attributes

Scientific opinion now almost universally agrees with Seguin's conclusion that soil's physical characteristics predominate as the main influence over grape and wine quality other than CLIMATE; and, further, that, among the physical characteristics, the most important are those that govern water supply to the vine. These and their relationship to individual soil types are discussed in some detail under TERROIR. See also SOIL WATER, SOIL TEXTURE, DRAINAGE, and VINE PHYSIOLOGY.

Here we may note briefly that the best wines come from soils that are very well drained and furnish a steady, but only moderate, even limiting, water supply to the vines. When combined with appropriate restrictive mineral VINE NUTRITION, this ensures that SHOOT TIP growth is restrained, especially immediately prior to VERAISON. Smaller berries are also usually less liable to congestion and compression within the bunch and are therefore less likely to split or suffer spoilage as a result of FUNGAL DISEASES or BACTERIA. WATER STRESS needs to be just enough to attain these ends and not enough to reduce photosynthesis too much.

Some other physical properties of soils almost certainly influence wine quality and characteristics in subtle ways.

SOIL COLOUR affects soil temperature and that of the air immediately above. Dark-coloured soils absorb and convert much of the sunlight falling on them into heat, and so these are warmer than light-coloured soils and, at night and during daytime cloud cover, radiate more warmth back to the vines and bunches. This can be critical in some cool MARGINAL CLIMATES, allowing fuller RIPENING and thus better wine quality (as in the very dark soils of the Neckar Valley in WÜRTTEMBERG or the Meuse Valley of southern BELGIUM, for example).

The presence of STONES AND ROCKS in the soil or on its surface influences both water and temperature relations. A high proportion of stones or GRAVEL throughout the SOIL PROFILE is commonly associated

with very good DRAINAGE but at the same time reduces water-holding capacity and encourages desirably extensive ROOT GROWTH to assure a vine's water supply. In Bordeaux, where the main risk is often excessive water supply to the vines, the most important positive effect on wine quality of stones in the soil is the limitation on water-holding capacity, leading to the level of water deficit that promotes red wine quality. Stony soils, whether sloping or not, usually have the further advantage for wine quality that they are at most only moderately fertile, as discussed below.

Soils containing a large proportion of rocks or stones have the additional advantage of being warm because they hold less water. Water has a high specific calorific capacity and needs a lot of energy to warm it. Wet soils are therefore cold soils. Moderately damp soil beneath surface stones is both a reasonable heat conductor and a good heat storer, because of the high heat-storage capacity of its water content. It is also protected from evaporative cooling. Stony soils also more readily absorb heat and transmit it to depth, because rocks are a comparatively good conductor of heat—much better than dry or loose soil. Such soils are efficient at absorbing and storing warmth and at retransmitting it to the above-ground vine parts during cloud cover and in the evening. See TEMPERATURE VARIABILITY, DIURNAL TEMPERATURE RANGE, and CLIMATE AND WINE QUALITY.

Whatever the mechanisms, there can be little doubt that stony and rocky soils produce many of the world's great wines, provided that water supply to the vine is adequate. Typical are the coarse gravels that characterize the most eminent châteaux of the MÉDOC in Bordeaux; the large stones (GALETS) that completely cover some of the best sites of CHÂTEAUNEUF-DU-PAPE in the southern Rhône; and the coarsely stony gravels that give wines of outstanding quality in the Marlborough region of NEW ZEALAND's South Island and, more recently, in the Gimblett Gravels region of Hawke's Bay in the North Island.

Chemical attributes

The relationship between soil chemistry and wine quality and individuality is in the main poorly understood. The belief that soil influences wine character because the vine takes up flavour compounds direct from the soil is totally unsubstantiated (see, for example, MINERALS and MINERALITY).

Soil NITROGEN is in part an exception to this lack of knowledge. It is clear from Seguin's work, and that of other researchers, that the optimum nitrogen supply to the vine is at most only moderate. The optimum supply for red-wine production is lower than for white wine because nitrogen deficiency increases berry skin PHENOLICS but also limits the build up of FLAVOUR PRECURSORS in white grapes (see Choné et al. and Helwi et al.). Vines receiving much nitrogen, unless severely constrained by other factors, have vigorous and leafy growth. This leads to excessive SHADE within the canopy and thence to poor fruit quality (see CANOPY MICROCLIMATE). The effects of nitrogen, water supply, and various other nutritional and environmental factors can to varying degrees reinforce or counteract each other in this regard. The best combination among them is that giving optimum vine BALANCE. Excessive nitrogen fertilization, leading to excessive vigour, can sometimes be problematic. However, this tendency is countered by the more widespread use of grass or cereal COVER CROPS, which can compete with the vine for nitrogen or even cause a deficiency.

A further complication has arisen from research showing that low nitrogen contents in the berries can be a cause of difficulties in winemaking, leading to STUCK FERMENTATIONS and the presence of HYDROGEN SULFIDE and its malodorous MERCAPTAN derivatives in the wine. This is especially common with grapes grown in warm, sunny climates. While it is known that at least much of the problem can be overcome by adding nitrogen-based YEAST nutrients during fermentation, the problem of combining suitable nitrogen nutrition for

vine balance with optimum concentrations of natural nitrogen compounds in the berries remains largely unsolved.

POTASSIUM availability is another soil factor with mixed relationships to wine quality. Deficiencies are common in cool and humid climates, where the efficiency of water use for growth and yield (see HUMIDITY and CLIMATE AND WINE QUALITY) means that potassium and some other elements are diluted in the plant. Potassium-deficient vines are more than usually susceptible to DROUGHT and VINE DISEASES, and the fruit lacks sugar (see SUGAR IN GRAPES) as well as COLOUR and flavour.

Conversely, vines in hot, atmospherically arid climates can accumulate excess potassium in the leaves, stems, and fruit, especially if the soil contains reserves of mica-type clay minerals that release potassium. High potassium levels and PH in grapes, often the result of excessive leaf shading in a poor canopy microclimate, can lead to high wine potassium and pH, with all its attendant quality defects, and improved CANOPY MANAGEMENT can help greatly in assuring more appropriate fruit potassium levels.

The rule for other mineral nutrients appears to be that adequate supplies are needed equally for vine health and for fruit and wine quality, though there is very little evidence concerning the possible role of elements such as magnesium, phosphorus, or iron.

Possible specific roles for the micronutrients (COPPER, ZINC, MANGANESE, IRON, BORON, and MOLYBDENUM) remain obscure but potentially interesting. Their contents in the soil and availability to the plant vary enormously from soil to soil and, in often disparate ways, with SOIL MANAGEMENT. At the moment, however, no micronutrient constituent has been shown to be a decisive factor, either in wine quality or in any particular wine characteristic, and opinions about the effect of micronutrients on grape quality are highly speculative and sometimes exaggerated in non-scientific literature.

SOIL ACIDITY and SOIL ALKALINITY are further possible influences; but again, little firm evidence exists at present. Extremes in either direction, sufficient to upset vine nutrition and health seriously, seem unlikely to improve wine quality. On the other hand, vines can

tolerate a fairly wide soil pH range without evident harm, while the potential micronutrient deficiencies that are often encountered at high pH levels can in most cases be readily overcome by foliar sprays or judicious choice of ROOTSTOCKS.

Although little studied by the Bordeaux school, properties related to the SOIL BIOTA can also affect vine growth and fruit quality. In particular, the ORGANIC MATTER in soils for viticulture needs careful evaluation. On the one hand, soils naturally high in organic matter tend to be too fertile, and to supply too much nitrogen, for good wine quality (as explained above). Soils naturally low in organic matter have a reduced nitrogen supply (unless fertilizers are added). On the other hand, many respected TERROIRS that have otherwise favourable characteristics for wine quality are naturally too low in organic matter, or have become so, so that both their physical and biological condition would benefit from its build-up and maintenance (see ORGANIC VITICULTURE). Very sandy soils need organic matter to give them sufficient capacity to store water and nutrients. All soils, and especially clayey soils, benefit from having an adequate organic matter content (1.5–3%) to give them friability (see SOIL STRUCTURE) and to encourage the activity of EARTHWORMS, which help to keep them well aerated and freely draining.

The nature and geological origin of the ROCKS or sediments from which soils are formed (see SOIL and GEOLOGY) are further factors sometimes held to influence wine quality and character. Soils formed from CHALK and LIMESTONE, for example, are highly valued in some cool climates, although not generally in warm regions such as the south of France or inland Australia. Most researchers consider the advantages of chalk and limestone to be related to their free DRAINAGE and the ability of the SUBSOIL to store water. Certain grape varieties, particularly Pinot Noir and Chardonnay, are also regarded by some as having a special requirement for chalk or limestone soils to produce their best wines; but again, this seems to be a largely northern French viewpoint. One universally positive role of chalk and limestone (or deliberately adding LIME) is that the resulting high level

of calcium absorption to the soil clay particles helps to maintain a friable and stable SOIL STRUCTURE, thus encouraging aeration and drainage, even at high clay contents.

On the general role of geology, we can conclude that any influence is mostly indirect, via the shaping of TOPOGRAPHY determined by the underlying GEOLOGY, and through effects which are more properly those of the derived soil rather than of the rock or sediment. There can be some direct effects on water supply, however, where vine roots penetrate into the geological stratum underlying the soil or where water stored in the calcareous subsoil can contribute to water supply through capillary movements. Chalk in Champagne, the limestone of St-Émilion, and the Médoc gravel beds of Bordeaux (see SOIL WATER) have been cited in this regard.

Other factors

The great variation of soils over even short distances means that generalizations of any kind are dangerous. In some vineyards, especially those on ALLUVIAL soils, the soil type may change dramatically over a few metres, despite an apparent uniformity at the surface. For the same reason, SOIL MANAGEMENT procedures are seldom equally appropriate across an entire vineyard, let alone between different vineyards.

A second point is that, despite this, management technologies are increasingly available which obviate many of the effects of this variability. This is especially so in the New World. Among the more important is the use of DRIP IRRIGATION, which in climates with a dry summer can go far towards giving the vines a controlled water regime that is little influenced by soil type. Similarly, techniques of soil and (especially) leaf or PETIOLE analysis make possible a more controlled vine nutritional regime, so that differences in nutrient supply by the soil are moderated or even potentially eliminated.

A third point is that most vineyards throughout the world are now grafted to PHYLLOXERA-tolerant ROOTSTOCKS. The various rootstocks differ in their ability to take up mineral elements and water, in their capacity to root to depth, and in their effects on the VIGOUR of the vines grafted on to them. It is therefore possible to compensate for and adapt to particular soils as a means of approaching an optimal combination of vigour, nutrition, and canopy management for vine balance. Rootstocks are particularly effective in modulating water supply to the vines, and drought-resistant rootstocks such as 110 R or 140 Ru should be used in soils with low water-holding capacity in dry climates. Any consideration of soils now has to acknowledge the role of rootstocks.

The growing awareness of soil effects on wine quality and character in the New World has had several repercussions. One is the planting of vineyards on the less fertile hillside soils, as is evident in California and Chile, for example. Another is carrying out detailed SOIL

MAPPING before planting as a prerequisite to VINEYARD DESIGN and the installation of irrigation, if used. More recently, ZONAL VITICULTURE, employing GLOBAL NAVIGATION SATELLITE SYSTEM and GEOGRAPHICAL INFORMATION SYSTEM technologies, allows differential management, including harvesting separate zones of a vineyard block to maximize quality. These effects, identified by REMOTE SENSING or PROXIMAL SENSING, are by and large due to soil differences and can be managed by means of PRECISION VITICULTURE techniques.

Conclusions

There can be no doubt that soil characteristics do influence grape quality, yield, and wine individuality, as has been shown by Seguin and by Renouf et al. in GRAND CRU vineyards in Bordeaux. However, in most situations the effects of soil are subsidiary to those of CLIMATE, VINE VARIETY, and VINE MANAGEMENT (see van Leeuwen et al. 2004). Of the influential soil characteristics, the most important are those governing the supply of water to the vine, probably followed by those influencing temperatures in and above the soil. Provided that vine growth is healthy, soil chemistry and vine nutrition do not play a major role, with the notable exception of nitrogen, and in some situations the effect of excess potassium on the pH of must and wine. Nitrogen in undoubtedly the most important nutrient the vine takes up from the soil: it has a major impact on vine vigour, yield, aroma compounds, and tannins (see Choné et al. and Helwi et al.).

Identifying the 'best' soil for winegrowing depends on the objectives of the winegrower and whether the vines are DRY-FARMED or irrigated. If the objective is to produce large yields of grapes for blending and producing lower-priced wines, then deep, well-drained soils that are fertile and either naturally well-watered or irrigated are best. However, if the objective is to produce low to moderate yields of high-quality grapes that can be used for higher-priced wines, and wines that reflect the particular TERROIR of a site, then infertile soils in which the vines are subject to a limiting factor (generally water deficit and/or limited nitrogen) perform best. Water deficit (see WATER STRESS) can be achieved naturally by dry-farming in deep, well-drained soils that have a significant proportion of sand and gravel. In the case of irrigated vines, where usually the soil water content of only the top 10–60 cm is controlled, this deficit can be applied through REGULATED DEFICIT IRRIGATION or PARTIAL ROOTZONE DRYING. In all cases, free drainage is very important. This is usually achieved in sandy, gravelly soils and in heavier textured soils that are well-structured, generally due to a predominance of calcium on the CLAY

particles. An organic matter content of 1.5–3% is also important to support a good soil structure, especially of the topsoil, and to sustain an active and diverse SOIL BIOTA. R.E.S., C.v.L. & R.E.W.

soil biota is the generic term used to describe the population of organisms living in soil. Broadly speaking, these organisms can be divided into the 'reducers' (such as EARTHWORMS, slugs and SNAILS, BEETLES and their larvae, MITES and springtails, Protozoa, and NEMATODES, which feed on leaf litter and animal excreta to break it

down into smaller fragments, without achieving much chemical decomposition) and the 'decomposers', which are much smaller organisms that colonize these organic fragments and gradually convert them into humus (see CARBON and ORGANIC MATTER). The decomposers, comprising Archaea, bacteria, actinomycetes, and fungi, are commonly called microorganisms, and the microbial biomass is measured by their collective weight. An active and diverse microbial biomass, interacting with the reducers, creates a soil's microbial ecosystem. Such a properly functioning soil ecosystem is important for the decomposition of ORGANIC MATTER and the turnover of NUTRIENTS in the soil, which is a prerequisite for good SOIL HEALTH. This applies equally well to conventional viticulture as to ORGANIC and BIODYNAMIC VITICULTURE. See also MYCORRHIZA, MICROBIAL TERROIR, and BIOCHAR. R.E.W.

soil colour, a term normally referring to the surface colour of a soil although it may also be applied to various layers or horizons in a SOIL PROFILE. Some viticultural folklore associates red wine with red soils, and white wines with white or grey soils. However, topsoil colour is very heterogeneous, as is the spatial distribution of SOIL TYPES within vineyards potentially planted to a single variety. So any support for such a relationship is at best circumstantial.

Colour can affect soil temperature and that of the air immediately above it. This depends on albedo, the reflectance of SUNLIGHT. Dark-coloured soils or rocks absorb much of the incoming sunlight energy and convert it to heat. Therefore, whereas they reflect less light than light-coloured soils, they radiate more heat at night. This may be especially beneficial in cool climates. Other examples of the exploitation of these thermal characteristics include the vineyards of Deidesheim in the PFALZ region of Germany, where black BASALT rock is mined and spread on the vineyards to help produce grapes with high sugar concentration. Fragmented dark-grey SLATE helps Riesling to ripen in the otherwise cool MOSEL. Dark-coloured SCHIST soils are reportedly the only ones on which grapes can be ripened at the

extreme northern limit of viticulture in BELGIUM. At the other extreme, the exceedingly reflective white ALBARIZA soils of JEREZ in southern Spain produce the best (white) grapes for sherry in a very hot climate, which would seem counter-intuitive.

The relationship between soil colour and temperature suitability for vine-growing is far from straightforward, however. Many reddish and brown soils are used for viticulture in hot areas such as the Mediterranean wine regions and also in much of Australia and California. However, such soils predominate in these regions and are not known to offer any advantage to viticulture because of their colour: see CLIMATE AND WINE QUALITY. Differences in soil colour have little effect on sunlight reflected back into the CANOPY which might affect PHOTOSYNTHESIS. French experiments have shown an improvement in grape (and apple) colour from using reflective foil on the soil surface. See further discussion under SUNLIGHT.

Soil colour is in any case a useful indicator of some of a soil's other properties, which probably have more effect on VINE PHYSIOLOGY and therefore on wine quality. For example, black soils may indicate a high content of ORGANIC MATTER. Red or brown are due to the presence of oxidized IRON compounds and normally indicate good DRAINAGE. A pale-grey soil surface, or soil layer, shows that most of the original iron compounds have been reduced as a result of bad drainage and waterlogging and eventually leached downwards, often to be deposited in a heavier-textured SUBSOIL.

The colour of the subsoil is a particularly important indicator of soil suitability for viticulture. Except where it consists largely of decomposing chalk or LIMESTONE, a blue-grey or mottled subsoil shows drainage that is usually too poor for viticulture—or at least, a need for artificial drainage. R.E.S. & R.E.W.

soil compaction in vineyards is due to the passage of machinery, especially if it is heavy and the soil is wet and CLAY-textured. Vineyards are particularly prone to compaction because tractor wheel

tracks are confined to narrow strips, often in close proximity to the vine row. The soil is compressed so that the surface absorbs less water and soil pores are destroyed, and the supply of air and water to vine roots is diminished (see SOIL STRUCTURE). Further, soil strength is increased, providing a physical barrier to root growth and EARTHWORM activity. Soil compaction can reduce vine VIGOUR and thus YIELD and, in some instances, wine quality. Soil compaction, which may be the most serious environmental damage done in many vineyards, can be reduced by avoiding the use of heavy machinery on wet soils and by using tracked rather than wheeled vehicles. Traditional horse-drawn equipment is enjoying a (very small) revival, particularly among practitioners of BIODYNAMIC VITICULTURE. R.E.S.

Lagacherie, P., et al., 'Spatial variability of soil compaction over a vineyard region in relation with soils and cultivation operations', *Geoderma*, 134/1–2 (2006), 207–16.

soil depth, a loose term for the depth to the boundary between the SOIL and its parent material; or, alternatively, the depth to which plant ROOT GROWTH is possible before reaching some impermeable barrier. Examples of the latter include the tight and/or poorly drained subsoils of many duplex soils (see SOIL), which occur in south-eastern Australia, South Africa, and the Piedmont region of the eastern US; cemented ironstone, or 'coffee rock', which forms at the base of some iron-rich podzolic soils that have been subject to leaching; or subsoils with poor structure due to exchangeable SODIUM, or excessively high concentrations of salt or acidity, or some other toxic factor which effectively prevents further root penetration.

Soil fertility is a combination of fertility per soil volume unit and the rooting depth, which determines the amount of soil available for each vine. Seguin's work shows that if soil is fertile or moderately fertile per soil volume unit, deep rooting leads to excessive soil fertility (due to the availability of water and nutrients) and thus excessive VIGOUR. As a result, in most cases shallow rooting is a quality factor, because it reduces vigour and yield. Only in soils with

very poor fertility per soil volume unit, such as the gravelly soils of the MÉDOC or MARLBOROUGH, New Zealand, is deep rooting an advantage. These soils have such a low water-holding capacity per soil volume unit that, unless the vines are irrigated, deep rooting is necessary to provide a regular supply of water to the vine. Seguin has also shown that deep rooting in these soils where water drains very rapidly prevents the rapid absorption by the root system of rain shortly before harvest, thus helping to prevent ROT.

There is a great deal of evidence, in many other situations, that great wines may be produced on soils where vine rooting is shallow. For example, most great ST-ÉMILIONS are produced on the limestone plateau, where vine rooting rarely exceeds 60 cm/23 in and can be as little as 30 cm (as in parts of the vineyard of Ch AUSONE). The roots do not penetrate the rock, although Duteau et al. have shown that water can move from the bedrock to the roots by capillarity. On the heavy clay soils in PETRUS and Ch CHEVAL BLANC, vine rooting does not exceed 130 cm/50 in because of the clay's physical resistance to root penetration. In the Languedoc, the best wines are produced on shallow soils on the hillsides and simple wines are produced on the plains, where rooting is much deeper.

Shallow soils are therefore of major importance in cool, wet climates, while somewhat deeper soils might be an advantage in very dry climates, especially when IRRIGATION is not allowed or not possible. C.v.L. & R.E.W.

soil disinfection. See FUMIGATION.

soil erosion, shifting or removal of soil by wind or running water. Wind erosion is not common in established vineyards, because the vines themselves constitute an effective WINDBREAK, although it can be a problem in young vineyards. Driving sand, in particular, can seriously injure young vines, and there can also be irreparable loss of most valuable topsoil. The danger can be minimized by growing grass COVER CROPS that act as windbreaks as well as directly binding the soil. VINE GUARDS can be used to protect young vines from sandblasting—and from attack by animals such as rabbits and hares.

Erosion by water, on the other hand, is always a potential problem on the sloping sites that normally afford the best MESOCLIMATES for wine quality (see HILLSIDE VINEYARDS). Some steeply sloping sites, such as in the MOSEL region of Germany and the northern RHÔNE, necessitate a constant and laborious replacement of soil from the bottom of the slope to the top. Even in more moderately sloping sites in the Côte d'Or and Champagne, clean TILLAGE of the mid rows may lead to soil erosion during summer storms.

Planting vines across a slope, rather than up and down the slope, provides some measure of erosion control, especially if the vine rows are hilled. Contoured TERRACES are an effective means of erosion control on steeper slopes (between 7 and 15%), as practised in the NAPA Valley, California, and the FRIULI region of north-east Italy. On very steep slopes on stony soils, as in the Vaud region of Switzerland and the DOURO Valley in Portugal, stone terraces have been constructed. However, vineyard cultural operations are easier with rows oriented up and down a slope, in which case other methods must be used to control erosion, such as avoiding unnecessary tillage, spreading MULCHES (including vine prunings) to protect bare soil surfaces, and planting mid-row cover crops. Permanent grass cover crops offer the best protection but are feasible only in those situations where water and NITROGEN supplies are sufficient for both grass and vines. Planting on convex hill slopes helps too, to the extent that there are no external sources of flowing water. Where occasional water flowing on to or across a site cannot be avoided, it

can often be made harmless by diversionary banks, directing the flow into drains or permanently grassed waterways which follow the natural flow line.

Other measures to control erosion include maintaining the soil's ORGANIC MATTER content and stable SOIL STRUCTURE (see also SOIL MANAGEMENT). These conditions enable rain to be absorbed readily where it falls. Row orientation and such cultivation as is unavoidable should ideally be directed just a little off the contour, so that any water flow along furrows will be gentle and harmless, able to spill out on to permanently grassed waterways. Cultivation straight up and down slopes predisposes to general erosion, but the practicalities of vineyard design often limit control over the direction and slopes of cultivation. R.E.W.

White, R. E., *Soils for Fine Wines* (2003).

soil fertility, the physical, chemical, and biological characteristics of a soil determining its ability to support vigorous plant growth. A fertile soil is generally understood to be one with a high content of available plant nutrients; moderate to high ORGANIC MATTER content supporting an active and diverse SOIL BIOTA; good SOIL STRUCTURE and DRAINAGE; and typically a LOAMY SOIL TEXTURE that can store large amounts of water. Neither SOIL ACIDITY nor SOIL ALKALINITY will be excessive, so that the mineral nutrients will all be in a favourable balance of availability for plant growth. Research in Australia by Oliver et al. and Riches et al. (see SOIL HEALTH) has identified a minimum set of important biophysical and chemical properties and their optimum ranges for healthy vine growth and yields of quality fruit.

Highly fertile soils, especially those rich in NITROGEN, are undesirable for wine grapes because they encourage excessive vegetation and a shaded CANOPY MICROCLIMATE. This in turn can reduce both YIELD and, especially, the composition of the grapes and their suitability for winemaking. Although vineyard management

cannot greatly improve this state of affairs, VIGOUR may be reduced by planting permanent grass COVER CROPS, using low-vigour ROOTSTOCKS, avoiding the use of FERTILIZERS except to correct nutrient deficiencies, and not over-irrigating the vines. On the other hand, the notion that only infertile soils can make good wines is undoubtedly mistaken. CANOPY MANAGEMENT techniques can allow vigorous vines on moderately fertile soils to mimic the canopy microclimates of traditional vineyards on less fertile soils, with resultant improvements in quality. These principles have been elucidated by Carbonneau and Casteran and successfully applied in many situations in the BORDEAUX environment as well as in many NEW WORLD vineyards.

soil health is, for a soil scientist, synonymous with soil quality, but the term emphasizes the living nature of soil, dependent on the healthy function of SOIL BIOTA. Soil quality may be defined holistically as 'the capacity of a soil to function within ECOSYSTEM boundaries to sustain biological productivity, maintain environmental quality, and promote plant and animal health'. A soil's condition and capability depend on the interaction of many chemical, physical, and biological processes and determine its suitability for the specific aims of a viticulturist or winegrower in a particular location. soil management, the practices of TILLAGE, or NO-TILL, of soils in vineyards, including the use of COVER CROPS, COMPOST, and MULCHES, and other measures to improve the soil's physical, chemical, and biological condition (see SOIL FERTILITY). In the broadest sense, this term can also embrace IRRIGATION, the use of HERBICIDES, and the addition of FERTILIZER.

In the past, soil management has consisted primarily of clean tillage to control WEEDS. The advantages of this approach include the avoidance of herbicides and encouraging roots to go deeper. The disadvantages are increasingly recognized, however. Over time, clean tillage leads to a loss of ORGANIC MATTER, a deterioration in SOIL STRUCTURE, and also a decline in SOIL BIOTA, particularly EARTHWORMS. Modern soil management seeks to conserve and, if necessary, increase the organic matter content; to conserve and improve soil structure and porosity, and thereby improve aeration and free absorption and DRAINAGE of SOIL WATER and resistance to SOIL EROSION; and to maintain a reserve of nutrients in organic and slowly available inorganic forms to provide a steady and balanced supply of SOIL NUTRIENTS matched to the plants' needs.

Aspects of soil management include growing cover crops, with minimal tillage for their establishment; using inorganic fertilizers (as needed) mainly to grow these crops, and thence to supply the vines as far as possible from organic sources; summer mulching with the residues of the cover crop grown *in situ* or with imported vegetable materials or manures, preferably composted; and, when essential,

the use of environment-friendly herbicides to control cover crops and weeds. The use of LIME or gypsum may be required for some soils. Avoiding SOIL COMPACTION is also very important. These practices encourage the roots to spread and grow more deeply, improve machine access to the vineyard after rain, help to control vigour, and reduce the use of herbicides.

All these measures serve to improve soil physical conditions for vine ROOT GROWTH, thereby improving vine health, YIELD, and in some instances wine quality. R.E.S. & R.E.W.

soil mapping, procedure used before vineyard planting to assist in decisions about IRRIGATION layout, location of VINE VARIETIES and ROOTSTOCKS, application of FERTILIZERS and soil amendments such as LIME and gypsum, and choice of TRAINING SYSTEM. Soil mapping is becoming more common in vineyard developments around the world and represents recognition of the idea that local conditions, especially the soil, have important effects on GRAPE COMPOSITION AND WINE QUALITY. It is also used after a vineyard has been planted, often much later, to help understand vineyard variability.

Ideally, an electromagnetic survey should be carried out (see PROXIMAL SENSING) to identify soil variations within a vineyard block. Accurately located by GLOBAL NAVIGATION SATELLITE SYSTEMS, these data are fed into a GEOGRAPHICAL INFORMATION SYSTEM so that high-resolution maps of the soil's variability can be prepared. Based on these maps, soil pits are dug, usually by a backhoe, at sites covering the full range of variation so that SOIL PROFILES can be described in detail. Where such a preliminary survey has not been carried out, pits may be dug on a grid so that the soil can be sampled and described

by a soil specialist, although this is less effective at capturing variability. Soil maps can be used in vineyard design; one of the most useful is that which estimates 'readily available water', or RAW. See TERROIR for a full discussion of the relevant issues; see also SOIL, SOIL AND WINE QUALITY, and PRECISION VITICULTURE. R.E.S. & R.E.W.

Proffitt, T., et al., *Precision Viticulture: A New Era in Vineyard Management and Wine Production* (2006).

soil nutrients, elements (see MINERALS) and ions occurring in the soil which are taken up by plant roots. Soils that are rich in nutrients are often termed 'fertile', but such soils do not always produce good-quality wine (see SOIL FERTILITY). The amounts of nutrients that are available to the vine depend on the soil's mineralogy, the amount and nature of ORGANIC MATTER, and also the soil PH. Soils with a long history of COVER CROPS containing LEGUMES have high levels of topsoil organic matter and are often rich in NITROGEN. However, grass and cereal cover crops compete with vines for nitrogen, in which case nitrogen is not as readily available to the vine. Soils in old vineyards, especially if clean-tilled (see TILLAGE), are often relatively impoverished of organic matter and may have high levels of available COPPER as a result of repeated FUNGICIDE application. Many nutrients including nitrogen and PHOSPHORUS, for example, are less available in acid soils (see SOIL ACIDITY). Others such as IRON, MANGANESE, COPPER, and ZINC are less available in alkaline soils. Nutrient deficiencies are diagnosed by symptoms in the vines, or by plant and soil tests, and can be remedied by applying FERTILIZERS and MANURES.

Robinson, J. B., 'Grapevine nutrition', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

soil potential, a viticultural term coined in South Africa to describe the ability of a soil to support vigorous vine growth,

sometimes referred to as site potential. A soil of high potential will be well supplied with water (by rainfall or IRRIGATION), nutrients, and air and will be free-draining, promoting a large and healthy root system. Such a soil will create vines of high VIGOUR, which in turn may require special management. R.E.S.

soil preparation, the treatment of SOIL before PLANTING a vineyard, can be an important viticultural operation. Proper attention at this stage can determine the long-term success or otherwise of a vineyard.

Having selected the best possible site (see VINEYARD SITE SELECTION, TOPOGRAPHY, and TERROIR) and vineyard layout, and having assured suitable DRAINAGE, the potential vine-grower should in most soils, especially in duplex soils (see SOIL) and shallow soils over LIMESTONE and SHALE, undertake deep RIPPING along the paths of the future vine rows. This should be done when the soil is dry enough for compacted layers (see SOIL COMPACTION) and any hard pans (cemented layers) to be shattered by the ripper. Such treatment opens up the SUBSOIL and facilitates penetration by the vine roots.

If a vineyard is replanted, particular care must be taken to remove the roots of the old vines since these can harbour VIRUS DISEASES or FUNGAL DISEASES. Where populations of pathogenic NEMATODES are large, FUMIGATION may be necessary.

If the SOIL ACIDITY is high, with a topsoil pH less than 5.5 in calcium chloride (see PH), adding LIME will be beneficial. SOIL TESTING should be used to identify any nutrient deficiencies or toxicities, to guide the use of lime and other FERTILIZERS, and also to indicate whether gypsum should be applied to improve SOIL STRUCTURE, especially in clayey soils.

Finally, WEEDS need to be controlled. In most climates it is usual to grow an autumn–winter green manure crop to suppress weeds and add ORGANIC MATTER before vine planting in spring. R.E.W.

Boehm, E. W., and Coombe, B. G., 'Vineyard establishment', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

soil profile, the vertical face of a SOIL, exposed by digging, that generally consists of visually and texturally distinct layers (known as horizons) which are more or less parallel to the Earth's surface. During SOIL MAPPING, the soil surveyor describes the properties of each layer (sometimes also sublayers), especially those that will have an impact on vine ROOT GROWTH. See also GEOLOGY and TERROIR.

R.E.S.

soil structure describes the physical arrangement of the fundamental mineral particles (as described in SOIL TEXTURE) into larger structures called aggregates. The size, shape, and stability of these aggregates help to determine the friability of the surface soil and its ability to accept rainwater and resist erosion (see SOIL EROSION). The creation of this physical framework also provides a variety of voids or pores that are important for air movement, water DRAINAGE, and ROOT penetration. A stable structure can withstand the effects of TILLAGE and SOIL COMPACTION by vineyard machinery.

To a varying degree in different soil types, soil structure depends on the following factors:

1. The amount and chemical composition of the CLAY. For stable structure, a soil must have a moderate clay content. Montmorillonite clays swell and shrink with wetting and drying, leading to a desirable 'self-mulching' of the soil surface, provided the content of exchangeable CALCIUM is not too high (see SOIL). Calcium ions flocculate clay minerals whereas SODIUM ions cause clay dispersion and the breakdown of aggregates. On the other hand, kaolinitic clays flocculate by edge-to-face attraction at PHs less than 6 and so can form stable aggregates. This effect is enhanced in the presence of iron and aluminium oxides. Illitic and mixed-layer clays are similar in structure to montmorillonite

but show much less shrink and swell. In CALCAREOUS soils, calcium carbonate can be an effective bonding agent for aggregation.

2. ORGANIC MATTER content. Well-decomposed organic matter bonds to clay particles and iron and aluminium oxides and so lays the foundation for good structure. Additionally, gums and mucilages secreted by roots and soil microorganisms play an important part in stabilizing soil aggregates, and fine roots can form a mesh holding larger aggregates together.
3. Soil disturbance by tillage. All tillage can be destructive of soil structure, especially in clayey soils when wet. Repeated tillage exposes the organic matter within aggregates to faster decomposition, which weakens soil structure. Tillage is sometimes done to improve the 'tilth' of the surface soil, but this is a temporary effect and does not improve soil structure in the longer term.

Good SOIL MANAGEMENT aims principally to preserve good soil structure or to improve it in soils suffering some degradation. R.E.W.

White, R. E., *Understanding Vineyard Soils* (2nd edn, 2015).

soil testing involves measurements made in the field or laboratory of soil properties that indicate the physical, chemical, and biological condition of the soil (see SOIL FERTILITY). White and Krstic discuss the possible range of indicator properties for which tests can be chosen. Soil testing is a necessary adjunct to SOIL MAPPING to determine soil PH (see SOIL ACIDITY, SOIL ALKALINITY), the amounts of available NUTRIENTS, and any adverse conditions such as SALINITY or too much SODIUM (see CATION EXCHANGE). Tests can be carried out for biological activity (see SOIL BIOTA) and for the presence of pathogenic organisms (see SOIL PREPARATION). Soil tests done before planting allow the grower to identify any deficiencies of essential elements and consequent FERTILIZER requirements or the existence of possible element

toxicities. However, because the grapevine is a perennial plant, tissue analysis of leaf blades or PETIOLES, rather than soil testing, usually gives a better guide to any ongoing fertilizer requirements in established vineyards.

Field inspection to determine SOIL TEXTURE and the soil's natural DRAINAGE to as great a depth as possible is an essential preliminary to any vine planting. See also SOIL AND WINE QUALITY, TERROIR, and VINEYARD SITE SELECTION. R.E.S. & R.E.W.

White, R. E., and Krstic, M. P., *Healthy Soils for Healthy Vines* (2019).

soil texture describes the size distribution of soil particles (those less than 2 mm diameter), simplified to indicate the proportions of clay, silt, and fine and coarse sand (STONES AND ROCKS and ORGANIC MATTER are excluded). The individual constituents are defined below. Soils predominantly of clay are described as heavy-textured. Loams are medium-textured soils, normally containing a fairly even balance of clay, silt, and sand. Sands are light-textured soils, often loose and gritty, with a low clay content. Certain mineral elements, most notably CALCIUM, complement textural differences in helping to determine soil friability (see SOIL STRUCTURE).

Clay is the finest of the size fractions, with particles less than 0.002 mm diameter. When mixed with water, clay particles may remain in colloidal suspension for some time, especially if the proportion of exchangeable SODIUM is greater than 6% of the CATION EXCHANGE CAPACITY. Because their surface areas are so large relative to their volumes, they have by far the greatest capacity for combining

with, adsorbing, and holding plant mineral nutrients and water. Fertile soils normally have at least a moderate proportion of clay.

Silt is an intermediate fraction, comprising particles between 0.002 and 0.02–0.05 mm diameter (the upper limit for silt varies according to the particle-size classification used). Silt particles are small enough to be carried large distances by wind and are also carried in suspension by turbulent rivers. Both clay and silt particles are prominent in ALLUVIAL soils deposited by river floods.

Sand particles are divided into fine sand (0.02 to 0.2 mm) and coarse sand (0.2 to 2 mm diameter); again, this size division varies according to the particle-size classification used. Unless mixed with a proportion of clay, sand remains loose under most conditions. In contrast to clay, the surface area of a sand particle is small relative to its volume, so it has little capacity for surface binding and storing of plant nutrients or water.

Soil texture can be measured by a rigorous particle-size analysis in a laboratory or by a soil specialist in the field, who determines texture by feel. Organic matter is destroyed before such a laboratory analysis, but in the field it can make sandy soils feel more silty and clay soils feel less sticky.

Stones and rocks appear to have particular significance for viticulture, through their effects on limiting soil water-holding capacity and, additionally, on TEMPERATURE both within and immediately above the soil. Stony soils are also usually well drained and have a low water-holding capacity, while a surface layer of stones greatly enhances resistance to SOIL EROSION and reduces surface water loss by EVAPORATION.

Commercial viticulture is carried out across a very wide range of soil textures. Clay and clay-loam soils can be suitable provided that they contain ample calcium (as in most LIMESTONE- or CHALK-derived soils) and organic matter to improve their structure. The strongest growth of vines, as with most other plants, is usually on loams and clay-loam soils. Whether or not this is desirable depends on various other management and environmental factors, as described for example under SOIL FERTILITY and VIGOUR. Soils of clay-loam to sandy

clay-loam texture can store in the vicinity of 15 mm/0.6 in of available SOIL WATER per 10 cm/4 in of soil depth, in forms that the vine roots can extract.

Soils consisting mostly of sand can pose problems for viticulture because of their lack of storage capacity for both water and nutrients. Typically they will hold 10 mm or less of plant-available water per 10 cm of soil depth. The great depth of some sandy soils can be an offsetting factor, however, as in parts of the BORDEAUX region, because vine roots penetrate many metres if the SUBSOIL texture and DRAINAGE permit and can thus exploit a large enough volume to compensate for the low water-holding capacity per soil volume unit. In soils of low water-holding capacity, the problems of water availability can be overcome by supplying IRRIGATION.

An ideal soil for wine quality, depending on CLIMATE and the rate of evaporation together with the potential for irrigation, will balance texture against root-available depth to give an adequate storage capacity for water and nutrients and to provide the vine with a steady moderate supply of both for BALANCED growth and fruiting. No single soil texture has a monopoly of these characteristics. Seguin notes that in the Bordeaux region the soils giving the best water regimes and producing the best wines range from the dominant deep, stony sands of the MÉDOC, because of their low water-holding capacity, to heavy (but well-structured) clays in POMEROL, because the water is present but not easily available to the vines. Thus in Bordeaux extreme textures are generally better than intermediate textures such as clay-loam soils, which can hold significant supplies of water readily available to the vine.

soil types. Soil types are identified using soil classifications which put soils into groups according to whether they are alike or unlike. Several national classifications are in use, but (with the exception of soil types such as RENDZINA) there is little common terminology. In the world of wine, therefore, terms reflecting the parent rock (e.g. 'granitic') or a soil's texture (e.g. 'sandy', 'gravelly') or its formation (e.g. 'alluvial') are most widely used. For further examples of types of SOIL and ROCK, see individual entries on ALLUVIUM, BASALT, CALCAREOUS, CHALK, CLAY, COLLUVIUM, GNEISS, GRANITE, GRAVEL, LIMESTONE, LOAM, LOESS, MARL, QUARTZITE, RENDZINA, SAND, SANDSTONE, SCHIST, SHALE, SILT, SLATE, TERRA ROSSA, TUFF, TUFFEAU, and VOLCANIC. See also SOIL AND WINE QUALITY and GEOLOGY, however, for evidence of soil's relatively indirect role in shaping wine and wine quality. R.E.W.

soil water, that water held in the pore spaces of the soil within the potential rooting zone for vines. When all the pore space is filled with water, the soil is said to be saturated. Unless the soil is a very heavy clay (see SOIL TEXTURE), it will normally drain within 48 hours to a state called its field capacity (FC), which corresponds to a soil water suction of about 10 kiloPascals (kPa) (see WATER STRESS). With soil EVAPORATION and, most importantly, extraction of water by the vine roots, the soil water content decreases until a point is reached when the vine can no longer extract water fast enough to avoid wilting during the day and non-recovery at night. This condition is called the permanent wilting point (PWP). The amount of water held in the vine rootzone between FC and PWP defines the available water capacity (AWC). The amount of plant-available water (PAW) in a SOIL PROFILE is the product of the AWC and rootzone depth and is sometimes called readily available water (RAW). In poor-draining soils, a lack of OXYGEN quickly kills the vine roots.

Water supply to the vines is the key factor in grape quality. Vines are Mediterranean plants that need very little water: they can easily grow in climates with only 400 mm/15 in of rainfall a year, provided that the soil has at least an average PAW and EVAPOTRANSPIRATION

rates are not too high. Some water deficits are essential to growing good-quality grapes, particularly for red winemaking (see WATER STRESS).

Water supply to the vine depends on climatic parameters (RAINFALL, potential evapotranspiration), soil parameters (AWC and soil depth), and plant-related factors (rooting depth, leaf area, crop load). Studies on TERROIR by Morlat and van Leeuwen et al., for example, show that terroir which produces high-quality red wine supplies only moderate amounts of water to the vines, thus inducing water-deficit stress. The gravelly soils of the MÉDOC were intensively studied by the late Gérard Seguin, who used a neutron moisture probe to investigate vine–water relations in these soils as early as 1966. However, the fact that these soils are deep is an exception rather than a general rule and can be explained only by their high gravel content and their low clay content (see SOIL DEPTH). These soils can be subject to temporary waterlogging until flowering, but generally the water table is not within reach of the roots during ripening. If it is, wine quality suffers (van Leeuwen et al. 1994). Mild water stress may become more severe as CLIMATE CHANGE leads to greater evapotranspiration and the need to introduce IRRIGATION to previously unirrigated vineyards in order to maintain quality.

Regular or permanent waterlogging, even if only of the subsoil or the zone immediately overlying it, is a clear counter-indicator for vines, particularly if it occurs during the vine-growing season. The optimum soil-water regime is thus usually found where there is an adequate depth of well-drained soil, with at least moderate contents of CLAY, SILT, and ORGANIC MATTER so that water can be supplied steadily from soil reserves over a long period. The less clay and organic matter, the deeper the soil needs to be to achieve that end. However, too much available soil water can be counter-productive in viticulture if it promotes too much vegetative VIGOUR or helps to prolong vegetative growth into the fruit-ripening period. (See also CLIMATE AND WINE QUALITY, SOIL AND WINE QUALITY.)

Ideally there should be ample available soil water during FLOWERING and FRUIT SET, diminishing so as to create just enough water deficit around VERAISON to inhibit further vegetative growth. Opinions vary as to the optimum water supply between veraison and RIPENING, but most agree that there should be no severe stress through this period; nor should there be so much water available, especially after preceding stress, as to encourage a sudden uptake into the berries or renewed vegetative growth.

The binding capacity of the soil for the water that remains after draining to its FC has its own significance for vine–water relations. Some is so tightly bound to the CLAY that roots cannot extract it at all, and some can only be extracted slowly. This explains why heavy clay soils, such as those of PETRUS in Pomerol which induce early water deficits, can produce very fine red wines (van Leeuwen et al. 1994). The small amount of available water in sandy soils, on the other hand, is readily extracted and therefore easily exhausted. However, in sandy soils, vine rooting is often very deep and the PAW can be too large to grow high-quality fruit (van Leeuwen et al. 1994, 2004).

Even in MEDITERRANEAN CLIMATES with very low summer rainfall, the best soils are not those on the plains with a large PAW but the more shallow, stony soils of the slopes, which have a much lower PAW. However, when the PAW is very small (shallow and very stony soils on hard LIMESTONE bedrock, as in LA CLAPE, near Narbonne), amount and timing of rainfall is critical and water stress might be so severe as to reduce wine quality. In such climates, relatively shallow soils, or sandy/stony soils with limited PAW, combined with supplementary irrigation when needed (and permitted), can have advantages in allowing the best control over water availability to the vines. In hot inland regions, such as the CENTRAL VALLEY, California, and the MURRAY DARLING region in Australia, evapotranspiration rates are so high in summer that, irrespective of soil type, irrigation is essential to grow healthy vines and produce reasonable yields. In the majority of drip-irrigated vineyards in the New World, irrigation may be managed so as to avoid severe water stress but produce a desirable amount of stress at the appropriate time. Solaris, increasingly popular, early-ripening, light-skinned, DISEASE-RESISTANT VARIETY bred by Norbert Becker in southern Germany in 1975. The vine's ability to reach high sugar levels in cool climates and produce fruity wines with good acidity has encouraged plantings around the world, for example in Scandinavia, Belgium, Holland, England, and cooler parts of Eastern Europe and Germany.

solera, system of fractional blending used in JEREZ and other wine regions in ANDALUCÍA for maintaining the consistency of a style of SHERRY which takes its name from those barrels closest to the *suelo*, or floor, from which the final blend was customarily drawn. The system was created for commercial reasons in the second half of the 19th century. Previously, sherry was vintage-dated.

The system is effectively a subtler, and much more labour-intensive, version of the BLENDING of TABLE WINES between one vintage and another, although the solera system concerns BARREL-AGED liquids and is made up of several scales. Depending on market demand, a fraction of wine is removed from the oldest scale of the solera, the so-called solera barrels themselves, and replaced (although the barrels are never filled completely) with wine from the next scale of barrels containing wine of the same type but one year younger, the so-called first criadera. They in turn are replenished from the scale two years younger (the second criadera) and so on, the youngest scale being replenished with new wine. This system is particularly useful for FLOR wines because the addition of younger wine provides micronutrients to sustain the flor yeast for several years. It takes several years' operation for a solera to reach an equilibrium average age. Many soleras in Jerez were started decades ago; since no barrel is ever emptied, there is always some of the oldest wine in the final blend. If a product is labelled 'Solera 1880', for example, it should come from a solera established in 1880.

Fewer scales are needed to produce consistent AMONTILLADO or OLOROSO sherries than FINO or MANZANILLA sherries because these fuller, richer wines vary less from year to year.

There is a common belief that the wine is normally bottled from the oldest scale of barrels, but this is not always so. It may well happen that the producer regularly bottles a combination of a few different criaderas, in a proportion that may change every year, so as to keep a sustainable and identifiable style of wine.

The solera system is also used for blending Brandy de Jerez and for many other strong wines such as those in CONDADO DE HUELVA, Alicante (see FONDILLÓN), MÁLAGA, MONTILLA, and MADEIRA in Spain, TOPAQUE AND MUSCAT in Australia, and MARSALA in Italy, as well as in some Roussillon wines in France, in VIN DES GLACIERS in Switzerland, and in the production of top-quality VINEGAR.

For mathematical calculations of the average age of a solera and the time required to reach equilibrium average age, see Baker et al.

Baker, G. A., et al., 'Theory and application of fractional blending programs', *Hilgardia*, 21 (1952), 383–409. J.B.

soluble solids, also called total soluble solids (TSS) and total dissolved solids (TDS), refers to the collective concentration in unfermented grape juice of all solutes (dissolved molecules and ions). The predominant solutes, accounting for about 90% of the total, in the juice of ripe grapes are the reducing sugars GLUCOSE and FRUCTOSE; others are acids (MALIC and TARTARIC), ions (organic and inorganic), and literally hundreds of inorganic and organic molecules that together contribute to the characteristics that make grapes such an adaptable and useful product. Collective concentrations of TSS range from 5 to over 25% and may be expressed in many ways, most usually either as degrees BRIX, BAUMÉ, or OECHSLE. See also MUST WEIGHT. B.G.C.

sommelier, widely used French term for a specialist wine waiter or wine steward, sometimes abbreviated to 'somm' in the US, where an eponymous 2012 FILM was devoted to four sommeliers' efforts to pass the MASTER SOMMELIER exam. The sommelier's job is to ensure that any wine ordered is served correctly and, ideally, to advise on the individual characteristics of every wine on the establishment's wine list and on FOOD-AND-WINE MATCHING. In some establishments, a sommelier, sometimes called a wine director, may also be responsible for compiling the list, buying and storing the wine, and restocking whatever passes for a CELLAR. (All too few restaurants today have their own serious collection of wines, although there are notable exceptions such as, in Paris, the Tour d'Argent, whose cellar is but a few feet from the River Seine, and Taillevent, whose cellar is so important that it has spawned a retail wine business.)

A sommelier should present the wine (or wines) ordered to the person who has selected the wine before opening to ensure that there has been no misunderstanding (and so that the customer can

especially check that the vintage corresponds to expectations). This is a good time for the customer to check that the bottle feels at the right SERVING temperature. The bottle should be opened in view of the customer, and, if a wine is to be DECANTED (and that is an option that any decent sommelier should be able to offer), that operation should be performed in public, too.

Some sommeliers offer the cork to the customer to smell, which is well meaning but is no certain guide to whether or not the wine is FAULTY. Some sublime wines come from under some rather unpleasant-smelling corks, and vice versa.

A surer guide to whether a particular bottle happens to be one of the relatively few to exhibit a FAULT (CORK TAINT is the most common) is to examine the small tasting sample usually offered by the sommelier to the customer for this very purpose. A glance will confirm that it is not cloudy, dull, or fizzing when it should not. A swift inhalation should confirm that it smells 'clean'. Few people can then resist actually tasting a mouthful, but it is generally unnecessary as the most common faults are apparent to the eye or nose. Besides, tasting a wine should clearly reveal its all-important TEMPERATURE. This is the moment to ask for an ice bucket (for red wines if necessary) or for a bottle of white wine to be taken out of an ice bucket.

In many countries there are official associations of sommeliers, often with a series of examinations, qualifications, or at least competitions. French, and other, sommeliers compete in these events all over the world; such is the average French person's reverence for the wine knowledge of a sommelier, to win the title Meilleur Sommelier du Monde (Best Sommelier in the World) is henceforth to inhabit another world.

Sommières, fairly large CRU in the eastern LANGUEDOC, located entirely in the Gard *département* 20 km/12 miles from Nîmes. The distinctive red wines are based on GRENACHE, MOURVÈDRE, and SYRAH; CARIGNAN and CINSAUT are also allowed.

Somontano, meaning 'under the mountain', is a DOP in the foothills of the central Pyrenees, in ARAGÓN in north-east Spain (see map under SPAIN), with some 4,000 ha/9,884 acres under vines in 2021. In stark contrast to much of inland Spain, Somontano looks like winemaking country. The heavy winter rains are supplemented by a network of rivers and streams flowing off the mountains. Even in summer, when temperatures can easily reach 35 °C/95 °F, the fields remain green and productive. The main selling point of Somontano in the early 1990s was its dedication to INTERNATIONAL VARIETIES, but by 2010 this had become its main problem, as competing on a varietal basis with Cabernets and Syrahs from all over the world proved an arduous task. The native MORISTEL and PARRALETA varieties represent only 2% of the vineyard surface. TEMPRANILLO, with 10%, is the only significant Spanish variety. The native GARNACHA was on the wane, being mainly used for rosés, until Viñas del Vero discovered and relaunched the impressive old vineyards at Secastilla with a very distinctive single-estate Garnacha red. Some 250 ha of Garnacha are planted. A little over 1,100 ha/2,710 acres of vineyard is planted to white wine grapes, mainly Chardonnay and Gewürztraminer, overtaking the traditional MACABEO and almost extinct Alcañón.

V. de la S. & F.C.

Sonoma , northern CALIFORNIA town, valley, and one of the state's most important wine counties, with 18 AVAs. The first vines entered Sonoma in the early 1800s, first with Russian colonists who settled at Fort Ross between 1812 and 1841 and then with Spanish missionaries who arrived in the 1820s. By 1920 the region boasted 250 wineries and more than 8,900 ha/21,992 acres of vines on land once tended by Sonoma's first peoples, including the Kashia Band of Pomo and Miwok in the coastal areas and the Micewal in the north and into the Napa Valley. The industry contracted significantly during PROHIBITION and the Second World War, not regaining that vine acreage until the 1970s. By 2021 the region boasted more than 25,091 ha/62,000 acres of vines. Historically, ZINFANDEL was the region's most important variety; today Pinot Noir and Chardonnay

predominate, and Cabernet Sauvignon and Sauvignon Blanc thrive in warmer inland areas. Of the 50-plus other grape varieties grown, Merlot also plays an important role, and Rhône varieties are increasingly exciting.

Bordered by the cold Pacific Ocean to the west and the Mayacama Mountains to the east, and stretching from San Pablo Bay to just beyond Preston some 97 km/60 miles north, the county's varied TOPOGRAPHY, ELEVATION, and MARITIME influences make growing conditions across the valley diverse, but fog is a commonality even far inland.

As in all of California, Sonoma receives rain only in winter. DROUGHT conditions in the last decade have made viticulture challenging, as parts of the region lose groundwater and reliance on local rivers is restricted. Some businesses have brought in water by truck. Drought also increases the threat of WILDFIRES as dry conditions increase natural kindling, and lack of surface water makes it hard to extinguish flame. Fires that overlap harvest create safety concerns for vineyard teams and the risk of SMOKE TAINT in wines.

The AVAs and subzones follow. See also CARNEROS, an AVA shared between Sonoma and NAPA, and map under CALIFORNIA.

Alexander Valley

The largest and most fully planted of Sonoma County's many vineyard valleys, Alexander Valley takes in the Russian River watershed upstream of Healdsburg north all the way to the Sonoma–MENDOCINO county line north of Cloverdale.

Before PROHIBITION, hops and prunes blanketed the Alexander Valley and remained the major crops, along with some plantings of mixed black grapes for BULK WINE, into the late 1960s and early 1970s. Attention began to turn to more to vines in the late 1970s and increased greatly in the 1990s. Alexander Valley daytime temperatures are among the warmest in Sonoma County, but the DIURNAL TEMPERATURE RANGE is dramatic, meaning that the wines, even when robust, tend to retain good natural acidity. Cabernet Sauvignon is the region's signature variety, with Merlot just behind. In whites, Chardonnay dominates. More recently Malbec has started to gain local interest. Most substantial plantings are on a broad and almost flat valley floor very nearly bisected by the river, although some vineyards climb the slopes surrounding the valley. Significant elevation is found on Alexander Mountain, owned entirely by the JACKSON FAMILY, where vineyards reach as high as 732 m/2,400 ft.

Bennett Valley

An elevated valley surrounded by hills and mountains just south of Santa Rosa, Bennett Valley had 283 ha/700 acres of vines in 2022 farmed primarily by smallholders. Soils are primarily VOLCANIC and CLAY; the climate is moderately cool, tempered by the marine breezes and fog that makes their way inland through the Petaluma Gap. Merlot is its most planted variety, followed closely by Pinot Noir and then Syrah; Chardonnay dominates in white grapes. Chilly spring temperatures make FROST a concern.

Chalk Hill

On the far north-eastern side of the Russian River Valley AVA, Chalk HIll has 603 ha/1,491 acres of vines climbing into the foothills of the Mayacamas. Soils here are primarily a chalky white volcanic ash, thus the name. Chardonnay and Sauvignon Blanc dominate, but Cabernet Sauvignon and Syrah do well in warmer pockets.

Dry Creek Valley

Dry Creek Valley encompasses 3,642 ha/9,000 acres of vines in a strip just 26 km/16 miles long and 2 miles wide heading north and west from Healdsburg, where Dry Creek trickles into the Russian River. The region's well-drained gravelly LOAM and pattern of warm days and cool nights have attracted grape-growers since the 1880s, when Zinfandel and FIELD BLENDS dominated the plantings. Several of these early vineyards are still producing, such as Teldeschi Ranch and Lytton Estate (see RIDGE Vineyards). Zinfandel still rules, sometimes with Petite Sirah and Carignan. Cabernet Sauvignon is next most important, while Rhône varieties such as Grenache, Mourvèdre, and Syrah are gaining attention. Sauvignon Blanc is the region's most lauded white wine grape, grown here since the 1970s, when it gained fame as FUMÉ BLANC; Chardonnay and Italian varieties such as ARNEIS and FIANO are also grown.

Fort Ross-Seaview

Defined by ELEVATION, this AVA sits atop Sonoma's rugged Coastal Mountains at 244–549 m/800–1,800 ft, many vineyards in view of the ocean and often surrounded by canyons or steep drop-offs. Though proximity to the ocean can mean cool temperatures, its exposure above the fog line often brings warmth and ample sun exposure. That said, it is one of the county's rainiest areas. While early plantings in the 1970s and 1980s included Zinfandel, the rainy season demands earlier ripening varieties, and by 2021 Pinot Noir dominated its 225 ha/555 acres of vineyard. Chardonnay and Syrah can also be successful.

Fountaingrove District

Established in 2015 on the far eastern side of Sonoma County, this AVA sits on the steep western slopes of the Mayacamas Mountains. While the appellation extends over 1,538 ha/38,000 acres, only 600 acres were planted in 2020, mainly to Cabernet Sauvignon as well as some Merlot and Syrah. Soils are volcanic and elevation reaches up to 610 m/2,000 ft.

Green Valley of Russian River Valley

On the far western side and fully within the Russian River Valley AVA, Green Valley AVA is the coolest, foggiest stretch of the famous river valley. Pinot Noir and Chardonnay thrive in the climate and the silty-sandy Goldridge soils, lending themselves to both still and sparkling wine.

Knights Valley

One of the more remote growing areas of Sonoma County, Knights Valley hosts only two wineries though 1,010 ha/2,496 acres of vineyard. Though its position as an upland valley on the inland side of the county brings warmer temperatures, afternoon breezes and nightly fog make their way in from the Pacific Ocean to help cool its valley floor, allowing grapes to ripen without losing acidity. Cabernet Sauvignon is the region's most successful variety; Syrah can be exciting, too.

Moon Mountain District

Moon Mountain sits at the south-western foot of the Mayacamas Range, with 607 ha/1,500 vineyard acres in 2020 planted on slopes rising 122–671 m/400–2,200 ft in elevation. Soils are ruddy loam over volcanic rock; the climate is warm, with some of its vineyards above the fog line. The AVA's most famous vineyard, Monte Rosso, was first planted in 1886, and some of its original Zinfandel and Sémillon vines are still productive. Most of the AVA, however, is now planted to Cabernet Sauvignon.

Northern Sonoma

At 133,146 ha/329,000 planted acres, this is the second largest AVA in Sonoma (after Sonoma Coast). It includes all of the county that drains into the Pacific Ocean, including the Alexander, Dry Creek, Green, Knights, and Russian River valleys, leaving out only Sonoma Valley and much of the Petaluma River watershed. It was proposed and is mainly used by E. & J. GALLO.

Petaluma Gap

Recognized in 2017, this is Sonoma County's southernmost AVA, reaching into MARIN County, just north of the Golden Gate Bridge. The 'gap' is a low spot in the coastal mountain range that funnels air inland from the Pacific Ocean, bringing morning fog and afternoon breezes to cool the vines; daily DIURNAL TEMPERATURE RANGE here can be as much as 10 °C/18 °F. Of the region's 1,619 ha/4,000 acres of vines, 75% are Pinot Noir; Chardonnay and Syrah make up most of the rest.

Pine Mountain-Cloverdale Peak

Defined by elevation, this AVA sits within Alexander Valley at its northernmost edge and spills into MENDOCINO county. Situated at 488–914 m/1,600–3,000 ft above sea level, the region's 310 acres of vines sit firmly above the fog line, allowing them many more hours of sunlight per day than lower-elevation sites; simultaneously, stiff winds help keep the vines refreshed. Long HANG TIMES allow for intense Cabernet Sauvignon, which makes up 80% of plantings, alongside other Bordeaux varieties such as Cabernet Franc, Merlot, and Malbec. Sauvignon Blanc dominates in white wine grapes.

Rockpile

When Warm Springs dam created Lake Sonoma in 1983, the reservoir drowned some good patches of Zinfandel, but since 2002 the rocky, shallow-soiled area north-west of the lake has been planted and christened Rockpile AVA, parts of which are within the Dry Creek Valley AVA. At 244–580 m/800–1,900 ft, daytime temperatures are cooler than in the lower elevations of Dry Creek Valley and more even overall. Zinfandel dominates.

Russian River Valley

Most of the Russian River's course is through other AVAs in MENDOCINO and Sonoma counties. Only when the river escapes from Alexander Valley through a narrow gorge in the mountains at Healdsburg then flows on, first south, then west, in its journey to the Pacific does it become the Russian River Valley AVA.

Covering some 6,070 ha/15,000 acres of vines, this AVA includes about one-sixth of all planted vineyards in Sonoma County. Though generally described as cool climate, portions of its eastern and northern stretches are quite warm. The AVA's unifying feature is the cooling nighttime fog that rolls in from the Pacific Ocean. The coolest area is the west, regarded as one of California's high-quality wine areas by the 1970s on the quality of its Zinfandel, although by the 2000s it was more famous for Pinot Noir as well as Chardonnay, its most planted variety. (See also its subappellations Chalk Hill and Green Valley, above.) Its middle zones do well with Sauvignon Blanc and Merlot, while the furthest eastern side is warm enough to ripen even Cabernet Sauvignon.

Sonoma Coast

This AVA stretches all the way from San Pablo Bay to the border with Mendocino county, encompassing coast areas as well as vast inland tracts including parts of the Carneros, Russian River Valley, and Sonoma Valley AVAs. The name created significant controversy when it was established in 1987, as, historically, there were few vineyards directly along the cold Pacific. However, the 2000s saw more plantings and subsequent establishment of the coastal Fort Ross–Seaview AVA (see above) and then the West Sonoma Coast AVA (see below). The AVA's 809 ha/2,000 acres of vineyard include parts of Carneros and Russian River Valley as well as the Petaluma Gap AVA. Pinot Noir and Chardonnay are the most established varieties here, but Syrah and Sauvignon Blanc can be quite exciting.

Sonoma Mountain

Situated on the western slopes of and within the Sonoma Valley AVA (see below), Sonoma Mountain sits on the eastern side of the mountain from which it draws its name, above the towns of Glen Ellen and Kenwood. Federally recognized in 1985, the area is considered the westernmost point in Sonoma County warm enough to consistently ripen Cabernet Sauvignon. It also does well with Chardonnay. Vineyards grow at 122–366 m/400–1,200 ft in gravelly, well-draining soils often surrounded by forest.

Sonoma Valley

For history, especially romantic history, no other AVA in California compares with Sonoma Valley. In addition to being the site of the ragtag 1846 Bear Flag revolt, which eventually secured Alta California for the US rather than Mexico, it had the last of the Franciscan MISSIONARY vineyards, one of the earliest commercial vineyards north of San Francisco (General Mariano Vallejo appropriated the Franciscan plantings), and, courtesy of public relations master Agoston HARASZTHY, the first great winery name of northern California, Buena Vista (now owned by BOISSET). In more modern times, its Hanzell Vineyard started the rush to using French oak BARRELS to age California wines and thereby revolutionized their style, most especially Chardonnay's. The valley runs parallel to the Napa Valley to the east, its southern extremity doubling as the Sonoma portion of CARNEROS. These southernmost areas are the region's coolest thanks to the influence of the San Francisco and San Pablo Bays, and Pinot Noir and Chardonnay dominate. Moving north, away from the bay, the valley tightens, framed by Sonoma Mountain on the west and the Mayacamas on the east, and the temperatures warm significantly. The wide array of soils, aspects, and mesoclimates allows for a broad range of grape varieties, including Gewürztraminer, Pinot Noir, Chardonnay, and Cabernet Sauvignon, although above all else Sonoma Valley is known for its ancient Zinfandel vines, many well over 100 years old (see HISTORIC VINEYARD SOCIETY) and continuing to pump out small yields of intensely flavoured, spicy grapes. Many old vineyards were planted to FIELD BLENDS of Zinfandel, Petite Sirah, Carignan, and other 'mixed blacks', and there is a growing appreciation in the valley for such vineyard-specific blends. See also Bennett Valley and Moon Mountain District (above).

West Sonoma Coast

Recognized in 2022, this AVA is the westernmost slice Sonoma County, encompassing the rugged terrain between the Coastal Range and the Pacific Ocean as far north as Mendocino County and as far south as the Petaluma Gap AVA. Elevation is varied, at 122–549 m/400–1,800 ft, but the steepness of the slopes means that its 405 ha/1,000 acres of vineyards in 2022 are planted almost entirely on the mountaintops, often surrounded by conifer forest. Generally shallow soils and a cool MARITIME CLIMATE tend to mean lower yields and more challenging farming. It is also the rainiest part of the region. Pinot Noir, Chardonnay, and Syrah do especially well.

L.M. & E.C.B.

sonomawine.com

sooty mould. See MEALYBUGS and SCALE.

Sopron , wine region and PDO in the extreme north-west of HUNGARY comprising 1,524 ha/3,766 acres. Its climate is much more temperate than that of most of the rest of Hungary, with cooler, wetter summers and milder winters. From the 14th century, when Hungary was recognized as a useful source of fuller, richer wines than those of northern Europe, Sopron was an important centre of the wine trade, dispatching not just its own wines but those of the rest of Hungary to Austria, Poland, and Silesia. Today Sopron produces mainly red wines, the most distinctive coming from grape varieties such as KÉKFRANKOS, Cabernet, Syrah, and Merlot.

sorbic acid (2,4-hexadienoic acid), winemaking additive and preservative discovered in 1940 to inhibit the growth of YEAST and other FUNGI. Sorbic acid, or its salt potassium sorbate, is used widely in food and drink production to inhibit the growth of yeast and

mould, notably on cheese and meat. It is classified as one of the safest food preservatives. Sorbic acid use has permitted the wide range of everyday commercial wines currently available which contain some RESIDUAL SUGAR but whose ALCOHOLIC STRENGTH alone is not sufficient to inhibit yeast metabolism.

There is a drawback, however. While most people detect about 135 mg/l, a small proportion of humans are sufficiently sensitive to sorbic acid to detect as little as 50 mg/l in wines. It has a particular taste and a rancid odour to some palates, even at levels that are hardly high enough to inhibit yeast. The EU and OIV limit in finished wines is 200 mg/l.

Sorbic acid inhibits the growth of some BACTERIA but not, unfortunately for winemakers, the large group of LACTIC ACID BACTERIA. SULFUR DIOXIDE must be used together with sorbic acid in sweet wines that are low in alcohol in order to prevent the growth of lactic acid bacteria. Some of these lactics metabolize sorbates to produce compounds such as 2-ethoxyhexa-3,5-diene, which has a perception threshold of around 10 mg/l and smells of crushed GERANIUM leaves—definitely a wine FAULT. A.D.W.

sorbitol, one of the sugar ALCOHOLS present in trace amounts in grapes and wines, and closely related to GLUCOSE. It has a mildly sweet taste, is very soluble in water, and, when present in high concentrations, confers a sense of BODY on a liquid.

Since sorbitol can be made easily and cheaply from many agricultural raw materials, this property has been harnessed by a few unscrupulous wine bottlers to increase consumer acceptance of thin, acid, ordinary wines. Sorbitol is not harmful to humans, but its use is prohibited by most wine regulations. A.D.W.

sorì is a PIEMONTESE dialect term used for vineyard sites of the highest quality, particularly for those with an exceptional favourable southern exposure. More subtle variations also exist: a ‘morning’ sorì

(*sorì di mattino*) has a south-eastern exposure; and an 'evening' sorì (*sorì di sera*) has a south-western exposure. The term was first used on a wine label by Angelo GAJA for his Sorì San Lorenzo Barbaresco 1967 and was widely imitated in the subsequent quarter-century.

sorting of grapes. See GRAPE SORTING.

sotolon, compound (3-hydroxy-4,5-dimethylfuran-2(5H)-one) formed from ACETALDEHYDE that is an important component of the spice fenugreek and is found in a wide range of products from BOTRYTIZED wines to roasted tobacco. At a higher level (tens of µg/l), it is responsible for the typical nut and spicy 'curry' aromas that characterize VIN JAUNE from the Jura but also TOKAJI and some fortified wines, including VIN DOUX NATUREL and PORT, especially those that are RANCIO. It forms partially during the ageing process, particularly if this is OXIDATIVE, but in *vins jaunes* it is known to increase after bottling. At a lower level (more than 3µg/l), it is also commonly identified by a honey or beeswax aroma in dry white wines suffering from PREMATURE OXIDATION. Discovered by Japanese scientists in the late 1970s as a flavour compound in raw cane sugar, sotolon has a very low flavour threshold in wine (3 µg/l). W.L. & V.L.

sour rot, term applied to a decay of injured, mature grapes which take on the smell of vinegar. In much of Europe and cool-climate regions of North America and Oceania, it is caused by the progressive colonization of various non-*Saccharomyces* yeast species and ACETIC ACID BACTERIA, mediated by fruit fly activity (see DROSOPHILA). In California and some similar climates, the term is applied to a breakdown caused by various mould fungi, presumably followed by the secondary colonization of yeast and bacteria. Common entry points for the causal microbes are splits in berry skin caused by tightly compacted clusters or rain as well as mechanical injuries such as bird pecks. The rot is encouraged by warm pre-harvest rain and high humidity. Control relies on avoiding fruit damage, encouraging fruit aeration, reducing cluster compaction, and controlling fruit flies.

Sousão, a dark-skinned grape variety widely planted in northern Portugal, where the wine is notably high in acidity as well as colour and is therefore increasingly valued in PORT blends, including vintage port. In the nearby Minho it is known as Vinhão, its official Portuguese name, and makes particularly lively red VINHO VERDE. Portuguese plantings totalled 4,337 ha/10,717 acres in 2023 and a few hundred hectares in GALICIA, north-west Spain, where, under the name Sousón, most goes into blends. Spelt variously Sousão, Souzao, and all stations in between, it has also been planted by aspirant makers of PORT-style wines in California, South Africa, and Australia, with a certain degree of success.

South Africa , prolific southern-hemisphere wine producer with a lustrous past and now in the midst of a significant renaissance. The

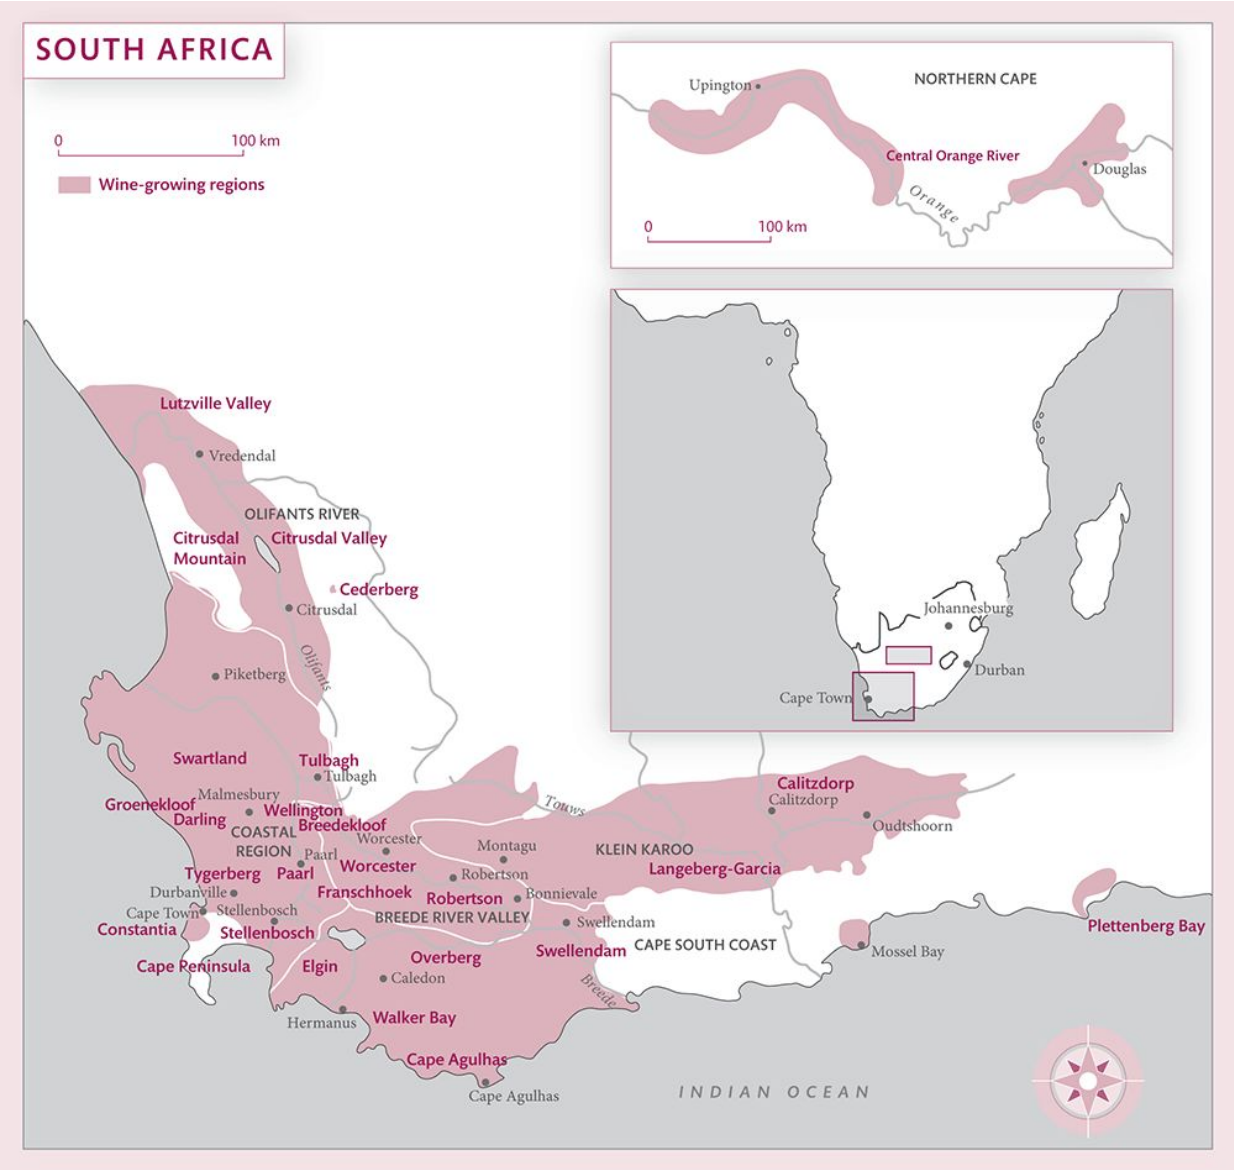
famous Muscat-based dessert wines of CONSTANTIA seduced 18th- and 19th-century Europe at a time when names such as LAFITE and Romanée-Conti (see DOMAINE DE LA ROMANÉE-CONTI) were still in the making. The two centuries which followed were, by comparison, a disappointment, with the ordinary being too plentiful and the individual too rare. Only since the early 1990s has the Cape shaken off its political notoriety and vinous obscurity.

With 1.2% of the world's vineyards, South Africa ranked 15th in area under vines in 2021, but its annual output, at around 10.6 million hl/280 million gal, makes it the eighth-largest wine producer in the world. Total area of vineyard for wine grapes has declined from over 100,000 ha in the early 2000s to 90,512 ha/223,660 acres in 2021. The number of cellars has also decreased: by 2021 there were 536, down from almost 600 a decade earlier. The same attrition has seen the number of growers fall from almost 5,000 in 1990 to around 2,613 three decades later.

As in Europe and America, people are drinking less, but better, wine, with average per capita consumption 8.6 l per year in 2021. Meanwhile, to an increasing extent, wine is the beverage of choice of middle-class families in many of the urbanized areas. This shift away from a beer-and-spirits-only consumption pattern has seen the growth of a more sophisticated domestic market. A virtual twenty-fold increase in exports between 1990 and 2019, coupled with compromised profitability at the lowest pricing tier, provides a significant incentive to vine-growers to pursue quality rather than quantity.

This scramble for excellence has confirmed the benefits both of cooler sites and of matching locality to grape varieties. The historic CONSTANTIA area has been rediscovered and replanted. Climatic conditions here and in recently pioneered areas such as ELGIN, WALKER BAY, and CAPE AGULHAS on the eastern seaboard and alongside the cold Benguela current along the west coast differ dramatically from those in the hot hinterland. Many of the country's more adventurous winemakers, working in the warmer SWARTLAND and Olifants River

regions, have produced some of the country's most exciting new-generation wines from these appellations.



History

The father of the South African wine industry was a 33-year-old Dutch surgeon sent to establish a market garden to reduce the risks of scurvy on the long sea passage between Europe and the Indies. Jan van Riebeeck, the Cape's first European settler, was a reluctant pioneer, and no viticulturist. But his brief was to set up a supply station for DUTCH EAST INDIA COMPANY sailors on the spice routes; and the Cape's MEDITERRANEAN CLIMATE suggested vines might well flourish.

Seven years after sailing into Table Bay on 6 April 1652, at the head of a ragtag band, he recorded: 'Today, praise be to God, wine was pressed for the first time from Cape grapes.' The cuttings came from 'somewhere in western France' according to viticulturist Professor C. Orffer. Conditions and quality improved when a new governor, Simon van der Stel, established the legendary 750-ha/1,850-acre CONSTANTIA wine estate outside Cape Town in 1685.

Constantia again became the focal point of the wine industry in 1778, when a portion of the now-divided estate was bought by a talented and ambitious grower, Hendrik Cloete. His Constantia dessert wines soon became the toast of European aristocracy. Cape wine exports flourished under British rule, even if mainly of cheap wines. When in 1861 the Gladstone government removed empire-preferential tariffs, French wines had only the Channel to cross to capture the British market, and far-flung Cape colony products became uncompetitive.

PHYLLOXERA struck in 1886, adding a 20-year recuperation period to the trade's already unhealthy fortunes. Making up for lost time, growers rebuilt the industry, planting some 80 million high-yielding vines such as CINSAUT by the early 1900s. A manageable flow swelled into a deluge; unsaleable wine was poured, literally, into local rivers.

The Cape (most South African vineyards are in the hinterland of the Cape of Good Hope) functioned as a vast distillery for much of the 20th century, draining a partly subsidized annual wine lake and guaranteeing a certain quality of life to a politically powerful farming

lobby. The growers' body founded in 1918, the KWV (Co-operative Wine Growers' Association), was until 1998 legally empowered to determine production quotas, fix minimum prices, and predetermine production areas and limits—a system which tended to handicap the private wine producer and favour the bulk grape-grower. Its powers were criticized by free-marketeers and some producers who, even if non-members, were subject by law to KWV regulations. The KWV argued it spared government the embarrassment of direct grower subsidies. Grower benefits, however, were indirect. Wine CO-OPERATIVES and farmers enjoyed Land Bank credit terms well below commercial interest rates, opportunities that were not available to non-whites until the end of the apartheid era. Such was KWV's political influence in pre-democratic South Africa that wine, alone among alcoholic drinks, was exempt from excise duty for many years. Additionally, the 'dop' system, put in place in the 1700s, provided workers with wine, nominally as a portion of their wages. This served to keep them in thrall to their employers and to their employment in the wine industry. This LABOUR system continued long after it was outlawed in 1960 and contributed both to high rates of alcoholism and to poverty among growers.

In the late 1990s, the newly structured KWV was relieved of all the statutory functions previously performed by the 4,600-strong growers' co-operative. Its conversion from co-operative to company was not without controversy. The process was challenged by the Minister of Agriculture, who cited the statutory void which would result from the process and a concern about the real ownership of some of the organization's assets as grounds for his intervention. Resolution was reached through an out-of-court settlement in which the KWV undertook to pay a sum of 369 million rand (equal at the time to $77 million) into the South African Wine Industry Trust to redress inequalities of the past and to assist in the management and promotion of the industry. Financial mismanagement, together with a controversial decision to allow the residue to be used to fund the purchase of 25% of KWV's shares by a black consortium, led to its being wound up after less than ten years.

The export boom which followed South Africa's first democratic elections in 1994 transformed an industry in which as recently as 1990 less than 30% of the harvest reached the market as wine. By 2019, 86% of the grape crop was used to produce wine, with the remainder supplying the domestic brandy and fruit juice industries. While large-scale producers and co-operatives crush a significant percentage of the 1.3-million-ton (2020) crop, most top-quality South African table wine, however, comes from private cellars and a few wholesaler-producers. The biggest wholesaler, DISTELL, still dominates the market in South Africa's vine-related alcohol products, as it has since 1979.

The organizations which are now independent but which were formerly part of KWV still fulfil functions such as research, vine PROPAGATION, advisory services, and administration of the WINE OF ORIGIN system. These include Vinpro, the service organization for the country's primary producers, SAWIS, which collects, processes, and disseminates industry information, and Winetech, which coordinates research, training, and technology transfer.

Climate and geography

Surrounded on all sides and largely in close proximity to the Atlantic Ocean, South Africa's quality wine regions seem so far to have avoided the worst excesses of CLIMATE CHANGE. The Benguela current makes the Cape cooler than its LATITUDE may suggest, and many new vineyard areas south towards Agulhas as well as on the Cape west coast offer the prospect of a long, slow ripening season.

The winelands are widely dispersed throughout the Western and Northern Cape, some 700 km/420 miles from north to south and 500 km across, strung mainly along the Atlantic, though with newer Cape South Coast vineyards adjacent to the Indian ocean.

Climates and soils vary as dramatically as landscapes: mountains rear out of the sea, unfolding into lush valleys, sere drylands, and a series of inland mountain chains. In the Stellenbosch district alone, just outside Cape Town, there are more than 50 soil types. On the hillsides, decomposing GRANITE prevails. Soils tend to be low in PH (4.5), with a predominance of CLAY (25% and more), but are well drained and moisture retentive.

That portion of the harvest reserved for inexpensive TABLE WINE as well as brandy and fruit juice concentrate comes from hot, irrigated river valleys such as the Orange, Olifants, and Breede, where vineyards yield prodigiously. Around inland Robertson there are some CALCAREOUS lime-rich outcrops akin to the calcareous soil of Burgundy's CÔTE D'OR. But in the cooler coastal areas, the ancient soils depend on substantial LIME additions.

Annual rainfall rises from 250 mm/9.7 in in the near-desert Klein Karoo to 1,500 mm in the lee of the Worcester Mountains, about 100 km inland from Cape Town. Growers, particularly those in the semi-desert areas who depend on IRRIGATION, argue they merely make up the shortfall to reach the 900 mm annual rainfall of a vineyard in the Bordeaux region of France.

Average summer daily temperatures often exceed 23 °C/73 °F during the February and March harvest months, and maximum

summer temperatures can rise to nearly 40 °C. However, an increasing proportion of new, cooler vineyard sites are making this caricature of the Cape as a hot-climate viticultural region as questionable a generalization as the old belief that Cape vintage variations are insignificant.

A unique but mixed blessing is the frequent gale-force summer south-easter, the 'Cape Doctor' WIND, that reduces humidity, mildew, and other FUNGAL DISEASES but also sometimes batters vines.

Most wine regions would, according to the WINKLER scale, be classified Region III sites (as in Oakville, Napa Valley) or Region IV (like Sydney and Florence), with some in V (Perth). But several areas experience cooler European (or Winkler II) conditions, especially in high-ELEVATION or sea-cooled vineyards. New appellations such as Walker Bay (on sandy SHALE), Constantia (granite and SANDSTONE), Elgin (shale), and Cape Agulhas have stretched horizons and broadened the Cape's climatological repertoire.

Winegrowing areas

South African wine country is divided into geographical units in which are regions, then districts, and then wards as in this table. For more explanation of their significance, see Wine of Origin below.

Production Areas Defined in Terms of the Wine of Origin Scheme

GREATER CAPE (overarching geographical unit)
1. WESTERN CAPE (geographical unit)

Overarching Region	Region	Subregion	District	Ward

Viticulture

The stark contrast between the traditional and the progressive in South African viticulture, often visible on adjoining farms, reflects the disparate objectives of growers. The bulk grape-farmer delivering to one of the less progressive BULK WINE cellars strives for quantity; growers bottling their own crop knows quantity can be the enemy of quality. From the second half of the 20th century, TRELLISING, low VINE DENSITY, and AGROCHEMICAL pest and weed control became common features of the South African viticultural landscape. However, in this century closer planting, greater use of SUSTAINABLE VITICULTURE methods and BIOLOGICALS to control pests and diseases, careful CLONAL SELECTION, painstaking SOIL PREPARATION that can involve additions of over 20 tons of LIME per hectare to achieve higher PH, and PRUNING for lower yields have become the norm on many properties.

Average planting densities are around 3,300 vines per ha/1,300 per acre. Yields in cooler, coastal climates are appreciably lower than the national average: about 49 or 56 hl/ha (2.8 or 3.2 tons/acre) for Cabernet Sauvignon and Chardonnay are considered consistent with quality in Cape conditions. Yields from virus-infected vineyards can drop to below 28 hl/ha (1.6 tons/acre).

Most vineyards are IRRIGATED in summer, with DRIP IRRIGATION having replaced overhead sprays or fixed sprinkler systems on the better estates.

The most common TRELLISING SYSTEM is a simple vertical 'hedge row' developed from a split vine cordon, supported by a wire raised about 750 mm/2.4 ft for ease of pruning. The summer foliage is trained upright in a CANOPY held by one or more wires above the CORDON. Short-SPUR PRUNING is commonly practised (eight to ten spurs, four to five on each cordon, pruned back to two or three buds each).

Most vine diseases and pests found their way from the northern hemisphere long ago. Chemical pesticides are widely used, especially in the higher-yielding vineyards, although farmers are now

encouraged by way of the INTEGRATED PRODUCTION OF WINE (IPW) programme to minimize the use of insecticides and to use a more ORGANIC approach. Baboons are also a pest in several areas.

POWDERY MILDEW, locally called 'white rust', is the most serious common disease. DOWNY MILDEW poses a seasonal threat. Both are containable by systemic fungicides. BOTRYTIS is not a serious problem most years and is welcomed by growers specializing in dessert wines.

Cape vineyards were decimated by PHYLLOXERA from 1886, and virtually all vines are grafted on to resistant American ROOTSTOCKS, the most common being Richter 99, 110, 101–14, and Ramsey.

Virus-infected vines, which were once widespread and remain a feature of older and less progressively farmed plantings, shorten the productive lifespans of vineyards. Affected vines succumb to LEAFROLL, CORKY BARK, and FANLEAF, inhibiting PHOTOSYNTHESIS and ripening, diminishing yields but not improving grape quality.

From the mid 1980s, HEAT-TREATED, virus-tested plant material was more freely available, along with a greater selection of imported CLONES of classic varieties. Healthier, earlier-ripening vineyards are the result, and it is now easier to distinguish a significant pattern of regional/varietal characteristics.

Burger, J., and Deist, J., *Viticulture in South Africa* (1981).

Winemaking

Since the advent of democracy in South Africa winemaking has been in a state of flux and experimentation. Younger winemakers who travel extensively, many working vintages in the northern hemisphere, have challenged the orthodoxies of earlier generations and have transformed the face and taste of the Cape's best wines. While many of the more commercial wines reflect an environment where irrigation, higher yields, a warm climate, and low-pH soils are the dominant factors, an increasing number of the better producers offer wines which embody considered viticultural practices, thoughtful vinifications, and ÉLEVAGE which does not depend on new OAK to achieve results.

Controlled MALOLACTIC CONVERSION is widely practised, while reduced dependence on flavour-stripping FILTRATION and STABILIZATION processes has also helped improve the quality of the better wines. New CANOPY MANAGEMENT strategies and increasing VINE DENSITIES also played a role.

Apart from isolated CALCAREOUS outcrops, wines from the Cape's often excessively acid soils tend to require TARTARIC ACID adjustments to MUSTS and wines, as well as severe TARTRATE removal procedures before bottling (see SOIL ACIDITY).

Vine varieties

In South Africa a vine variety is usually known as a cultivar, and South Africa is a cultivar-conscious wine country. Regionality has limited commercial value, with many producers electing to apply the broadest possible appellation in order to maintain flexibility in terms of fruit sourcing. Accordingly, grape variety is still the major factor driving perceptions of quality, style, labelling, and marketing of a wine, although increased VINE AGE and a greater focus on site are changing this. While white varieties used to dominate South African vineyards, the post-1994 transformation of the wine industry has seen premium red varieties reach virtual parity. CHENIN BLANC was long the most planted variety in South Africa and still comprised 18.6% of the national vineyard in 2021. From the 1980s, Sauvignon Blanc and Chardonnay were energetically planted, and by 2021 they comprised 11% and 7.3% of all plantings respectively. Other major white wine grapes include, in decreasing quantity: Colombar(d), Muscat of Alexandria, Sémillon, and Viognier.

Cabernet Sauvignon is South Africa's most planted red grape variety, comprising 11% of the nation's vineyard. Syrah (often called Shiraz in South Africa) has come to rival Cabernet Sauvignon and in 2021 accounted for 10% of all plantings. Merlot, often blended but popular enough in its own right, occupies slightly more than half the area dedicated to Cabernet. Pinot Noir has improved dramatically as new CLONES have been planted and cooler regions established. PINOTAGE, the Cape's own cross of Pinot Noir and Cinsaut, remains relatively stable at just over 7%. For most of the first half of the last century, high-yielding Cinsaut was the most widely planted red wine grape, but it has declined dramatically in importance and now represents less than 2% of all vineyards. There are yet smaller plantings of Grenache, Mourvèdre, Carignan, Zinfandel, Cabernet Franc, and some PORT varieties—most commonly TINTA BARROCA, often made into a dry red. Italian varieties, notably Nebbiolo and Sangiovese, are beginning to attract attention.

Wine of Origin and labelling

Wine of Origin (WO) legislation introduced in 1973, and variously updated since then, ended decades of a labelling free-for-all in which confused South African wine nomenclature and unverified vintage and grape variety claims baffled the consumer. The following types of wine production zones are now classified: geographical unit (e.g. Western Cape); region (e.g. Coastal), which may represent a merging of several districts; district (e.g. Stellenbosch); and ward (e.g. Bottelary). While the larger units are broadly geographical and/or political, a ward is based on shared soils, climate, and so on (i.e. aspects of TERROIR). 'Estates' are no longer official places of origin, but registered 'estate wines' must be grown, made, and bottled on a single property. Single vineyards may be indicated as such on labels provided they are not larger than 6 ha/15 acres, are planted to a single variety, and are registered in accordance with the legal provisions.

A wine may also be 'certified' for vintage provided at least 85% comes from one harvest. For a wine to be labelled as a single VARIETAL, it must contain at least 85% of the variety stated. Varieties in a blend may be indicated on the label providing they are stated in descending percentages and only if they are vinified separately.

A certified wine is identified by a seal which contains a tracking number enabling the authorities to trace every component batch or variety (in the case of a blend) back to the vineyard and the date of harvest. Vineyards are subject to inspection, and wines may be monitored in the cellars. Certification follows an official analysis, tasting, and final label approval. Participation is voluntary, and a little under 50% of the country's wine production is now certified. The process is under the supervision of the government-appointed Wine & Spirit Board. Non-certified wine is liable to spot-check analysis for health requirements.

South Africa meets requirements on prohibition of ADDITIVES and for LABELLING, which must state the ALCOHOLIC STRENGTH (from 1992) to within 0.5%. TRADITIONAL METHOD Cape sparkling wine is labelled

Méthode Cap Classique. FLOR-yeast FORTIFIED WINES matured in a SOLERA system are in decline and may no longer be sold as sherry. But wines made in the image of PORT, generally using very similar varieties and the same techniques as in port country, have been very successful.

Although the WO regulations borrow from France and Germany, there are no rulings on crop YIELDS, FERTILIZER quantities, or IRRIGATION levels. CHAPTALIZATION and all other forms of ENRICHMENT are banned, although grape juice concentrate may be added as a sweetener to most wines (see SWEET RESERVE). ACIDIFICATION is permitted. Wines sold as 'dry' on the domestic market may not have a RESIDUAL SUGAR content exceeding 5 g/l (see SEE WEB LINKS www.sawis.co.za). J.P. & M.F.

South America , the world's second most important wine-producing continent, after Europe, with ARGENTINA the most productive of its nations and CHILE right behind, followed by BRAZIL. Other, relatively minor, wine producers are, in descending order of importance, URUGUAY, PERU, BOLIVIA, and PARAGUAY, although see also COLOMBIA, ECUADOR, and VENEZUELA. Spain and, in some parts, Portugal were important influences in the 16th and 17th centuries, although more recently France, Italy, and the United States have helped to shape South America's wine industries. Wine quality has improved extremely rapidly in those countries—Chile, Argentina especially, and Brazil and Uruguay as well.

History

The late 15th century European voyages of discovery, notably to the Americas, were followed by migrations of European settlers there, associated with substantial movement of animals and plants between the two continents. Although INDIGENOUS VARIETIES grew in Central America (see VITIS), there is no evidence that the Aztecs made wine from them. The Spanish conquistadores of the 16th century thus first introduced European VINIFERA vines, their cultivation, and winemaking to MEXICO; as early as 1522 Cortés is recorded as having sent for vine cuttings from Spain. Moreover, by 1524 the planting of vines was a condition of *repartimiento* grants, through which the Spaniards were granted land and labour on the foundation of Mexico City. From Mexico, the spread of viticulture followed swiftly on the heels of Spanish conquests to the south.

Vines were planted in Peru soon after Pizarro's defeat of the Incas between 1531 and 1534, and within 20 years Spanish commentators described vineyards producing a substantial quantity of grapes. Some of the earliest Peruvian vines appear to have been introduced from the CANARY ISLANDS, whereas others seem to have been derived from the seeds of dried grapes brought from Spain. From Peru, viticulture and winemaking then spread south to Chile and Argentina, where vines were cultivated as early as the mid 1550s, although there were even earlier experimental plantings on Argentina's coast. See also MONKS AND MONASTERIES.

The traditional explanation for the rapidity of this spread was that the Spanish conquerors required a ready supply of wine for the EUCHARIST and that monks therefore played a central role in establishing vineyards. There is, however, little evidence to support this view, and many of the early vineyards and attempts to produce wine were on secular estates. Economic factors, such as the cost of importing wine and the difficulties of transporting it overland, meant that the early Spanish conquerors had a very real interest in establishing vineyards if they wished to continue to consume the

main alcoholic beverage that they had known in Iberia. In particular, the long sea voyage across the Atlantic, followed by an overland haul across Panama and then a further voyage down the Pacific coast, meant that most wine reaching Peru and Chile from the Iberian peninsula was likely to have deteriorated, even if it had originally been of good quality.

By the end of the 16th century, Spanish restrictions on wine production in 'New Spain', designed to protect the metropolitan wine producers and merchants in Iberia, served to limit further secular development of viticulture in Mexico, but they also appear to have provided an incentive to Peruvian producers, who rapidly became the dominant wine suppliers to the region as a whole. Subsequently, in the 17th century, Jesuit MISSIONS along the coastal valleys of Peru became the most important centres of viticulture in the region.

South Australia , *the* wine state in AUSTRALIA, responsible for 50% of the annual CRUSH. This share may have fallen from the 75% of the 1940s and 1950s, but the state still dominates the country's wine output. Vine-growing and winemaking are major contributors to South Australia's gross domestic production, yet they occupy only a small percentage of the state's vast land mass. Vine-growing is concentrated in the south-eastern corner, much of it within an hour's drive of the capital Adelaide. The two most significant outposts are the Riverland sprawling along the Murray river and Coonawarra and Padthaway 325 km/200 miles south-east of Adelaide, not far from the border with VICTORIA.

South Australia includes one 'super' zone, Adelaide Zone, which encompasses three subzones (MOUNT LOFTY RANGES ZONE, FLEURIEU ZONE, and BAROSSA ZONE), each of which contain several more specific GEOGRAPHICAL INDICATIONS (GIs). South Australia grapes also are often subsumed in wines labelled with the multi-regional super-zone GI SOUTH EASTERN AUSTRALIA.

Within the Barossa Zone, the BAROSSA VALLEY, an hour north-east of the city of Adelaide, is arguably Australia's best-known wine region, with 11,609 ha/28,686 acres of vineyards spread between warm areas on the valley floor and cooler MESOCLIMATES at higher ELEVATIONS in the surrounding hills. To this day, the Germanic influence of its 19th-century Silesian immigrants is everywhere to be seen—in the town names, the Lutheran churches, the stone buildings, and the names of the leading families. Many of Australia's largest companies have a strong presence here, including PENFOLDS. The valley is also home to the world's oldest continuously producing Shiraz, Grenache, Mataro, Cabernet Sauvignon, and SÉMILLON vines. Substantial plantings of Shiraz date as far back as 1860, the DRY-FARMED and GOBELET-trained vines often yielding as little as 16 hl/ha (1 tonne/acre).

EDEN VALLEY, also within the Barossa Zone, sits 200 m/656 ft higher than the Barossa Valley floor to the east, rising to 450 m/1,480 ft. Overall growing season temperatures are significantly lower than those of the Barossa Valley, hence the final stages of ripening and harvesting take place in much cooler conditions. Riesling, Shiraz, Chardonnay, and Cabernet Sauvignon are the main varieties planted in its 2,169 ha/5,360 acres of vineyards, although increasingly growers are looking to the cooler climate to grow more white varieties. Eden Shiraz is generally spicier and more elegant than Barossa floor examples, with finer tannins and lower alcohol.

CLARE VALLEY headlines the Mount Lofty Ranges Zone. A long, narrow region two hours north of the city of Adelaide, at the gateway to the Flinders Ranges, it has 5,093 ha/12,585 acres of vineyards, some at significant elevation. With a strongly CONTINENTAL CLIMATE,

with warm days but cool-to-cold nights in summer, it tends to produce intensely coloured, deeply flavoured Shiraz and Cabernet Sauvignon, often with a patina of EUCALYPT mint. MALBEC also flourishes here, used as a blend component. The region's aromatic, mineral-driven, long-lived Riesling is one of South Australia's most iconic wines.

ADELAIDE HILLS, also part of the Mount Lofty Ranges Zone, is just 15 minutes south-east of the city of Adelaide and incorporates the GIs of Piccadilly Valley and Lenswood, each of which have less than 270 ha/667 acres of vineyards but produce high-quality cool-climate fruit and have been distinguished due to their rare soils and specific mesoclimates. Ripening conditions in Piccadilly Valley are ideally suited to growing Chardonnay and Pinot Noir, and Lenswood is renowned for its Sauvignon Blanc and Merlot. As a whole, Adelaide Hills encompasses 3,957 ha/9,778 acres of vineyards, some at as high as 650 m/2,130 ft. In the 21st century, it has become one of South Australia's most important fine-wine regions, and its proximity to Adelaide lends itself to TOURISM, with over 50 cellar doors operating by 2022. Grapes have been grown here as long as anywhere in the state, but plantings took off in the late 1970s and early 1980s when Petaluma and others recognized the region's potential for growing cool-climate varieties such as Pinot Noir and Chardonnay for both sparking and table wines. The region also excels elegant, cool-climate Shiraz. The Adelaide Plains GI to the north-west has a radically different climate, its flat, hot and fertile soils producing a decidedly warmer style of Shiraz.

The Fleurieu Zone contains the GIs MCLAREN VALE, LANGHORNE CREEK, KANGAROO ISLAND, CURRENCY CREEK, and SOUTHERN FLEURIEU. All are highly MARITIME, with the warmer McLaren Vale, 45 minutes south of the city of Adelaide, making up the bulk of production. Its 7,438 ha/18,380 acres of vineyards connect with the Adelaide Hills in the north and the sandy beaches of the Adelaide coastline in the west. With its MEDITERRANEAN CLIMATE, diverse soils, and a culture of innovation, its 100-plus wineries produce a myriad of wine styles from a multitude of varieties, with a focus on Shiraz, Cabernet

Sauvignon, and Grenache and an increasing presence of alterative Mediterranean varieties.

The LIMESTONE COAST ZONE in the far south-east of the state includes the coastal regions of Mount Benson and Robe and the inland regions of Coonawarra, Wrattonbully, Padthaway, and Mount Gambier. Of those regions, COONAWARRA has the largest planted area, at 5,784 ha/14,293 acres of vineyards. Coonawarra experiences a maritime influence due to upwelling of cold ocean currents at certain times of the year and is largely regarded as a cool region. While vines were first planted in Coonawarra in 1890 (by John Riddoch), for all practical purposes it became commercially significant in the early 1960s, celebrated for its TERRA ROSSA soils. It has long been highly regarded for its Cabernet Sauvignon, which accounts for 60% of production, followed by Shiraz and Merlot which collectively make up almost 30%.

WRATTONBULLY, north of Coonawarra, has 2,727 ha/6,739 acres of vineyards. Almost 70% of production is dominated by Cabernet Sauvignon and Shiraz. Nestled in the Narcoorte Ranges, it is characterized by rolling hills and shallow terra rossa soil upon LIMESTONE. The region is home to the World Heritage–listed Naracoorte Caves, many of which were discovered as a result of vineyard development and some of which contained significant ancient fossils and prehistoric remains.

PADTHAWAY sits yet further north, a long, narrow, relatively cool-climate region with 4,160 ha/10,280 acres of vineyards on soils with considerable limestone and an extensive underground water table. Approximately 50% of overall production is equally dominated by Cabernet Sauvignon and Shiraz, and Chardonnay accounts for another 20%.

Mount Gambier, a GI established in 2014, is nestled in the far south-eastern corner of South Australia, pushing up against the Victorian border. Its 327 ha/808 acres of vineyards produce predominantly Sauvignon Blanc, with the balance of the crush dominated by Pinot Noir and Chardonnay.

On the coastal side of the zone, the small GIs of MOUNT BENSON (541 ha/1,337 planted acres) and ROBE (681 ha/1,683 planted acres) are slightly cooler than the inland GIs, with a maritime climate and sand and limestone interspersed. Shiraz predominates, with Sauvignon Blanc steadily increasing and Cabernet Sauvignon making up a significant share of the balance.

Finally, there is the RIVERLAND, with over 1,000 grape-growers and 22,032 ha/54,442 acres of vineyards producing 30% of the nation's crush. About 200 km north-east of the city of Adelaide, stretching along the Murray river from Waikerie to Renmark, the climate here is continental, with long, sunny days and noticeably cooler nights. It built its reputation on Chardonnay, Shiraz, and Cabernet Sauvignon, but there is a new wave of innovative producers exploring alternative varieties and crafting edgy wines. J.H., H.H. & R.J.T.

www.winesa.asn.au

South Burnett, relatively hilly Australian wine region and GEOGRAPHICAL INDICATION (GI) in Queensland about 2.5 hours' drive north-west of Brisbane. It has a subtropical climate with long summers and mild winters. Summer rainfall can be a problem, bringing POWDERY MILDEW. There are excellent examples of SÉMILLON, Chardonnay, Shiraz, and, more lately, VERDELHO, TEMPRANILLO, and ALTERNATIVE VARIETIES. The vineyards, planted in generally fertile red soils, extended 204 ha/504 acres in 2020. A.C.

South Coast, extensive AVA defining vineyards close to the California coast from Los Angeles County to the Mexican border. The region's most substantial vineyards are in TEMECULA VALLEY in Riverside County. It also includes the AVAs MALIBU COAST and Palos Verdes Peninsula in Los Angeles County and San Pasqual and Ramona Valleys in SAN DIEGO COUNTY.

South Coast Zone, expansive area encompassing all of coastal NEW SOUTH WALES south of Newcastle and east of the Great Dividing Range, stretching to the border with VICTORIA. Includes the Southern Highlands and Shoalhaven Coast regions.

South Eastern Australia, official 'super zone' and GEOGRAPHICAL INDICATION encompassing all relevant wine regions in QUEENSLAND, NEW SOUTH WALES, VICTORIA, and SOUTH AUSTRALIA, used for multi-region, inexpensive blended wines constituting a significant proportion of all wine exported from Australia.

Southern Fleurieu, strongly maritime wine region at the tip of the Fleurieu Peninsula in SOUTH AUSTRALIA.

Southern Flinders Ranges, most northerly wine region of SOUTH AUSTRALIA with 176 ha/435 acres of vines in 2022, mainly Shiraz. The warm, dry climate is moderated by ELEVATIONS of up to 958 m/3,143 ft and broad DIURNAL TEMPERATURE RANGE.

Southern Glazer's is the biggest wine company you've never heard of. The behemoth American distributor stands between wineries and retailers, serving as a licensed wholesaler in 41 US states. *Forbes* estimated the company was the 11th largest private company in the US with revenues of $21 billion in 2021.

The company known as Southern Wine & Spirits was founded in 1968 when Walter Jahn, a drinks executive from New York, bought out a local wine and spirits distributor in Miami. The original financing came from a bank with ties to organized crime, which competitors (but not Southern) frequently mention. The company grew first in Florida and then nationally, with its sales force championing the emergent interest in wine. In 2016 a merger with Dallas-based Glazer's expanded the company's reach to distribute over 150 million cases of wine and spirits every year.

While they have some enormous facilities, such as a streamlined 40,000 sq m/425,000 sq ft warehouse in Nevada, the company has also been known to use sharp elbows in its rise to become the country's largest wine and spirits wholesaler. As with other large distributors, it is a donor to politicians of all stripes and at all levels of POLITICS. The policy goals include maintaining the legally mandated middle-tier in the controversial THREE-TIER SYSTEM or otherwise tilting the playing field in their direction. T.C.

Emshwiller, J., and Freedman, A., 'Early relationships help shape Southern Wine & Spirits', *Wall Street Journal*, 4 October 1999.

Southern Highlands, Australian wine region in NEW SOUTH WALES located high on the Great Dividing Range, south-west of Sydney. The vineyards, situated at about 700 m/2,297 ft in ELEVATION, endure an erratic climate, with cold winters, humid summers, and often problematic late-season rainfall. Some producers get around this by making TRADITIONAL METHOD sparkling wines, alongside a broad range of table wines produced from varieties such as Chardonnay, Sauvignon Blanc, Pinot Noir, Shiraz, and Cabernet Sauvignon. A.R.P.

South West Australia Zone comprises the Blackwood Valley, Geographe, Great Southern, Pemberton/Manjimup, and Margaret River wine regions in WESTERN AUSTRALIA.

South West France, generally accepted but unofficially recognized region within FRANCE which incorporates all of the wine districts in the south-western quarter of the country with the exception of BORDEAUX and Cognac.

The vine was cultivated in most of these districts in the Roman era (see FRANCE and GAUL), but winemaking was developed sometimes for the benefit of pilgrims to St-Jacques de Compostelle under the medieval influence of MONKS AND MONASTERIES.

Production has always exceeded the needs of the inhabitants, so producers have had to find ways of establishing markets outside the immediate area. The Adour river was the only means of transport for winemakers to the south of it (the most important being those from Madiran, Jurançon, and Irouléguy), but it was hard to navigate, and there was competition from the growers of other crops. Wines from the areas to the north, in the 'high country' or HAUT-PAYS (mainly Bergerac and its family, Côtes de Duras, Marmande, Buzet, Brulhois, Gascony, Cahors, Fronton, and Gaillac), travelled down the Garonne and its tributaries to Bordeaux, where, however, the authorities imposed severe tolls before allowing the wines to gain access to the open seas.

The HUNDRED YEARS WAR was to have an enduring effect on their trading history, opening the door for the DUTCH WINE TRADE to take the place of once-powerful ENGLAND. It was not until 1776 that the Bordeaux tolls were outlawed.

The climate is heavily influenced by the Atlantic, though few generalizations can be made about such an extensive area. The nearer to Bordeaux, the more Cabernets and Merlot in the vineyards. Further upstream the wines are made from an exciting series of INDIGENOUS VARIETIES such as ABOURIOU, ARRUFIAC, BAROQUE, COURBU, DURAS, FER (Servadou), GROS MANSENG, LEN DE L'EL, MAUZAC, NÉGRETTE, PETIT COURBU, PETIT MANSENG, and TANNAT. The south-west is one of the proudest and greediest regions of France; they need its local wines to drink with *foie gras*, duck, and goose.

For more details, see the individual entries for the wines of AVEYRON, BÉARN, BERGERAC, BRULHOIS, BUZET, CAHORS, CORRÈZE, Côtes de DURAS, Côtes de MILLAU, Côtes du MARMANDAIS, Coteaux du QUERCY, ENTRAYGUES-LE FEL, ESTAING, FRONTON, GAILLAC, IROULÉGUY, JURANÇON, MADIRAN, MARCILLAC, MONBAZILLAC, MONTRAVEL, PACHERENC DU VIC-BILH, PÉCHARMANT, ROSETTE, ST-SARDOS, ST-MONT, SAUSSIGNAC, and TURSAN.

P.S.

Soviet Union , the Union of Soviet Socialist Republics, which until the fall of communism included such wine-producing republics as

MOLDOVA, UKRAINE, the CRIMEA, UZBEKISTAN, RUSSIA, AZERBAIJAN, GEORGIA and, producing very much less wine, ARMENIA, ESTONIA, KYRGYZSTAN, TAJIKISTAN, KAZAKHSTAN, LATVIA, LITHUANIA, TAJIKISTAN, and TURKMENISTAN. Once a wine-producing behemoth, the USSR lost one-third of its vineyards in the 1980s due to Mikhail GORBACHEV's anti-alcohol measures. In 1990 it accounted for 12% of the world's total vineyard area and 5% of the wine produced. The dissolution of the republic wreaked further havoc on the wine industries of the individual countries as the struggle for economic survival in the new free market economies resulted in a flood of alcohol substitutes, cheap vodkas, brandies, and wines from central and western Europe. By 1996, according to OIV statistics, the former Societ bloc countries accounted for 11% of the world's vineyard but only 3% of the wine produced. By the 21st century, former Soviet bloc countries such as Georgia and Moldova had established robust, respected wine industries while others such as Kyrgystan and Tajikistan continue to struggle.

spacing. See VINE DENSITY.

Spain , country with the most land under vine in the world (964,000 ha/2,382,096 acres in 2021, according to OIV estimates) and yet most years only the world's third most important producer of wine. The dramatic 21st-century increase in irrigated surface and a more controversial insistence on high-yielding CLONES have abundantly offset a 30% reduction in vineyard surface over the past quarter-century, although, after a period of inflated yields that saw Spain's annual average wine production averaging more than 40 million hl/1,060 million gal after 2010, they have returned to early 1990s levels, hitting just 35.3 million hl in 2021.

Spain occupies most of the Iberian peninsula and is the third largest country in Europe, extending from the Pyrenees that form the frontier with France in the north to the strait of Gibraltar just 15 km/9 miles from Africa to the south. Spain is a diverse country with distinct

regional and cultural differences. The principal language spoken throughout Spain is Castilian, although Galician is dominant in GALICIA, Catalan and Spanish are roughly tied in CATALUÑA, and Basque remains a minority language in the BASQUE region.

The country's regional diversity is reflected in its wines, which range from light, dry whites in the cool Atlantic region of Galicia to heavy, alcoholic reds in the Levante and the Mediterranean south. ANDALUCÍA in the south-west is known for the production of fortified and dessert wines, the most famous of which is SHERRY.

Modern production methods were slow to reach Spain but, when they did, typically in the early 1990s, they did so with a vengeance, with modernization sweeping one region after the other, including some (but not all) of the less glamorous ones. A programme of investment which began a decade earlier was further helped by Spain's accession to the EU in 1986. In 1996 vineyard IRRIGATION was legalized throughout the country, radically changing prospects for the drought-stricken central and south-eastern areas.

History to Columbus

Although the winegrowing PHOENICIANS founded Cádiz *c.*1100 BCE on the coast of southern Spain, they did not introduce viticulture to the Iberian peninsula, for the vine had been cultivated in Spain since 4000–3000 BCE. Grapes, found in Spain from the close of the Tertiary era onwards, predate *Homo sapiens* by millions of years.

Cádiz, gateway to the Atlantic, was an important Phoenician trading post. After the Phoenicians came the Carthaginians, themselves inhabitants of a city, Qart Hadasht (see CARTHAGE), founded by Phoenicians. The Carthaginians grew wine in Spain; more importantly, they were a threat to the emerging republic of ancient ROME.

The 2nd century BCE was a time of much unrest under Roman rule in Spain, and no systematic colonization was attempted until Rome finally 'pacified' the whole of the peninsula under Augustus. Political stability furthered trade: as the evidence from AMPHORAE shows, a great deal of wine from Baetica (which approximated to ANDALUCÍA) and Tarraconensis (TARRAGONA) was sold in Rome, and Spanish exports far exceeded exports of Italian wine to Aquitaine and south-eastern GAUL via Bordeaux. Spanish wine reached the Loire valley, Brittany, Normandy, and England, and it was given to the troops guarding the Roman frontier with Germany. Literary evidence confirms the discoveries of archaeology. Strabo says in his *Geography* (completed 9 CE) that, since the fall of Carthage, Baetica has been famous for the beauty of its many vineyards. COLUMELLA, a native of Cádiz in Baetica, sees the wine imports from Baetica and Gaul as symptomatic of the decline of Roman agriculture (1, *Praefatio.* 20).

Most of the Spanish wines, and particularly that of Saguntum, sold in Rome appear to have been PLONK: perfect for getting the porter of one's mistress drunk on, is Ovid's advice (*Ars amatoria* 3. 645–6). Some wines earn praise, however: PLINY says that Tarraconensis is

good (*Natural History* 14. 71) and so repeatedly does MARTIAL, himself a native of Spain.

Spain was no mere outpost of empire. It was the birthplace of other Roman authors besides Martial and Columella: Seneca, Lucan, and Quintilian. The emperors Hadrian and Marcus Aurelius came from Spanish families. When the Roman Empire disintegrated, Spain was invaded by barbarians, first by the Suevi and then by the Visigoths. We do not know what happened to viticulture and the wine trade; presumably it continued.

The overthrow of the Visigoths by the Moors in 711 did not mean the end of viticulture, for the ISLAMIC conquerors were enlightened rulers who did not impose their own way of life on their subjects. Better still, many of them liked wine themselves. The Moorish position with regard to wine was ambiguous. Although the Prophet forbade the use of wine, the emirs and caliphs of Spain grew wine; although its sale was illegal, it was subject to excise (see TAXATION). By the time ENGLAND was importing considerable quantities of wine from Spain in the mid 13th century, the Christians had largely succeeded in their reconquest.

Around 1250, wine was regularly shipped from Bilbao to the English ports of Bristol, Southampton, and London. The quality of the wines varied. The best wines were very good indeed: when Edward III fixed maximum prices for wines in 1364, a cask of the best Spanish wine was to cost as much as a cask of the best Gascon, which fetched more than wine from LA ROCHELLE. Spanish wines were popular because being from a hot climate they were high in alcohol and therefore kept better than French or German wines. But some of these wines were just high in alcohol, and that was their only merit. Hence they were often used to ADULTERATE more expensive and weaker wines. Laws forbidding this practice were widely disregarded.

History from Columbus

Spain emerged as a united Christian country under a single crown in January 1492 following the final defeat of the Moors at Granada. Christopher Columbus reached the West Indies in October of the same year, opening up a whole NEW WORLD to Spanish trade.

The wine regions around Cádiz and MÁLAGA, both important Spanish ports, were the first to attract the attention of foreign traders, and SHERRY, often called SACK, became a popular drink at the English court. Foreign traders in the sherry town of SANLÚCAR DE BARRAMEDA were granted special privileges by the duke of Medina Sidonia in 1517, and an English church was built to encourage more merchants. But relations between England and Spain began to deteriorate in the 1520s and after Henry VIII's divorce from Catherine of Aragón in 1533 brought English merchants into direct conflict with the Spanish. The Anglo-Spanish War lasted 1585–1604, after which trade in wine resumed. But 17th-century trade was sporadic, and trade in Spanish wines was blighted by excessive English import duties. Not surprisingly, the Spanish fostered markets elsewhere in Europe and the New World.

Spanish wine has historically depended on exports to a larger extent than wines from other traditional producing nations in Europe (and this continues to be the case today). During the 17th and 18th centuries, exports to Spain's American colonies surpassed in volume and value those to Britain and northern Europe. Vines had been planted all over the Americas since the very first days of Spanish colonization, and wine was made in MEXICO from the early days of the 16th century. But successive monarchs, particularly Philip III, tried to protect the flourishing export trade by writing edicts curtailing the spread of American vineyards. These were followed very unevenly—the local administration practically ignored them in Chile, but in Argentina they virtually quelled all attempts at developing a national wine industry until independence came in the early 19th century. For more details, see SOUTH AMERICA.

See SHERRY for details of 18th- and 19th-century trade in that important SPANISH WINE.

At the same time, Málaga also enjoyed a spectacular increase in popularity, producing an estimated 35,000 BUTTS of wine in 1829, equivalent to 175,000 hl/4.62 million gal. 'Mountain', as the wine was popularly known in its 19th-century heyday, sat alongside PORT, MADEIRA, and sherry as one of the world's great FORTIFIED WINES.

By all accounts there was little wine of exportable quality from the rest of Spain. Even RIOJA, already Spain's leading table wine at the turn of the 19th century, found few markets other than neighbouring Basque country and South America. The chronicler Richard Ford writing in 1846 notes that Spanish 'wine continues to be made in an unscientific and careless manner'. Cyrus REDDING, writing in the 1851 edition of the *History and Description of Modern Wines*, observes 'the rude treatment of the grape' in Spain. It seems that, outside Jerez and Málaga, little had changed since Roman times. In central and southern Spain, wines continued to be made in crude earthenware TINAJAS, while to the north wooden casks were used. Wine was frequently stored in *cueros*, pigskins lined with pitch or resin, which tainted the wine. Winemaking progressed slowly in Spain.

From the middle of the 19th century, wholesale change was forced on the Spanish wine industry, first by POWDERY MILDEW, which was found in Cataluña in the 1850s, and then by PHYLLOXERA when it arrived in Málaga in 1878. But phylloxera spread relatively late and slowly through Spain, partly because of the long distances between the various Spanish wine regions, and in the 1860s the French, who had also suffered powdery mildew for ten years, had crossed the Pyrenees to compensate for the shortfall in French wine. Rioja and NAVARRA, the closest wine regions to BORDEAUX, benefited most from France's misfortune and the resulting influx of French influence and expertise.

The BARRICA (225-l/59-gal oak cask) which is now used throughout Spain was introduced from Bordeaux, and winemaking was refined along the Bordelais lines (although American OAK continued to be

preferred thanks to Spain's flourishing transatlantic trade in the late 18th century, the hardness of American oak—much appreciated in Jerez—and its relatively low cost). Rioja BODEGAS belonging to Marqués de Murrieta, Marqués de Riscal, López de Heredia, and CVNE date back to this period when up to 500,000 hl of wine a month were shipped across the Pyrenees to France.

Phylloxera took hold in Jerez in 1894 and reached Rioja in 1901, by which time the epidemic had been controlled by grafting European vines on to resistant American ROOTSTOCKS. Vineyards were replanted throughout the country, but many INDIGENOUS VARIETIES in such regions as Galicia and Cataluña were rendered virtually extinct. In Cataluña, the post-phylloxera period coincided with the development of the sparkling wine industry which is today one of the largest in the world. Following a visit to the Champagne region, José Raventós introduced the TRADITIONAL METHOD for the production of sparkling wine to the family firm of Codorníu in 1872. The wine, originally christened *champaña*, was a success, and vineyards around the town of San Sadurni de Noya were replanted with the trio of white grapes that now produce over 1.8 million hl of CAVA annually.

The first half of the 20th century was a turbulent era for Spain. Political infighting led to the abdication of Alfonso XIII in 1931 and the proclamation of a republic. However, one of the lasting measures introduced by the monarchist dictator General Primo de Rivera was the DOP system of CONTROLLED APPELLATIONS administered by a CONSEJO REGULADOR, which was first established in Rioja in 1926. Jerez and Málaga followed suit in 1933 and 1937 respectively.

In July 1936, following the election victory of the Popular Front, Spain erupted into civil war. For three years sentiment ran high and Spain tore itself apart, often along regional, separatist lines. Some parts of the country, notably Asturias, Cantabria, Euskadi, Cataluña, and Valencia, were affected more than others, but throughout the country vineyards were neglected and wineries were destroyed. The Nationalist victory in 1939 brought political stability to Spain under the dictatorship of General Franco, but economic recovery was

hampered by the Second World War, which effectively closed European markets to Spanish exports.

In the 1950s, the wine industry began to revive, helped by the nationwide construction of large CO-OPERATIVE wineries which had begun some years earlier. This turned Spain, with its vast area of vineyard, into a natural source for inexpensive BULK WINE either sold under proprietary BRAND names or labelled with spurious GENERIC names such as Spanish Chablis or Spanish Sauternes, subsequently outlawed by EU authorities.

The post-war history of the Spanish wine industry was for some time marked by the Rumasa saga, outlined under SHERRY. But Rumasa's horizons ran far beyond Jerez, and by the late 1970s José María Ruiz-Mateos seemed to control Spain. Ruiz-Mateos contributed greatly to the much-needed modernization of the Spanish wine industry, but by the early 1980s there were signs that the empire was in trouble.

The 1960s sherry boom was followed by the international 'discovery' of Rioja, which had reached the top in the domestic market early this century. In the 1970s and 1980s, the family firm of FAMILIA TORRES wrought a single-handed transformation of the wines of PENEDÈS. The death of General Franco in 1975 and the restoration of the monarchy set the foundations for a modern, multi-party democracy in Spain. Greater economic freedom has led to the growth of an urban middle class which has in turn stimulated a new interest in high-quality wine.

Economically deprived rural regions such as La Mancha and Galicia have further benefited from EU finance, which is helping to change the face of the Spanish wine industry. In the 1990s, a fast-paced chain of events brought about more changes than during possibly the previous 90 years. International FLYING WINEMAKERS flocked to Spain; private estates overtook co-operatives in most regions; INTERNATIONAL VARIETIES became commonplace in vineyards from La Mancha to Navarra; irrigation and WIRE-trained vineyards sprouted up

everywhere; and wine styles changed radically to the fruitier type favoured on international markets.

Spanish wine law

Spanish wine law is administered through a network of Consejos Reguladores (regulatory councils) representing each delimited region (DOP). The first Consejo was established in Rioja in 1926; the first wine law came in 1932, with the creation of 19 DOPs. The laws have changed many times since then, most notably with a move to align with EU systems in 1996, and again in 2003. Currently, the law recognizes five levels. In ascending order of rank, they are:

Vino de España: allowed only to mention country, grape variety, and vintage, this is the most basic level, although some producers use it for high-end wines, taking advantage of the flexibility it allows.

Vino de la Tierra (VT): equivalent to PGI, these come from legally designated zones that do not qualify as DOPs. There were 42 in 2022.

Vino de Calidad con Indicación Geografica (VC): transitory Spanish denomination between Vino de la Tierra/PGI and DOP (the next step up), of which there were seven in 2022. The EU considers it a PDO level.

Denominación de Origen Protegida (DOP): previously known as (and still often called) DO, and equivalent to PDO, defining the boundaries of the wine region, permitted VINE VARIETIES, maximum YIELDS, minimum alcoholic strength, and any other limitations pertaining to the zone.

Denominación de Origen Calificada (DOCa): a step above DOP, with more stringent rules. In 2022 there were just two: RIOJA and PRIORAT.

Vino de Pago (VP): a PDO launched in 2003 to highlight established vineyards with track records of producing singular wines. Any winery in Spain with singular vineyards may apply to have its own Denominación de Origen Vino de Pago (DOVP). In this way, a Vino de Pago is similar to a Bugundian MONOPOLE or to a single-vineyard appellation such as CHÂTEAU-GRILLET, but a DOVP does not

have to be within any tiered system of controlled appellations for that region.

In 2022 there were 101 DOPs (including the 24 Vinos de Pagos, two DOCa, and seven Vinos de Calidad) plus the 42 PGI (Vino de la Tierra).

As each region's Consejo Regulador regulates the growing, making, and marketing of wines within its boundaries, many have also created additional designations and classifications particular to their region's wines.

Geography and climate

Around much of Spain, the land rises steeply from the coast reaching a maximum ELEVATION of 3,482 m/11,420 ft at Mulhacén in the Sierra Nevada just 50 km/30 miles from the Mediterranean. The average elevation countrywide is 600 m/1,969 ft, with a vast plateau taking up much of central Spain. Known as the *meseta*, this undulating table land ranges in elevation from 600 to 1,000 m, tilting slightly towards the west. Four of Iberia's five major rivers (the Duero, Tajo, Guadiana, and Guadalquivir) drain westwards into the Atlantic, while the Ebro flows south-east to the Mediterranean. Other rivers are seasonal, many drying up completely in the summer months.

Great mountain ranges known as *cordilleras* divide Spain into distinct natural regions. The north coast, from Galicia to the Pyrenees, is relatively cool and humid with few extremes. Annual RAINFALL in this part of Spain ranges from 1,000 mm/39 in on the coast to over 2,000 mm on the mountain peaks inland. Galicia, Asturias, and the BASQUE country are intensively cultivated and densely populated.

The Cantabrian cordillera, a westerly spur of the Pyrenees which rises to over 2,600 m in the Picos de Europa, protects the main body of Spain from cool, rain-bearing north westerlies. Rioja in the upper Ebro valley is therefore shielded from the Bay of Biscay so that, although annual rainfall reaches around 1,500 mm on the Basque coast, it declines sharply to the east and is just 450 mm at Haro, the winemaking capital of Rioja, only 100 km inland.

The Spanish climate becomes more extreme towards the centre of the central plateau. Winters are long and cold with temperatures falling well below freezing point (the lowest recorded temperature is −22 °C/−7.6 °F in Albacete). Summers here can be blisteringly hot with daytime temperatures sometimes rising above 40 °C/104 ?F. Little rain falls in the summer months, and DROUGHT is a constant problem. Agriculture has adapted to the lack of rainfall, which struggles to reach 300 mm in places. Much of this comes in sudden

downpours in spring and autumn, sometimes causing devastating flash floods on the Levantine coast.

South and east from the central plateau the climate is increasingly influenced by proximity to the Mediterranean. The climate on the narrow coastal littoral is equable with long, warm summers giving way to mild winters. These are Spain's holiday Costas, but there are lush market gardens producing rice and citrus fruit around Valencia, and, on the mountain slopes inland, olives, almonds, and TABLE GRAPES are important crops. The hottest part of Spain is the broad Guadalquivir valley in Andalucía, north of the Sierra Nevada, where summer temperatures rise to 45 °C/113 ?F. The south-west corner of Andalucía has a climate of its own, strongly influenced by the gulf of Cádiz and the Atlantic (see SHERRY).

Viticulture

The DRIP IRRIGATION that became prevalent in the early years of this century markedly changed the vinous landscape of inland Spain. In most of central and southern Spain, the old BUSH VINES are widely spaced to survive the summer drought with VINE DENSITIES ranging from 900 to 1,600 vines per ha (375–650 per acre) according to the amount of water available (less than one-eighth of the vine density in some MÉDOC or CÔTE D'OR vineyards, for example). Growers have adopted a system of planting known as the *marco real* with 2.5 m between each vine in all directions. Yields from the shrinking proportion of old vines are frequently less than 20 hl/ha (1.1 tons/acre). However, one considerable advantage that accompanies a dry climate is the lack of FUNGAL DISEASES. POWDERY MILDEW, DOWNY MILDEW, and BOTRYTIS BUNCH ROT are virtually unknown in central Spain.

IRRIGATION was one of the most important new developments of the 1990s. The practice had begun to spread unofficially—particularly during the DROUGHTS in south-east Spain of 1994 and 1995—and was formally legalized in 1996. Drip irrigation, pioneered on the Marqués de Griñón Valdepusa estate in Toledo province under the supervision of Australian viticulturist Richard Smart, is the favourite of many growers. Subsurface drip irrigation, which minimizes the losses due to EVAPORATION, became increasingly popular in the early 21st century. Irrigation has been followed by considerably increased YIELDS throughout the country. This, together with a rapid increase in new plantings and productive CLONES, has triggered concerns about wine quality.

Viticultural practices vary sharply from one part of Spain to another. In areas such as Rioja and Penedès, where more systematic replanting is taking place, vines are more densely planted (up to 5,000 vines per ha) and are increasingly trained on wires. In Galicia vines were traditionally trained on pergolas (see TENDONE), both to make maximum use of the limited space in this densely populated

part of Spain and to lessen the risk of fungal diseases in the humid climate. Newer vineyards are planted on lower vine-TRAINING SYSTEMS to ease cultivation but have to be regularly sprayed to combat disease. That said, an increasing number of wineries throughout Spain have adopted ORGANIC VITICULTURE: official statistics in 2020 put the total at 12%, but the actual number is thought to be higher as many organic producers do not pursue certification.

In the past, most grapes were harvested by hand and grapes frequently arrived at co-operative wineries already starting to ferment, having been squashed when loaded into large trailers. Quality-conscious bodegas increasingly provide growers with stackable plastic containers to keep the grapes whole during transportation (see HARVEST). Some firms also set out a harvest regime refusing grapes delivered after midday when they have been heated by the sun. Some estates harvest at night. The number of MECHANICAL HARVESTERS is increasing as fast as the acreage of vineyards supported on wires.

Vine varieties

The Spanish have about 250 grape varieties, although 13 varieties make up 83% of the country's vineyards. Since the arrival of phylloxera at the end of the 19th century, farmers tended to favour varieties well adapted to local climatic conditions, but irrigation has changed this tendency considerably. The drought-resistant white AIRÉN is Spain's most planted grape, with 204,699 ha/505,822 acres in 2020, followed by the red grape TEMPRANILLO with 201,502 ha. It travels under such aliases as Cencibel, Ull de Llebre, and Tinto Fino in different parts of the country. GARNACHA is the second most planted red wine grape with 58,764 ha/145,209 acres, and the traditional BOBAL is third with 56,184 ha/138,834 acres. Monastrell (the MOURVÈDRE of France) is fourth with 37,881 ha/93,606 acres. Other white varieties which are also important in Spain are the sherry grapes PALOMINO (planted in Jerez, RUEDA, and parts of Galicia) and PEDRO XIMÉNEZ (Montilla-Moriles and Málaga). The white MACABEO (also called Viura) is widely planted in Rioja and Cataluña, especially Penedès, where, along with Parellada and Xarel-lo, it is grown for Cava sparkling wine. High-quality white varieties which are gaining ground include ALBARIÑO (Galicia) and VERDEJO (Rueda), while other promising grapes which are making a more limited comeback include the white LOUREIRA, TREIXADURA, and GODELLO (all three in Galicia) and the red GRACIANO (Rioja) and MENCÍA (Galicia and Castilla y León).

INTERNATIONAL VARIETIES have made significant inroads in some parts of Spain. Cabernet Sauvignon, Syrah, Merlot, Petit Verdot, Sauvignon Blanc, and Chardonnay have become increasingly important in Cataluña, Somontano, Navarra, Castilla y León, and Castilla-La Mancha. Cabernet Sauvignon, with a total of 18,651 ha/46,807 acres of vineyards, is the most important of these.

Winemaking

Spanish winemaking has changed radically since the 1960s. Stainless steel, once a rarity, is now commonplace, and virtually all bodegas have the means of TEMPERATURE CONTROL for fermentation. These improvements transformed Spanish wines, especially in La Mancha and the Levante, where temperature control is essential to preserving the primary fruit character in both red and white wine. The epoxy-lined CONCRETE tanks still to be found in some co-operative wineries are regaining favour with top producers for red wines, as are oak vats, in a return to traditional fermentation vessels which ensure less temperature variation than stainless-steel tanks.

A vogue for crisp, technically perfect, simple young whites was followed in the 1990s by a resurgence of BARREL-FERMENTED whites.

Spain continues to foster the long-established tradition of ageing red wines in OAK. The use of wooden BARRELS as vessels for fermentation and storage dates back many centuries, but in the second half of the 19th century the French introduced the 225-l BARRIQUE (*barrica*) to Rioja, and its use has subsequently spread throughout the country. Unlike the French, however, traditional Spanish winemakers use at least some American oak, which not only is considerably cheaper than French oak but also can impart a stronger flavour to the wine. The Tempranillo grape in particular seems to produce wine that responds to maturation in new oak. However, French oak has made significant inroads since the early 1990s. Spanish oak-aged reds are usually denoted by the words CRIANZA, RESERVA, or GRAN RESERVA, which are enshrined in local legislation. From the 1970s to the 1990s, the wines often showed a pungent vanilla character, but this was superseded by more FRUIT-DRIVEN aromas and flavours, partly in response to FASHION. After 2000 a return to some TRADITIONS, sometimes including the use of TINAJAS, was apparent among a newer generation of producers keenly attuned to the worldwide trend towards using less technology in high-quality wines.

Most Spanish DOs also stipulate minimum BOTTLE AGE, and traditionally very few Spanish wines were released before they were ready to drink. But some growers, led by the PRIORAT newcomers, started a new habit of renouncing both Crianza and Reserva back labels, selling oak-aged wine without an age classification and often with little bottle age.

For specific wine regions, see ANDALUCÍA, ARAGÓN, BASQUE, CASTILLA-LA MANCHA, CASTILLA Y LEÓN, CATALUÑA, GALICIA, NAVARRA, and RIOJA.

Spanna, local name for the NEBBIOLO grape grown in the north of PIEMONTE in north-west Italy, particularly in a historic wine zone in the hills of Biella, Vercelli, and Novara provinces referred to as Alto Piemonte. The exceptions are the Carema and Valli Ossolane DOCs, which use the word 'Nebbiolo'.

Five DOC wines and two DOCGs, Gattinara and Ghemme, are made either wholly or in part from Spanna: three in the Vercelli hills (BRAMATERRA, GATTINARA, LESSONA) and four in the province of Novara (BOCA, FARA, GHEMME, and SIZZANO). Only Gattinara and Ghemme, responsible for some of the longest-lived Spanna wines, are made in any quantity today, but in the 19th century this area had greater plantings and was more famous for its wines than the LANGHE. After the Second World War, the region's wines lost ground to the Langhe's

richer Nebbiolo wines, particularly BAROLO and BARBARESCO. The extreme fragmentation of vineyard property and a workforce that moved to the textile factories of nearby Biella accelerated the decline of winemaking in this area, but this group of wine zones is attracting attention once more, not least because of the finesse of its best wines. W.S.

sparging means stripping a wine of a gas by the action of another gas—for example, removing OXYGEN or CARBON DIOXIDE by purging it with fine bubbles of an INERT GAS, usually NITROGEN. The oxygen and carbon dioxide from the wine transfer into the bubbles of inert gas and leave with it out the top of the tank. Sparging can also refer to the removal of HYDROGEN SULFIDE by the action of carbon dioxide produced during fermentation. An alternative to sparging is the use of membrane contactors. Gas passes into or out of the wine without bubbles through a hydrophobic membrane that divides the wine from a gas or vacuum flowing on the other side of the membrane. The membrane is in the form of many thin hollow tubes contained within a cylindrical module. In combination with in-line carbon dioxide and oxygen sensors, they are well suited to automated dissolved gas control and can allow for carbon dioxide to be adjusted up or down to a set level, while oxygen is removed in a single pass. S.N.

Nordestgaard, S., 'Gains in speed, labour and gas consumption for winemakers', *Australian and New Zealand Grapegrower & Winemaker*, 648 (2018), 61–7.

sparkling wine, wine which bubbles when poured into a glass, an important category of wine increasingly seen as an everyday drink rather than one for special occasions. The bubbles form because a certain amount of CARBON DIOXIDE has been held under pressure dissolved in the wine until the bottle is unstoppered (see FIZZINESS). According to the OIV, in 2018 world sparkling wine production (not including carbonated wines) reached 20 million hectolitres for the first

time (i.e. 7% of the world's total wine production), with an overall increase of 57% since 2002. Some 70–80% is produced in the EU. IWSR data for 2020 show a global dip in consumption of 4% in volume and 6% in value compared with 2019 but predict growth over the five years to 2025.

Sparkling wine may vary in as many respects as still wine: it can be any wine COLOUR (it is usually white or pink, but sparkling reds such as Australian sparkling Shiraz enjoy a certain following); it can be any degree of SWEETNESS (although a high proportion tastes bone dry and may be labelled BRUT, while Italians specialize in medium-sweet SPUMANTE); it can vary in ALCOHOLIC STRENGTH (although in practice most dry sparkling wines are about 12–12.5%, while the sweeter, lighter *spumante* are 5.5–8%); and it can come from anywhere in the world where wine is produced.

According to EU regulations, the sweetness level of EU wines and those marketed in the EU must be shown on the label. For official EU definitions, see DOSAGE.

Sparkling wines also vary in FIZZINESS, not just in the actual pressure under which the gas is dissolved in the wine but also in the character of the foam. Some sparkling wines seem to froth aggressively in the mouth while others bubble subtly. The average size, consistency, and persistence of the bubbles also vary considerably. Study of foam and foaminess, along with research into YEASTS, are two of the few areas which unite the (sparkling) wine industry with the beer industry.

To the winemaker, however, the most obvious way in which sparkling wines differ is in how the gas came to be trapped in solution in the wine: traditional method, transversage, transfer, tank method, or carbonation, in declining order of cost, complication, and likely quality of sparkling wine, together with the rarer *méthode ancestrale* and *méthode dioise ancestrale*. (See SPARKLING WINEMAKING for details of each method.)

The most famous sparkling wine of all is CHAMPAGNE, the archetypal sparkling wine made in north-eastern France, which represents about

13% of global sparkling wine production. A significant proportion of all sparkling wine is made using the same basic method as is used in Champagne (now called the traditional, rather than the champagne, method), much of it from the same grape varieties—Pinot Noir, Chardonnay, and, to a lesser extent outside Champagne, Pinot Meunier—even though different wine regions often stamp their own style on the resulting sparkling wine. Examples of such wines were made with ever-increasing frequency from the 1980s onwards in CALIFORNIA, AUSTRALIA, and ITALY particularly.

A host of fine, very individual sparkling wines is made using the traditional method but with non-champagne grapes, however. The most prodigious example of this is the popular Spanish CAVA. The LOIRE region of France also produces traditional-method sparkling wine in great quantity, notably in SAUMUR. All of France's CRÉMANTS also use the traditional method. In almost every wine region in the world with aspirations to quality, some traditional-method wine has been made. Wines made by this, the most meticulous method, may be described on the label within Europe as *méthode traditionnelle*, *méthode classique*, or *méthode traditionnelle classique*. Other descriptions include bottle-fermented (although strictly speaking wines made by the transfer method, described below, may be labelled 'bottle-fermented', while only those made by the traditional method can be labelled 'Fermented in this bottle').

Similarly, in almost every wine region in the world, tank-method sparkling wine is made in considerable quantity, often for specific local BRANDS, especially for SEKT in Germany and a host of wines such as PROSECCO, LAMBRUSCO, and ASTI in Italy. RUSSIA has been an enthusiastic market for sparkling wines ever since the imperial court imported such vast quantities of champagne (and base wine to make sparkling) at the end of the 19th century. Today sparkling wine is still made in enormous quantity in both Russia and UKRAINE. Asti and a number of other low-alcohol, sweet Italian, or Italianate, sparkling wines are made using a variation of the tank method.

The transfer method is used for some better-quality branded wines, particularly in Germany, Australia, New Zealand, and the

United States.

Some characterful sparkling wines are made eschewing DISGORGEMENT and selling the wine together with the LEES of its second fermentation in bottle. These include dry or lightly sweet PÉTILLANT NATUREL, as well as some of the sweeter styles of wine from GAILLAC, LIMOUX, and CLAIRETTE DE DIE made by specific but similar local methods sometimes called *méthode ancestrale*. In Italy, sparkling wines labelled *sui lieviti*, occasionally *sur lí,* meaning 'on the lees', are always dry. J.R., J.E.H. & E.C.

sparkling winemaking, the process of making SPARKLING WINES, most obviously involves the accumulation of gas under pressure in what was initially a still 'base wine' or, ideally, blend of base wines. The most common methods of achieving this are discussed below, but these are matters of technique rather than substance. Almost all of them depend on initiating a second FERMENTATION, which inevitably produces CARBON DIOXIDE, and most of them incorporate some way of keeping that gas dissolved under pressure in the wine (see FIZZINESS) while separating it from the inconvenient by-product of fermentation, the LEES. What matters most to the quality of a sparkling wine, however, is the quality and character of the blended base wines.

Making and blending the base wine

Wines that are good raw material for the sparkling winemaking process are not usually much fun to drink in their still state. They are typically high in acidity and unobtrusively flavoured. There is a school of thought that the austerity of the still wine of the CHAMPAGNE region, Coteaux CHAMPENOIS, is the most eloquent argument of all in favour of champagne's carbon dioxide content.

It is not just in Champagne, however, that sparkling winemakers argue that BALANCE is the key to assembling a base wine to make sparkling and that the best sparkling wines are therefore essentially blended wines. Some fine VARIETAL sparkling wines exist (some of the best BLANC DE BLANCS champagnes, for example), but a great sparkling wine never tastes just like the still wine version plus gas; the very nature of sparkling winemaking is to try to make a sum that is greater than the parts (although this may not be achieved, or even attempted, for cheaper wines). Those who aspire to make good sparkling wine are acutely aware that any minor fault in a base wine may be amplified by the sparkling winemaking process.

Accordingly, for better sparkling wines, grapes are invariably hand picked since WHOLE-BUNCH PRESSING is the norm. MECHANICAL HARVESTERS have improved, but there is still a risk of splitting berries and extracting harsh PHENOLICS into the grape juice, which could cause astringent, coarse characteristics which would be magnified by the pressure of bubbles. It is therefore essential to rapidly separate the juice from the skins to reduce phenolic extraction. It is possible that gentler mechanical harvesters will change this, although it is essential to press grapes as soon as possible after picking. Press houses in the vineyards have long been *de rigueur* in Champagne and are increasingly common for other top-quality sparkling wines.

Grapes destined for sparkling wines are usually picked at lower MUST WEIGHTS than the same varieties would be if they were to be sold as a still wine. In very general terms, average YIELDS can be higher for sparkling wines than for still wines (see below), partly

because there is no imperative to achieve high sugar levels. In California, for example, HARVEST begins in mid, or sometimes early, August for Pinot Noir and Chardonnay destined for sparkling wines. In Australia, the aim is to pick such varieties just as HERBACEOUS characters have been lost when ripe fruit FLAVOUR COMPOUNDS are beginning to develop (in practice at about 17 to 20 °BRIX in Australia's cooler areas).

PRESSING is an important stage in sparkling winemaking, particularly in Champagne, where black grapes are used, as it is essential that the concentration of phenolics, both ASTRINGENCY and COLOUR, is kept to a minimum. There has been much experimentation with horizontal PRESSES of various types, and modern pneumatic or tank presses can certainly offer a reliably high standard of HYGIENE, but modern technology has found it difficult to improve upon the traditional vertical presses of Champagne, although they are LABOUR intensive. So-called 'thin layer' presses, which minimize pressure, and therefore the extraction of phenolics, by pressing a layer of grapes no more than 70 cm/27 in thick, are used increasingly.

The winemaker can then make the usual still white wine decisions concerning OXIDATIVE versus PROTECTIVE methods of JUICE HANDLING; juice CLARIFICATION; choice of YEAST strain and FERMENTATION rate; protein STABILIZATION; and MALOLACTIC CONVERSION.

The winemaker must also choose the type of vessel to use for the primary fermentation and for maturation of reserve wines (see diagram). STAINLESS STEEL tanks are the most common choice. If oak vessels are used, they will have a more significant influence on the style of the wine, depending on the size, shape, and age of the BARREL or CASK.

Then comes the crucial blending stage, the true art of making sparkling wine and one in which experience is as important as SCIENCE. A large champagne house such as MOËT & CHANDON may be able to use several hundred base wines in order to achieve the house style in its basic expression, that year's NON-VINTAGE blend. A small,

independent concern, especially outside Champagne, may have access to only a very limited range of base wines—a disadvantage in a poor vintage, although not necessarily in a good one. And a producer of the most basic carbonated or tank-method wine may simply blend suitable base wines available on the open market.

Traditional method

This method, once known as the champagne method and now known variously as traditional method, classical method, and classical traditional method (or their equivalents in other languages), is the most meticulous way of making wine sparkle; the raw ingredients vary considerably but the basic techniques do not.

Pressing and yield Pressing is the first operation defined in detail by the traditional method, which understandably differentiates rigorously between the fractions of juice from each press load, for the first juice to emerge from the press is highest in sugar and acidity and lowest in phenolics, including pigments. A maximum extraction rate is usually defined in any regulations concerning sparkling wine production (such as those for France's CRÉMANTS). Those who produce traditional-method sparkling wine acknowledge that the first juice to emerge from the press is generally the best, even if there is a certain amount of VINTAGE variation. The extraction of juice is strictly monitored and in the case of champagne is limited to a maximum of 638 litres (169 gal) per 1,000 kg (2,205 lb) of grapes (see CHAMPAGNE for more detail). (This compares with an approximate average extraction rate of 95 l of wine from about 130 kg of grapes for softly pressed still red wines; see YIELD.) Producers of top-quality sparkling wine from other countries tend to follow this guideline but are not as constrained by local regulations and have more flexibility in processing techniques.

Base wines After the making of the base wines (described above), which usually takes place over the winter following the harvest, the final blend is made after extensive tasting, assessment, and ASSEMBLAGE. There is extreme flexibility in blending a non-dated wine, and a high proportion of 'reserve wine' made in previous years may be used. Some producers include up to 45% of reserve wines in their non-vintage blend. (In Champagne, for example, KRUG indulge in the luxury of using base wines from up to ten vintages being held in reserve.) The ingredients in a vintage-dated sparkling wine are more limited, depending on the regulations in the country or region of origin. Many of the base wines made from dark-berried grapes, however lightly pressed, may have a light pink tinge at this stage, although the PIGMENTS are precipitated during *tirage*, the crucial next stage during which the blended wine rests on the lees of a second fermentation in bottle. As soon as the new blend has been made in

bulk blending tanks, it usually undergoes cold STABILIZATION in order to prevent subsequent formation of TARTRATES in bottle.

Second fermentation This new blend then has a mixture of sugar and yeast added to it before bottling in particularly strong, dark BOTTLES, usually STOPPERED with a CROWN CAP, so that the carbon dioxide of the second fermentation is captured in the bottle, creating the all-important fizz. Conventionally, an addition or TIRAGE of about 24 g/l of sugar is made. This creates an additional 1.2 to 1.3% ALCOHOLIC STRENGTH and sufficient carbon dioxide to create a pressure inside the bottle of 5–6 atmospheres after disgorgement (see below), which is roughly the FIZZINESS expected of a sparkling wine and one which can safely be contained by a wired champagne cork. During this second fermentation, known as *prise de mousse* in French, the bottles are normally stored horizontally at 12–16 °C/54–61 °F until the fermentation has produced the required pressure and bubbles, usually for four to eight weeks.

Special types of YEAST culture which help sparkling winemakers have been developed (and are much used for still wines too). Such yeasts are particularly good at flocculating and produce a granular deposit that is easy to riddle, or shake, to the neck of the bottle for extraction.

At this stage, RIDDLING agents are increasingly added with the yeast and sugar. Made of some combination of TANNINS, BENTONITES, gelatines, or alginates, they help to produce a uniform skin-like yeast deposit that does not stick to the glass but slips easily down it during the riddling process. The development of smoother glass bottles has also helped.

Ageing on lees Timing of the riddling process after the second fermentation is a key element in quality and style of a traditional-method sparkling wine, the second most important factor affecting quality after blending the base wine. The longer a wine rests on the lees of the second fermentation in bottle, the more chance it has of picking up flavour from the dead yeast cells, a process known as yeast AUTOLYSIS.

Most regulations for traditional-method sparkling wines specify at least nine months' ageing on lees, and the minimum period for non-vintage champagne was increased to 15 months in the early 1990s (vintage champagnes are usually aged for several years). During the bottle-ageing process, the yeast cells autolyse, releasing increasingly complex flavour compounds. The chemistry of autolysis is not fully understood, but it seems that autolysis has significant effects only after about 18 months on the lees and that the most obvious changes occur after five to ten years of lees contact, which inevitably increases production costs considerably. It may be that compulsory periods of lees contact in bottle of only a few months have less effect on quality than has been imagined.

In parallel with the increase in autolytic character over time, the wine is also maturing from the pale and light characteristics of a base wine to a progressively more deeply coloured and richer-flavoured wine. It is this combination that give the complexity and depth to mature sparkling wines.

Riddling The riddling process, known as *remuage* (or shaking) in French, is one of the most cumbersome (and most publicized) parts of the traditional method, but it is undertaken for cosmetic rather than oenological reasons: to remove the deposit that would otherwise make the wine cloudy (as it does in the *méthode ancestrale* described below).

Traditionally, bottles were gradually moved from the horizontal to an inverted vertical by hand, by human *remueurs* or riddlers who would shake them and the deposit every time they moved them towards the inverted vertical position in special *pupitres* or riddling racks. This was a slow and extremely labour-intensive way of moving the deposit from the belly of the bottle to its neck. The CAVA industry based in Cataluña developed an automatic alternative in the 1970s, the *girasol* or GYROPALETTE, which has since been widely adopted for traditional-method sparkling winemaking the world over. The bottles are stacked in large metal crates (300–504 bottles per crate, depending on bottle shape), and their orientation changed at regular intervals (including night-time, unlike the manual method), with accompanying shake, from the horizontal to inverted vertical by remote control. Using riddling agents, well-adapted yeasts, and gyropalettes, bottles may now be riddled in as little as three days, as opposed to the six weeks or more needed for hand *remuage* without riddling agents.

Disgorgement and dosage The final stage in a complicated production process—though it may be shorter than, say, that of a fine oak-aged red—is to remove the deposit now in the neck of an inverted bottle. The conventional way of achieving this is to freeze the bottleneck and deposit by plunging the necks of the inverted bottles into a tray of freezing solution. The bottles are then upended and the crown cap flipped off, and the 2-cm deposit flies out as a solid pellet of ice. Bottles are then topped up with a mixture of wine and sugar syrup, the so-called DOSAGE, stoppered with a proper champagne CORK held on with a wire MUZZLE, and prepared for labelling. Many of the bigger producers employ a technique known as jetting, long familiar to brewers, to protect the wine from OXIDATION: just before the cork is inserted, a small dose of wine, or bisulfite diluted in water, is injected into the neck of the bottle at high pressure; this creates bubbles that rise just to the lip of the bottle, pushing out any oxygen in the head space. Most dry sparkling wine is sweetened so that it contains between 5 and 12 g/l RESIDUAL SUGAR. The higher the natural ACIDITY of the wine, the more dosage is generally required to counterbalance it, although the longer a wine is aged on lees, the less dosage it needs. One of the apparent effects of CLIMATE CHANGE seems to be a noticeable trend towards reducing the amount of sugar added, with grapes being picked riper, with lower acidity.

Alternative methods Riddling and disgorgement are unwieldy processes which contribute nothing to the innate quality of the sparkling wine. It is not surprising therefore that, as LABOUR costs spiralled in the 1980s, there was considerable research into alternative methods of expelling the sediment.

One of the most successful has been the development of encapsulated yeast. Yeast can be trapped in a 'bead' made of calcium alginate. Such beads are a few millimetres in diameter and are able to hold the yeast trapped in their interior while having large-enough pores to admit sugar and nutrients into the bead so that a full second

fermentation can proceed as normal. The great advantage is that the riddling stage takes seconds as the beads simply drop into the neck of the inverted bottle.

Another possible method is to insert a membrane cartridge into the neck of the bottle. Yeast is dispensed into it, and it is then plugged before the bottle is stoppered with the usual crown cap. Like the beads, the cartridge allows ingress of sugar and nutrients for fermentation to take place there, as well as allowing the carbon dioxide gas out. In this case there is no need at all for riddling, and disgorgement simply entails taking off the crown cap and allowing the pressure inside the bottle to expel the cartridge.

Both these alternatives result in a significant amount of non-recyclable packaging, which is apparently the reason the Champenois have not taken them up. However, the market for encapsulated-yeast beads is growing since this method is useful to small wineries—or those taking the first tentative steps towards traditional-method sparkling winemaking—for whom the investment in riddling and disgorgement equipment has been prohibitive. In some cases, the beads are used for a small proportion of a winery's production as it allows the producer to keep stock of wine ready to disgorge and label at short notice. It is particularly suited to LARGE FORMAT bottles. Suppliers of these beads estimate that in the last five years more than one hundred million bottles have been produced using this method.

Transversage

Transversage is an occasional twist on the traditional method whereby, immediately after disgorgement, the contents of bottles of sparkling wine made by the traditional method are transferred into a pressure tank to which the dosage is added before the wine is bottled, typically in another (often small) size of bottle, under pressure. This is how many half-bottles, all airline 'splits' or quarter-bottles, and virtually all BOTTLE SIZES above a jeroboam of champagne are filled.

Transfer method

The transfer method, known as *méthode transfert* in French and Carstens in the United States, also depends on inducing a second fermentation by adding sugar and yeast to a blend of base wines and then bottling the result. It differs from the traditional method, however, in that riddling and disgorgement are dispensed with; after a period of lees contact, the bottles are chilled and their contents transferred to a bulk pressure tank where the sediment is removed by clarification, usually FILTRATION. A suitable dosage is then added and the result is once again bottled, using a counter pressure filler, before being corked and wired. There have been significant improvements in the equipment used for this method, particularly at the filtration stage, reducing the previous loss of wine character. It is popular for the production of large-volume good-quality sparkling wine because it retains the positive attributes of traditional fermentation and maturation on lees while allowing re-blending prior to final bottling in a range of bottle types and sizes.

Continuous method

This process, similar to that used for the tank method but continuous rather than in batches, was developed in the USSR in the 1950s for sparkling wine and was once used to a very limited extent in Portugal for large-volume inexpensive fizz. The main advantages are speed—sparkling wine in a mere three weeks—and cost, though the equipment is necessarily complicated. Base wine, together with sugar and active YEAST culture, is pumped into the first of a series of pressurised tanks, and the second fermentation crucial to virtually all methods of sparkling winemaking begins. This creates CARBON DIOXIDE, which increases the pressure in the tank, but the yeast cannot grow under this pressure and so further yeast has to be added continuously. The second and third tanks are partly filled with some material such as wood shavings, which offer a substantial total surface area on which the dead yeast cells accumulate, and a very limited amount of AUTOLYSIS, or at least reaction between the dead yeast cells and the wine, takes place. In the fourth and fifth tanks there are no yeast cells, and the wine eventually emerges relatively clear, having spent an average of perhaps three or four weeks in the system.

Tank method

This very common method, also called Charmat, *cuve close* (French for sealed tank), bulk method, *granvas* in Spanish, *autoclave* or *metodo Martinotti* in Italian, and *Tankgärung* in German, was invented by the Italian Federico Martinotti a decade before it was improved and patented by Frenchman Eugène Charmat in the early years of the 20th century, even though Charmat gets most of the credit. Its advantages are that it is very much cheaper, faster, and less labour intensive than the above processes, and it is better suited to base wines which lack much capacity for AGEING. A second fermentation is initiated by yeast and sugar added to base wine held in bulk in a pressure tank; after a rapid fermentation, the fermentation is typically arrested by cooling the wine to −5 °C/23 ºF when a pressure of about 5 atmospheres has been reached. The result is clarified, a dosage is added, and the resulting sparkling wine is bottled using a counter pressure filler. This style of sparkling wine is the most likely to taste like still wine with bubbles in it, rather than to have any of the additional attributes which can result from fermentation in bottle.

Carbonation

Initially known as the injection, or simply the 'bicycle pump', method, carbonation of wine is achieved in much the same way as carbonation of fizzy soft drinks: carbon dioxide gas is pumped from cylinders into a tank of wine which is then bottled under pressure, or very occasionally it is pumped into bottles. Significant technological improvements allowing carbon dioxide to be introduced immediately prior to bottling via direct injection and membrane systems have resulted in improved (smaller) bubble size and gas retention. However, in general wines produced by this method still tend to have larger bubbles and reduced mousse compared with those produced by a second fermentation. It must have a pressure of at least 3 atmospheres and in EU parlance is referred to as aerated sparkling wine. This is the cheapest, least critical, and least durable way of making wine sparkle and is generally used for perhaps budget and fruity sparkling wines.

Méthode ancestrale or méthode rurale

This method (given new life by the PÉTILLANT NATUREL vogue) results in a lightly sparkling wine, often with some sweetness and sediment, and most closely parallels how wines were originally made sparkling. It involves bottling young wines before all the RESIDUAL SUGAR has been fermented into alcohol. Fermentation continues in bottle and gives off carbon dioxide. Today it is becoming increasingly common in parts of France such as the Loire and the Jura and is spreading throughout the wine world, but variants on this theme are still made in BUGEY, GAILLAC, LIMOUX, and for CLAIRETTE DE DIE *méthode ancestrale* (see below).

The resulting wine, generally stoppered by a CROWN CAP, is less fizzy than a traditional-method sparkling wine. Although no dosage is allowed, the wines may be slightly sweet if the fermentation stops before all the sugar has been consumed by the yeast. The wine may in some cases be decanted off the deposit and rebottled under pressure in a form of transfer method.

Méthode dioise ancestrale

This is an unusual variation on the *méthode ancestrale* above and the transfer method, producing wines similar to ASTI. It is used for the sweet wine Clairette de Die *méthode ancestrale*, most of which is made by the local CO-OPERATIVE. The base wines are fermented in stainless-steel tanks at very low temperatures over several months. The wine is then filtered to remove most but not all of the yeast and is bottled; fermentation continues in bottle until an alcoholic strength of 7–8.5% has been reached. The wine is disgorged six to 12 months after bottling (the minimum time on lees is four months) before being filtered again and immediately transferred to new bottles. The use of liqueur de tirage and liqueur d'éxpedition is both prohibited and unnecessary. E.C.

Spätburgunder is the chief German synonym for PINOT NOIR although 'Blauburgunder' is widely used in Switzerland and Austria. This variety experienced a most dramatic rise in popularity during a red-wine boom in Germany that began in the 1990s and saw total plantings increase from 3,400 ha/8,400 acres in 1980 to more than 11,000 ha by 2003, rising to 11,660 by 2020. There is considerable dispute over the vine's importance in Germany during the Middle Ages, but in modern times it has been cultivated throughout Germany, most notably in parts of the RHEINGAU (especially Assmannshausen), where it owes its toehold to the same 13th-century Cistercian MONKS responsible for its rise to fame in the Côte d'Or, in the southern PFALZ, and in BADEN, WÜRTTEMBERG, and westernmost FRANKEN, as well as along the steep slate slopes of the AHR, where pale, slightly sweet wines have been replaced since the 1980s by dry, full-bodied, deeply coloured ones. Today, impressive Pinot Noir also comes from sites in the NAHE, MOSEL, and RHEINHESSEN. For many years, demand in Germany was so strong that very little Spätburgunder was exported, but examples are attracting increasing attention abroad.

Spätlese, means literally 'late harvest' but, as a so-called PRÄDIKAT, is officially defined by grape sugar at harvest. In Germany, specific minimum MUST WEIGHTS are laid down for each combination of vine variety and region, ranging from 76 to 90 °OECHSLE. In Austria, where the designation is no longer used for dry wines and seldom for sweet, the minimum across the board is 19 °KMW (approximately 94 ºOechsle). The designation 'Spätlese TROCKEN' was widely utilized in the late 20th century, but since the turn of the millennium, increasingly—and within Germany's VDP growers' association, officially—Prädikat terms are being dropped from the names of dry wines. A wine that would once have been labelled 'Spätlese trocken' is likely to be marketed instead as GROSSES GEWÄCHS. D.S.

Spätrot, synonym for ZIERFANDLER.

special late harvested, term which should, according to EU labelling law, be applied to wines made in Australia from 'fresh ripe grapes of which a significant proportion have been desiccated under natural conditions in a manner favouring the concentration of sugars in the berries'. In South Africa, the term refers to a lighter style of dessert wine harvested at a minimum of 22 ºBalling (see MUST WEIGHT) and with at least 11% alcohol. If the RESIDUAL SUGAR is less than 20 g/l, the label must indicate whether the wine is extra dry, dry, semi-sweet, or sweet.

specific gravity. See DENSITY.

Spergola, synonym for VERNACCIA DI ORISTANO in the Emilia region of Italy, where it makes tart whites.

spiced wines. See FLAVOURED WINES and MULLED WINE.

spinning-cone column, gas–liquid counter-current device for making DE-ALCOHOLIZED WINE or GRAPE CONCENTRATE and for removing SULFUR DIOXIDE from juice, and reducing some wines' ALCOHOLIC STRENGTH, particularly in California. Spinning-cone technology is an advance on the processes operating in a one- or two-stage vacuum evaporator. The device consists of a vertical stainless-steel column containing inverted cones, half of which are fixed to the wall of the column, while the other half spin along a central shaft. The spinning cones continuously and repeatedly spin the wine out in thin liquid films. Simultaneously, vapour that is evaporated from the thin film of liquid (under vacuum at low temperature, and with the aid of an inert stripping gas) flows up the column in the spaces between the successive fixed and rotating cones. Through a process of repeated evaporation and condensation on the cones, the volatiles are enriched in the up-flowing vapour stream. The volatiles, after passing through a condenser, are finally captured in liquid form at the top of the column while the stripped liquid is pumped out the bottom of the column. After the first pass through the column, most of the volatile components of the wine are collected. During the second pass the ETHANOL can be removed. Thus the aroma fraction is recovered separately from the alcohol and can be added back to the wine to restore the flavour profile at a lower alcohol concentration. Spinning-cone technology offers extremely high separation efficiency, with a low pressure drop across the column and low liquid hold-up; hence the juice or wine spends a short time in the column. Accordingly, alcohol and aroma removal are achieved with much less of the product evaporated than in a traditional evaporator. One application of the spinning-cone column is reducing the alcoholic strength of excessively alcoholic wines by 1–3% without loss of FLAVOUR COMPOUNDS to produce a wine with the flavour intensity afforded by fully ripe fruit but without an unacceptable alcohol content. An entire batch of wine can be treated to remove a small amount of alcohol, or a fraction can be treated to remove most of the alcohol and blended back into untreated wine to lower the overall alcohol content.

Advocates of the spinning-cone column claim it can be used to selectively remove unwanted flavours from a finished wine such as those from HYDROGEN SULFIDE, MERCAPTANS, and even excess HERBACEOUS notes. Because of the cost of equipment, this is mainly a service industry since very few producers can afford to buy a spinning cone themselves. An alternative and equally popular technique for reducing alcohol levels in wines is REVERSE OSMOSIS. A.O.

Block, D. E., and Miller, K. V., *Unit Operations in Winery, Brewery, and Distillery Design* (2022).

spitting is an essential practice at professional TASTINGS where several dozen, often more than 100, wines are regularly offered at the same time. Members of the wine TRADE, and WINE WRITERS, rapidly lose any inhibitions about spitting in public. Since there are no taste receptors in the throat, spitting allows the taster to form a full impression of each wine, while minimizing the blunting effects of ALCOHOL. It does not, unfortunately, leave the taster completely unaffected by alcohol. Some ethanol is vaporized and absorbed in the nose and mouth, and, no matter how assiduous the taster, it can also be extremely difficult to prevent any liquid from dribbling down the throat. According to the estimates of this writer, tasting 30 wines can involve ingesting almost a glass of wine, depending on the personal mechanics of TASTING.

Whatever tasters spit into is called a spittoon. These can vary from specially designed giant funnels on a stand through wooden CASES filled with sawdust, ice buckets, jugs, or, particularly convenient at a seated tasting and most hygienic and convenient for disposal, personal paper cups. Many professional tasting rooms are equipped with channels or sinks with running water designed to drain away expectorated wine.

spontaneous fermentation refers to alcoholic FERMENTATION that occurs due to AMBIENT YEAST rather than inoculated, cultured

yeast. Some producers and marketers prefer the term 'wild ferment'. See YEAST for the terminology used in this book.

spotted lanternfly, an invasive planthopper (*Lycorma delicatula*), native to Asia, first identified in Pennsylvania in 2014 and now found in vineyards in mid-Atlantic states and beyond. It feeds on many plants, including grapevines, cucumbers, and ornamentals, and can cause significant damage that affects the winter hardiness of grapevines. Tree-of-heaven is a favoured host and should be removed around vineyards. The insect lays conspicuous egg masses in and near vineyards; it may be treated by ovicidal and adult insecticide sprays. R.E.S.

www.extension.psu.edu/spotted-lanternfly-management-in-vineyards

spraying, a vineyard practice of applying liquids and powders to control pests, diseases, and weeds. Late last century, vineyard sprayers were often drawn by draught animals and operated with manual pumps; nowadays they are usually mounted on TRACTORS, or drawn by them, and are sometimes mounted on MECHANICAL HARVESTERS in order to spray several rows at once.

The aim of economically and environmentally sound spraying is to achieve maximum coverage of the target (leaves, bunches, or weeds) by applying minimum amounts of the appropriate AGROCHEMICAL (or other products). There should be ideally no spray material lost to the surrounding environment as spray drift. Good coverage depends on having very small droplets, although these are more readily blown off target by wind than large drops. A tractor-mounted tunnel sprayer prevents spray escaping into the environment because the vine canopy beside the tractor is enclosed by a cover or tunnel, usually made of fibreglass, with the spray jets mounted inside the tunnel. Any spray droplets not caught by the vine are caught by the opposite

side of the tunnel and can therefore be retrieved and returned to the spray cart. Such units save a lot of spray material, especially early in the growing season when the 'target' is small. Sprayers have also been designed that use LiDAR (Light Detection and Ranging) sensors to detect gaps in the CANOPY and switch the sprays on and off automatically. See also ROBOTS.

Vineyards can also be sprayed from the air using fixed-wing aircraft or HELICOPTERS. Costs can be lower, but coverage is typically not as good as for ground spraying, and low wind conditions are required. Aerial spraying can be used when ground conditions are unsuited for tractors, such as following heavy rain. However, spray drift may endanger the ORGANIC or BIODYNAMIC status of a neighbouring vineyard.

Relatively few vineyards are now sprayed from containers strapped on workers' backs, although this is still done in Portugal's DOURO Valley and on one-person properties. The costs of such spraying operations are very high and generally not sustainable for most commercial vineyards. Agrochemicals in dry powder form are applied by a process known as DUSTING.

See also RESIDUES. R.E.S.

Landers, A., *Effective Vineyard Spraying: A Practical Guide for Growers* (2020).

sprinklers are used for IRRIGATION and (in some vineyards) as a means of FROST PROTECTION. Sprinkler irrigation has largely been replaced by DRIP IRRIGATION, which uses much less water and does not leave wet leaves vulnerable to FUNGAL DISEASES and possible SALINITY damage. Sprinklers have also been used in hot regions of Australia for vineyard cooling, by operating the system intermittently during the hottest part of the day, but this is not economical and wastes WATER. J.G. & R.E.S.

spritzer, common name for a mixture of white wine and sparkling water that is usually drunk as an APERITIF.

spritzig, German term for wines with a slight, attractive prickle of CARBON DIOXIDE. Spritz has become an international TASTING TERM, perhaps for onomatopoeic reasons.

spumante, Italian word for sparkling wine from the verb *spumare*, meaning 'to foam or froth', which can appear on labels as *Vino Spumante*, *Vino Spumante di Qualità* or *Vino Spumante di Qualità* followed by a denomination of origin. It is allowed only for wines made sparkling by a second fermentation, either in bottle (*metodo classico*) or by the TANK METHOD and with a minimum pressure of 3.5 bar (see SPARKLING WINEMAKING). By far the most important example in terms of volume is PROSECCO, with more than 400 million bottles of *spumante* produced in 2020.

Second best-known is ASTI made from the MOSCATO Bianco grape cultivated in the provinces of Asti, Cuneo, and Alessandria in PIEMONTE.

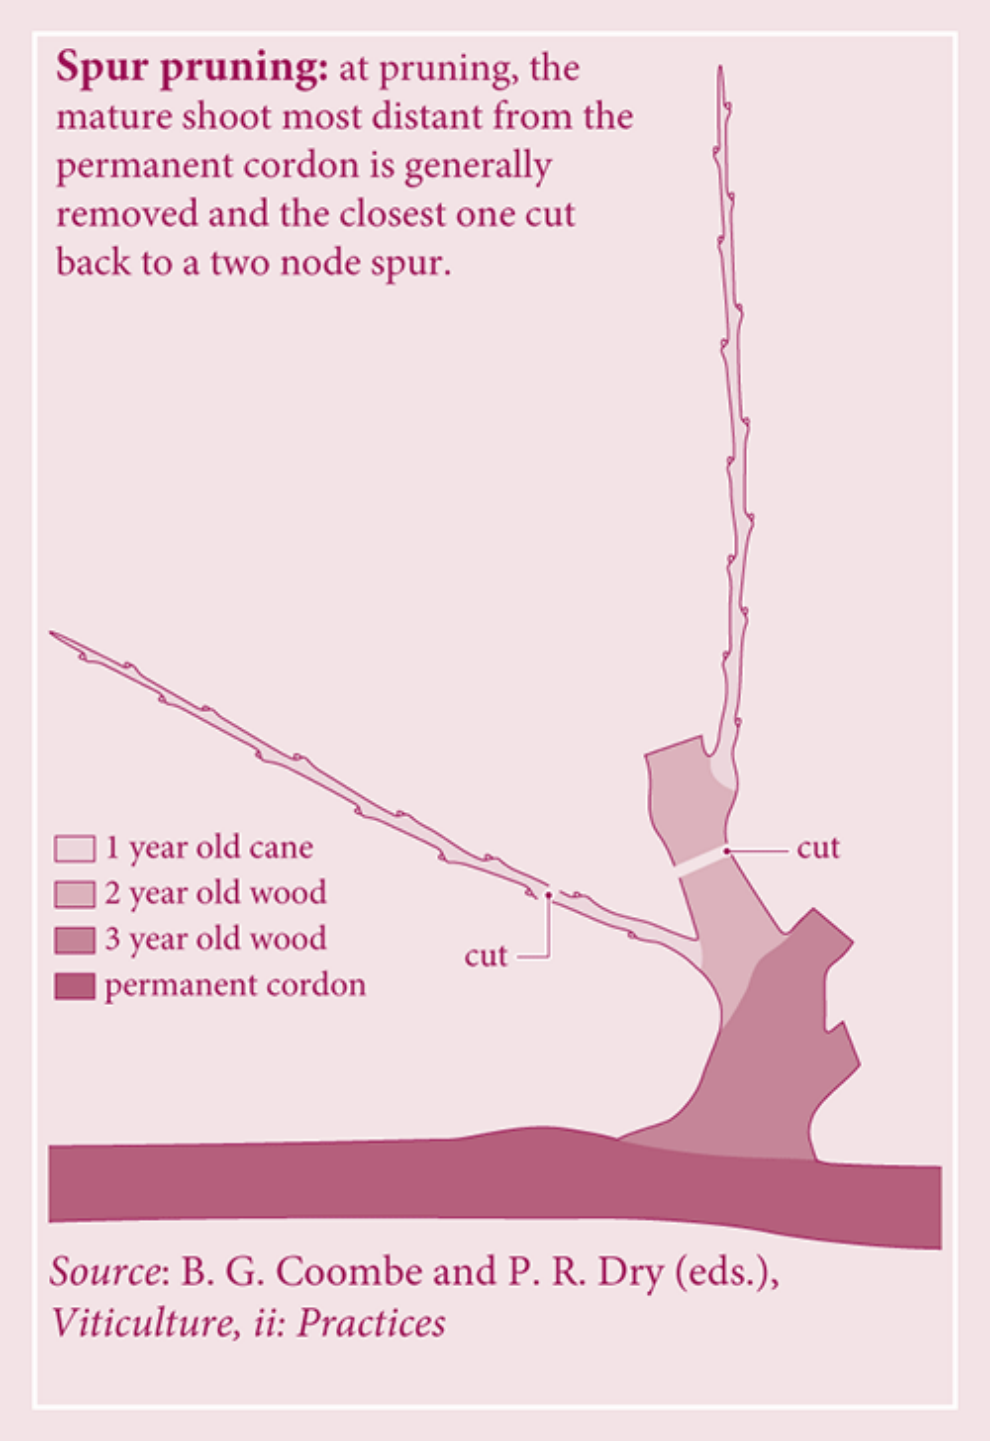
Significant quantities of sparkling wines from CHARDONNAY and PINOT NOIR, the classic grapes of CHAMPAGNE, are produced throughout Italy—some using the tank method but most bottle-fermented. The most important, with over 18 million bottles produced in 2020, is Franciacorta, a DOCG solely for sparkling wine and the only Italian fizz to have eliminated the word *spumante* from labels, thus emulating CHAMPAGNE, with which it is often compared. Trento DOC, which produced 9 million bottles in 2020, is reserved for classic-method wine in TRENTINO. OLTREPÒ PAVESE's vast Pinot Noir vineyards supply both base wine for many Piemonte sparkling wines as well as its own Oltrepò Pavese Metodo Classico.

Inspired by the extraordinary commercial success of Prosecco, almost every DOC now has a provision for the production of sparkling wine. While classic-method wines are considered more prestigious,

most Italian sparkling wines are tank-method wines and FRIZZANTE rather than *spumante*. W.S.

spur, a viticultural term for a shortened grapevine cane. A spur is a stub formed by pruning the CANE to between one and four NODES, usually two. Spurs are used to provide the next season's fruiting SHOOTS. Of all PRUNING systems SPUR PRUNING is the most severe, since over 90% of the previous year's cane growth is removed. Spurs are also left on cane-pruned vines to provide replacement canes at next pruning. B.G.C.

spur pruning, a form of winter vine PRUNING whereby the canes are cut back to two-bud SPURS (see diagram). Normally the spurs are spaced along a CORDON top and point upwards (although see SMART-DYSON). There are several advantages to spur pruning: among these are that it takes less time to prune by hand and that the operation can also be mechanized easily (see MECHANICAL PRUNING). Also, setting the spur spacing results in the appropriate shoot spacing in the canopy, which in turn leads to well-exposed leaves and fruit (see CANOPY MICROCLIMATE). Spur pruning is not particularly well suited to very vigorous vineyards, however, as excessive SHADE of the fruit and leaves can lead to the loss of both yield (due to low bud fruitfulness) and quality. The other main form of vine pruning is CANE PRUNING. See also CORDON TRAINING.



Spurrier, Steven (1941–2021), influential and much-loved wine-merchant-turned-wine-writer whose most famous act turned out to be, much to his surprise, organizing the JUDGMENT OF PARIS in 1976, which, almost by chance, opened the door for non-French wines to

make their mark. He inherited a fortune which was largely frittered away on projects, usually wine-related, that took his fancy. He could never have been accused of a lack of enthusiasm.

Inspired to work in wine by a glass of Cockburn 1908 given to him by his grandfather when he was 13, he began in the cellars of London wine merchant Christopher's after Rugby school, the London School of Economics, and life as a deb's delight. He went on to set up a wine shop in Paris, Cave de la Madeleine, and then a wine school, l'Académie du Vin, at which the wine flame was lit for countless wine professionals on both sides of the Channel. He worked briefly in the United States and then even more briefly for Harrod's before becoming a wine educator, running Christie's wine school for Michael BROADBENT, and acting as both wine taster and writer. He was the leading taster as well as columnist for *Decanter* magazine and was instrumental in setting up their lucrative annual wine awards. For all his power and influence, he was unusually modest and generous, always obsessed by his latest scheme, which included most permanently Bride Valley, a vineyard opposite his home in Dorset.

As keen a buyer of art as of wine, he deserved far more honours than he was given, especially from the French, whose wines he adored but who apparently never forgave him for the results of that 1976 blind tasting. The 2008 FILM *Bottleshock* was based on it, with Alan Rickman playing a misleading caricature of Spurrier.

Spurrier, S., *A Life in Wine* (2020).

Sri Lanka , tropical Indian Ocean island nation where fledgling, very small-scale ventures have tried to make wine from established plantings of Cardinal, Black Muscat, and Israel Blue vines originally grown for TABLE GRAPES. In 2022 there is no commercial wine production with locally grown grapes, but there are companies licensed to make wine from imported MUST and GRAPE CONCENTRATE as well as local fruit, including grapes. One is a collaborative venture with an Italian company. D.G.

stabilization, group of wine-processing operations undertaken after CLARIFICATION to ensure that the wine, once bottled, will not form hazes, clouds, or unwanted deposits; become gassy; or undergo rapid deterioration of flavour after BOTTLING. Some deposits and subtle changes in flavour that occur with lengthy AGEING are considered normal in a stable wine (see also SEDIMENT).

There are three main causes of instability: unstable PROTEINS and TANNINS; TARTRATES; and microbiological activity.

Many wines contain molecules of proteins and tannins that are not entirely stable and can join together, creating larger molecules that cause a haze to form. This gradually becomes dense enough to form a cloud and, ultimately, a solid deposit. These substances, which are completely harmless and have no effect on the taste of the wine even if they make it appear unpalatable, are most simply dealt with by FINING.

The four basic types of treatment used to stabilize tartrates—refrigeration, additives, ion exchange, and electrical methods—are described in detail under TARTRATES.

Microbiological stability is achieved by ensuring the absence of spoilage microorganisms (such as ACETOBACTER, LACTIC ACID BACTERIA, and YEASTS) at the bottling stage by sterilizing all bottling machinery and submitting the wine to an aseptic FILTRATION. This is easily achieved by the use of a good filtration regime, starting with earth and pad filtration and finishing with a fine membrane filter which will remove all troublesome yeasts and bacteria. The removal of yeasts is especially important for wines that contain residual sugar.

SULFUR DIOXIDE is also valued for its antimicrobial properties.

D.B.

Bird, D., and Quillé, N., *Understanding Wine Technology* (4th edn, 2021).

stabulation, winemaking technique used for aromatic whites and rosé wines that increases FLAVOUR PRECURSORS and FLAVOUR COMPOUNDS

but does not involve extended MACERATION—ideal if you are trying to make a flavourful but pale rosé or a white with more flavour but without the tannins of a SKIN-FERMENTED wine. After PRESSING, the juice is kept with its LEES (mostly PULP) for 5–15 days before CLARIFICATION, with the lees stirred up once a day by injecting carbon dioxide or adding dry ice. The temperature must be kept low to avoid the onset of fermentation. The technique, first used in Gascony, has also been used in the Loire for Sauvignon Blanc but has become particularly popular for Provence rosé.

Stags Leap District, California wine region and AVA within NAPA Valley known for supple, bright Cabernet Sauvignon.

stainless steel, sometimes referred to as inox (from the French *acier inoxydable*), is widely used for holding wine, especially for FERMENTATION but also during ÉLEVAGE. For wines made PROTECTIVELY it has the great advantage over wood that it is easy to clean and OXYGEN can be completely excluded from it, by the use of INERT GAS to fill the HEAD SPACE if necessary. It has the advantage over CONCRETE that TEMPERATURE CONTROL is even easier, especially with REFRIGERATED jacketing and cooling/warming coils, and any TARTRATES can be hosed out rather than having to be chipped off the concrete walls. For some wines, the exclusion of oxygen can be a disadvantage, however, and there is a risk of REDUCTION. Nor is there any possibility of the gradual, natural CLARIFICATION and STABILIZATION processes that are possible in wooden containers.

stake. The simplest form of vine support is a stake driven into the ground beside the vine. A stake supports an individual vine, whereas POSTS, which are usually thicker than stakes, support several vines from suspended wires. Stakes are a very traditional form of vine support, having been used for centuries. Vines trained to stakes are most common in Europe, although they are not unknown in

California. Since vines are climbing plants, they are unable to support themselves unless specially trained with a short trunk which thickens with age, as for GOBELET vines.

Materials used for stakes vary enormously between wine regions, reflecting local availability. Most common is WOOD, which has been used for centuries, although it is only recently that timber has been treated chemically, preventing softwoods from rotting in the ground. However, such treated wood requires special handling for disposal as it is toxic when burnt. Sometimes stakes are made from round timber, as in much of Europe, or from sawn timber, as in California. They can also be made from stone (slaty schist), as in the DOURO Valley of Portugal, or from concrete, as in parts of Italy. R.E.S.

stalk. For information about the stalk of an individual grape or berry, see PEDICEL. For information about the stalk of a bunch of grapes, see STEM.

stamen, pollen-bearing part of a flower that consists generally of an ANTHER borne on a filament. A grapevine flower is small and has five erect stamens that become evident after the CALYPTRA or cap has fallen off at FLOWERING. B.G.C.

standard drinks, unit of measurement used by governments to quantify a normal or regular pour of alcoholic drink by the amount of pure ALCOHOL it contains; also known as a unit of alcohol. Once this has been agreed upon, the theory goes, it is easier for authorities to set safe limits for consumption. There are many stumbling blocks, however, including wide variance among countries with regard to how much alcohol a 'standard drink' contains: 14 g in the US, 13.6 g in Canada, 12 g in France, 10 g in Australia and 8 g in the UK. In addition, both standard servings and the average ALCOHOLIC STRENGTH of wine are greater than when the standards were first set (see

HEALTH, Sensible drinking). In some countries it is compulsory to state on wine labels the number of standard drinks each bottle contains.

C.S.S.

starch, vine, an insoluble carbohydrate polymer composed of GLUCOSE residues. It is non-osmotic and is the principal storage substance in plants, forming as starch grains. Starch grains occur in the leaf and in cells of storage tissue in stems and roots of the vine. During daylight hours, when SUCROSE levels rise in leaves due to PHOTOSYNTHESIS, starch grains build up. At night they are metabolized to provide the sugar needed for RESPIRATION (this is also their fate in the human gut). Starch, natural storage reserves, are remobilized when buds burst and shoots begin to grow. Unlike many fruits, grape berries do not contain much starch, which is one reason grapes do not ripen after picking (apart from changes associated with dehydration). Starch is the principal CARBOHYDRATE reserve of vines.

B.G.C.

state winemaking though less common than it once was, has been important not just in Eastern Europe—during the communist era, when all activity took place under the auspices of the state—but also in TÜRKIYE; in Germany, where the state has owned a number of important vineyards and cellars, including KLOSTER EBERBACH; and, at certain points in their history, in North African countries such as ALGERIA, EGYPT, and MOROCCO.

staves are the shaped wooden planks that are cut and formed into BARRELS. See BARREL MAKING for more details.

Shorter lengths designed to impart OAK FLAVOUR to wines stored in used barrels or in tanks may be called inner staves (see BARREL INSERTS and INNER STAVES, respectively).

Steen, name by which CHENIN BLANC used to be known in South Africa.

Steiermark, wine region in AUSTRIA known in English as Styria, comprising the south-east corner of the country and incorporating the official wine regions of SÜDSTEIERMARK, VULKANLAND STEIERMARK, and WESTSTEIERMARK. In the age of Imperial Austria, vineyards in what is now SLOVENIA were also considered part of Steiermark, making a total viticultural area more than twice the size of that remaining in Austria today. In 2006 Slovenia officially renamed a large share of the Podravje region 'Stajerska Slovenija', about which some Austrian neighbours had misgivings. The traditional centre for Styrian viticulture was in fact Maribor in Slovenia (Marburg in German), whence in the early 19th century Archduke John of Austria directed expansion and improvements in winegrowing, including the introduction of most grape varieties found there today. D.S.

Steinfeder, the lightest in terms of MUST WEIGHT and alcohol among the trio of dry white wine categories in AUSTRIA's WACHAU region—specifically for unchaptalized grapes of 73–83 °OECHSLE (15–17 °KMW) which result in wines with no more than 11% alcohol. Consumers will pay much higher prices for the fuller-bodied wines of the categories FEDERSPIEL and SMARAGD, and achieving quality at low levels of POTENTIAL ALCOHOL is increasingly challenging. (See CLIMATE CHANGE.) So Steinfeder wines today, however charming and refreshing, tend to be rendered from relatively few cool sites and solely for local consumption. The name comes from a feathery grass species indigenous to the local vineyard terraces. D.S.

Stellenbosch , important wine district in SOUTH AFRICA, named after the charming university town at its heart 45 km/28 miles east of Cape Town with its Cape Dutch, Cape Georgian, and Victorian buildings shaded by long-established oaks.

Stellenbosch is the Cape's most famous wine district, traditionally associated with the country's most celebrated reds. It has been producing wine since 1679. As well as STELLENBOSCH UNIVERSITY, it is

also home to the Wine & Spirit Board and the biggest wine wholesaler DISTELL with its 6,500-barrel maturation cellars. Stellenbosch is surrounded by valleys of vines and the soaring blue-grey mountains of Stellenbosch, Simonsberg, and Helderberg. The district's wards—Banghoek, Bottelary, Devon Valley, Jonkershoek Valley, Papegaaiberg, Polkadraai Hills, Simonsberg-Stellenbosch, and Vlottenburg—all yield wines capable of displaying distinctive differences. Vineyards on the Helderberg (which runs from Stellenbosch to False Bay at Somerset West) enjoy a considerable reputation. Soils and climate vary, from sandy ALLUVIAL loam along the valley floors and river courses to deep, moisture-retaining decomposed GRANITE on the hillsides. The climate is tempered by the Atlantic sweeping into False Bay, a 15-minute drive from the town. The average daily summer temperature is 20 °C/68 °F.

Stellenbosch returns low average YIELDS; it makes less than 9% of the country's wine despite having 17% of the country's vines, as well as South Africa's greatest concentration of leading estates, an extensive wine route network, and scores of restaurants.

Stellenbosch University is the only one in South Africa offering professional degrees in both VITICULTURE and OENOLOGY. Informal teaching in these two subjects started in 1889, but the Department of Viticulture and Oenology was formally opened only in 1917, with Professor A. I. Perold as chair. The university has been an important influence on the Cape wine industry over the decades and continues to produce most of the Cape's leading viticulturists and winemakers. The town is also home to the Agricultural Research Council's ARC Infruitec-Nietvoorbij Institute for Horticulture, Viticulture, and Oenology; and the College for Agriculture and Oenology at nearby Elsenburg. Stellenbosch University is the site of the Institute of Wine Biotechnology.

As elsewhere (see the University of BORDEAUX, DAVIS, and GEISENHEIM, for example), the PHYLLOXERA crisis was a powerful motivation for viticultural research, and from 1890 until about 1920

most of Stellenbosch's work was concentrated on re-establishing the phylloxera-devastated vineyards of the Cape.

During the 1920s, considerable effort was expended on improving the quality of fruit-bearing vine SCIONS, a range that was naturally restricted by strict QUARANTINE regulations. This involved VINE BREEDING which led to NEW VARIETIES, of which PINOTAGE has been the most widely acclaimed. Under the guidance of Stellenbosch oenologists, South Africa was one of the first wine-producing countries to apply widespread TEMPERATURE CONTROL to fermentations. Other globally admired advances have been in plant-material quality, ROOTSTOCKS, root systems, PRUNING, CANOPY MANAGEMENT, vine spacing, vine-row orientation, grape and wine flavour profiles, and optimal ripeness for different wine styles.

Stelvin. See SCREWCAPS.

stem, or bunchstem, of a grapevine INFLORESCENCE or bunch of grapes, known by botanists as the peduncle and in French as a *rafle*. The form of the stem, especially the position and length of lateral branches, determines the shape of the BUNCH and is one of many characteristics used to identify vine varieties in the science of AMPELOGRAPHY.

The terms 'stem' and 'stalk' tend to be used somewhat carelessly by winemakers, if not by viticulturists. For information about the stem of an individual berry, see PEDICEL. The practice of stem inclusion, using the technique of WHOLE-BUNCH FERMENTATION or occasionally by adding stems to the fermenter, is both traditional and fashionable. It may result in wines described—both approvingly and disapprovingly—as stemmy, with vegetal or HERBACEOUS aromas and flavours that typically increase the perception of freshness. See also DESTEMMING.

stemming, paradoxically alternative term for DESTEMMING grapes.

stem pitting, vine virus disease. See RUGOSE WOOD.

stemware. See GLASSES.

sterile bottling or, more correctly, aseptic bottling, is the technique of getting wine into a closed bottle without incorporating any microorganisms that would harm the wine (notably YEAST and BACTERIA). Borrowed from the pharmaceutical packaging industry, this technique does the job of PASTEURIZATION without the use of heat. Aseptic techniques have become the norm for wine bottling because the use of membrane filters (see FILTRATION) has made the task very simple. Many everyday modern wines have small amounts of RESIDUAL SUGAR and therefore require bottling in an aseptic manner, but the degree of care needed depends upon the levels of residual sugar and alcohol.

An aseptic bottling line involves the creation of a clean room, modifying the usual equipment so that it may be sterilized easily. The room is kept under a slight positive pressure of filtered air, and entry is restricted to the few specially trained and clothed personnel required. Microorganisms are removed from the wine by sterile FILTRATION using membranes, and the corks or other CLOSURES are sterilized by gaseous SULFUR DIOXIDE or other chemical sterilizing agents such as peracetic acid. The bottling and corking machines are usually sterilized by steam, hot water, or chemical sterilants. Frequent sample bottles are removed at random for microbiological analysis, and each bottling run is held in storage until it is certain that no organisms are growing. D.B.

Bird, D., and Quillé, N., *Understanding Wine Technology* (4th edn, 2021).

steward, wine. See SOMMELIER.

stickie, Australian term for sweet, usually fortified, wines. Typical examples are the TOPAQUES AND MUSCATS of RUTHERGLEN and Glenrowan in North East Victoria.

stigma. See FLOWERS, VINE.

stilbene. See RESVERATROL.

stirring, winemaking term which may be used as a synonym for LEES STIRRING or may refer to the important operation of stirring, usually in much larger containers, when blending disparate components in a blend. This is particularly necessary when grape spirit is added to wine, as during FORTIFICATION, since the spirit, with its lower DENSITY, tends to float on top of the wine. Stirring, or dynamizing, also plays an important role in the production of some BIODYNAMIC preparations.

stomata (plural of stoma), minute openings on the surface of leaves bordered by two guard cells which open and close, thus regulating the exchange of gases between the atmosphere and the air chambers inside the leaf, especially of water out and carbon dioxide in (see TRANSPIRATION and PHOTOSYNTHESIS). The stomata of the grapevine occur only on the underside of each leaf blade, and there are also limited numbers on berries. B.G.C.

stones and rocks are coarse fragments of bedrock. The two words are practically synonymous, though some may think of rocks as larger or rougher and more angular. Whereas most farmers do their best to get rid of any fieldstone, not least because of potential damage to machinery, in vineyards stony soils are typically revered, probably because many celebrated vineyards around the world are spectacular in their stoniness.

Stones promote good DRAINAGE and restrict SOIL FERTILITY, leading to reduced vine VIGOUR, which in turn influences GRAPE COMPOSITION AND WINE QUALITY. They form an efficient mulch against surface EVAPORATION, protect against SOIL EROSION and force the vine to develop a beneficial extensive ROOT system. The much-repeated claim that stones absorb warmth during the day to re-radiate it at night (see BASALT) is probably overstated, except where the grape bunches are trained close to the ground and where grape ripening is difficult.

Stones exist because they are resisting weathering: they are effectively inert chemically. There is, therefore, no scientific basis for the popular claims that stones imbue wine with certain flavours, such as MINERALITY or 'stoniness'. However, stones exposed to the air rapidly become veneered with bacteria, algae, moulds and the like, and the aromatic compounds derived from them can be tasted by licking the stone and can be smelt when they volatilize, for example on a hot summer day, after a shower of rain, or when wetted at a river's edge. Stones are themselves tasteless and odourless. Only specialized organisms such as lichens and mosses can grow directly on them.

See also SOIL AND WINE QUALITY. A.J.M.

Maltman, A., *Vineyards, Rocks, and Soils: The Wine Lover's Guide to Geology* (2018).

stoppers for wine bottles. See CLOSURES.

storing wine is an important aspect of wine consumption, since wine is relatively sensitive to storage conditions and is one of the very few consumer products that can improve with age (although see AGEING for details of how few, and which, wines this applies to). Until the era of inflation, wine producers and merchants regarded storing and ageing wine as part of their business, but since the 1960s they have steadily relinquished this role. The development of the EN PRIMEUR market and the increase in the number of wine COLLECTORS

leaves many wine drinkers with the problem of how to store wine over long periods, often a decade or two.

There are two basic choices: to consign the bottles to professional storage and/or to establish some form of domestic cellar. If wine is put in storage, it is vital to choose a specialist in wine storage since wine is a much more fragile commodity than most things kept in warehouses, and it needs special treatment and conditions. It is important that the wine storage specialist is in sound financial health itself, that it understands the detail of storage conditions needed, and that it provides some facility for marking individual CASES with some identification of their owner. In the case of business failure, this can make the difference between establishing possession and not.

For more details of how to identify and, if necessary, convert part of a home into a suitable place to store wine, see CELLAR.

Ideal storage conditions

Even in ancient GREECE there was some appreciation of the importance of storage conditions on the evolution and health of wine. The key factors are TEMPERATURE, light, HUMIDITY, and security.

If wine is kept too hot or is exposed to strong sunlight, it rapidly deteriorates. If it is kept too cold, it can freeze, expand, and push out the stopper of whatever container it is held in.

For bottles stored for a few weeks, the primary concern is to keep them from strong direct light (white wines in colourless glass are most at risk; see LIGHTSTRIKE) and to ensure that they do not reach temperatures more than about 25 °C/77 °F (although there is some latitude here, depending on the fragility of the wine), at which point the wine may be spoilt and forever afterwards taste cooked.

A fairly wide range of temperatures is suitable for wine storage, although, in general, the lower the storage temperature, the slower the reactions involved in wine maturation and, the theory goes, the more complex the wine eventually. Dramatic temperature swings should be avoided, and an average temperature somewhere in the range of 10–15 °C/50–59 °F is considered suitable (see TEMPERATURE for more details).

Some degree of humidity is beneficial, to ensure that the exposed end of corks don't dry out and allow in oxygen. A level of 75% relative humidity is usually cited, although this, like so many aspects of wine consumption rather than production, suffers from a lack of scientific research. The disadvantage of very damp cellars is that damp labels eventually deteriorate and make identification difficult (and some COLLECTORS prefer pristine labels so any resale value is not prejudiced).

Bottles to be stored for more than a few weeks, however, should be stored so that any cork is kept damp and there is no possibility of its drying out and allowing in the enemy, OXYGEN. This usually entails storing the bottles horizontally, ideally in a wine rack so that individual bottles can easily be extracted, or in a BIN full of wines of

the same sort. Many wine producers deliberately mark their CASES ('this way up', for instance) in an effort to keep bottles upside down, and corks damp, during shipment. The increased use of alternative CLOSURES, however, particularly SCREWCAPS, suggests that horizontal storage may no longer be strictly necessary, although horizontal storage tends to save space.

The wine itself in an inverted bottle comes to no harm. Research in the late 1990s suggested that an ideal storage position for wine bottles stoppered with a natural cork is at a slight angle from the horizontal so that the cork is kept damp but the air bubble of ULLAGE just touches the cork rather than lying on top of the middle of the bottle. It has also been suggested by some that champagne ages most gracefully when stored in bottles that are kept upright rather than horizontal, but this was disproven in 1996.

If a maturing wine is agitated, it may disturb the sediment and therefore the AGEING process (although this is an unproven hypothesis). Some cellars are specifically designed with rubber racks for bottles in order to minimize any likely vibration. The need for a secure storage space is obvious, especially since bottles of alcoholic drink seem to be widely regarded as common currency rather than private property.

It is also important that there are no strong, persistent smells in a long-term wine storage area.

See also BULK STORAGE.

Valade, M., 'Extrait de la presentation sur les activités techniques oenologiques en 1995', *Le Vigneron Champenois* (February 1996).

Straccia Cambiale, synonym for the white grape BOMBINO BIANCO.

Strathbogie Ranges, hilly, elevated Australian wine region in the Central Victoria Zone. (See VICTORIA.) Despite its dry, warm-to-hot summers, wide variations in SOIL, ASPECT, and ELEVATION make this a

diverse region where Chardonnay and Pinot Noir lead the plantings and Shiraz often comes in a cool-climate guise. E.N.H.M.

straw wines, sweet wines made from grapes dried on straw. See VIN DE PAILLE, ALSACE, AUSTRIA, CZECHIA, LUXEMBOURG, VIN SANTO, and DRIED-GRAPE WINES.

Strevi , independent DOC for a sweet white wine made from late-harvested or dried MOSCATO Bianco grapes in the hills around Strevi in the east of the ASTI zone. As it is usually riper in flavour than most MOSCATO D'ASTI thanks to Strevi's warmer MESOCLIMATE and steep vineyards, it has also been granted subzone status within the Moscato d'Asti DOCG zone. W.S.

Strohwein is German for STRAW WINE, an official category of DRIED-GRAPE WINES in AUSTRIA and SWITZERLAND.

structure, TASTING term that refers not to any FLAVOUR but to the TANNINS, particularly their intensity. It may sometimes incorporate ACIDITY.

Stück, German term for a large wooden BARREL, typically one with a capacity of 1,200 l/317 gal used in the RHINE regions of GERMANY. (In the MOSEL region, the FUDER is more common.) A Halbstück contains 600 l and was commonly used for transporting wine in the pre-tanker era, while a Doppelstück contains 2,400 l.

stuck fermentation, winemaker's nightmare involving an alcoholic FERMENTATION which ceases before completion. Such fermentations are notoriously difficult to restart, and the wine is at risk of spoilage from OXIDATION and BACTERIAL DISEASE. Before cooling

equipment was commonplace, fermentation TEMPERATURES could reach a dangerously high level, often in excess of 35 °C/95 °F. In extreme cases, with temperatures nearing the range at which YEASTS are killed (over 40 °C), the yeast cells release compounds which inhibit future yeast growth, thereby making it difficult or impossible to restart such fermentations even after cooling.

Stuck fermentation has many documented causes, and because there can be several concurrent causes, diagnosis is often difficult. However, one clear cause is the tendency over recent decades to harvest grapes at higher maturity levels (see PHYSIOLOGICAL RIPENESS), which has resulted in grapes with higher sugar levels and wines with a higher alcohol content. Unless fermentation conditions are optimal, various stresses culminate in decreased or, in some cases, complete cessation of fermentation activity before the target sugar content has been reached. One common stress is deficiency of the essential nutrient NITROGEN. Grapes which come from vineyards deficient in nitrogen have a low level of available nitrogen, or yeast-assimilable nitrogen (YAN). This limits the development of yeast cells, and fermentation activity is not sustained after they have become starved of nitrogen. This problem is exacerbated in the fermentation of highly clarified musts (see CLARIFICATION), with which the winemaker is aiming to produce wine low in PHENOLICS. The very low content of suspended grape solids in such musts means that the level of LIPIDS, the compounds that allow yeast to build strong membranes needed to limit the toxic effects of alcohol, is also low. Fermentation at low temperatures (below 15 °C/60 °F) with strict protection from air (oxygen), which prevents yeast from making lipids, greatly increases the risk of stuck fermentation.

There are several ways to reduce the risk of stuck fermentation: adding nitrogen to the juice, either in the form of an ammonium salt (most commonly DIAMMONIUM PHOSPHATE) or a proprietary yeast food which contains significant nitrogen; adding back the 'fluffy' or light fraction of must settlings to increase the level of grape solids (lipids); using a yeast starter culture of a high-alcohol-tolerant strain that has been propagated with excess air; or adding nitrogen and exposing

the fermentation to a small amount of air once the yeast is active. These options are usually effective, especially when several are used in combination. The last treatment is most simply achieved by stirring, SPARGING with air or OXYGEN, or PUMPING OVER. Failure of the yeast inoculum to dominate the AMBIENT YEASTS that are invariably present in grape must can result in a stuck fermentation if the ambient yeasts have a lower tolerance to alcohol. Ambient yeasts which produce 'killer toxin' (called zymocidal yeasts; yeast toxin has no effect on human cells) can be especially aggressive by actively eliminating the killer-sensitive wine yeast. Certain LACTIC ACID BACTERIA, which can grow rapidly during the early stages of fermentation when SULFITES have not been added to the must prior to fermentation, can interrupt fermentation. Inhibition of fermentation by ambient yeasts and bacteria can be diminished considerably by using a highly active yeast starter culture, choosing a yeast that is resistant to killer toxin (broad-spectrum resistant strains are not yet available commercially), and by any method that reduces the number of wild microorganisms present in the must. Should a ferment become stuck despite the use of these procedures, increasing concentrations of the problem stuck wine should be added to a new rescue-yeast starter culture, in the presence of adequate nutrients, including oxygen. Styria, English name for the Austrian wine region STEIERMARK.

subjectivity plays an unavoidable part in wine TASTING. Personal preferences, like SENSITIVITIES, inevitably play some role in wine assessment. For more discussion of this, see PHILOSOPHY AND WINE and QUALITY IN WINE.

submerged cap is a way of keeping the CAP wet and mixed with the fermenting wine to facilitate EXTRACTION. A perforated screen is positioned just under the surface of the liquid to keep the cap submerged, but the pressure of the rising CARBON DIOXIDE tends to force the cap against the screen, making extraction less efficient. A pipe to allow the gas to escape can help to resolve this. It is still quite common to see header boards performing the same function in traditional CONCRETE tanks in the BAROSSA VALLEY. See also PUNCHING DOWN, PUMPING OVER, and MACERATION.

subsoil, the layer of a SOIL PROFILE which underlies the topsoil containing most of the ORGANIC MATTER. It overlies the bedrock (see ROCK) or sediments from which the soil is formed. The subsoil can be heavier-textured in ancient soils and in forest (especially pine forest) regions, due to the progressive downward leaching of the fine CLAY particles.

A fairly heavy-textured subsoil, provided that it drains freely enough, can have advantages for viticulture because it provides a good store of moisture that is well protected against direct EVAPORATION and exploitation by shallow-rooted WEEDS. The usual relative sparseness of vine roots in the subsoil, together with the strength with which clay particles hold water (see SOIL WATER and SOIL TEXTURE), ensures that the stored water can be used only at a limited rate. Seguin cites the clay soils of POMEROL as an example of this. It helps to provide the vine with the consistent regime of water supply

that is important for wine quality. See also TERROIR and SOIL AND WINE QUALITY.

On the other hand, many heavy subsoils impede DRAINAGE, particularly those formed from acid rock materials. These can be detrimental to viticulture, unless carefully drained and, possibly, LIMED to overcome SOIL ACIDITY and improve the SOIL STRUCTURE. J.G.

Seguin, G., '"Terroirs" and pedology of wine growing', *Experientia*, 42 (1986), 861–72.

subsoiling. See RIPPING.

succinic acid, an acid found to a limited extent in both grapes and wine. Present in low concentrations in ripe grapes, it is a contributor to the fresh or tart taste of the fruit, albeit to a much lesser extent than TARTARIC ACID or MALIC ACID. Like these two principal grape acids, pure succinic acid is a white crystalline solid that is very soluble in water and alcoholic water solutions such as wine.

Succinic-acid concentrations tend to be higher in wine than in grapes because the acid is a by-product of the complex nitrogen metabolic processes involved in YEAST growth during FERMENTATION. Concentrations are generally higher in red wines than in whites. In some wines, a considerable proportion of the succinic acid reacts with one molecule of ETHANOL to form an ESTER, mono-ethyl succinate, which has a very mild, fruity aroma. G.T.

Coulter, A. D., et al., 'Succinic acid: how is it formed, what is its effect on titratable acidity, and what factors influence its concentration in wine?', *Australian and New Zealand Wine Industry Journal*, 19/6 (Nov/Dec 2004), 16–25.

suckering. See DESUCKERING.

sucrose, cane sugar, the most common of the SUGARS, is ubiquitous in plants because it is the preferred compound for PHLOEM translocation of energy and carbon around the plant. Sucrose consists of a GLUCOSE molecule joined to a FRUCTOSE molecule. Breakdown (HYDROLYSIS) of sucrose is achieved readily by the enzyme INVERTASE, which 'inverts' it to these hexoses.

Invertase in the vine occurs in CELL wall spaces but not in those of the leaf, which is why sucrose is confined in vines mainly to leaves and phloem tubes. Invertase is abundant in grape berries both in the cell walls and in the VACUOLES; hence the sugars that accumulate in berries are mainly glucose and fructose. B.G.C.

Südburgenland stretches along AUSTRIA's south-east border with Hungary as far south as SLOVENIA, but the region's 505 ha/1,200 acres of vines in 2021 represent barely more than 1% of the country's total. While fascinating white wines of GRÜNER VELTLINER, WELSCHRIESLING, and WEISSBURGUNDER (Pinot Blanc) are emerging, the region is best known for its profoundly complex and ageworthy BLAUFRÄNKISCH, particularly that grown in Deutsch-Schützen and neighbouring EISENBERG, which gives its name to the DAC that now applies throughout Südburgenland. Non-DAC QUALITÄTSWEIN grown here may only specify BURGENLAND as its place of origin. A curious regional relic of PHYLLOXERA's aftermath is UHUDLER. D.S.

Süd-Oststeiermark, wine region of AUSTRIA, now officially known as VULKANLAND STEIERMARK. D.S.

Südsteiermark, a dramatically hilly Austrian wine region fanning south from Graz, the capital of STEIERMARK, and hugging some 40 km/25 miles of frontier with SLOVENIA. Its reputation and densely planted 2,744 ha/6,781 acres (as of 2021) are disproportionate to its deceptively small outline on a viticultural map. Südsteiermark gained

national prominence in the wake of Austria's 1985 wine scandal (see AUSTRIA), when wine lovers sought out small wine estates which had little truck with NÉGOCIANTS and whose vineyards were within walking distance of the point-of-sale. That said, one's shoes and heart need to be stout to tackle the steep terrain of a region whose cool, well-watered growing season and complex mingling of VOLCANIC and sedimentary soils support success with a wide range of white wine grapes, most importantly Sauvignon Blanc, Chardonnay (here generally labelled Morillon), MUSKATELLER, and WELSCHRIESLING but also WEISSBURGUNDER (Pinot Blanc), GRAUBURGUNDER (Pinot Gris), Riesling, and TRAMINER. The few reds are made primarily from Austria's ubiquitous ZWEIGELT, although there is some fine Pinot Noir and BLAUFRÄNKISCH. Varietal diversity was already a feature of greater Steiermark in the early 19th century, but the choice of principal grapes today—and especially the pre-eminence of Sauvignon Blanc—stem from regional dry-wine pioneers of the late 1970s and 1980s, in particular Willhelm Sattler Senior and Manfred Tement.

The Südsteiermark DAC encompasses all eight of the above-mentioned white grapes, as well as BLENDS of these. It recognizes bottlings in the categories regional, communal, and single-vineyard, and it consolidates Südsteiermark's many small wine villages into five official communes (*Gemeinden*)—Eichberg, Ehrenhausen, Gamlitz, Leutschach, and Kitzeck-Sausal—each associated with a more restricted set of 'leading' grape varieties from among Gelber Muskateller, Morillon, Riesling, and Sauvignon Blanc. Other than Welschriesling, no Südsteiermark DAC wine may be marketed before 1 March following its harvest, while the term 'Reserve' may be applied to wines held for 18 or more further months before release.

Since the 1990s, South Styrian wines have typically been marketed in two categories. Steierische KLASSIK refers to tank-aged, early bottled, bracing, dry VARIETALS with 11.5–12.5% alcohol and no MALOLACTIC CONVERSION. Vineyard-designated wines represented a fuller-bodied category, more ambitiously vinified and matured, often featuring pre-fermentative SKIN CONTACT, malolactic conversion, and

LEES CONTACT during BARREL AGEING. Both size and age of casks have been increasing in recent years after a period during the 1990s and the early 21st century when new BARRIQUES were FASHIONABLE. There were subsequent signs of these two stylistic categories blurring at some important addresses; meanwhile, the advent of Südsteiermark DAC places the emphasis on place of origin rather than style. A small but strong cadre of contrarian growers espousing NATURAL winemaking techniques, no friends of DAC, has emerged to enliven the 21st-century Südsteiermark scene.

Twelve of the region's most prominent growers, under the name Steierische Terroir & Klassik, have classified their best vineyards as premier or grand cru using the abbreviations '1-STK' and 'G-STK' on price lists and labels. Just as elsewhere in Austria, however, there is not yet a consensus on vineyard CLASSIFICATION, and Austrian wine law recognizes no such classification. D.S.

Südtirol, or South Tyrol. See ALTO ADIGE.

sugar addition, winemaking practice more usually called CHAPTALIZATION or, in EU parlance, ENRICHMENT.

sugar concentration in grapes. See MUST WEIGHT.

sugar in grapes, the *raison d'être* of VITICULTURE. The central role of sugar in the utility of grapes for wine, TABLE GRAPES, RAISINS, and other viticultural products cannot be over-emphasized. SUGARS produce SWEETNESS and ferment to produce ETHANOL, both of which are valued by humans. However, of all sugary plant produce, none yields a commodity as highly valued or widely produced as grape wine.

The free sugar that accumulates in grapes, GLUCOSE and FRUCTOSE, is the result of translocation of SUCROSE photosynthesized in leaves

and moved via PHLOEM tubes into grape berries during RIPENING, where it is inverted (hydrolysed) by the enzyme INVERTASE. The astonishing feature of grapes is that this accumulation occurs at the same time as water is accumulating in the berry, yet concentration is also increasing; in other words, sugar is increasing proportionately more than water. Other phloem-provided sucrose moves throughout the vine, dispensing energy and the carbon skeletons for all organic molecules. Additionally, sugar is used for carbon storage, as STARCH in wood, and for the formation of GLYCOSIDES in the storage of secondary metabolites in VACUOLES of cells (see FLAVOUR PRECURSORS and FLAVOUR COMPOUNDS).

While total sugar content (see MUST WEIGHT) is a key factor in determining optimum RIPENESS of grapes for wine, sugar–acid balance is equally important; hence the use of sugar–acid ratio as a guide to the date of harvest. See also PHYSIOLOGICAL RIPENESS and GRAPE QUALITY ASSESSMENT. B.G.C.

Keller, M., *The Science of Grapevines* (3rd edn, 2020).

sugars, simpler members of the large group of natural organic chemical compounds called CARBOHYDRATES. The sugar of common parlance, SUCROSE, comes from either sugar cane or sugar-beet plants and is a major international commodity. Sucrose is a molecule made up of one unit of each of GLUCOSE and FRUCTOSE linked together with the elimination of a molecule of water.

Plants produce sucrose by PHOTOSYNTHESIS, many of them accumulating sucrose within their cells but others, such as the common wine vine VITIS VINIFERA, breaking this sucrose down into its two simpler constituent parts, glucose and fructose, which are stored in the berries. AMERICAN VINES store small amounts of sucrose in the fruit along with the two simpler forms. Over the millennia during which people have selected grape vines, they have chosen those

capable of photosynthesizing high levels of sugars and storing them in berries. For more detail, see SUGAR IN GRAPES.

Although the amounts of sugars other than glucose and fructose detected in grape must are very small, the process of PHOTOSYNTHESIS involves sugars with three, four, five, and seven carbon atoms as well as the six-carbon glucose and fructose.

Sucrose, usually in the form of sugar-beet concentrate or some form of GRAPE CONCENTRATE, may be added to some grape MUSTS during fermentation in order to increase the ALCOHOLIC STRENGTH of the resultant wine (see ENRICHMENT).

The total amount of sugars left in a finished wine is called its RESIDUAL SUGAR.

Some of the sucrose resulting from photosynthesis, stored in the berries as glucose and fructose before grape harvest, is converted into STARCH and stored in the vine's trunk and larger arms and roots during winter DORMANCY; when spring temperatures begin the annual cycle of leaf and fruit production once more, the starch is remobilized to soluble sugars, mainly glucose.

See also MUST WEIGHT. A.D.W.

sui lieviti, Italian for 'on the lees', typically refers to sparkling wines which are not disgorged after the second fermentation has taken place in the bottle. See also SPARKLING WINEMAKING.

sulfides are the compounds of SULFUR with hydrogen or metallic elements in which the sulfur atom exists in its most reduced state (see REDUCTION).

Sulfides occur naturally from YEAST metabolism during FERMENTATION. HYDROGEN SULFIDE is the most common and can be formed in significant amounts from the reduction of elemental sulfur residues on the grapes from fungicides. It has an intense smell of bad eggs but is fortunately very volatile and can usually be removed by simple AERATION.

Sulfide chemistry in wine is complex with multiple equilibria existing between compounds, including the simple HYDROGEN SULFIDE, MERCAPTANS, disulfides, and polysulfides. The various concentrations of these depends on how reductive or oxidative the environment is. See REDUCTION.

Sulfides can have unpleasant aromas such as garlic, rotten vegetables or sewers, but they can also confer positive attributes. Benzyl mercaptan, for example, is responsible for the flintiness of some BARREL-AGED wines, especially whites (see MINERALITY).

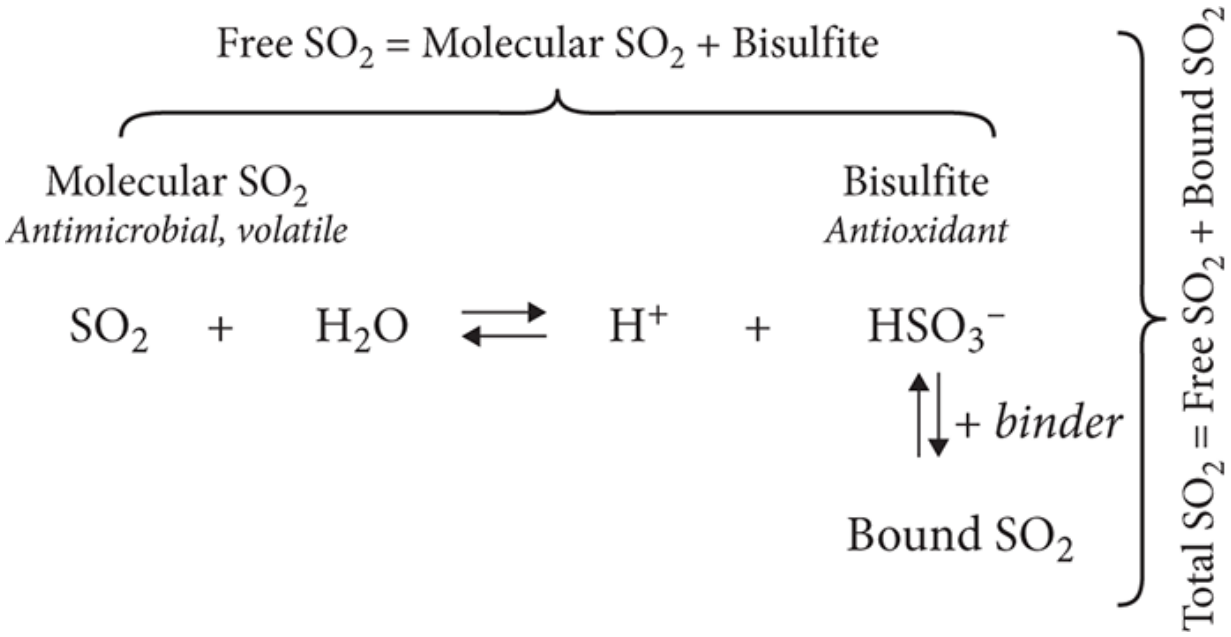
Dimethyl sulfide (DMS), which increases with bottle AGEING, can contribute a positive aroma of truffle to some white or red wines but is considered a FAULT at higher concentrations (aromas of cabbage and asparagus).

Winemakers will typically remove problem levels of sulfides through aerobic RACKING, or judicious additions of tiny amounts of copper (less than 1 ppm).

The removal of disulfides is more complicated because they will not react directly with copper ions. First they must be reduced to the corresponding mercaptan, through the addition of ASCORBIC ACID. The mercaptan will then react with the copper ions.

In a winemaking context, any reference to 'sulfide' or 'sulfides' is usually a criticism. Sulfides should not be confused with SULFITES, however. V.L. & M.J.T.

sulfites, a term familiar to wine consumers (most wine labels now state 'Contains sulfites'), winemakers, and regulators. It is an inclusive term for both sulfur dioxide (SO_2) and related compounds formed after the addition of SO_2 to must or wine. For more information, see SULFUR DIOXIDE.



sulfur, an element that constitutes about 0.5% of the weight of the Earth's crust and is one of the more important elements for humans. It is extremely important in wine production because of the wide-ranging uses of SULFUR DIOXIDE. A pale yellow, brittle, solid substance at room temperature, sulfur was already known to the speakers of ancient Sanskrit as *sulvere*. The book of Genesis in the Bible refers to sulfur as brimstone.

History

Sulfur has been used as a cleansing agent and wine preservative since antiquity. The discovery in the volcanic areas of Mediterranean Europe that sulfur could be used effectively to fumigate rooms led to the Greeks and Romans experimenting with its use to avoid food—and wine—spoilage. Authors such as CATO and PLINY, for example, mention sulfur among the various substances, such as pitch and resin, used by the Romans to prepare vessels in which wine was stored and to assist in its preservation. In late medieval times, it seems that Dutch and English merchants also used it for similar purposes, and in 1487 a German decree specifically permitted winemakers to burn woodchips soaked in sulfur in barrels before they were filled. By the 18th century, sulfur wicks were being regularly used to sterilize barrels in the best châteaux of Bordeaux (having been introduced by the DUTCH), and advances in chemistry had also led to the synthesis of derivatives of elemental sulfur, thus enabling inorganic salts containing sulfur to become widely used in winemaking. See SULFUR DIOXIDE and SULFIDE. In the vineyard, sulfur products have been commonly employed for over a century to protect vines against POWDERY MILDEW. P.T.H.U.

Johnson, H., *The Story of Wine: From Noah to Now* (2020).

Viticulture

Sulfur is essential for vine nutrition, although sulfur deficiency in vineyards is very rare. Vines usually obtain sufficient quantities from soil supplies or from FUNGICIDES. Long-term application of sulfur to vineyards to control POWDERY MILDEW has led to excess SOIL ACIDITY in many European vineyards. Sometimes periodic LIMING may be needed to counter soil acidification. R.E.S.

Winemaking

See SULFUR DIOXIDE, HYDROGEN SULFIDE, and SULFITES.

sulfur dioxide, or SO_2, a colourless, pungent gas formed by burning elemental SULFUR, has been used since antiquity as a sanitizing agent and preservative during food production and storage (see SULFUR for more historical detail). Sulfites may be added throughout the winemaking process: to harvested grapes, to pre-fermentation juice or must, to wines post-fermentation, during storage, or prior to packaging.

SULFITES, referring to SO_2 and related compounds, may be added to must or wine, either as SO_2 gas or in the form of a salt (e.g. potassium metabisulfite). Both salt and gas forms of sulfites will rapidly dissolve in water (the main component of grape juice and wine) to yield neutral, volatile molecular SO_2 and negatively charged bisulfite (HSO_{3-}) in equilibrium. The sum of bisulfite and molecular SO_2 is referred to as free SO_2. In wine, free SO_2 exists predominantly (>95%) as bisulfite, with higher proportions of molecular SO_2 with decreasing PH (more acidic conditions).

Bisulfite may also react with other wine components to form bound SO_2. A major SO_2 binder is ACETALDEHYDE (bruised-apple aroma), which can be formed by yeast during fermentation or through OXIDATION of ETHANOL. Other SO_2 binders are weaker and include fermentation products such as PYRUVIC ACID; grape-derived compounds such as ANTHOCYANINS in red wines; and GLUCOSE in sweet wines. Bound SO_2 has negligible preservative activity compared with that of free SO_2. Bound SO_2 has negligible antimicrobial effect on yeasts, but some spoilage bacteria are sensitive to even very low concentrations. However, bound SO_2 and free SO_2 forms are in equilibrium (i.e. they interchange during storage). Total SO_2 or total

sulfites refers to the sum of free and bound SO_2, the form regulated in most wine-producing countries (see below).

Sulfites have several important roles in wine production: enzyme inhibition, antimicrobial, and antioxidant.

Free SO_2 (as bisulfite) inhibits enzymatic activity, including polyphenol-oxidase (PPO) enzymes in grapes responsible for browning and oxidation of must following CRUSHING and PRESSING. Uninhibited, these reactions can lead to finished wines with browner hues and lower concentrations of important aroma compounds, including THIOLS, critical to the fruity aromas of Sauvignon Blanc.

Molecular SO_2 is an excellent broad-spectrum antimicrobial. Conveniently, wine YEASTS are relatively more tolerant of molecular SO_2 than many spoilage yeasts. Sulfites are commonly added before fermentation, either to newly harvested grapes or after CRUSHING in order to favour the growth of desired wine yeasts. Post-fermentation additions are used to discourage spoilage yeasts such as BRETTANOMYCES or to stop SWEET WINES refermenting. Molecular SO_2 is particularly effective in preventing bacterial spoilage, including from ACETOBACTER and many strains of LACTIC ACID BACTERIA. Winemakers therefore limit the addition of sulfites to wines intended to undergo MALOLACTIC CONVERSION until after this step is complete.

Finally, free SO_2 (as bisulfite) is an antioxidant which can limit the effects of non-enzymatic OXIDATION during wine AGEING. This antioxidant effect is not due to the direct reaction of sulfites with OXYGEN. Instead, oxygen reacts with wine PHENOLICS to produce oxidized phenolics (called quinones) and hydrogen peroxide, and these oxidation products can have unwanted effects—for example, producing acetaldehyde and other compounds that create oxidized aromas, the loss of some desirable odorants, and generating products that cause wine browning. Free SO_2 acts as an antioxidant by rapidly reacting with both quinones and hydrogen peroxide, preventing further undesirable reactions involving these compounds. Free SO_2 will mostly be converted to sulfate during these reactions, and a

portion of free SO_2 will be regenerated from weakly bound SO_2. Free SO_2 is also able to bind acetaldehyde and related oxidized-smelling odorants, as described above, and the resulting bound SO_2 forms are non-volatile and odourless.

Most commercial winemakers aim to have at least 20–40 ppm free SO_2 in stored or packaged wines to limit unwanted oxidation reactions and/or the release of weakly bound oxidized-smelling odorants. Winemakers also typically aim for 0.4–1 ppm molecular SO_2 to prevent microbial spoilage, with the higher end of the range used for sweet wines due to the greater risk of refermentation. Since the proportion of molecular SO_2 increases with decreasing pH, these two targets (molecular, free) must be considered separately.

Winemakers avoid excess addition of sulfites for several reasons. Most consumers perceive the characteristic (and undesirable) burning/irritating sensation of sulfites when the volatile molecular SO_2 form is present at > 2 ppm. Sulfites will also bind and bleach anthocyanins, and high concentrations are therefore undesirable in red wines. Total sulfites are also regulated in most wine-producing countries. Regulatory limits for total sulfites are typically stated in parts per million (ppm) or else the equivalent or near-equivalent units of mg/kg or mg/l. US regulations use the same limit for all wines (350 ppm), but most other wine-producing regions adjust limits based on wine style. In most countries, limits are higher in whites than in reds because whites typically have more SO_2-binding ACETALDEHYDE, and limits are higher in sweet wines than dry wines both because the former have more SO_2-binders such as GLUCOSE and because they are at greater risk of microbial spoilage. For example, in the EU, maximum permitted levels for total sulfites are 150 mg/l in dry red wines, 200 mg/l in dry white, dry rosé, and sweet red wines, 235 mg/l in sparkling wines, and 250 mg/l in sweet white and rosé wines. Certain sweet wines, including SAUTERNES, JURANÇON, BEERENAUSLESE, TROCKENBEERENAUSLESE, and EISWEIN, are permitted to have up to 400 mg/l. EU limits for ORGANIC WINE are lower, with 100 mg/l allowed for dry reds and 150 mg/l for white and rosé. Total

sulfite limits in other major wine-producing countries are generally comparable with EU limits (100–400 ppm, depending on style), but in practice most wines contain far lower sulfites than what is permitted. A 2021 survey of international wines commercially available in Korea revealed an average total sulfites content of 100 mg/kg, and only two wines (out of 180) had sulfites over 200 mg/kg.

Total sulfites are regulated for two reasons. First, high levels of total sulfites may indicate unsound winemaking practices such as the use of spoiled fruit or oxidized wine. Second, there are health concerns surrounding sulfites, although consumer concerns about sulfites present below regulatory limits are not supported by existing medical literature. The best-established concern is 'sulfite sensitivity', which may result in adverse, allergy-like responses (e.g. respiratory distress, hives, anaphylaxis) in a small fraction of asthmatics. See ALLERGIES AND INTOLERANCES for more information.

For the majority of the wine-drinking population, sulfites consumed through wine (about 15 mg in a typical glass) are well below the (conservative) acceptable daily intake (ADI) guidelines of a joint committee involving the World Health Organization: *c.* 50 mg/day for a typical 70 kg adult. Even so, research into alternatives to SO_2 is not new, as reported by Lisanti and colleagues, and today there is growing consumer interest in wines produced with minimal or no addition of sulfites (e.g. NATURAL WINES).

With regard to sulfites' antimicrobial function, there are viable alternatives. For example, sulfites can be limited by good winery HYGIENE along with physical techniques such as PASTEURIZATION and sterile FILTRATION, which are effective for preventing microbial growth but may not be suitable for all wines. Chemical additives approved by the EU and the OIV but which may not appeal to non-interventionist winemakers include DMDC (for all microorganisms), the ENZYME lysozyme (for LACTIC ACID BACTERIA), and SORBIC ACID (for YEAST). Additives such as PHENOLICS (e.g. tannins from grape skins or other plants, RESVERATROL from grape skins) and CHITOSAN are approved for other purposes but are reported to have modest antimicrobial activity.

Replacing the antioxidant properties of SO_2 has been less successful, especially for FRUIT-DRIVEN wine styles, because the antioxidant capacity of sulfites is more challenging to replace as free SO_2 is uniquely capable of rapidly scavenging hydrogen peroxide and binding to ACETALDEHYDE and related compounds. Yeast lees can consume oxygen, but storing wine SUR LIE is not appropriate for all wine styles. Other antioxidants such as ASCORBIC ACID and yeast extracts may partially limit the need for SO_2 in these wine styles, as does selecting wine packaging with low OXYGEN TRANSMISSION RATES, but identifying alternatives that are as effective as SO_2 and do not affect the sensory characteristics of the wine remains a challenge. They may be better suited as a complement to reduced SO_2 usage rather than as a replacement.

However effective such alternatives prove to be, producing entirely sulfite-free wines is not feasible, as yeast will convert naturally occurring sulfate into sulfites as part of their AMINO ACID metabolism. Thus, in most wine-producing regions, wine labels are required to bear the phrase 'contains sulfites' (or variations on that theme) only if total sulfites exceed 10 ppm (see LABELLING INFORMATION). sulphate, sulphide, sulphite, and sulphur, the British and non-technical spellings of sulfate, SULFIDE, SULFITE, and SULFUR respectively. This book follows the International Union of Pure and Applied Chemistry (IUPAC) nomenclature recommendations and uses 'sulfate', 'sulfide', 'sulfite', and 'sulfur' throughout since the terms are generally used in a technical context.

Sultana, also known as Sultaniye, Sultanina, and Sultanine. Its origins are thought to be eastern Mediterranean. Even further east it is known by variants on Kismis and in Egypt as Banati. It is the most important white grape variety used to produce the golden RAISINS sometimes called sultanas; in its time it was the single most planted vine variety in the world, covering an estimated 344,000 ha/850,000 acres of vineyard, much of it in the Middle East. The fruit of the Sultana vine, called THOMPSON SEEDLESS in California, is remarkable for its versatility. As well as being dried, it can be vinified into a neutral white wine and, especially after treatment with GIBBERELLIN growth regulators to increase BERRY SIZE, is a much sought-after crisp, green, seedless TABLE GRAPE. In widely varying locations, it has provided base material for some (usually undistinguished) wines. In some viticultural regions, such as Australia's RIVERLAND and California's CENTRAL VALLEY, the Sultana harvest has occasionally been diverted to whatever happens to be the most profitable end use, including wine in times of wine-grape shortage.

Sumer. In ancient Sumer (3500–1900 BCE), the earliest literate civilization of southern MESOPOTAMIA, wine and BEER were both widely consumed and are often mentioned as being drunk on the same occasion. 'Wine' almost certainly refers to grape wine in most contexts, although date wine was also prepared by the Sumerians.

At the sacred city of Nippur, just downstream from Babylon, which stood on an important branch of the river Euphrates, the principal quay of the temple was known as the 'Quay of the Vine', although it

is not clear if this refers to an original commercial activity or to irrigation or is simply an ornate epithet of the sort beloved of Sumerian poets. In praise poetry addressed to King Shulgi, who was deified in his own lifetime (*c.* 22nd century BCE), the king's martial prowess with the double-edged axe is eulogized with the image of him 'spilling his enemies' blood on the mountain-side like the contents of a smashed wine jug'.

DRUNKENNESS seems to have carried no stigma of disapprobation. In a number of Sumerian literary works, the gods get drunk on wine and beer in circumstances which are not merely amusing but are dramatically important.

Sumoll, minor CATALAN red wine grape usually blended but starting to find favour, particularly in PENEDÈS, where it produces light and refreshing reds. Known as Vijariego Negra on the Canary Islands. The rare Catalan white Sumoll Blanc, unrelated to Sumoll, is also promising.

sunburn can damage grapes and is a viticultural term used loosely for a range of conditions. Classical sunburn produces a round halo of burnt skin on the side of the berry facing the sun's position in the western sky, as damage normally occurs in the afternoon. Such sunburn is due to a combination of bright sunshine, high air temperatures, and low winds, and the so-called 'hot spot' can be up

to 15 °C/27 °F above air temperature. Berries which were previously shaded from the sun are most sensitive, as their skins have not been conditioned by exposure to sunlight. Sunburn sensitivity is higher for vineyards suffering WATER STRESS because the leaves droop, leading to greater sun exposure.

The condition in which grapes develop pigmentation in response to the ULTRAVIOLET component of sun exposure is also loosely called sunburn, although this is a change in skin colour rather than damage. This is particularly obvious with some white varieties, and the skin can develop deep yellow or even brown colours. Whether such exposure is harmful to the berry is arguable, and exposure to sun encourages the production of a range of PHENOLIC compounds, including QUERCETIN (see FLAVONOLS), which are generally associated with wine quality, especially for red varieties. Smart, R. E., and Sinclair, T. R., 'Solar heating of grape berries and other spherical fruits', *Agricultural Meteorology*, 17/4 (1976), 241–59.

Sunbury , historic Australian wine region in VICTORIA close to Melbourne's northern suburbs, principally known for Shiraz, that enjoys the cooling influence of the Macedon Ranges to the north and the ocean to the south.

sunlight, the ultimate energy source of all life and of wine itself. Through a process known as PHOTOSYNTHESIS, part of sunlight's energy is used by plants such as grapevines to combine CARBON DIOXIDE from the air with WATER taken up from the soil, to form SUGAR IN GRAPES. This is the building block for other plant products, as well as being the immediate source of energy for all of a plant's biochemical processes, via its RESPIRATION back to carbon dioxide and water.

In climatology the traditional measurement of sunlight was as hours of bright sunlight, but it is now generally measured in terms of

total energy using electronic sensors. This is more pertinent in viticulture since photosynthesis of individual grapevine leaves is 'light-saturated' at around one-third full sunlight, although a CANOPY of leaves will photosynthesize at higher rates with increased sunlight. Photosynthesis is reduced at very low light levels in a shaded canopy. It is also reduced by high (> 35 °C/95 ?F) or low (< 15 °C/59 ?F) temperatures and by WATER STRESS.

The amount of sunlight received at the Earth's surface depends primarily on factors related to location and cloudiness. LATITUDE, time of day, and time of year determine the potential sunlight at any one place—higher at lower latitudes, at midday, and in summer. Clouds have two important characteristics: they absorb and scatter sunlight. So at the Earth's surface, the proportions of direct and diffuse sunlight depend on cloudiness. This in turn depends on atmospheric conditions and location, typically higher in maritime than in interior regions. The latter are generally more arid and have fewer clouds, receiving more sunlight and therefore being hotter. They are more common in, for example, North and South America, Australia, and South Africa, while much of Europe is more cloudy.

Cloudiness may have more implications for viticulture and wine quality than have been reported. With cloudless skies, around 85% of sunlight is in the direct solar beam, so there are shadows of low sunlight intensity behind a single leaf layer (see CANOPY MICROCLIMATE), and either shadows or sunlit portions occur within the canopy. However, when the sky is cloudy, the solar beam is diffused and comes from all over the sky; there are no distinct shadows, and light penetrates deeper into the canopy, so that a higher proportion of the leaves and berries are sunlit, although they receive lower sunlight levels and will be cooler. A cloudy climate may therefore affect GRAPE COMPOSITION AND WINE QUALITY in ways that have not been widely researched.

Another important role of sunlight in viticulture is that of heating the vines and the soil. Grape berries for example may be heated up to 15 °C/27 ºF above air temperature for black berries exposed to bright sunlight in low wind conditions. Leaves are heated less when

exposed to sunlight, as they are evaporatively cooled by the process of TRANSPIRATION. Berry temperatures are of considerable importance in affecting the chemical make-up of the grapes. Similarly, leaf temperatures have important effects on photosynthesis and RESPIRATION, and this also directly affects GRAPE COMPOSITION AND WINE QUALITY. Soil temperature depends on the reflectivity to sunlight of the soil surface; thus dark soils absorb more sunlight and are warmer than white or light-coloured soils (see SOIL COLOUR). The total amount of sunlight energy over all of the spectrum is important in heating vines and soils.

The intensity of sunlight is not its only characteristic of importance to grapevines. Another is spectral quality or the proportion of sunlight at different wavelengths. This does not vary greatly from region to region or under full sunlight versus cloud; but it does vary enormously within the vine canopy.

The total spectrum of solar radiation comprises ULTRAVIOLET RADIATIONS, visible light, and infrared (heat) radiations, in order of increasing electromagnetic wavelengths. Visible light is in the wavelength range 400–760 nanometres (nm) (1 nm is one-millionth of a millimetre). Within that range, in order of increasing wavelength, are the component colours of the visible light spectrum: violet, indigo, blue, green, yellow, orange, and red.

Most of the wavelengths between 400 and 700 nm are absorbed by leaves and are used to varying degrees for photosynthesis. Those absorbed and used most efficiently are in the blue and (especially) red parts of the spectrum, centred around 440 and 660 nm respectively. It is the partial reflection of the intermediate wavelengths, by the photosynthetically active pigment chlorophyll, that gives plant leaves their characteristic green colour. Thus shade light, as well as being much less intense than full sunlight, is still more impoverished of its photosynthetically useful wavelengths. If overall light intensity is reduced eight- or tenfold, that of red light around 660 nm can be reduced a hundredfold in deep canopy shade.

Also important physiologically are the barely visible far-red wavelengths, between 700 and 760 nm. These and the adjacent

infrared wavelengths are hardly absorbed at all, being either reflected or transmitted through the leaves. Canopy shade light is therefore relatively rich in them. The ratio of normal red to far-red wavelengths (measured as 10-nm-width bands centred around 660 and 730 nm, and known as the R : FR ratio) is between 1.0 and 1.2 in the open, whereas in deep canopy shade it can be 0.1 or less.

It is the R : FR ratio, rather than light intensity as such, that appears to govern many plant reactions to shading within the canopy, probably through the action of a wavelength-sensitive pigment known as phytochrome. A low R : FR ratio, characteristic of deep canopy shade, promotes rapid spindly stem growth (trying to reach the light); sparse leaves and light-green colour; sparse lateral branching; and poor bud FRUITFULNESS. Conversely, a high R : FR ratio, as in normal external light, promotes stocky growth, with strong lateral branching; deep green leaf colour; and good bud fruitfulness. Direct exposure of the bunches to such light also promotes the formation of ANTHOCYANIN pigments in the berry skins of red wine grape varieties and appears to be associated with superior flavour and potential wine quality.

Smart reviews general aspects of light-quality effects on grapevine growth and fruit composition and deals comprehensively with sunlight relations in the context of vine canopy microclimate, canopy management, and wine quality.

Suntory, traditional Japanese food and alcoholic drinks company that has discreetly become a significant player in the world's wine business. Founded in 1899, the company was selling a sweet red wine in 1907 and by 1936 was developing its vineyards in the Tomi

no Oka region of Yamanashi prefecture. It has since invested considerably in developing viticultural and oenological prowess in JAPAN and is one of the country's most important wine producers.

Its first foreign acquisition was Ch Lagrange in ST-JULIEN in 1983 when Suntory became the first non-Western company to own a Bordeaux CLASSED GROWTH. Five years later they acquired Weingut Robert Weil, one of the best-run estates in the RHEINGAU, still run by Wilhelm Weil. Both properties have benefited from considerable investment. In 2010, when the Chinese wine market was booming, they acquired ASC, one of China's most successful importers, together with its Hong Kong and Macau operations. In Bordeaux, Suntory first participated with CASTEL in Grands Millésimes de France in 1989, and the company now operates both Chx Beychevelle and Beaumont as well as the négociant Barrière Frères.

www.jancisrobinson.com/articles/a-yen-for-quality.

Supérieur, Supérieure, or Supérieures, French term appended to the name of some AOC wines (see BORDEAUX AOC and GRAVES) or to the term PREMIER CRU, generally signifying a more ambitious level.

Superiore, Italian term applied to DOC wines which are deemed superior because of their higher minimum ALCOHOLIC STRENGTH, usually by 0.5 or 1%, a longer period of AGEING before commercial release, a lower maximum permitted YIELD or all three. Among the more significant wines which fall into this category are the three BARBERA DOCs or DOCGs of PIEMONTE (Alba, Asti, Monferrato), BARDOLINO, CALDARO, FRIULI GRAVE, VALPOLICELLA, and VALTELLINA. Triggered by the EU reforms of 2008, the Superiore versions of several DOCs such as FRASCATI have been elevated to DOCG status while, confusingly, the normal DOC continues to co-exist. Promotions

like this are often petty compromises, born out of resistance to elevating the often much smaller historic CLASSICO heartland of a zone to DOCG status. W.S.

super second, a specialist term in the FINE WINE market for CLASSED GROWTH wines from BORDEAUX to denote the best-performing wines that are not actually FIRST GROWTHS. There is no absolute agreement about which properties qualify as super seconds, and reputations are constantly changing, but in the MÉDOC and GRAVES Chx Pichon-Lalande, Pichon-Baron, Pontet Canet, and Lynch Bages in PAUILLAC, Cos and Montrose in ST-ESTÈPHE, all three Léovilles and Ducru-Beaucaillou in ST-JULIEN, Ch Palmer in MARGAUX, and Ch La MISSION HAUT-BRION in PESSAC-LÉOGNAN have all been nominated at one time or another.

Supertuscan, term which emerged in the 1970s to describe the wines labelled as VINO DA TAVOLA made in the central Italian region of Tuscany. Prototype Supertuscans were Tignanello and SASSICAIA, both initially marketed by ANTINORI. The Vino da Tavola denomination was replaced by IGT in 1992, while 'Supertuscan' continues to be used for Bordeaux blends aged in BARRIQUE. For more details, see TUSCANY.

sur lie, French term meaning 'on the lees', customarily applied to white wines whose principal deviation from everyday WHITE WINEMAKING techniques was some form of LEES CONTACT. The term has been used most commonly for the French dry white MUSCADET to differentiate those wines which remained on their lees after fermentation, usually in tank, in an effort to increase flavour and texture. The practice, and term, has since spread south to the LANGUEDOC and outside France and has proved a useful way of adding flavour and value to the produce of relatively neutral grape varieties. See also STABULATION.

surmaturité, French for OVERRIPENESS.

surplus production was for years the single greatest problem facing the world's wine industry, aggravated by improved efficiency in the vineyard and falling consumption in Europe's important wine markets. The most palatable effect of this surplus for wine consumers has been its dampening impact on PRICES at the bottom end of the wine market.

Even in the late 1950s, relatively soon after the shortages of the Second World War, the world produced almost 15% more wine than it consumed, but wine consumption was rising rapidly, and it was assumed that demand would catch up. By the late 1970s, average YIELDS began to increase substantially. This was largely the result of increased viticultural proficiency but also reflected the availability of particularly productive CLONES of established vine varieties, as well as FERTILIZERS and the more widespread use of AGROCHEMICALS to combat VINE DISEASES. Just at this point, consumption began to decline, especially markedly in the principal wine-producing countries (which had been the principal wine markets): France, Italy, USSR, Spain, and Argentina.

The exceptionally large European harvests of 1979 and 1980 plunged what is now the EU into crisis and forced measures which included compulsory DISTILLATION of about one-fifth of total production (only of the lowest-quality wine), a VINE-PULL SCHEME, and a somewhat fruitless attempt to control yields, which continued to rise by an average of about 0.5% a year. By the late 1980s, the world was producing 19% more than it could consume (see table), with particularly marked surpluses in France, Italy, and Spain as well as a surplus of industrial alcohol as a result of compulsory distillation.

World totals in million hl of wine

	Production	Consumption	Surplus	% Surplus
1976–80	326.0	285.7	40.3	12

Note: These figures are based on OIV official statistics.

The breakup of the Soviet Union, long a net wine importer, and the introduction of free-market economies within the former Soviet republics in the early 1990s deprived many Eastern European wine producers of their traditional and none too fastidious market, creating fresh pressure on the world's wine suppliers.

Surpluses on a smaller scale, sometimes simply of the wrong type of wine, have resulted in national vine-pull schemes such as those enacted in NEW ZEALAND and ARGENTINA in the late 1980s and early 1990s respectively.

By the early and mid 1990s, there was over-production in all continents except the Americas, most especially in Europe and particularly of poor-quality TABLE WINE. This did nothing to alleviate severe shortages in the mid to late 1990s of red wines suitable for export in many countries, however, most notably in South Africa and Australia, where there was a shortage of commercially desirable wine grapes of both colours. Substantial plantings of Chardonnay vines in the mid 1990s in Australia and California resulted in a surplus of that grape variety.

In the late 2000s, the EU, concerned about the size of its WINE LAKE, embarked on a rigorous programme of draining it with a vine-pull scheme and limitations on new plantings. The result was a dramatic decrease in total EU vineyard area, and total vineyard area shrank throughout the ex-Soviet republics, but this was partly outweighed by extraordinary vineyard expansion in China.

However, this has been offset to a large extent by increased vineyard productivity and vineyard expansion outside Europe—especially in China. Overall, the total annual volume of wine produced since 2000 has see-sawed within a range of 250–290 million hectolitres according to the vagaries of weather, government policies, and global events. At the same time, global wine consumption has fluctuated within a range of 230–250 million hectolitres. The gap between production and consumption is narrowing, but for the time being the global wine surplus remains a stubborn fact of life.

Surrentine wine from vineyards on the slopes of the Sorrento peninsula in southern Italy achieved prominence from the latter half of the reign of Augustus in the first decade of the 1st century CE. It ranked high in Classical ROME, but behind CAECUBAN and FALERNIAN, in PLINY's assessment. It was produced from the vine known as the

Aminea Gemina Minor, which, unusually for one of the classic wines, was trellised rather than grown up trees. The wine itself was a rather thin white wine, which nevertheless could be described as 'strong'. It may well have had high acidity. There are recommendations to age it for 20 to 25 years. It never won universal approval—'a high-class vinegar' was the opinion of both the emperors Tiberius and Caligula, and there are some signs that its MEDICINAL properties were among its most important selling points. J.J.P.

Pliny the Elder, *Natural History*, translated by H. Rackham (1945), Book 14.

sur souches, French expression meaning 'on the stumps' or, in the context of a purchase of a future vintage of wine, 'on the vine'. The BORDEAUX TRADE has, at times of particularly buoyant sales, occasionally bought futures in a crop even before it was harvested.

Süss, literally 'sweet' in German. Used on labels in AUSTRIA to designate wines with more than 45 g/l RESIDUAL SUGAR.

Süssreserve, German term for SWEET RESERVE, the unfermented or part-fermented MUST much used in the 1970s and 1980s to sweeten all but the finest or driest German wines. Its use has drastically declined because GERMANY is making an increasing proportion of dry wines (see TROCKEN and HALBTROCKEN) and because better producers of sweeter wines prefer to stop the fermentation while there is still some RESIDUAL SUGAR in the wine rather than add unfermented juice.

sustainability has become an increasing concern for wine producers, shippers, merchants, and consumers. In an era of CLIMATE CHANGE, environmental concerns have been uppermost, but considerations of economic and social sustainability are becoming increasingly common too. Santiago-Brown defines sustainability as

'the continuous pursuit of equilibrium between economic, social, and environmental variables and their trade-offs over time'.

For producers, and certainly for vine-growers, SUSTAINABLE VITICULTURE is the most obvious first step, but an increasing number are considering their entire CARBON FOOTPRINT, including thorough consideration of all vehicles, equipment, and products used in the vineyard, winery, cellar, packaging, and even shipping. Some producers market themselves on their sustainable credentials, planting trees and practising REGENERATIVE VITICULTURE to act as carbon sinks, insulating their buildings, recycling with a vengeance, and switching to low-input (such as electric) vehicles and alternative energy sources. Many of these decisions result in increased costs, however, demanding a reconciliation of environmentally sound choices with economically feasible ones—and all of these decisions have to be made with potential wine QUALITY in mind. For example, temperature-controlled shipping containers can increase carbon use, but many producers and retailers of fine wine would argue that they are necessary to avoid heat damage. On the other hand, a producer of more basic wine may well decide that shipping to export markets in BULK is more sustainable than BOTTLING at source. Others may decide to reduce the amount of energy needed for packaging and shipping by choosing ALTERNATIVE PACKAGING for their wine.

Within the winery, some of the most important considerations are water and energy usage and what happens to the wide range of WINERY WASTE. Winery waste-water recycling is becoming more widespread worldwide, often through legislative pressure, with waste water typically recycled for non-potable purposes such as IRRIGATION and cooling systems. But temperature control can use enormous amounts of energy. Sustainability-aware producers are increasingly locating or relocating temperature-sensitive operations (i.e. most of them) to hillsides or underground where temperatures are naturally low. Sustainability concerns are becoming increasingly important in WINERY DESIGN. Outside pressure, including generous tariffs for adopters (notably in Germany and California), is also encouraging the

use of renewable energy, often helped by dramatic reductions in the price of alternative energy sources such as solar-powered cells.

The final stage of production, BOTTLING, is the heaviest consumer of energy via glass BOTTLE production. Wineries may select lighter glass and recycled glass bottles to reduce energy consumption.

Around the globe, many regions have developed sustainability schemes to encourage producers to improve their practices. Oregon, California (especially the Napa Valley), New Zealand, and South Africa were quicker off the mark than most. The social and economic elements of long-term sustainability depend fundamentally on the overall health of the LABOUR force, a business's compliance with local laws, the financial stability of the business, and the local ECONOMY.

For many consumers, recycling wine bottles is one of their most obvious contributions to sustainability of any sort. In some parts of the world it is possible to recycle other aspects of wine packaging, including CLOSURES. There has also been a discernible increase in selling wine in bulk to environmentally aware consumers with their own recycled bottles, a throwback to traditional practice in some of Europe's wine-producing areas.

sustainable viticulture, a systemic approach to growing wine grapes that pursues the goal of a socially equitable, environmentally sound, and economically feasible vineyard and takes into account the particular context of the wine region where the grapes are grown. Its objective is to promote a vineyard that will provide economically for the winegrower while maintaining its ability to consistently produce and improve grape quality over time. Because of the unpredictable nature of agriculture, there may be trade-offs over the medium term. For example, in a wetter growing season with higher disease pressure, money may be spent on extra fungal sprays and not on improving an irrigation system; in the event of FROST or fire damage, financial resources might not be sufficient to invest in new machinery at the same time.

Conventional, ORGANIC, BIODYNAMIC, and REGENERATIVE farming systems are all pathways to achieving sustainability in wine-grape growing provided all pillars of sustainability—environmental, social, and economic—are embraced and the grower is committed to following sustainability principles and best practices in viticulture. Different sustainability programmes use different methodologies to assess vineyards, and to date there is no consensus on the minimum targets or the best methods to assess them.

Inkwell Wines' ORGANICALLY certified SHIRAZ vineyard in the South Australia's MCLAREN VALE is farmed according to the principles of SUSTAINABLE and REGENERATIVE VITICULTURE. The meadowflower insectary in the foreground dramatically decreases PEST and VINE DISEASE pressure. Mid-row COVER CROPS promote soil life and CARBON sequestration while promoting water conservation and a healthy CANOPY. © Dr Irina Santiago-Brown

Environmentally sound vineyards aim to carefully manage external on-farm inputs (e.g. water, chemicals, fuel) and reduce the use of synthetic chemicals. Socially equitable vineyards employ staff ethically and without bias and support the communities to which they belong. Economically feasible vineyards endure as businesses over time.

Sustainability assessments were developed in order to collect data, educate growers, and respond quickly to a world in constant change. Climate change, race, gender, and social-equity awareness movements as well as scientific discoveries are key factors in the evolution of programmes in viticulture. In response to such factors, many have been reshaped to improve decision-making, make claims of sustainability more measurable, and give consumers the ability to see beyond marketing-speak. Such assessment programmes include California Sustainable Winegrowing Alliance (CSWA), Sustainable Winegrowing New Zealand (SWNZ), Sustainable Wine South Africa (SWSA), and HVE, among others.

Susumaniello, lively, deep-coloured PUGLIAN red wine grape. One of SANGIOVESE's many offspring.

Svatovavřinecké, Czech name for ST-LAURENT.

Swan District, Australia's second oldest wine region, established in 1829, in WESTERN AUSTRALIA. FORTIFIED WINES, long a specialty in the hot climate, remain the state's best when produced by the likes of Talijancich, Faber, and John Kosovich. These days, however, more attention is paid to dry wines, especially CHENIN BLANC (the district provides nearly 60% of the state's Chenin production) as well as SHIRAZ and GRENACHE from 890 ha/2,199 acres of vines in 2020.

E.L.L.

Swan Hill, hot Australian wine region immediately south-east of the Murray Darling region, straddling the Murray river, partly in VICTORIA and partly in NEW SOUTH WALES.

sward. See COVER CROP.

Swartland, fashionable wine-producing district in SOUTH AFRICA which, since the late 1990s, has attracted some of the country's most adventurous and least interventionist winemakers. This focus is partly explained by the relatively high percentage of older vineyards planted with varieties well suited to DRY FARMING. For red wines these are mainly Rhône varieties, while the whites are typically blends based on low-yielding old CHENIN BLANC vineyards. There is a strong community spirit here and an energetic local association of Swartland Independent Producers.

Sweden has a fringe climate for winegrowing, though CLIMATE CHANGE is increasing its potential. Though there is evidence of grape-growing for winemaking that dates to the Stone Age, modern Swedish wine production started in the 1990s and is centred around the southernmost municipality Skåne. Other winegrowing areas include the Baltic islands Gotland and Öland, Halland on the west coast, and Blaxta outside Stockholm. By 2020 Sweden had an estimated 150 ha/371 acres under vine. Key challenges include RIPENESS and ROT. SOLARIS is by far the dominant vine variety; RONDO,

Siramé, Cabernet Cortis, Muscat, Johanniter, FRÜHBURGUNDER, LÉON MILLOT, and REGENT are also favoured, as is VIDAL for ICE WINES. Some ambitious producers grow Chardonny, Merlot, and Pinot Noir. Sweden does not have to apply for EU PLANTING RIGHTS and does not have CONTROLLED APPELLATIONS. The potential for SPARKLING WINE production has inspired the Swedish Sparkling Wine Association to create rules to ensure even quality, including a minimum requirement of 85% Solaris, which keeps notable ACIDITY and generous fruit aromas.

Only one-eighth of Sweden's 200-plus wine growers are commercial operations. The Swedish MONOPOLY bans cellar-door sales, which forces wineries to rely simply on wine TOURISM. E.L.-L.

svensktvin.se

sweetness, one of the primary tastes involved in TASTING and a fundamental component of wine. It varies considerably and is sensed by taste buds principally on the tongue. Wines taste sweet mainly because of the amount of RESIDUAL SUGAR they contain (although the impact of this on the PALATE is greatly influenced by factors such as the levels of ACIDITY, TANNINS, and CARBON DIOXIDE in the wine as well as by the serving TEMPERATURE). ETHANOL, or alcohol, can also taste sweet, as can GLYCEROL and a high level of PECTINS. Any wine with less than 2 g/l residual sugar is considered bone dry, but a dry wine with residual sugar of less than 2 g/l that is relatively high in alcohol (such as many a Chardonnay, for example) can taste quite sweet. A sweet VOUVRAY, on the other hand, made in a cool region from the naturally acidic grape variety CHENIN BLANC, may contain well over 30 g/l residual sugar, but in youth it can taste dry.

A wide variety of different terms in different languages are used to describe sweetness, although they invariably relate strictly to the residual sugar rather than to the taste impression. The table below gives the official EU classification of sweetness levels. Producers are

not generally obliged to put this information on the label of a still wine (although see ALSACE), though it is mandatory for sparkling wines. See DOSAGE for specific terminology.

Some wine drinkers have been conditioned to be suspicious of any sweetness in a wine, perhaps because neophytes generally prefer some residual sugar (which is why it is not uncommon for wine BRANDS to contain some, up to 20 g/l even in red wines), and sweetness is therefore associated with a lack of sophistication. Some of the greatest wines of the world are sweet, however. So long as there is sufficient ACIDITY to balance the sweetness, a sweet wine is by no means cloying. Indeed, a comparative tasting of great young sweet wines is more likely to leave the taster with the impression of excess acidity than excess sugar.

See SWEET WINES and SWEET WINEMAKING for more details of sweeter wines.

sweetness codes are becoming more common on back labels and in sales literature. This is particularly true of RIESLINGS and ALSACE whites because they can vary so widely in how sweet they taste. They may take the form of a scale or numerical rating.

sweet reserve, preserved GRAPE JUICE held for BLENDING purposes, to sweeten wines. The unfermented grape SUGARS counterbalance the sometimes overly high ACIDITY of wines produced in cool regions (it was once widely used in parts of GERMANY, where such juice is known as *Süssreserve*) or from grapes naturally high in acidity such as RIESLING, UGNI BLANC, and COLOMBARD. The alternative, stopping the fermentation and leaving some RESIDUAL SUGAR, is harder to manage accurately.

Historically grape juice was preserved simply by adding offensively high doses of SULFUR DIOXIDE.

Modern REFRIGERATION and near-sterile FILTRATION enable the production of sweet reserve that does not reek of sulfur dioxide. The

sweet juice usually undergoes CLARIFICATION and refrigeration to eliminate yeast growth and can be stored at very low temperatures for up to 12 months.

In many wine regions, sweet reserve is being replaced by GRAPE CONCENTRATE or RECTIFIED GRAPE MUST. Grape concentrate is cheaper to store because it is much richer in sugar, which also prevents the growth of microorganisms so that it can be stored without recourse to expensive refrigeration. Rectified grape must is preferred simply because it more closely resembles a solution of sugar and water than does preserved juice.

sweet winemaking, the production of wines with noticeable amounts of RESIDUAL SUGAR and which may vary considerably in ALCOHOLIC STRENGTH and production techniques. Local regulations differ significantly but, with a few exceptions, non-grape sugar may be added only (and rarely) for the purposes of CHAPTALIZATION, to increase the final alcoholic strength, and not to add sweetness after fermentation. The most common method of sweetening basic wine is the addition of some form of sweet grape juice, followed by STABILIZATION (for any wine containing sugar is theoretically susceptible to a SECOND FERMENTATION).

RS g/l	English	French	German	Italian	Spanish
up to 4 (or not exceeding 9 provided that the total acidity expressed as grams of tartaric acid per litre is not more than 2 grams below the RS content)	dry	sec	trocken	secco or asciutto	seco
more than 4 and not exceeding 12 (or not exceeding 18 provided that the total acidity expressed as grams of tartaric acid per litre is not more than 10 grams below the RS content)	medium dry	demi-sec	halbtrocken	abboccato	semiseco
more than 12 and not exceeding 45	medium (or medium sweet)	moelleux	lieblich	amabile	semidulce
at least 45	sweet	doux	süss	dolce	dulce

The finest sweet wines are made by concentrating the SUGAR IN GRAPES, however, and the combined effect of the alcohol produced and the residual sugar tends to inhibit further YEAST activity. The four common ways of doing this are by the benevolent NOBLE ROT effect of

the botrytis fungus on the vine as it nears maturity in perfect conditions (see BOTRYTIZED wines); by processing frozen grape clusters (see ICE WINE and CRYOEXTRACTION); or by drying mature grapes either on the vine or after picking (see DRIED-GRAPE WINES). Many sweet wines are made by simply leaving the grapes on the vine for as long as possible in order to concentrate the grape sugars (see LATE HARVEST). If BOTRYTIS BUNCH ROT fails to materialize, the grapes simply start to raisin or shrivel, a condition known in French as *passerillé*. Such wines (sweet JURANÇON, for example), described as *moelleux* in French, can be extremely rich and satisfying but are typically less complex and less long-lived than those made from grapes transformed by the action of noble rot.

Some everyday sweet wines are made simply by fermenting the wine out to dryness and subsequently adding SWEET RESERVE, GRAPE CONCENTRATE or RECTIFIED GRAPE MUST just before a sterilizing membrane FILTRATION and sterile BOTTLING. These wines owe their stability not to their composition but to the fact that all microorganisms have been filtered out. They are best drunk within a year of bottling and within a day or two of opening the bottle. LIEBFRAUMILCH is an example of this type of wine, and the sweetening agent is called SÜSSRESERVE in German.

Another technique, sometimes employed for inexpensive sweet white wines, is to ferment a must relatively high in sugars, between 200 and 250 g/l, until the alcohol level has reached about 11 or 12%, and then chill the wine and add a substantial dose of SULFUR DIOXIDE.

One quite different way of transforming grapes into a liquid that is both sweet and stable is to add spirit to grape juice either before fermentation (see MISTELA) or during it (see VIN DOUX NATUREL). Such liquids are usually more than 15% alcohol, much stronger than most table wines.

Many FORTIFIED WINES are sweet. See also LATE HARVEST, BOTRYTIZED wines, DRIED-GRAPE WINES, and ICE WINE for details of how these particularly fine sweet wines are made.

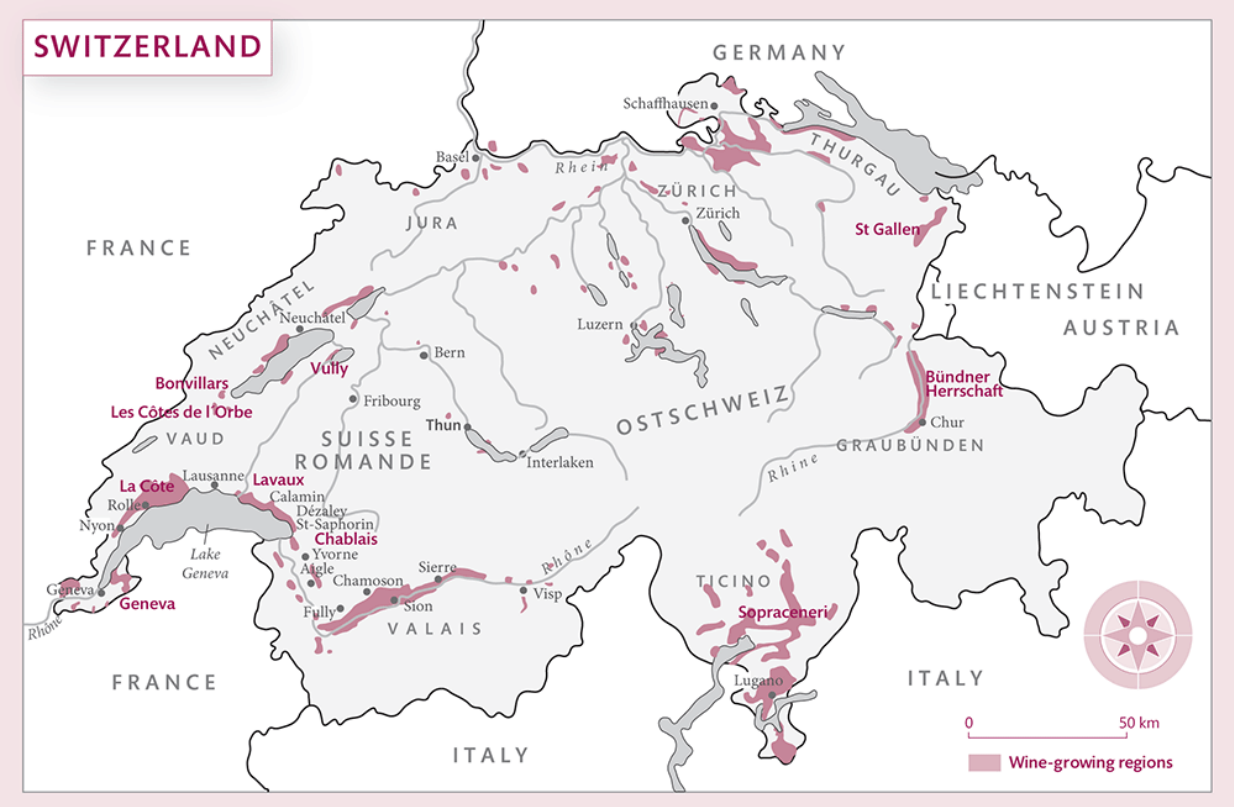
sweet wines are widely under-appreciated, especially in view of how difficult some of them are to make (see SWEET WINEMAKING). Sweet wines have been popular for various periods since ancient times; indeed, most of the most admired wines of classical ROME were sweet and white, many of them DRIED-GRAPE WINES made by deliberate raisining to concentrate the sugars. In the Middle Ages the great city states of Italy such as VENICE and GENOA profited from the popularity of wines made so much sweeter than northern European wines by the effects of the MEDITERRANEAN CLIMATE. By the late 17th century, the DUTCH WINE TRADE was energetically profiting from the sweet wines of western France. And subsequently the sweet wines of CONSTANTIA and TOKAJ in particular were considered the height of FASHION.

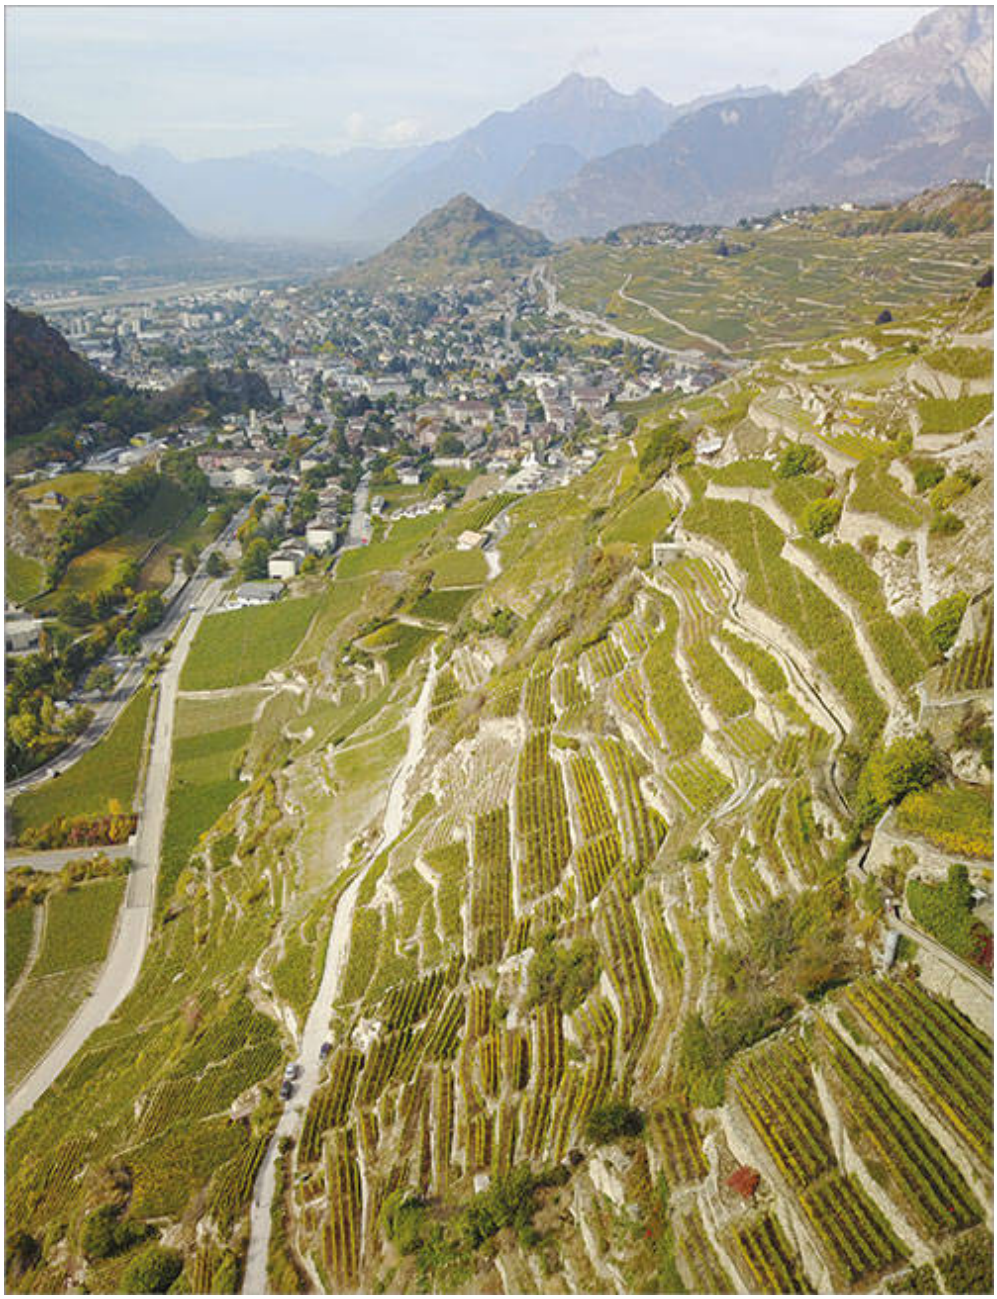
For specific modern sweet wines, see AUSLESE, BANYULS, BARSAC, BEERENAUSLESE, BONNEZEAUX, BOTRYTIZED wines, CÉRONS, CLAIRETTE DE DIE, EISWEIN, ICE WINE, JURANÇON, LAYON, LOUPIAC, MAURY, MOELLEUX, MONBAZILLAC, MONTLOUIS, various MOSCATELS, MOSCATO, MUSCAT, PICOLIT, PREMIÈRES CÔTES DE BORDEAUX, PX, QUARTS DE CHAUME, RASTEAU, RECIOTO, RIVESALTES, STE-CROIX-DU-MONT, SAUTERNES, SÉLECTION DE GRAINS NOBLES, SPECIAL LATE HARVESTED, TROCKENBEERENAUSLESE, VENDANGES TARDIVES, VIN DE PAILLE, VIN SANTO, and VOUVRAY.

See SWEETNESS for details of sweet-wine descriptions in various languages and what they entail.

Switzerland , small Alpine country in central Europe beginning to look outwards into the greater world of wine. Annual wine production is steady at slightly less than a million hl/26.4 million gal from about 15,000 ha/37,050 acres of often spectacular vineyards. The majority of these are in the western, French-speaking part of the country, Suisse romande. There are also extensive vineyards all over eastern, German-speaking Switzerland (or Ostschweiz) and many vineyards in Ticino, the Italian-speaking south of Switzerland (or Svizzera italiana). The country is divided into 26 cantons, of which all produce some

wine (see map). For many years, Swiss wine labelling lacked the discipline applied to the north in Germany or the controls imposed to the west in France, but from the early 1990s a CONTROLLED APPELLATIONS system was applied with increasing rigour, initially in French-speaking Switzerland. Since controls on wine imports were relaxed in the mid 1990s (and disappeared altogether in 2006), the Swiss wine industry has been forced to up its game, replacing much of the light, white, and relatively neutral wine that was once the norm with serious offerings of both colours. The principal white grape variety is CHASSELAS, and, when well vinified, it can express well the country's diversity of soils and climates. The Valais has a clutch of interesting INDIGENOUS VARIETIES, and some increasingly sophisticated red wines are made in all Swiss wine regions, particularly Ticino and Graubünden. Switzerland is able to supply only 35% of domestic consumption; 65%, mainly red wine, is imported.





TERRACED vineyards shaped by dry-stone walls—up to 23 m/75 ft high in some places—make viticulture possible and reduce SOIL EROSION in these HILLSIDE VINEYARDS in Sion above the Rhône Valley in SWITZERLAND's Valais region. Slopes are typically 50%, making MECHANIZATION in these small PARCELS virtually impossible. © Dr José Vouillamoz

History

Seeds from WILD VINES of the Neolithic Age, 3000–1800 BCE, have been found at St-Blaise in Neuchâtel, and recent findings of a significant amount of VITIS pollen in deposits below a lake near Sion in the Valais, as well as grape pips and PEDICELS at the Iron Age archaeological site of Gamsen near Brig in the Haut-Valais, suggest that winemaking already existed *c.* 800–600 BCE, before the ROMAN era. In the Middle Ages, vine-growing spread under monastic influence, notably that of the Cistercians (see MONKS AND MONASTERIES), who planted the original Dézaley vines in Vaud. As elsewhere, medieval wines were thin, acidic, and often helped by the addition of honey and other flavourings. In the 17th century, Swiss vignerons were already feeling the effects of wine imports from warmer climes, notably from further down the RHÔNE Valley.

Switzerland was far more seriously affected by the viticultural catastrophes of the late 19th century (see DOWNY MILDEW, PHYLLOXERA, and POWDERY MILDEW) than most other wine-producing countries. Between 1877 and 1957 the total Swiss vineyard declined by 60%, from 33,000 ha to 12,500 ha/30,890 acres, a decrease encouraged by competition from cheaper imported wines, increasing industrialization, and development of the all-important lakesides. In the mid 20th century, CLONAL SELECTION and FERTILIZERS were harnessed with particular enthusiasm in attempts to increase productivity from Switzerland's relatively inconvenient, expensive-to-work vineyards. More recent developments in both vineyard and cellar are concerned with quality.

Climate

Although Switzerland is on a particularly suitable latitude for wine production (45–47° N), a large proportion of the country is simply too high in ELEVATION. However, the country's lakes and the föhn, a local WIND which warms up sizeable portions of the south of the country, particularly Graubünden in the upper Rhine Valley, enable full grape ripening to take place in many valleys and on lakesides. And in the Valais in the south-west, sunshine is so dependable (an average of more than 2,000 hours a year, rising sometimes to over 2,500 hours) that vineyards can be up to 750 m/2,460 ft; some, such as Visperterminen, reach as high as 1,090 m above sea level. The Valais is sheltered by the Alps and, like south-east Switzerland, benefits particularly from the föhn, but it can be dry, and IRRIGATION with mountain water is sometimes necessary. Most Swiss wine regions have an annual rainfall of 500–1,800 mm/19.5–70 in a year, the wettest region being Ticino, which suffers violent but short (HAIL)storms and is also the warmest, with average July temperatures of more than 21 °C/70 °F. Elsewhere, average July temperatures are 17.5–20 °C with wide DIURNAL TEMPERATURE RANGE, and winter temperatures in the vineyards rarely fall below danger level for vines. The Valais is most at risk.

Viticulture

Slopes as steep as 90% in places and (in some regions) rainfall make SOIL EROSION a prime concern for many Swiss vine-growers. TERRACES are common in Switzerland's steep vineyards, and COVER CROPS are increasingly common. Sophisticated MECHANIZATION is possible only on some of the flatter vineyards on the plain or on some of the terraces of eastern Switzerland. A wide variety of TRAINING SYSTEMS are used, including CORDON, GOBELET, GUYOT, TENDONE (in Ticino), and the Swiss German speciality *taille à l'onglet* designed to protect the vines against spring FROST danger there. Elaborate monorail systems and sometimes even helicopters may be used to transport equipment and, at harvest, grapes.

Many vine-growers sell their grapes direct to NÉGOCIANTS or CO-OPERATIVES. YIELDS are nationally restricted, according to Switzerland's somewhat microscopic unit of measurement, to 1.4 kg/sq m for Chasselas grapes and 1.2 kg/sq m for red and superior white grapes, quite generous allowances, although some cantons, such as those of eastern Switzerland and Geneva, Neuchâtel, and the Valais, apply their own stricter limits, and national average yields are about the same as in France.

The most common viticultural problems are downy mildew, powdery mildew, BOTRYTIS BUNCH ROT, soil erosion, and occasional spring frost in the east of the country.

Switzerland's most important viticultural research station is at Changins (see AGROSCOPE) near Nyon in Suisse romande.

Winemaking

The essential stylistic difference between Swiss wine and that of neighbouring Germany and Austria is that ACIDITY is sometimes seen as an evil rather than a virtue; MALOLACTIC CONVERSION (MLF) is occasionally practised, particularly in the Vaud. However, many indigenous varieties, such as Arvine, Completer, and Rèze, have high acidity and do not undergo MLF. The resulting softness can be emphasized by the additional alcohol provided by CHAPTALIZATION. This pre-fermentation sugar addition had been common for many Swiss wines, although the practice is unnecessary in much of the Valais and the Rhine Valley and is eschewed by most of Switzerland's best artisan winemakers. Ordinary wines may have their alcohol content increased by up to 3%, although Swiss consumers are increasingly favouring lighter, drier wines.

Swiss PRESSES, made by Bucher and Sutter, are known throughout the winemaking world and are put to particularly effective work in their native land, where the aim is to extract as much juice as possible from the country's precious grapes with only the gentlest of pressure from an inflatable membrane.

DESTEMMING is the norm, and some form of CARBONIC MACERATION is often employed for German-speaking eastern Switzerland's red wines. As elsewhere, BARREL MATURATION has become increasingly popular for Swiss reds in general.

Switzerland has several pink wine specialities such as the Valais' Dôle Blanche, a blend of Pinot Noir and GAMAY grapes, and Œil-de-Perdrix ('partridge eye'), made only from Pinot Noir, originally in Neuchâtel. Federweisser (sometimes Federweiss) or WEISSHERBST are respectively white or rosé wine made from dark-skinned grapes in German Switzerland, where SCHILLERWEIN is a local rosé made from both red and white grapes grown and processed together, like GEMISCHTER SATZ in Austria.

Before the practice was banned in 2005, Swiss wine merchants depended on imported wines, particularly deeply coloured red ones,

to add bulk to many of their wines. Although Switzerland remains outside the EU, its CONTROLLED APPELLATIONS are in some instances stricter than those of the EU.

Vine varieties

Switzerland's most planted grape variety is Pinot Noir, or Blauburgunder as it is known by Swiss German speakers, planted on 29% of the country's vineyard land. CHASSELAS, or Gutedel in German, is the most planted white variety, with 27%. In the Valais it is called Fendant, a name used until the late 19th century in Vaud, where wines have since then been sold under their geographical appellations. Dorin in Vaud and Perlan in Geneva are brand names introduced in the late 20th century with mitigated success.

The conveniently early ripening MÜLLER-THURGAU, in Dr Müller's native land erroneously still known as Riesling-Silvaner or Riesling-Sylvaner, is the most common white grape variety in German Switzerland, having substantially replaced the historic RÄUSCHLING vine, particularly around Zurich just south of the German border.

Other white grape varieties include, in decreasing order of importance, CHARDONNAY, which can be elegant in the cantons of Neuchâtel and Geneva, richer in Vaud and the Valais; SILVANER, whose wines, fuller bodied than Chasselas, are sold as Johannisberg in the Valais; PINOT GRIS, called Malvoisie in the Valais; Arvine, the Valais' most revered indigenous variety; SAVAGNIN BLANC, known as Heida in the Valais, especially high up at Visperterminen, and its aromatic pink variant GEWURZTRAMINER; and SAUVIGNON BLANC, notably in Geneva canton.

Other red wine grapes include MERLOT, Switzerland's second most widely planted dark-skinned variety, reigning in Ticino to such an extent that it accounts for 80% of production; GAMAY, which is widely planted in Vaud, the Valais, and Geneva; GAMARET and GARANOIR, the most successful CROSS obtained at Changins; and SYRAH, which can produce respectably ripe wine in sheltered parts of the Valais. The northern Ticino speciality Bondola has largely been replaced by Merlot. In addition to Gamaret and Garanoir, a number of popular crosses have been developed since 1965 at Changins as suitable for Switzerland's very particular growing conditions: Charmont and Doral

(both Chasselas × Chardonnay); a Valais speciality, Diolinoir (Robin Noir × Pinot Noir); Mara, a full sibling of Gamaret and Garanoir; and Divico and Divona, two recent PiWis (see DISEASE-RESISTANT VARIETIES)

But of most interest to students of AMPELOGRAPHY is the Valais' rich collection of 14 ancient INDIGENOUS VARIETIES, each with substantial body, ageing potential, and its own whiff of history: the dry or sweet AMIGNE, mainly in Vétroz; the powerfully scented and complex ARVINE; the elegant HUMAGNE BLANCHE; the almost extinct RÈZE; the local rarities of the Haut-Valais LAFNETSCHA and Himbertscha; and, among dark-skinned varieties, the noble and historical Rouge du Pays, today more usually known as CORNALIN, and the powerful HUMAGNE ROUGE, both initially originating from the neighbouring AOSTA VALLEY in Italy; Rouge de Fully (or Durize) and Eyholzer Roter are even rarer; COMPLETER is Graubünden's indigenous white wine grape.

The wine regions

Swiss wine country is divided into six main regions: in decreasing order of importance, Valais, Vaud, German-speaking Switzerland, Geneva, Ticino, and Trois-Lacs (Neuchâtel). The country's emerging controlled appellation system is applied by each canton individually.

Valais The 4,766 ha/11,777 acres (2020) of productive vineyards of this south-western canton produce 40% of every Swiss vintage. Concentrated on the south-facing slopes of the sunny upper Rhône Valley, the region is known as 'the California of Switzerland'. Many of these beautiful vineyards are terraced with historic dry-stone walls into *tablars*, horizontal slices of vineyard cut into the mountainside, farmed as a part-time activity by 22,000 smallholders. Typical of what they produce is the ubiquitous FENDANT (made from the Chasselas grapes which cover one-quarter of the *vignoble*) and medium-weight reds labelled either Pinot Noir or Dôle, a blend in which Pinot Noir must dominate the Gamay element, while up to 15% of other varieties may be included. (Dôle Blanche is a pale rosé made from a blend of Pinot Noir and Gamay grapes, with the permitted inclusion of up to 10% white wine in the final blend.)

Some of the most concentrated Silvaners, sold here as JOHANNISBERG, come from particularly well-favoured sites at Chamoson. ARVINE is accorded the greatest respect, however, for its exotic intensity; while Cornalin (or Rouge du Pays), Syrah, and Humagne Rouge (confusingly known as Cornalin in Aosta) make some of Switzerland's most characterful reds. Fine, sweet, late-harvest wines, made from Amigne, Ermitage (Marsanne), Malvoisie (Pinot Gris), and Arvine picked in November and December, can easily reach 20% POTENTIAL ALCOHOL. They may be described as FLÉTRI, or withered, a reference to partial raisining on the vine. In 1996 a few dozen of the best producers introduced a strict quality charter, Grain Noble ConfidenCiel. Wines made from such indigenous varieties as Rouge de Fully (Durize), Lafnetscha, Himbertscha, and Rèze are curiosities, the last featuring historically in the VIN DES GLACIERS from the Val d'Anniviers above Sierre.

Vaud Switzerland's second most important wine canton is also in French Switzerland, round the northern shore of Lake Geneva, or Lac Léman (almost everything has at least two names in Switzerland). The canton's six wine regions are La Côte, Lavaux, and Chablais on the north shore of Lake Geneva, Les Côtes de l'Orbe on the plain between lakes Geneva and Neuchâtel, Bonvillars on Lake Neuchâtel, and Vully on Lake Morat. The canton's eight appellations encompass the six regions as well as two GRANDS CRUS: Dézaley in the commune of Puidoux and Calamin in the commune of Epesses. Chasselas accounts for 70% of the production from about 3,800 ha/9,390 acres, although, under the influence of the Vaud's varied soils, its character can vary from almost insultingly innocuous to an almost POUILLY-FUMÉ-like steeliness. In La Côte, the aromatic floral notes of the variety itself tend to dominate the wines. In Yvorne, Aigle, Bonvillars, and Calamin the mineral character of individual soils can easily dominate the fruit, while Dézaley and St-Saphorin often manage to demonstrate both fruit and MINERALITY.

A little Chardonnay and Pinot Gris are also grown here. Red wines, especially Gamay, are a speciality of La Côte, although Plant Robert, an old BIOTYPE of Gamay, is a speciality of Lavaux. Salvagnin, a designation accorded by a special tasting panel, approximates to a Vaud version of the Valais' Dôle, although it can be made from Pinot Noir or Gamay or both. Similarly, Terravin is a Chasselas whose quality has a local seal of approval. Many of Switzerland's largest NÉGOCIANTS are based here.

In 2002 some of the best producers, including Domaine La Colombe, Pierre-Luc Leyvraz, and Blaise Duboux, created the association Arte Vitis to promote Vaud's TERROIRS.

Geneva The 1,400 ha/3,460 acres of vineyards around the city at the south-western end of the lake are much flatter than those of the Valais and Vaud and benefit from good sunlight, those next to the lake often escaping spring frost danger. Chasselas dominates white wine production, and Riesling-Sylvaner (Müller-Thurgau) is on the wane, while all manner of newcomers, including Chardonnay, Aligoté, Sauvignon, Sémillon, and Kerner, have become popular. In reds, Gamay clearly dominates and is particularly successful here, whether as a well-STRUCTURED red, a PRIMEUR or a rosé. Pinot comes second, closely followed by GAMARET, planted extensively in recent years (120 ha/297 acres by 2020). GARANOIR, Merlot, and even Cabernet Sauvignon are increasingly popular with growers and consumers alike. This was the birthplace of Switzerland's burgeoning controlled appellations.

Neuchâtel Only 600 ha/1,480 acres of the ancient CALCAREOUS soils, on the well-situated south-facing slopes above Lake Neuchâtel, grow vines, but with characterful results. Pinot Noir and Chasselas feature as usual. The pale pink Pinot Œil-de-Perdrix is a Neuchâtel invention, as is the Chasselas *non filtré* (unfiltered) released on the third Wednesday in January following the harvest. This was the first canton to restrict yields.

Eastern cantons In Switzerland's 17 German-speaking cantons are 2,600 ha/6,425 acres of vines, ranging from 0.2 ha in Nidwald to more than 600 ha in the canton of Zürich. Schaffhausen, effectively an outcrop into south BADEN in Germany, has nearly 500 ha/1,483 acres of vines. Here in eastern Switzerland nearly 80% of production is red wine, particularly the rot-resistant Mariafeld and 2–45 clones of Blauburgunder (Pinot Noir) and, to a lesser extent, the crosses Gamaret and Garanoir developed locally at the Changins viticultural research station. Räuschling is once again gaining ground in Limmatal and on the shores of the lake south of Zürich, where Blauburgunder is often labelled Clevner. Riesling–Sylvaner (Müller-Thurgau) is the dominant white grape variety of eastern Switzerland, while Completer

is a local speciality of Bündner Herrschaft near the border with Austria and Liechtenstein in Graubünden, where a small quantity of sweet Freisamer and serious red wine, mainly Blauburgunder, is also produced.

Italian-speaking Switzerland There are just over 1,100 ha/2,718 acres of vineyard in the southern canton of Ticino, with barely 30 ha over the border with Graubünden in the Italian-speaking Mesolcina Valley. This makes Ticino Switzerland's fourth most important wine canton, and 80% of its production is of the Bordeaux red variety Merlot, imported in 1906. Here, vineyards lower than 450 m/1,475 ft are sunny enough to ripen this variety; higher vineyards may have to concentrate on Pinot Noir. Merlot del Ticino can be relatively light or, from well-sited vineyards and carefully vinified, often using new oak, can be a serious challenge for fine red bordeaux. The pale yellow Merlot Bianco, made from gently pressed black-berried Merlot, has become quite popular. Sopraceneri, north of Monte Ceneri, is an important wine region of which the local red grape variety Bondola is a speciality. It tends to be included in the rustic local version of 'house wine' called Nostrano, or 'ours', as opposed to Americano, which may include the HYBRIDS and AMERICAN VINES still representing 7% of total production here.

Other cantons The German-speaking but central canton of Bern has more than 200 ha/495 acres of vines, mainly on the north shore of Lake Bienne, although there are some vines on the Thunersee west of Interlaken. On the southern shores of Lake Neuchâtel are 100 ha of mainly Chasselas and Pinot Noir in the canton of Fribourg, most of them on the north shore of Lake Morat. The Swiss canton of Jura also has a few hectares of vines. J.R. & J.V.

www.swisswine.ch

Sylvaner is the French name for the Eastern European variety known in German as SILVANER (under which name details of all non-French plantings appear). In France it is practically unknown outside ALSACE, where it was the most planted vine in the lower, flatter, more fertile vineyards of the Bas-Rhin until Riesling overtook it in the 1990s. Total plantings had fallen to 891 ha/2,202 acres by 2019.

Sylvaner may be an old vine and, at one time, an extremely important one in Germany at least, but in Alsace many of the wines are dull, even if quite full-bodied with good acidity (unlike many Pinot Blancs). Only specific TERROIRS such as the Grand Cru Zotzenberg and old vines manage to imbue Alsace Sylvaner with as exciting a character as the best FRANKEN Silvaners.

Sylvoz, a vine-TRAINING SYSTEM developed by the Italian grower Carlo Sylvoz in which canes of up to, say, ten BUDS in length are tied to a wire below a high CORDON. The vines can be trained with a high cordon, about 2 m/6.5 ft, or a mid-height cordon at about 1 m. Depending on the number of buds retained, the system can be very high yielding. A variation of the Sylvoz is the Casarsa system common in northern Italy, where the canes are not tied below the cordon but fall downward as a result of their own weight when bearing leaves and fruit. The Sylvoz system is suited to vines of high vigour, where high YIELDS are acceptable and where it is necessary to minimize pruning LABOUR. R.E.S.

Eynard, I., and Dalmasso, G., *Viticoltura moderna: manuale pratico* (1990).

Symingtons, leading family of PORT wine shippers for five generations whose group of port companies includes Graham, Dow,

Warre (the oldest British port company, founded in Oporto in 1670), Quinta do Vesúvio, Smith Woodhouse, and COCKBURN. The founder of the family firm was Andrew James Symington, who arrived in Oporto from Glasgow in 1882 at the age of 19 and afterwards married the Anglo-Portuguese Beatriz Leitão de Carvalhosa Atkinson, whose ancestors had been in port since the 17th century. (Many of the Symingtons are now dual nationals.) Andrew became a partner in Warre in 1908. At the time George Warre was senior partner in Dow, and in 1912 a swap took place whereby Symington took a share in Dow while Warre regained a part of the firm that his family had founded. The Symingtons ran production and the vineyards for the two firms while the Warres ran sales and marketing in London. The Warre family sold their remaining shareholding to the Symingtons in 1961. W. & J. Graham & Co. was purchased from the Graham family in 1970 along with the smaller sister company of Smith Woodhouse. The family owns Quinta do Bomfim near Pinhão, which provides the fruit for Dow (along with Quinta da Senhorada Ribeira, acquired in 1998, having originally been sold by the family in 1954 when the fortunes of port were at a particularly low ebb). It also owns Warre, Quinta da Cavadinha in the Pinhão Valley, and Graham, Quinta dos Malvedos at Tua. The group was instrumental in reviving interest in single-quinta ports in the late 1980s (see PORT, styles). In 1989 the Symingtons acquired Quinta do Vesúvio, a 326-ha/806-acre estate widely regarded as one of the finest vineyards in the Douro (see FERREIRA). From 1991 Quinta do Vesúvio has been a brand in its own right. The family personally own substantial additional vineyards whose fruit is sold to their various port companies. In 1996 a new winery, Quinta do Sol near Regua, was opened. The Symingtons operate another six small wineries on individual vineyards throughout the Douro, some of them equipped with the ROBOTIC LAGARES that the family pioneered in 1998. Between 2006 and 2010 the Symingtons bought COCKBURN, but each of these many companies has its own separate stocks, and the family maintains a full range of vintage and wood ports for each company.

In 1988 the BLANDY family offered the Symingtons a partnership in their MADEIRA business, hoping to reverse a general decline in sales of madeira. The Symingtons acquired a controlling interest in the Madeira Wine Company and ran it until 2011, when the Blandy family regained control, with the Symingtons remaining shareholders. The Symingtons have established their own wine distribution companies in Portugal, Britain, and the US.

The Symingtons have become firm believers in DOURO table wines. Their flagship wine Chryseia is made jointly with Bruno Prats, past owner of Ch Cos d'Estournel of ST-ESTÈPHE. In 2009 the two families acquired Quinta de Roriz, where Chryseia is now made. The Douro TABLE WINES Quinta do Vesúvio, Quinta do Ataíde, and the Altano range are grown on the family's Douro vineyards.

In 2017 the Symingtons acquired the 206-ha Quinta da Fonte Souto in the Alentejo with 42 ha/104 acres of vineyard situated at 490 m/1,608 ft in ELEVATION near Portalegre. Symington Family Estates is a B Corp, one of a group of companies independently audited for social and environmental standards, and is a member of IWCA (International Wineries for Climate Action).

Symphony, white-berried vine cross of red-skinned GRENACHE and light-skinned MUSCAT OF ALEXANDRIA developed in CALIFORNIA at DAVIS by Dr H. P. Olmo. It has lived the tenuous existence of all crosses, especially ones that make powerfully aromatic wines. A small vogue as an off-dry white wine in the 1990s led to a flurry of new plantings, but the state total is again in decline, standing at 596 ha/1,472 acres in 2020.

symposium, meaning 'drinking together', was one of the most important social forms in the world of ancient Greece—a considerably less cerebral affair, then, than its 20th-century counterpart. From Greece it spread to Etruria and the rest of Italy and flourished until the end of antiquity. Symposia were usually intimate gatherings: the room normally held seven or 11 couches, on each of which two men

reclined on their left side, a custom adopted from oriental feasting; respectable women did not take part, and the servants and entertainers were mostly handsome slaves, both male and female. As part of the lifestyle of the leisured class, symposia were lavish affairs: in the richest households, the vessels for the mixing and drinking of wine would have been of gold or silver, although most will have been content with fine painted pottery. Both the shapes and the decoration of Greek pottery bear witness to the strong influence of the symposium.

The drinking of wine at the symposium followed the meal and was distinct from it, although a dessert of nuts, fruit, cakes, and the like often accompanied the wine. The end of the meal proper was marked by the drinking of a small amount of neat wine in honour of the 'Good Daemon' as a 'demonstration of the power of the good god', after which the tables were removed and the guests washed their hands and were offered garlands and perfumes. The wine was then mixed with water in a *krater* (mixing bowl; see CRATER) according to one of the numerous possible ratios (as detailed under ancient GREECE). From each bowl, a LIBATION was first offered together with a prayer (the god or gods invoked seem to have varied), and the Paean, a hymn of praise to Apollo, was also sung at the beginning of the proceedings by the whole company. A standard *krater* had a capacity of 14 l/3.7 gal, and various ancient writers indicate that three *kraters* would be emptied at a temperate symposium, so, although the alcoholic strength of the mixture was not high, the amount consumed must have been considerable (42 l for 14 or 22 people, apparently). The ratio for the dilution of the wine was determined by a *symposiarch* or master of ceremonies, chosen from the company, who also regulated the progress of the drinking: he could propose toasts and order any member of the company to drink more, the aim being to maintain a level of pleasurable but controlled intoxication. However, since the drinking involved an element of competition and the proceedings might last all night, the outcome was often outright DRUNKENNESS, as vase paintings and literary evidence make clear.

The most basic forms of entertainment arose out of the drinking itself: there were various drinking challenges with forfeits, and the heeltaps of wine were used to play the game of *kottabos*, in which each drinker would shoot the last drops of wine from his cup with a flick of the wrist at the target, which was usually a light bronze disc, balanced on top of a stand or tripod; when hit, it would fall into the basin beneath with a satisfying clatter.

Music and poetry played an important part in the entertainment: most, if not all, of the LYRIC POETRY of archaic Greece is now thought to have had its origins in the symposium, with its preoccupations of warfare and politics, wine and feasting, and love. Some extemporized poetry was no doubt sung at classical symposia, but it was more normal to perform existing poems, which often celebrated great men and deeds of the past: the collection of Athenian songs of this type (*skolia*) preserved in ATHENAEUS' *Deipnosophistae* (694–96 BCE) offers a sample of the traditional songs of one city.

Like the drinking, the singing was both communal and competitive: a branch of myrtle was passed round, and each man as he received it had to sing, sometimes picking up the song from the last singer, although good singers might be called on for a 'party piece'. Singers often accompanied themselves on the lyre, but slave girls were also hired to play the flute to entertain the company, to accompany singers, and to provide music for dancing; professional dancers, acrobats, and mimes might also perform. Flute players would also be expected to provide sexual services at the end of the evening if required (hence the assumption that any women present at a symposium were not respectable).

Urbane and cultured conversation was also an essential feature; at times this might be structured, and given a competitive aspect, by the posing of riddles or the exchange of witty (and often abusive) comparisons applied to fellow guests. This too might be stimulated by professional help: the career of the parasite who pays for his dinner with his jokes and clowning can be traced back to HOMER. The genre of the literary symposium, a gathering of learned figures conversing on literary or philosophic issues, as in Plato's *Symposium* (whence the

modern use of 'symposium'), may give a misleadingly high-minded impression of the average Greek symposium, but such discussion clearly had its place, albeit at a less rarefied level.

Finally, those revellers still awake might go out into the street as a *komos*, a mobile party with wine and music, calling on other symposia or making rowdy attempts to rouse those now asleep.

R.B.

Bibliographical note: the most recent detailed studies are Hobden, F., *The Symposion in Ancient Greek Society and Thought* (2013), and Węcowski, M., *The Rise of the Greek Aristocratic Banquet* (2014), especially Part I; Murray, O., 'The culture of the symposion', in K. A. Raaflaub and H. van Wees (eds.), *A Companion to Archaic Greece* (2009), 508–23, is an excellent overview.

Athenaeus' *Deipnosophistae* collects many stories of symposia, while XENOPHON's *Symposium* gives the flavour of a classical symposium better than the more famous one of Plato; both are accessible in translation in the Loeb Classical Library.

synthetic closures, also known rather imprecisely as 'plastic corks'. See CLOSURES.

Syrah, one of the noblest and most fashionable red wine grapes, if nobility is bestowed by an ability to produce serious red wines capable of AGEING majestically for decades and if fashionability is measured by the extent to which new CUTTINGS have been going into the ground all over the world, despite the depredations of SYRAH DECLINE. So valued was the durability of France's HERMITAGE, arguably Syrah's finest manifestation, that many red BORDEAUX were in the 18th and 19th centuries *hermitagé* (see ADULTERATION AND FRAUD). And so popular is the variety that in 2016 it was the world's sixth most planted wine grape of either colour, with a global total of 185,568 ha/458,353 acres.

Syrah's origins have been the subject of much debate and hypothesis, involving Syracuse in SICILY, ancient PERSIA (SHIRAZ being

its most common synonym, especially in Australia), the vine family *Vitis allobrogica* recognized as producing fine wine in the Rhône since Roman times (see RHÔNE, history). However, DNA PROFILING at DAVIS and MONTPELLIER in 1998 established that Syrah is in fact the progeny of two vines from south-east France, MONDEUSE BLANCHE and DUREZA. DNA probability analysis strongly suggests that PINOT is a great-grandparent of Syrah, and both Viognier and Mondeuse Noire seem to be closely related to Syrah too.

The vine is relatively productive and disease resistant, sensitive to COULURE but conveniently late budding and not too late ripening. Care has to be taken with ROOTSTOCKS because it is sensitive to CHLOROSIS. Its distinctively savoury qualities are much reduced once the YIELD is allowed to rise, and it has a tendency to lose aroma and ACIDITY rapidly if left too long on the vine.

Many vignerons in the northern Rhône, Syrah's homeland, distinguish between a small-berried, superior version of Syrah, which they call Petite Syrah (not to be mistaken for the variety known in North and South America as PETITE SIRAH), and the larger-berried Grosse Syrah, which produces wines with a lower concentration of PHENOLICS. However, AMPELOGRAPHERS reject this distinction; Grosse Syrah is a synonym of MONDEUSE NOIRE. On the other hand, the BIOTYPE that goes by the name of SERINE is worth distinguishing. The total ANTHOCYANINS in Syrah can be up to 40% higher than those in the tough, dark Carignan, which makes it, typically, a wine for the long term that responds well to OAK maturation, even new oak when the grapes are really ripe.

The most famous prototype French Syrahs—Hermitage and CÔTE RÔTIE—are distinguished by their longevity or, in the case of newer producers, ambition. Only ST-JOSEPH and that paler shadow CROZES-HERMITAGE can sensibly be broached within their first five years. Syrah that has not reached full maturation can be simply mean and ASTRINGENT, with more than a whiff of black pepper or burnt rubber. When planted on the fringes of the Rhône such as in the ARDÈCHE,

Syrah may avoid this fate only in riper vintages, which are becoming increasingly common.

Until the 1970s, French Syrah plantings were almost exclusively in and around the very limited vineyards of the northern Rhône Valley and were dwarfed in area by total Syrah plantings in the vine's other major colony, AUSTRALIA, where it is known as Shiraz and has been that country's major black grape variety for decades. For more details, see SHIRAZ.

Since then, however, Syrah has enjoyed an extraordinary surge in popularity throughout southern France so that total French plantings rose from 2,700 ha/6,670 acres in 1968 to exactly ten times that 20 years later; it had reached 67,040 ha by 2019, making it the country's third most planted red grape after Merlot and Grenache. The increases were noticeable throughout the southern Rhône, particularly in Châteauneuf-du-Pape country, where there was a FASHION for planting Syrah (although Mourvèdre is increasingly regarded as a more suitable blending partner for Grenache this far south). And in the Languedoc and Roussillon, Syrah has been so enthusiastically adopted as an officially approved 'improving variety' that adds STRUCTURE and savour to blends as well as yielding exciting VARIETAL wines that its 39,206 ha in 2019 made it the region's most planted variety, just ahead of Grenache. Yields very much in excess of the low yields that characterize the arid hill of Hermitage have tended to dilute its northern Rhône characteristics in many cases, producing a much more supple, more obviously fruity, if still savoury style of Syrah, often distinguished by a particularly polished TEXTURE. In the northern Rhône it is rarely blended, except perhaps with a little Viognier (the original CO-FERMENTATION recipe), while in the south it is typically blended with Grenache, Mourvèdre, Carignan, and/or Cinsaut. In Provence, the very Australian blend of Syrah and Cabernet Sauvignon is relatively common, and Syrah is one of the most successful vine imports to Corsica, where there were 509 ha/1,258 acres. Another unexpectedly successful site for mature, concentrated Syrah is the Valais in Switzerland, particularly around the suntrap village of Chamoson on the upper reaches of the Rhône

Valley. Here classic northern Rhône techniques are employed, sometimes to great effect. Although keener on Bordeaux grapes, Italians have been planting Syrah, whose total area in 2015 was 7,693 ha/19,010 acres, most successfully so far around Cortona in southern Tuscany. The variety was initially introduced to Piemonte from MONTPELLIER in 1899. Spanish growers have embraced the variety with even more enthusiasm with 2020 plantings of 17,617 ha/43,533 acres, more than half of them in CASTILLA-LA MANCHA. Spanish Syrah tends to be plumper than most, but pioneer Marqués de Griñon has made convincingly fine examples. In Portugal there were 6,133 ha/15,155 acres in 2020, mostly in the Alentejo and Lisboa regions. Syrah is planted to a limited extent in most warmer wine regions of Europe and the eastern Mediterranean, but only Türkiye has more than a few hundred hectares planted. To ripen fully, Syrah demands a warm climate, but if temperatures are too high its telltale fragrance is lost. This has acted as a brake on Syrah's success in the US. Perhaps partly thanks to the RHÔNE RANGERS, California growers rushed to plant the variety in the late 20th century; there were still barely 400 acres of it in the state in 1992, but by 2003 there were 6,800 ha/17,000 acres. But many of these plantings were opportunistic, Syrah the wine had no clear identity, the *SIDEWAYS* effect suggested Pinot Noir was more fashionable, and the variety may have been damaged by the low-quality image of cheap Australian SHIRAZ (see YELLOW TAIL, for instance). In 2020 total plantings were back down to 6,035 ha/14,912 acres, with a much more significant proportion of them in suitable areas and vinified by a sensitive hand. For more details, see CALIFORNIA.

Promising results from such vineyards as Red Willow, Cayuse, and various Red Mountain vineyards suggest that WASHINGTON State may have considerable potential for fine, bright Syrah wines. In 1999 only a handful of Washington Syrahs were produced, but by 2011 total plantings exceeded 1,850 ha/4,572 acres, surpassed only by Cabernet and Merlot. It is much less important in Oregon but is planted to a limited extent in many other US states warm enough to ripen the variety. Syrah, sometimes labelled Shiraz (the choice

generally reflecting the style of the wine), has been hugely popular in SOUTH AFRICA, so that its 2020 total plantings of 9,151 ha/22,613 acres make it the country's second most planted red wine grape after Cabernet Sauvignon. It is planted in all but the very coolest spots and makes wines in a wide range of styles. The introduction of virus-free CLONES has improved wine quality, but the variety is so susceptible to South Africa's own, fatal vine virus that can be transmitted via GRAFTS that it is known as Shiraz disease.

Much of New Zealand is too cool for Syrah, but plantings have increased to 444 ha/1,097 acres, chiefly in HAWKE'S BAY.

The variety has been hugely successful in CHILE, on the other hand, where total plantings grew from under 700 ha in 1998 to 7,400 ha/18,286 acres by 2020. The wines are generally relatively rich and dense although the range of styles has been widening as cooler areas are developed, resulting in more elegant, Rhône-like styles of Syrah. Argentina, where Malbec rather than Syrah is an obvious alternative to the Bordeaux grapes, nevertheless has even more land planted with Syrah, nearly 11,796 ha/29,149 acres by 2020, making it the country's sixth most planted variety of any colour. San Juan province seems particularly well suited to the variety, which is also grown in Bolivia, Peru, and Uruguay.

Syrah decline, mysterious fatal phenomenon affecting SYRAH exclusively, known as *dépérissement* in French, whereby a part of the trunk swells and becomes bulbous, generally around the graft (see GRAFTING), forming splits in the wood. The vine may continue to function normally for a few years, but eventually the leaves redden prematurely during summer, VIGOUR rapidly declines, and within a year or two the vine is dead. It was first noticed in the Languedoc in the 1990s and has affected Syrah virtually wherever it is grown, apart from Australia. The most susceptible Syrah clones are 73, 99, 100, 174, 300, 381, 382, 383, 525, 585, and 877; the least susceptible are 470, 471, 524, and 747. Syrah decline appears to be attributable to

physiological incompatibility between certain SCION clones and ROOTSTOCKS rather than to a VIRUS or other biotic agent. W.W.

Syria , country in the Middle East with—almost incredibly, considering its recent history (see WAR, EFFECTS ON WINE)—at least one first-class wine producer. Domaine Bargylus was founded in 2005 by the Saade family (also owners of Ch Marsyas in LEBANON) in the mountains above the port city of Latakia. Working with 12 ha/30 acres of vines planted in CLAY and LIMESTONE soils at 900 m/2,953 ft in ELEVATION, they produce a fine red blend of SYRAH, CABERNET SAUVIGNON, and MERLOT and a Bordeaux-style white blend.

Syria has a particularly long history of wine production (see ORIGINS OF VINICULTURE and MESOPOTAMIA).

Szamarodni, term used in Tokaj to denote a wine made from a mix of both ASZÚ and healthy berries. See TOKAJ for more detail.

Szekszárd , wine region and PDO in southern HUNGARY with a special LOESS soil as deep as 10–15 m/35–50 ft in places. The varied landscape allows different MESOCLIMATES to shape the wines. The steep slopes of the Szekszárd Hill are dissected by erosional valleys and ravines with the eastern and southern slopes generally providing the best wines. The KADARKA grape, once the chief component of BIKAVÉR, made Szekszárd's viticulture famous in the 18th and 19th centuries, and its attractively scented, relatively soft wine can once again be found fairly easily, either as a varietal Kadarka or in blends including BIKAVÉR. G.R. & G.M.

Szepsy, István , The most respected winemaker in Hungary. Records of his winemaking forebears date from at least the 16th century. He currently owns about 107 ha/264 acres of the best vineyard land in the TOKAJ villages of Mád, Bodrogkeresztúr, Tarcal,

Tállya, Mezőzombor, and Rátka, of which 54 ha/133 acres are planted. He created the new style of Tokaji dry wines by perfecting the selection of old Furmint CLONES and concluded that the best-quality wine can only be achieved by making dry wines or Tokaji Aszú from old vines from the first-growth PARCELS and in the best vintages such as 2017.

Szürkebarát, Hungarian name for PINOT GRIS.

TA. See TOTAL ACIDITY.

table grapes, the common term for those grapes specially grown to be eaten as fresh fruit. Of the grapes grown worldwide, table grapes represent the second most frequent use, following wine. Nearly 27 million tonnes were grown in 2016, and the trend is upwards. The most important producing country is China, followed at quite some distance by India, Türkiye, Egypt, and the US. The fruit is consumed primarily within the producing country because it is relatively low in value and perishable. However, with refrigeration the opportunities for export are increasing; Chile, for example, has developed a substantial export trade in table grapes over the last four decades. Table grapes are used widely by the emerging wine industries of ASIA.

The varieties of grapes for fresh consumption are usually specialized and different from those for wine and drying. They should taste good and have a reasonably consistent BERRY SIZE, bright colour, firm flesh texture, not too many seeds, and skins tough enough to withstand storage and transport. Recently developed seedless varieties are increasingly popular. Some important table grape varieties are Barlinka, Calmeria, CARDINAL, CHASSELAS, Dattier, Emperor, Flame Seedless, Gros Vert, Italia, MUSCAT OF ALEXANDRIA, MUSCAT OF HAMBURG, Perlette, Ruby Seedless, Alphonse Lavallée (Ribier), and SULTANA (or Thompson Seedless).

Table grapes are typically grown in warm to hot regions to encourage early maturity and freedom from any ROT brought on by rain. Low night temperatures assist the colour development of some varieties, while both very high and very low daytime temperatures

may inhibit colour development. Many of the table grape regions of the world are inland DESERT areas.

There are some important differences between table grape and wine grape vineyard management. For table grapes, the aim is generally to produce maximum berry size, and so IRRIGATION and FERTILIZERS are used more liberally than for wine grapes. Sloping and overhead TRELLIS SYSTEMS such as the pergola and TENDONE are common, where the shoots and leaves form a canopy over the fruit, avoiding excessive and direct sun exposure (see SUNBURN).

Because they are worth more than most wine grapes (although see Ch d'YQUEM, MONTRACHET, and DOMAINE DE LA ROMANÉE-CONTI), table grapes typically require more manual vineyard work. This can include SHOOT THINNING, CROP THINNING, and sometimes berry thinning. These practices lead to larger berries which ripen early. GROWTH REGULATORS are also commonly used to thin flowers, but more particularly to increase berry size of seedless varieties such as Sultana. CINCTURING or girdling can also be used to hasten ripening.

Table grapes are harvested earlier than wine grapes, as a lower sugar level and higher acidity make them taste more refreshing, in the range of 15 to 18 °BRIX (whereas wine grapes would preferably be harvested for dry wines at about 22 °Brix).

Some table grape varieties can be kept in cool stores for up to 20 weeks, although 8–12 weeks is more common. Long storage life is promoted by low temperatures such as −1 °C (at which the sugar content stops them freezing), a relative humidity of about 96%, and SULFUR DIOXIDE fumigation for mould control. R.E.S. & J.E.H.

FAO-OIV Focus, *Table and Dried Grapes* (2016).

table wine, term used internationally to distinguish wines of average ALCOHOLIC STRENGTH from FORTIFIED WINES, which have been strengthened by the addition of alcohol. In this context, 'table wines' rely solely on FERMENTATION for their alcoholic strength, which tends to be between 9 and 15%, occasionally even higher.

Within the EU, the term 'table wine' had until the reforms of 2008 a specific meaning and was applied to the vast but declining quantity of wine produced within it that did not qualify as superior so-called QUALITY WINE. Within Italy the situation was rather different, as explained in VINO DA TAVOLA.

In the US, the term 'table wine' denotes wine with less than 14% alcohol, while wines with between 14 and 24% alcohol are officially 'dessert wines', whether fortified or not, and attract a higher tax rate.

Tacoronte-Acentejo, DOP wine region of 1,014 ha/2,506 acres of vines on the west-facing slopes up to 800 m/2,625 ft in the north-east of the volcanic island of Tenerife in the CANARY ISLANDS. Tacoronte-Acentejo produces red wines made predominantly from the dark-berried LISTÁN Negro and NEGRAMOLL grapes. The fertile VOLCANIC soil imparts a peculiar character to these wines. V. de la S. & F.C.

Tahiti in French Polynesia has about 6 ha/15 acres of CARIGNAN, Italia, and MUSCAT OF HAMBURG on the island of Rangiroa on the Tuamotu archipelago which supplies Domaine Ampélidacées with two harvests a year using TROPICAL VITICULTURE techniques.

Tai Bianco, north-east Italian synonym for SAUVIGNONASSE that has replaced the name Tocai Bianco, to which Hungarians objected.

taille, French term for PRUNING. The name is also used in CHAMPAGNE and sometimes elsewhere for the coarser, later juice which flows from the PRESS in the traditional method of SPARKLING WINEMAKING.

taint is the term used to refer to the effect of an external CONTAMINANT once its presence can be tasted in a wine. See, for example, CORK TAINT, LADYBUG TAINT, and SMOKE TAINT. An off-flavour,

on the other hand, is generally the result of a chemical or microbial action within the MUST or wine.

Tai Rosso, north-east Italian synonym for GRENACHE.

Tairov. See UKRAINE.

Taiwan , otherwise known as the Republic of China, island off, and independent of, CHINA with about 3,128 ha/7,729 acres of vines in 2020 but fewer than 100 ha devoted to wine grapes. Prior to the dismantling of the government alcohol MONOPOLY following Taiwan's accession to the World Trade Organization in 2002, winemaking was prohibited. Today there are only a handful of wineries. Grape-growers favour HYBRIDS such as Black Queen for red wines and Golden Muscat for whites to deal with the heat, humidity, and rain, which averages over 2,500 mm/98 in annually, much of it falling during typhoon season. D.G.

Tajikistan , mountainous, former Soviet, central Asian republic between UZBEKISTAN and CHINA with 36,281 ha/89,652 acres of vineyards in 2020 according to the OIV, most of it for TABLE GRAPES and RAISINS.

Viticulture and winemaking were developed in Tajikistan even before the military campaigns of Alexander the Great in the 4th century BCE. Ancient documents testify to the cultivation of numerous VINE VARIETIES in the country, which were made into wine, vinegar, and *bekmes* (GRAPE CONCENTRATE), as well as being traded as table grapes and raisins. Viticulture was highly developed in Osrushan in Ura-Tyube, Fergana, and the Zeravshan Valley.

In the north, the adoption of ISLAM inspired growers to replace wine varieties with table and raisin varieties. Central, south, and south-eastern parts of the country were less affected by this trend. In

the Soviet era, grape production was ramped up such that the country was putting out 600,000 liters/158,503 gal of wine annually. Production nosedived after Mikhail GORBACHEV's anti-alcohol campaign in 1985, with massive uprooting of vineyards across the country; further economic and political stress has taken a toll such that fewer than five wineries remained in the 2010s.

talha, AMPHORA-like vessel traditionally used in the ALENTEJO in southern Portugal to ferment wine on skins (see SKIN-FERMENTED). The Roman ruins at São Cucufate evidence a long history of winemaking around Vila de Frades in VIDIGUEIRA, the epicentre of talha winemaking. The name is thought to derive from the Latin *tinalia,* meaning 'large pot'. Typically hand-made of local clay (although moulded concrete examples also exist), talhas come in different shapes and sizes. They are usually coated inside with *pez,* a mix of beeswax and pine resin, to reduce wine seepage and oxygen ingress through the clay. Seals of cloth, clay, wood, or olive oil protect wines from OXIDATION. A hole about 30 cm/12 in from the bottom is stoppered with a cork, or *batoque*, which is replaced with a spout for decanting the finished wine. The rise of Alentejo's CO-OPERATIVES in the 1950s and 1960s dealt a blow to this artisanal production method, but some local *tascas* (taverns) and families maintained the faith. With growing interest in clay-fermented and ORANGE WINE this century, talha winemaking has undergone a revival. In 2010 VINHO DE TALHA DOC was introduced to preserve the traditions for contemporary (bottled) examples, which can be sophisticated. In 2021 Portugal's most expensive wine was a single-talha red. S.A.

An 18th-century clay TALHA in the XXVI Talhas winery in Vila Alva in the south of Portugal's ALENTEJO region. Around 1.6 m/5.25 ft tall, 1 m wide, and holding around 600 l/158 gal, it is relined every 6–8 years with a mixture of dearomatized resin and beeswax to reduce OXYGEN ingress. © Julia Harding MW

Tália, occasionally written Thalia, Portuguese name for the ubiquitous white grape variety known in France as UGNI BLANC and in Italy as TREBBIANO Toscano.

Tămâioasă, name for MUSCAT grape or wine in ROMANIA. Most widely seen as Tămâioasă Românească, a name which has been used both for MUSCAT BLANC À PETITS GRAINS and for a different variety that has been given the name Tămâioasă București to avoid confusion. Tămâioasă Roză is the pink-skinned MUTATION of the former.

Popescu, C. F., et al., 'Identification and characterization of Romanian grapevine genetic resources', *Vitis*, 56/4 (2017), 173–80.

Tamarez, old but relatively uninspiring white grape grown in the ALENTEJO.

Tamar Valley, the largest winegrowing area of TASMANIA, stretching from Relbia, just south of Launceston, following the Tamar River/kanamaluka north to Rowella. Its diverse MESOCLIMATES and sheltered slopes support many grape varieties and wine styles.

Taminga, white grape variety bred specifically for hot AUSTRALIAN conditions by A. J. Antcliff, with TRAMINER as one of its parents. Taminga is not widely planted but is capable of producing fresh, aromatic white wine of fair quality in a variety of different sites with

an average yield of 90 hl/ha (5 tons/acre). It seems well suited to making BOTRYTIZED sweet wines.

Tamyanka, Bulgarian, Russian, and Serbian name for MUSCAT BLANC À PETITS GRAINS.

tank method, a bulk sparkling-winemaking process which involves provoking a second fermentation in wine stored in a pressure tank. See SPARKLING WINEMAKING for more details and alternative names.

tanks. See CONTAINERS.

Tannat, distinctive, tannic, deep-black-berried vine variety most famous as the principal ingredient in MADIRAN, where its inherent ASTRINGENCY is mitigated by blending with Cabernet Franc, some Cabernet Sauvignon, and FER and wood ageing for at least 20 months. If Madiran is Tannat's noblest manifestation, slightly more approachable (if sometimes more rustic) wines are made to much the same recipe for ST-MONT, as well as for the distinctively firm reds and rosés of IROULÉGUY and the rare reds and pinks labelled TURSAN and BÉARN.

Overall plantings in France have remained fairly static and were 2,790 ha/6,894 acres in 2019. Although it may owe its French name to its high tannin content, the vine may well be Basque in origin and, like MANSENG, was taken to URUGUAY by Basque settlers in the 19th century, where it is by far the most important vine variety; rather like MALBEC in ARGENTINA, it seems to thrive better in the warmer climate of its new home in South America than in SOUTH WEST FRANCE. In Uruguay, where it has been called Harriague after its original promulgator, there were 1,575 ha/3,892 acres in 2022. Strategies for softening the grapes' tannins include blending with such grapes as Pinot Noir and Merlot as well as all the usual winemaking techniques

(see MACERATION and MICRO-OXYGENATION, the latter having been developed for Tannat in Madiran in particular). PORT and BEAUJOLAIS styles have also been made from it. From Uruguay it spread to other wine-producing countries in South America, and there were 257 ha/636 acres in California in 2020. The variety is seen as a minor but intriguing challenge by winemakers all over the world.

tannins, diverse and complex group of chemical compounds that occur in the bark of many trees and in fruits, including the grape. Strictly speaking, a tannin is a compound that is capable of interacting with PROTEINS and precipitating them; this is the basis of the process of tanning animal hides (hence the name tannin) and is also a process that is believed to be responsible for the sensation of ASTRINGENCY. Tannins in wine come predominantly from the grapes and, to a much lesser extent, from the WOOD in which the wine is aged. See also OAK FLAVOURS.

The natural tannins of grapes, or condensed tannins, also called PROANTHOCYANIDINS since they release red anthocyanidin pigments when heated in acidic media, are FLAVONOIDS consisting of oligomers and polymers of CATECHINS. Formation of proanthocyanidins occurs under the control of ENZYMES as part of the metabolism of the grape, but they may rearrange to longer or shorter molecules in the acidic wine medium. Other catechin polymers can be formed in wine as a result of enzymatic or chemical oxidation reactions. These polymeric flavonoids that can range from colourless through light yellow to amber, as well as PIGMENTED TANNINS resulting from reactions of anthocyanins with catechins and tannins, may also be regarded as tannins. Wine may also contain hydrolysable tannins, deriving from gallic acid and ellagic acid, extracted from oak COOPERAGE in the course of BARREL AGEING, from OAK CHIPS, or added as OENOLOGICAL TANNINS.

Tannins play an important role in the ageing of wine, particularly red wines, where pigmented tannins are crucial to the colour and

sensory properties. Handling tannins during RED WINEMAKING is one of the most critical steps in optimizing the quality and character of a red wine, yet the process is based almost totally on experience and intuition because our understanding of the principles involved is still incomplete.

The tannins in grapes are predominantly in the skins and seeds of each berry and also the STEMS, the amount of tannins in grape pulp being much lower. Thus, the more skins, seeds, and stems are involved in the winemaking process, the higher the possible resultant level of tannins. Tannin levels in white and rosé wines, which are made largely by excluding or minimizing these grape components, are therefore lower than in reds. Although white wines contain structures similar to the pigmented tannins of a red wine, the absence of ANTHOCYANINS condensed into the tannins of white wines accounts for how different they look.

Tannins are most often encountered by the human palate in over-steeped tea, and by wine drinkers in young reds designed for a long life in bottle and in whites made with prolonged or excessive SKIN CONTACT. They produce the taste sensation of bitterness and the physical tactile 'drying' sensation of astringency. Catechins and small tannins are said to be responsible for bitterness, while larger ones elicit the astringency sensation, presumably by interaction with the proteins of the mouth but also by the adherence of the tannins to the oral mucous membranes (see below).

Traditional methods for measuring tannins report them as if they were all gallic acid, and such analyses, including the widely used Folin Ciocalteu method, are popular because of their analytical convenience. Alternative methods for measuring the phenolic compounds of grape tannins more directly and as other than gallic acid are time consuming and require considerable analytical expertise. Gallic acid or GA-equivalent concentration averages about 300 mg/l in white wines but 1,800 mg/l in reds. The tannin types and their extraction rates vary considerably with VINE VARIETY and WINEMAKING methods. Varieties notably high in tannins include CABERNET SAUVIGNON, NEBBIOLO, SYRAH, and TANNAT.

Since the late 1980s, much research into red winemaking has been aimed at minimizing the bitter and astringent impression made by tannins on the palate while enhancing the TEXTURE and AGEING properties which they confer on a wine. These studies have involved, among other variations, ever more refinement of MACERATION techniques and deliberately controlled exposure to OXYGEN at various points during the winemaking process (see MICRO-OXYGENATION, for example). It is also widely recognized that the influence of such viticultural factors as grape RIPENESS and grape composition on the properties of tannins is not yet understood.

Different WOOD TYPES contain different sorts of tannins, but these have the most effect on wine when the cooperage is new. The tannins of the various species and varieties of OAK, the most common wood used in winemaking, vary among themselves and according to how the oak was seasoned (see BARREL MAKING). Oak tannins differ in significant ways from grape tannins, although the consequences of such differences on the stability of wine colour and on the sensory properties (including mouthfeel) of barrel-matured red wines in particular are yet to be scientifically rationalized. For more details, see OAK FLAVOUR. Wine consumers may experience a certain amount of wood oak flavour in a wide range of wines, including some relatively immature wines, both red and white, whether the result of genuine BARREL AGEING or the use of OAK CHIPS. They are therefore often exposed to the effects of tannin on the palate, which can be considerably mitigated by the right choice of accompanying food (see DIET).

Winemakers can adjust excessively high tannin levels by FINING with casein, gelatin, or albumin, which selectively precipitate large-sized astringent tannins. Formation of soluble complexes with macromolecules such as proteins may also prevent tannins from interacting with salivary proteins and eliciting astringency. Given sufficient time, tannins are removed naturally, however, during wine ageing. The tannins POLYMERIZE and form aggregates that eventually precipitate as SEDIMENT so that they no longer have any bitter or

astringent effect on the palate. Depending on the wine composition and PH, reactions of tannins can also yield smaller tannins and pigmented tannins, thus resulting in lower astringency.

See also OENOLOGICAL TANNINS, which may be deliberately added in the course of winemaking to increase a wine's tannin level.

Cheynier, V., 'Flavonoids in wine', in O. M. Andersen and K. R. Markham (eds.), *Flavonoids: Chemistry, Biochemistry and Applications* (2006).

Tasting tannins

Tannins cannot be smelt or tasted; they cause tactile sensations. A significant development of the 1990s was a keener appreciation of the different sorts of sensory impact of tannins on the palate (see TEXTURE). In Australia, this led in particular to the development of a MOUTHFEEL wheel rather like the AROMA WHEEL. Tannins may be variously described as hard, bitter (if accompanied by BITTERNESS), green, ripe (if perceptible but only after the impact of fruit that has reached PHYSIOLOGICAL RIPENESS has been felt on the palate), coarse, grainy, wood (if obviously the effect of CASK AGEING), long chain (an American expression for POLYMERIZED), short chain, and polymerized. Research in the US by Revelette et al. has shown that it is not just the quantity of tannins in a wine that determines its astringency but also the quality of those tannins, specifically their tendency to 'stick' to another surface such as the mucous membranes.

Tanzania is the second largest wine producer in sub-Saharan Africa. VITIS VINIFERA vines were brought by European missionaries as early as the 1930s; since the 1970s the country has been producing

wine on a commercial basis. Most vinegrowing is focused in the Dodoma region, a plateau at about 1,150 m/3,773 ft in ELEVATION. In the warm, arid climate, vine-growers harvest twice a year (see TROPICAL VITICULTURE). Most farms are very small, and growers sell to the CO-OPERATIVE or larger wineries. Italian varieties such as MARZEMINO, TEROLDEGO, and AGLIANICO are popular, as is CHENIN BLANC for white wines. In 2020 the Tanzania Agricultural Research Institute began the process of importing 13 new grape varieties from SOUTH AFRICA in a bid to increase wine-grape production.

tariffs applied to imports (as opposed to a country's TAXATION policy) can have a considerable effect on the structure of the world's wine trade. In late 2020, for example, China imposed punitive tariffs on imports from Australia, including wine, which had the effect of virtually robbing Australian wine producers of their most lucrative market overnight. In 2019, as part of a dispute about subsidies for aircraft manufacturers, President Trump imposed a 25% import tariff on wines from a variety of European countries, including France. The dispute was settled in 2021 but not before it had a direct effect on the fortunes of many French vignerons and the range offered by some American retailers.

Tarragona , Mediterranean port in Spanish CATALUÑA which has played an important part in a flourishing wine industry since Roman times (see SPAIN, history, and map). Until the 1960s, wines called Tarragona were predominantly sweet, red, FORTIFIED, and drunk as a cheap alternative to PORT. Awarded DOP status in 1976, Tarragona continues to ship communion wine all over the Christian world (see EUCHARIST). Over 70% of Tarragona's wine production today is white, however, a large proportion of which is sold to the CAVA houses in PENEDÈS. The MONTSANT DOP created in 2001 was carved out of the original Tarragona zone.

Tarrango, red wine grape variety developed at Merbein in AUSTRALIA in 1965. The aim of this TOURIGA × SULTANA cross was to provide a slow-ripening variety suitable for the production of light-bodied wines with low TANNINS and relatively high ACIDITY. As a result, some Australian wines have been fashioned in the image of BEAUJOLAIS, but the variety will ripen satisfactorily only in the hot irrigated wine regions of Australia such as the RIVERLAND. Brown Brothers of Milawa have been particularly persistent with this variety.

tartaric acid, the most important of the ACIDS found in grapes and wine. Of all the natural organic acids found in plants, this is one of the rarer. The grape is the only fruit of significance that is a tartrate accumulator, and yet it is of critical importance to the winemaker because of the major part it plays in the taste of the wine. Tartaric acid exists in wine in equilibria, as the acid form, the tartrate, and bitartrate ion forms. It is the principal component of the mixture of acids and salts that constitutes wine's all-important buffer system (see BUFFERING CAPACITY) and maintains the stability of its ACIDITY and COLOUR.

Tartaric acid is of further interest because its potassium acid salt (potassium tartrate or cream of tartar), while being moderately soluble in grape juice, is less soluble in alcoholic solutions such as wine. Most winemakers therefore try to ensure that no excess tartrates remain in the wine when it is bottled lest these crystals frighten less sophisticated consumers by their resemblance to glass shards. See TARTRATES for more on this important by-product of the winemaking process.

Grapes and the resultant wines vary considerably in their concentrations of tartaric acid. Among the thousands of cultivated VINE VARIETIES, some are noted for their high concentrations of tartaric acid, while others have very low levels. In general, wine grapes have higher concentrations of acids than do TABLE GRAPES. Among wine grape varieties, however, there is considerable variation in concentrations of the two principal acids: tartaric acid and MALIC ACID.

For example, Palomino, the sherry grape, is particularly high in tartaric acid, while Pinot Noir and Malbec, or Côt, are relatively low in tartaric.

The relative amounts of these two acids that are present in grapes, which varies with VINTAGE, do not necessarily govern the relative amounts in wines, however. Precipitation of potassium acid tartrate, as outlined above, reduces tartaric-acid concentration, while malic acid is frequently decomposed by MALOLACTIC CONVERSION. Wines that have not undergone this conversion generally have slightly more tartaric acid than malic acid.

Weather and soil, as well as grape variety, affect the amounts of different acids in the grape and wine. Cooler climates in general favour higher concentrations of acids and lower levels of POTASSIUM in the grape skins. Malic acid is much more effectively metabolized in warm conditions during the grape ripening period than is tartaric acid. Soils deficient in potassium may result in grapes of low PH because potassium ions are exchanged with hydrogen ions during the ripening process. Another curious difference is that tartrate levels are very high in grape flowers. Tartaric acid is not respired during ripening, meaning that its amount per berry stays relatively constant during berry RIPENING. More than half of the tartrate in ripe berries can be present as a salt. The proportion of free to salt form varies with variety and the concentration of metal cations in the juice; potassium is by far the most abundant. B.G.C. & M.J.T.

tartrates, the general term used by winemakers to describe the harmless crystalline deposits that separate from wines during FERMENTATION and AGEING. In French the substances are called *tartres*, in German *Weinsteine* (literally, 'wine stones'), *tartrati* in Italian, and *tartratos* in Spanish. The principal component of this deposit is potassium bitartrate, the potassium salt of TARTARIC ACID, which has therefore given rise to the name. Small amounts of pulp debris, dead yeast cells, precipitated phenolic materials such as TANNINS and

PIGMENTED TANNINS, and traces of other materials make up the impurities contaminating the potassium bitartrate (see SEDIMENT).

The LEES that sink to the bottom of the FERMENTATION VESSEL during the later stages of fermentation contain lower concentrations of tartrates than do the crystalline deposits that form on the walls of the vessel, making the latter the preferred source for commercial tartrates.

The main forms of tartrates used commercially are pure crystalline tartaric acid used as an acidulant in non-alcoholic drinks and foods, cream of tartar (pure potassium bitartrate) used in baking, and Rochelle salt (potassium sodium tartrate) used mainly in electroplating solutions. The wine industry is the only source of tartrates available to commerce and the crystalline encrustations left inside fermentation vessels are therefore regularly scraped off and purified for eventual commercial use.

Tartrates separate from new wines because potassium bitartrate is less soluble in solutions of alcohol and water such as wine than it is in plain water or in grape juice. The exact figures for wines vary slightly according to grape variety and region, but experience shows that about half of the tartrate soluble in grape juice is insoluble in wine. The problem is that the tartrate may remain in a supersaturated state in the complex wine mixture only to crystallize at some unpredictable later time (during storage or in bottle).

Although tartrates precipitated in red wines usually take on some red or brown colouring from adsorbed wine pigments and are commonly regarded as mere sediment, in white wines they can look alarmingly like shards of glass, or sugar, to the uninitiated. The modern wine industry has in the main decided that tartrate STABILIZATION is preferable to consumer education.

There are four basic types of treatment used to stabilize tartrates: REFRIGERATION, ADDITIVES, ION EXCHANGE, and electrical methods.

The historic method is to cool the wine to just above its freezing point (−8 °C/17.6 °F) and hold it at that temperature for a period of around a week. The crystals fall to the bottom of the vat, and the stabilized wine is racked off and filtered. However, this is a rather

drastic treatment, risking a reduction in the quality of the wine, and has been superseded by the contact process. In this method the wine is seeded with finely divided potassium bitartrate crystals that act as seed crystals. It works at a higher temperature and, with vigorous stirring, takes two hours or less, causing little damage to the wine. The risk of these methods is the higher levels of dissolved oxygen in the wine.

The oldest treatment is to add metatartaric acid prior to bottling. Unfortunately, this protection is not permanent because the metatartaric acid gradually decomposes into tartaric acid, adding to the tartaric-acid concentration, and its protection is temperature dependent: at 25 °C/77 °F it will generally work for around six months, whereas at 10 °C/50 °F it will last for 18 months. MANNOPROTEINS derived from decomposing yeast cells are entirely natural and have several useful properties in that they not only inhibit the crystallization of tartrates but also protect against PROTEIN haze in white and rosé wines and increase the foaming properties of SPARKLING WINE. The greatest advantage of mannoproteins is that their properties are long-lasting. A similar additive is carboxymethylcellulose (CMC), otherwise known as cellulose gum and chemically similar to wallpaper glue; it is used especially for white wines but is not allowed in the production of ORGANIC wines. A new additive with similar properties, potassium polyaspartate, was approved by the OIV in 2016.

Using ION EXCHANGE, the wine is passed through a column of polymerized resin where the potassium ions in the wine are exchanged for sodium ions from the resin. The resultant wine contains sodium bitartrate, which is much more soluble than potassium bitartrate. When the resin becomes saturated with potassium ions it can be regenerated by passing a solution of sodium chloride (common salt) through it, which is identical to the process of using ion exchange resins to soften hard water.

The principal electrical method is known as ELECTRODIALYSIS and is suitable only for large wineries because the equipment is expensive, but the treatment is very successful. It involves passing the wine

through specially designed membranes under the influence of an electric charge where the potassium, calcium, and tartrate ions are attracted through the pores of the membrane thus reducing the concentration of the potassium bitartrate in the wine.

Tartrates are most commonly encountered in untreated wines from relatively cool regions because they have the greatest concentration of tartaric acid. In white wines, colourless, perfectly shaped crystals of potassium acid tartrate are found. In red wines, there are usually sufficient adsorbed tannins and PIGMENTED TANNINS to colour the crystals reddish brown and to ensure that they are small and irregular in shape.

Although much is made of potassium bitartrate, calcium tartrate can also cause problems. It cannot be removed by any form of refrigeration because its solubility does not decrease with temperature. It forms much smaller crystals than the potassium version, and these can be avoided only by using ion exchange or electrodialysis. D.B.

Tasmania , or lutruwita in palawa kani, the revived language of Tasmanian Aborigines, is a cool, small island-state to the south of Victoria in mainland AUSTRALIA. The country's coolest region overall, it has increasingly attracted winemaking interest, growing from 20-odd winemakers in the early 1990s to almost 200 farming 2,000 ha/4,942 acres of vines in 2022.

The island has a single GEOGRAPHICAL INDICATION but a complex geography with diverse soil types and varied levels of rainfall. There are seven unofficial but generally recognized growing areas, all

concentrated at the eastern end of the island, which is far drier than the western end. Tamar Valley is the oldest and largest, producing 39% of Tasmania's crush in 2022. A sheltered river valley, it follows the Tamar River/kanamaluka from Relbia, just south of Launceston, north to Rowella near the coast. Average temperatures are similar to those in mainland southern VICTORIA, although the wide array of MESOCLIMATES and soils (GRAVEL, CLAY, BASALT, sandy LOAM, and LIMESTONE) supports many grape varieties, from CHARDONNAY and PINOT NOIR destined for sparkling wines to CABERNET SAUVIGNON and MERLOT for richer reds.

To the Tamar Valley's west is the small but growing **North West/Cradle Coast** region (2% of crush), and to the east is Pipers River (14.3%). Cool and wet thanks to the cooling influence of the Bass Strait, the marked DIURNAL TEMPERATURE RANGE, and the surrounding mountains, the area has become particularly known as a source for Chardonnay and Pinot Noir for sparkling wines.

Almost one-quarter of Tasmania's crush comes from the Coal River Valley on Tasmania's south coast, just east of Hobart/nipaluna. One of the warmest and driest locations in Tasmania due to the rain shadow of Mount Wellington/kunanyi, the region was pioneered by Swiss entrepreneur Peter Althaus, who established the Bordeaux-centric Domaine A (now owned by Moorilla Estate) in 1973. Long-lived, full-bodied red blends and oaked Sauvignon Blanc can be found here.

The climate is similar in Derwent Valley, just west of Hobart, where Moorilla Estate, Tasmania's oldest winery, began planting vines in 1958. Huon Valley and d'Entrecasteaux Channel, south of Hobart, are cooler locations with a capacity for FROST in spring but boast some of the highest levels of ULTRAVIOLET RADIATION in the state. Finally, the East Coast, a spectacularly scenic stretch of land between Bicheno and Dunalley along the coast of the Tasman Sea, is growing in importance, producing 12.8% of crush in 2022.

PINOT NOIR makes up nearly 50% of vineyard plantings, and CHARDONNAY another one-quarter, much of both destined for sparkling

wine, which makes up 37.4% of all wine produced. A small amount of PINOT MEUNIER is also grown.

In still wines, white wines prevail, with aromatic white varieties such as SAUVIGNON BLANC (8.6%), PINOT GRIS (8%), and RIESLING (6.3%) following Chardonnay. Meanwhile, SYRAH, at 1.2%, has overtaken CABERNET SAUVIGNON and MERLOT to be Tasmania's third most planted red grape variety.

PHYLLOXERA has never infected Tasmania, and many vines remain UNGRAFTED, while others are grafted as a precautionary measure. Nearly half the island's vineyards are managed under VinØ (Vin Zero), a non-accredited SUSTAINABLE VITICULTURE initiative established by governing body Wine Tasmania that looks at soil health, biodiversity, environmentally responsible pest management and water usage, and the acknowledgement and respect of the aboriginal people of Tasmania/lutruwita who have long been custodians of the land.

taste. What we call the sense of taste is to a very great extent the sense of SMELL. See TASTING for more details. As for our own personal taste in wine, it is overall SUBJECTIVE, even if subject to our own personal SENSITIVITIES. There are no rights and wrongs in wine preferences. See also QUALITY IN WINE and PHILOSOPHY AND WINE

tastevins, or wine tasters, as they are known by collectors of wine antiques, are shallow, often dimpled, saucers used for TASTING by professionals (and occasional self-conscious amateurs). Because they

were usually used in a cellar or on purchasing journeys where robust construction was essential, they were almost invariably made of silver. The earliest English references to tasters date from the 14th century, but only a single extant example predates 1600. British tasters mostly copy the BORDEAUX model, being 65–110 mm (2.5–4.5 in) in diameter with sloping sides and a domed base and lacking a handle. Extremely rare tasters were made of glass or porcelain, usually Worcester.

Tastevins are far more plentiful in France than elsewhere. Most have a single handle and a slightly domed base. Many are decorated with a different pattern on either side of the handle. Late-19th- and 20th-century examples are often plated. R.N.H.B.

Some BURGUNDY producers still use tastevins in their own cellars, where they can be useful to demonstrate hue and clarity even in a dim light. For actual tasting, GLASSES are more efficacious, even if less easily portable. Contemporary manufacture of tastevins is sustained by many CONFRÉRIES, most obviously the Burgundian Chevaliers du Tastevin.

tasting, the act of consciously assessing a wine's quality, character, or identity (see BLIND TASTING). It is certainly not synonymous with, nor necessarily contemporaneous with nor accompanied by, the act of drinking it. The ideal conditions for the act of tasting, and the organization and classification of formal wine tastings, is outlined under TASTINGS. This article is concerned with the activities and mechanisms involved in consciously receiving the sensory impressions a wine can stimulate.

How we taste

Most of what is commonly called the sense of taste is in fact the sense of SMELL, whether applied to wine or to any food or drink, since by chewing we transform our food into liquid which gives off smellable vapour. To verify this it is enough to eat or drink something with the nose pinched shut or to consider the extent to which we 'lose our appetite' when we have a head cold which blocks the nose. The human brain senses what we call flavours and aromas in the olfactory bulb, which, as Buck and Axel so elegantly demonstrated in their Nobel prize-winning work, is reached via a thousand different olfactory receptor cells, each expressing a single odorant receptor gene, these genes representing about 3% of an individual's genetic make-up. Unexpectedly, each olfactory receptor cell is sensitive to a very small group of related aromas. From the olfactory bulb these messages are sent to other parts of the brain and processed, combining them and forming a pattern. Most aromas are composed of many different molecules, each of which activates several of these olfactory receptors, making odorant patterns, so that humans are able to recognize and, particularly, memorize up to 10,000 different aromas. The olfactory bulb is reached mainly by the nostrils and to a lesser extent by a channel at the back of the mouth called the retronasal passage (which is why most healthy people can still perceive some flavour even if they do not consciously smell what they consume). The human olfactory sense is extremely acute and possibly as acute as that of most mammals. Concentrations of some compounds of one part per trillion (see Bushdid et al.) can be sensed, recognized, and remembered by the average person. A single whiff can transport us immediately to something experienced many years before.

The tasting capacity of the mouth is much more limited. In the mouth, our tactile sense can register FIZZINESS, TEMPERATURE, VISCOSITY, EXTRACT, the apparent heat generated on the palate by excessive ALCOHOL, and the sensation induced by TANNINS of drying out the insides of the cheeks.

The tongue also has certain taste receptors located in taste buds, which can sense the five 'primary tastes' of SWEETNESS, ACIDITY, BITTERNESS, saltiness, and (more recently recognized) UMAMI. There is considerable genetic variation in how many taste buds we have, with roughly one-quarter of the population considered extremely sensitive 'supertasters'. To supertasters the substance PROP (6-n-propylthiouracil) tastes extremely bitter and taste sensations in general are intensified and exaggerated. To so-called 'non-tasters', PROP is virtually tasteless, while about half of us are 'medium tasters', find PROP mildly bitter, and experience taste sensations without distorting extremes. It was thought that different parts of the tongue were particularly sensitive to one of these primary tastes, but Bartohuk et al. showed that in fact we have taste receptors for all the primary tastes in each taste bud.

With the exception of some wines matured near the sea such as MANZANILLA or some produced from vineyards with a serious SALINITY problem, very few wines taste salty, and in even fewer can umami be detected. Sweetness and acidity, on the other hand, are two of the most important measurements of a wine, although it is important to recognize that the apparent sweetness of a wine is not necessarily the same as its RESIDUAL SUGAR. High acidity can easily make a wine taste much drier than it actually is, for example.

It is clear that the mouth's tasting ability, apart from being usefully linked to the olfactory bulb by the retronasal passage, is in *measuring* the wine, assessing its dimensions of sweetness, acidity, bitterness, fizziness, viscosity, potency, and ASTRINGENCY. The mouth is capable of making an overall assessment of a wine's TEXTURE and STRUCTURE, while the nose senses what we call its flavour. Just as what is commonly called the sense of taste is really the sense of smell, so what is commonly called flavour is really AROMA or, in older wines, BOUQUET. (See FLAVOUR, however, for a proposal that the word be used to incorporate all the measurements sensed by the mouth.)

The essential character and most complex distinguishing marks of any wine are in its smell, which is made up of hundreds, probably

thousands, of different FLAVOUR COMPOUNDS, present in widely varying permutations and concentrations in different wines.

What is commonly called tasting therefore involves persuading as many of these flavour compounds as possible to reach the olfactory bulb, while ensuring that contact is made between the wine and all of the inside of the mouth for the purposes of assessing a wine's dimensions and texture.

How to taste

The operation of tasting is generally divided into three stages involving sequentially the eye, the nose, and the mouth (although, as outlined above, this is not the same as the simple sequential application of the senses of sight, smell, and taste).

Eye The job of the eye in wine tasting is mainly to assess clarity and colour, as well as to monitor the presence of CARBON DIOXIDE and ALCOHOL (the former indicated by bubbles, the latter possibly by any TEARS of the wine that may form on the inside of the glass when it is rotated).

The clarity of a wine is an indication, hardly surprisingly, of the extent to which CLARIFICATION has been carried out and also of the wine's condition. Many wine FAULTS result in a haze of some sort. In the late 1990s, anti-FILTRATION sentiment was so strong in California that some highly priced Chardonnays looked positively cloudy, a common characteristic in many NATURAL WINES. A wine with particles floating in it, however, may simply be an innocent casualty of poor SERVING technique in which a wine has not been properly separated from its entirely harmless SEDIMENT. Experienced tasters can sometimes discern quality simply by looking at a wine's luminescent clarity and subtle range of hues.

The colour of a wine, both its intensity and its hue, is one of the potentially most valuable clues to any BLIND TASTER. Intensity of colour is best judged by looking straight through a glass of wine from directly above (preferably against a plain white background). Different grape varieties tend to make deeper or lighter coloured wines (Cabernet Sauvignon, Syrah, Tannat, Malbec, and TEINTURIER varieties make particularly deep red wines; Gewürztraminer and Pinot Gris are examples of varieties which make particularly deep white wines, because the grape skins are deep pink). A deep colour also indicates youth, long MACERATION (possibly over-EXTRACTION), and thick-skinned grapes in a red wine; sometimes age, SKIN-FERMENTATION, some OXIDATION, and BARREL AGEING, although not if preceded by BARREL FERMENTATION, in white wines.

The actual hue can also provide clues and can be best assessed by tilting the glass away at an angle so that the different shadings of colour at the rim can be seen, again preferably against a plain white background. A bluish tinge in a red wine indicates youth, while

orange/yellow indicates AGE (or OXIDATION). Very pale green in a white wine may indicate Riesling, while a pink tinge suggests that the wine was made from pink-skinned grapes such as Gewürztraminer and Pinot Gris. For more information, see COLOUR.

This stage in tasting for any purpose other than identification is usually very short and, if tasters are SCORING various aspects of a wine, many wines gain maximum points for appearance.

Nose As demonstrated above, this is the single most important stage in wine tasting. The trick is to persuade as many flavour compounds as possible to vaporize and come into contact with the olfactory bulb (although what we smell is in fact an AZEOTROPIC mixture of many, rather than isolated individual, flavour compounds). It is then necessary, of course, to be in a suitable frame of mind to interpret the messages received by the olfactory bulb, which is why the act of tasting requires concentration.

The simplest way to maximize the evaporation of a wine's volatile elements is by the judicious use of TEMPERATURE and agitation. Higher temperatures encourage any sort of evaporation, so ideal tasting temperatures tend to be slightly higher than ideal SERVING temperatures. It is unwise to taste wines so hot that the alcohol starts to evaporate at such a rate that it dominates the flavour, however, so an ideal tasting temperature for wines, red or white, is somewhere between 15 and 20 °C/59–68 °F. At these relatively elevated temperatures, faults as well as attributes should be perfectly apparent. What is lost is the refreshment factor, but then the point of tasting rather than drinking is analysis rather than pleasure. Sparkling wines tend to be tasted slightly cooler to retain the carbon dioxide.

Many professional tasters first smell, or 'nose', a wine without agitating it to see how powerful its aroma is without this encouragement, then deliberately increase the number of molecules liberated by a wine by agitating the wine and increasing its surface area, preferably rotating it in a bowl-shaped glass with a stem (see GLASSES) so that no wine is lost.

As soon as the wine has been agitated, the aroma collects in the bowl of the partly filled glass above the wine and can be transmitted to the olfactory bulb up the nostrils with one thoughtful inhalation.

The taster monitors first whether the wine smells fresh and clean or whether any off-odours indicate the presence of a wine FAULT. The next basic measurement might well be of the intensity of the aroma (if it is an attractive smell, then intensity is preferable). And then comes the complex part of the operation, which is much more

difficult to describe: the sensation and attempt at description of the individual components that make up the aroma, or 'bouquet' as it is sometimes called if it has taken on the complexities associated with AGEING. For a discussion of this, see TASTING TERMS.

Quite apart from those components which result from the grapes themselves, the aroma can provide certain overall hints about viticulture and winemaking techniques. Leaf aldehydes suggest that the grapes were less than fully ripe. Oak ageing may be betrayed by a certain amount of OAK FLAVOUR; scents of spices and toast can be the result of the degree of TOAST which the barrels received. Tropical fruit aromas suggest that the fermentation was particularly long and cool. DIACETYL, which can smell like butter and other dairy products, is a particularly obvious sign of MALOLACTIC CONVERSION. The subject is too complex for more than the most cursory treatment here, but the books cited below provide more detail.

As a wine undergoes gentle AERATION in the glass, it may well begin to give off other compounds with time. World-famous taster Michael BROADBENT, for example, kept a series of records of how a single glass of wine tasted, marked according to how long after pouring each note was made. Most good wines seem to get better with time and then to start to deteriorate. In blind tasting, however, a taster's first impressions are usually the most accurate, and insights are rarely provided by constant repetition of the 'nosing' process.

Mouth In terms of aroma—'flavour' in its narrow sense—the mouth, or palate as it is sometimes called, usually merely confirms the impressions already apparent to the nose when some vapour escapes the mouth and reaches the olfactory bulb via the retronasal passage. Many tasters take in a certain amount of air over their mouthful of wine to encourage this process (and are often mocked for the accompanying noise).

The main function of the mouth in the tasting process is to assess the texture and measure the dimensions rather than the character of a wine by assessing sweetness, acidity, bitterness, saltiness, umami if any, viscosity, and tannin level. Monitoring the combination of sweetness, viscosity, and any sensation of 'heat' gives a good indication of the likely alcohol content of any individual wine, ETHANOL tending to leave a burning sensation in the mouth. The insides of the mouth may also register the TEXTURE, analysing the impact of the TANNINS. For this reason, it is a good idea to rinse the mouth thoroughly with wine so that all possible touch receptors may come into contact with it—another reason why wine tasting looks both ridiculous and disgusting to outsiders.

After rinsing a wine around their mouths and noting the impressions given by the vapour rising up the retronasal passage, most professional tasters then demonstrate their devotion to duty rather than alcohol by SPITTING. The taster then notes how LONG the impressions given by the wine seem to persist after spitting or swallowing.

Conclusions Perhaps the most important stage, however, is a fourth stage of analysis, in which all previous impressions are evaluated. This includes most particularly considering whether the measurements taken by the mouth suggest that the wine is in BALANCE and monitoring the LENGTH of the aftertaste, these last two factors being important indicators of quality. A fine wine should continue to make favourable sensory impressions throughout the entire tasting process.

Experience is necessary to judge balance. A significant, if decreasing, proportion of young red wines designed for long-term evolution, for example, are not by any objective criterion in balance. Their tannins may still be very marked and make the wine an unpleasantly astringent drink, even if they suggest that the wine will keep well. (Making red wines with less obvious tannins so that they can be both aged and drunk in their youth has been one of the prime recent preoccupations of winemakers.) Similarly, the acidity in a young German wine may be aggressively dominant, but experience shows that it is essential to preserve a top-quality Riesling, for example, for the ten or 20 years' bottle ageing it may deserve.

Professional tasting usually involves making TASTING NOTES, often under the four headings noted above. It may also involve SCORING by allotting NUMBERS to different elements according to a carefully predetermined scale, especially if wine JUDGING is involved. Tasting notes can be set out in many different ways, and experienced tasters tend to devise their own abbreviations and symbols.

Tasting for pleasure, which is what most wine drinkers do every time they open a bottle, requires nothing more complicated than a moment's concentration and an open mind.

Factors affecting taste

We cannot know what other tasters experience, for the tasting mechanism is far from public. Furthermore, individuals vary in their SENSITIVITY to different compounds and dimensions of wine. But even as individuals, the way our brains process information sent from sensory receptors changes all the time so that the same wine will have a different effect on us depending on the state of our PALATES. The most obvious example of this is how different something tastes before and just after we have had a mouthful of red-hot chilli or brushed our teeth with a mint toothpaste. But even something as apparently innocuous as a particularly hot drink or salty solution can affect the way we taste. An acid wine will seem less acid if tasted immediately after a very acid one, which is why the ORDER of serving and tasting is crucial but extremely difficult to get right until every wine has been tasted. See also FOOD-AND-WINE MATCHING.

Our overall physical well-being affects how we taste. If we are run down, we tend to produce less saliva and, because saliva contains compounds which have a buffering effect on many aspects of taste, both foods and drinks can taste quite different (this is quite apart from the fact that good HEALTH is needed to tackle a succession of alcoholic liquids).

How we taste can be quite markedly affected by our mood and of course by the physical environment in which we taste (see TASTINGS). Tasting in a very humid atmosphere is markedly more difficult than when the atmospheric pressure is high, flavour compounds are readily volatilized, and taste impressions seem crystal clear.

tasting notes are the usual record of professional or serious wine TASTINGS. They are conventionally divided into notes (sometimes together with SCORES or NUMBERS) for what is sensed by the eye, the nose, and the mouth, together with overall conclusions (see TASTING). The thoughtful organizer of a tasting prepares a tasting sheet which provides as a minimum a list of complete names of all the wines served, in the relevant ORDER of serving, with sufficient space to write full tasting notes. Sometimes these are carefully divided into sections —Appearance, Aroma/Bouquet, Taste, and Conclusions, for example —but this is an optional extra as tasters vary according to how much they want to write on each aspect. Most experienced tasters develop their own shorthand and habits, both good and bad. The number of words in a personal average tasting note can vary between one and 100 or more, in the case of a particularly complex wine which evolves in the glass. Tasting notes, especially of wines worth AGEING, are all the more valuable if they are dated. Most tasting notes remain of personal use only, but the late Michael BROADBENT produced two important books based entirely on his, and the majority of Robert PARKER's output was made up of his. Comparison of the two authors provides a reasonable guide to the different styles of British and American tasting notes respectively. Many tasting notes contain a long list of flavours (subject to considerable SUBJECTIVITY and variation in SENSITIVITY), but assessment of a wine's vital statistics—SWEETNESS,

ACIDITY, TANNINS, and ALCOHOLIC STRENGTH, as well as MATURITY—is also useful.

The advent of sophisticated INFORMATION TECHNOLOGY has introduced the possibility of entering tasting notes directly into a database, and many wine websites are made up principally of tasting notes, although any nearby liquid poses a threat to a keyboard (which can become unpleasantly sticky during a tasting of sweet wines). This method of record-keeping should, in theory at least, lessen the usual problem of declining legibility of tasting notes towards the end of a tasting.

tasting-notes language. The language we use to write or speak about wine may vary according to our intended audience—is the aim to sell to a potential customer, to inform an enthusiast, or to display academic rigour in an exam or a BLIND-TASTING competition? The language of wine can be descriptive (what is this wine like?) or evaluative (how good a wine is this?).

Using language to convey sense impressions, as we do when we describe a wine's properties, is inherently problematic. The brain receives so many data through the senses of smell, taste, vision, and touch that it has to select in order to prevent it from being overwhelmed. Thus the brain does not measure the world around us but models it by constant filtering (known as higher-order processing), and there is no one-to-one correspondence between sense data and conscious perception. Hence a TASTING NOTE cannot be an exact representation of a wine: it conveys the taster's interaction with the wine.

A further problem is that an individual's experience shapes their later perceptions, giving people not only different prototypes of sense impressions (i.e. different notions of what a typical X should be) but also different grids with which to make sense of the raw data received by the brain: a taster who has never encountered a gooseberry cannot detect the smell of gooseberries in a wine. In other words, what is selected in the brain's higher-order processing is

determined by a taster's personal history and culture and, if he or she is part of a tasting-group, for example, other tasters' comments.

Finally, due to physiological and genetic factors, individuals vary in their perceptual acuity, especially in their sensitivity to the thousands of possible AROMAS. It follows that no two people will describe a wine in identical terms. Ann C. Noble's AROMA WHEEL, for example, is an excellent teaching aid in that it can be used to broaden tasters' vocabularies and sharpen their perceptions, but its range of aromas can be neither exhaustive nor definitive.

This is not to say that everything we say about a wine is subjective: some components of wine, such as ACIDITY, RESIDUAL SUGAR, TANNIN level, and ALCOHOLIC STRENGTH, are measurable, so it is possible for a taster to be right or wrong about these. However, human tasters are not calibrated scientific instruments, and perception of one component may influence that of another: high acidity can make residual sugar less noticeable, and, conversely, low acidity can make a sweet wine appear cloying. Hence a good tasting note will not just list observations about appearance, NOSE, PALATE, and FINISH but must attempt a holistic description by considering how a wine's components balance each other. BALANCE and LENGTH being criteria for quality assessment, a holistic tasting note must inevitably be evaluative as well as descriptive.

Although tasters who resort to florid use of metaphor and simile are often mocked as pretentious, we cannot analyse a wine without using figurative language. Some descriptive terms are literal—adjectives denoting colour, for instance—but to describe the TEXTURE of a wine a taster will need figurative language such as 'silky', 'grainy', or 'chewy'. Some descriptions of the nose will be literal because they are grounded in fact; others are analogies. Yet a taster who describes a Gewürztraminer as smelling of roses without knowing that one of the variety's constituents is damascenone (rose oil) would regard their choice of language as figurative. Dullness is not a virtue: a dry list of the component parts of a wine may fail to communicate the beauty and complexity of a high-grade wine; on the other hand, excessive inventiveness is liable to be counterproductive. A tasting

note should be not only precise but also comprehensible, and this means that competent tasters must draw, to a greater or lesser extent, on a shared vocabulary which needs to be taught.

An agreed vocabulary, such as the systematic approach that is mandatory for the WSET diploma, represents a learnt culture of wine. The discipline of putting sense impressions into words is indispensable if the taster is to analyse and remember a wine and, later, to recognize and identify examples of the same wine style. Competence develops with experience, and this means knowing not only what to look for but also how to describe it.

tastings, events at which wines are tasted. Informal tastings take place every time a bottle of wine is opened by a wine enthusiast. More formal ones take place when wine producers show their wines to potential buyers or commentators. The most common sort of formal tasting is one held for the purposes of wine assessment, typically by wine MERCHANTS keen to sell their wares, sometimes by a generic body keen to promote wines of a particular style or provenance. Formal tastings are also held by wine clubs and societies for less commercial purposes: EDUCATION or simple pleasure perhaps.

A horizontal tasting is one in which a number of different wines of the same VINTAGE are compared, while a vertical tasting is a comparison of different vintages of the same wine, most commonly

the same Bordeaux CHÂTEAU. George SAINTSBURY is credited with the first recorded use of these expressions.

A BLIND TASTING is one whose purpose is that the taster assesses unknown wines as objectively as possible, in some contexts also identifying them as closely as possible.

A comparative tasting is one in which various different examples of the same sort or style of wine—CLASSED GROWTHS of the same vintage, or wines from the same appellation, or a single VARIETAL, for example—are tasted and compared. Such tastings form the basis of much modern WINE WRITING and should be conducted blind for a true, unprejudiced assessment.

Equipment

The only essential equipment for a wine tasting, apart from the wine, is suitable GLASSES and, if bottles are stoppered with a cork, a CORKSCREW, but it is almost impossible to hold a tasting without a substantial area of flat surface on which to put bottles and glasses safely, usually in the form of a table to which there is good access. The next most useful objects are undoubtedly spittoons (see SPITTING) and something in which to pour away LEFTOVER WINE from a tasting sample (bottles plus funnels are customary, although spittoons can also be used for this purpose). The thoughtful organizer ensures that there is some plain white surface against which to hold a glass of wine (see TASTING). This typically involves lining up bottles on a table with a white surface (to see a wine's colour and clarity most easily) or a covering such as a tablecloth or sheet. A truly assiduous host provides tasters with a tasting sheet on which is a full and accurate list of wines to be tasted, in the correct order, with appropriate space for tasting notes. Water for rinsing of glasses and palates and some neutral-tasting food for 'cleaning the palate' can be helpful too. Cheese is usually too strong (see FOOD-AND-WINE MATCHING); bread or dry, savoury crackers are generally preferred by professionals.

Conditions

Ideal conditions include a strong natural light, ambient temperature between 15 and 18 °C/59–64 °F, and an absence of any extraneous smells. (It is clear therefore that tasting in most cellars, even those of the finest winemakers, is far from ideal.) In practice, a tasting that involves many people inevitably generates its own heat and smell, so it is wise to begin at a lower ambient temperature and not to be too exercised about a whiff of aftershave or polish, which is soon absorbed into the ambient atmosphere.

Organization

One glass per taster usually suffices, and between one-fifteenth and one-twentieth of a bottle is enough for a decent tasting sample. Ensuring that tasters are served rather than serving themselves can limit wine consumption.

The number of different wines suitable to be shown at a single tasting is a controversial topic. Some tasters claim to be able to assess up to 200 wines in a day at JUDGING sessions such as the Australian wine SHOWS, while the most experienced professionals in CHAMPAGNE deliberately limit themselves to fewer than a dozen wines at a time. A novice taster should probably start with no more than four wines, while a professional might feel a tasting which offered only 15 was hardly worth the detour.

What is clear is that it is difficult to *enjoy* more than a dozen wines at a time and that the ORDER in which any selection is served is vital to the impression they give.

tasting terms, the myriad and oft-mocked words used by tasters in an often vain attempt to describe sensory impressions received during TASTING.

The difference between a taster and a social drinker is this need to describe, to attempt the difficult task of applying words to individual, invisible sensations, particularly the aromas sensed by the OLFACTORY BULB.

The sense of smell is an exceptionally private one, for which there is no common public domain which can be codified. The best we can do is describe aromas by other aromas of which they remind us. Hence 'blackcurrant' or CASSIS, frequently for Cabernet Sauvignon; 'strawberry' or 'raspberry' perhaps for Pinot Noir; 'vanilla' for OAK; and so on. Science is starting to correlate the FLAVOUR COMPOUNDS found in different GRAPE VARIETIES (if not yet different TERROIRS) with those found in the objects used as taste descriptors.

There is as yet no official wine-tasting LANGUAGE, or even TASTING-NOTES LANGUAGE, although there have been many valiant attempts at establishing one and, particularly as research on flavour compounds and FLAVOUR PRECURSORS continues apace, this is becoming an increasingly attainable goal. The Scottish doctor Alexander HENDERSON was one of the first to attempt it in the English language in *The History of Ancient and Modern Wines* in 1824, CHAPTAL having applied about 60 French terms in his *L'Art de faire le vin* in 1807. These early tasting vocabularies tended to concentrate on the dimensions of a wine rather than its flavour or aroma, using words such as 'acidic', 'sweet', 'bitter', and 'light'.

Terms used for mouth sensations

The most straightforward of these 'dimensional terms', which describe what is sensed in the mouth (and the even more public and obvious visual impressions), are still in use today; since for the most part they describe what is measurable, they are useful, indisputable, and not affected by SUBJECTIVITY or SENSITIVITY. Inevitably, some jargon has evolved, of which the following are the most obvious examples.

Body—a noun; see BODY.
Big—high in alcohol.
Concentrated—having intense (though possibly subtle) flavours.
Crisp—attractively high in ACIDITY.
Fat—full-bodied and viscous.
Finish—a noun for aftertaste; see FINISH.
Flabby—lacking in ACIDITY.
Full—of BODY.
Green—too acid, made of unripe fruit; see GREEN.
Hard—too much TANNIN and too little fruit.
Heavy—too alcoholic; too much EXTRACT.
Hot—too alcoholic.
Light—agreeably light in BODY.
Long—impressively persistent aftertaste; see LONG.
Short—opposite of LONG.
Smooth—imprecise term for pleasing TEXTURE.
Soft—low in tannins.
Well balanced—having good BALANCE.

Terms used for aroma

It is in their attempts to find 'character terms' to apply to these more subtle, more private olfactory sensations that wine tasters can seem so foolish.

Some 'idioterms' are just plain fanciful, descriptions obviously applied in sheer desperation at the apparent impossibility of the task. In this category come the 'fading but well-mannered old lady', and who can forget James Thurber's 'naive domestic burgundy but I think you'll be amused by its presumption'? A more recent example is 'sexy', an increasingly common, but delightfully imprecise, tasting term.

Other sorts of terms, 'simile terms', are applied in a serious attempt to recall palpable objects which give rise to similar aromas: the fruits, flowers, vegetable, and mineral descriptors, for example.

Particularly common terms used to describe aroma, or flavour, include:

Buttery—see DIACETYL.
Fruity—intense impact of fruit flavours, sometimes a euphemism for 'slightly sweet'.
Grapey—mixture of intensely aromatic and the aromas associated with MUSCAT grapes.
Oaky—pejorative term for a wine excessively marked by OAK.
Toasty—see TOAST.

There are also 'derivative terms', which must once have been coined by an authority and continue to be widely used even though they are literally inaccurate. So many wine tasters have been taught to describe the powerful and characteristic smell of GEWÜRZTRAMINER as 'spicy', for example (perhaps because *Gewürz* is German for 'spice'), that this is the most common tasting term for the aroma, even though it does not smell like any particular spice at all (much more like lychees or rose petals, in fact).

It will be of the 'simile terms' that a common tasting vocabulary is finally composed—although there is the obstacle of many different languages, cultures, and national conventions to be overcome first. Max Leglise, a researcher in Burgundy, has attempted to concoct essences of each of his approved terms so that there is an objective standard for them. (Unfortunately, synthetic flavourings deteriorate.) Professor Ann C. Noble at DAVIS, clearly frustrated by the looseness with which tasting terms are applied, has done sterling work with her AROMA WHEEL. This corresponds sufficiently closely with the tasting terms suggested by Professor Émile PEYNAUD, Bordeaux's tasting guru, as to give us all hope that an international tasting language that is no more ambiguous than any other will one day be available to the world's wine tasters.

Brochet and DUBOURDIEU established in 2001 that each expert taster has his or her own set of tasting terms which typically correspond to a personal set of prototypes, 'ideal' wines, rather than detailed analytical description. In a separate study involving white wines coloured red, they also demonstrated that many tasting terms are colour-specific and that if tasters see red wine they will assign tasting terms associated with objects of that colour.

Taurasi, full-bodied reds from CAMPANIA produced from the distinctive AGLIANICO grape grown on 1,153 ha/2,849 acres of

vineyards in a zone north-east of the city of Avellino. Taurasi is regularly referred to as 'the BAROLO of the south' due to its high levels of ACIDITY and TANNINS which demand AGEING. DOCG regulations require three years of ageing, one of which must be in wood; RISERVA bottlings must be aged for four years.

By 2020 there were 60 producers of Taurasi—up from just ten in the 1980s—and more than 200 grape-growers. Mastroberardino was until the early 1990s the only label on the export market, absorbing most of the grapes produced by farmers. This dynamic changed when grape-growers began bottling their own produce with the help of consulting OENOLOGISTS. The downside of this is that many wines tend to taste similar, but several producers are experimenting with ORGANIC VITICULTURE, AMBIENT YEAST fermentations, and ageing in large CASKS rather than BARRIQUES, resulting in muscular, concentrated, and complex wines which develop notes of red berries, tobacco, tamarind, and iron with age.

The Taurasi DOCG comprises 17 villages on both sides of the river Calore in the province of Irpinia. The valley can be divided roughly into four sections:

The north-west section is the lowest part, at 300 m/984 ft in elevation, and the warmest, with full southern ASPECT and ALLUVIAL and CALCAREOUS clay soils, producing earlier-drinking Taurasi reds.

The north-east section is higher, with CLAY and calcareous soils, and gives more compact, lower-alcohol wines.

The south-east section, with vineyards on the slopes of the Picentini Mountains rising well over 700 m, includes diverse soil types, including calcareous clay, TUFF, SANDSTONE, and VOLCANIC soils. Here the grapes ripen slowly and retain high levels of acidity, creating wines that require extensive ageing.

The south-west part, which partially overlaps the Fiano di Avellino DOC (see CAMPANIA), produces a wide range of styles from mainly calcareous clay and sandstone soils.

In the absence of academic research into Taurasi's geology and terroir, Feudi di San Gregorio has been mapping the region in detail

while producing a range of wines specific to different parts of the region, resulting in a range of publications which are bound to become fundamental for the study and recognition of the various Taurasi styles. W.S.

De Cristofaro, P., *Feudistudi: Irpinia's Vineyards and Wines Almanac 2021/2022* (2022).

Tautavel, communal appellation of Côtes du ROUSSILLON-Villages which applies to the relatively low-ELEVATION clay-LIMESTONE vineyards of the communes Tautavel and Vingrau. The opulent reds are not unlike nearby FITOU. Syrah and Mourvèdre must account for 30% of the blend, with Grenache Noir and/or Lladoner Pelut at least 20%, and there should be no more than 60% Carignan. R.E.G.

Tavel is one of France's few appellations to produce exclusively rosé wine. Situated on the west bank of the RHÔNE to the south of LIRAC, it was one of the first six *appellations d'origine côntrolées* (see AOC) to be established in France in 1936. Its wines have fallen out of fashion in recent years due to their dark hue, which is stipulated in the appellation rules. Soils are mixed, with outcrops of SAND and a bed of the round stones called *galets roulés* towards the eastern part of the appellation nearest the river, while the Malaven Valley in the western part is littered with white LIMESTONE scree known locally as *lauses.* Wines must be a blend of Grenache with other permitted varieties, of which Cinsaut is particularly notable, making up nearly 20% of plantings. Once picked, grapes are cold-macerated (see MACERATION) for 12–48 hours before PRESSING. The wine is always dry and can be unusually long-lived for a rosé, up to ten years for top examples from estates such as Ch d'Aqueria and Domaine de la Mordorée. Tavel is

also home to Eric Pfifferling of Domaine l'Anglore, whose wines are inspiring a renaissance of Tavel wines. M.C.W.

Tavira , fishing port and easternmost DOC in the ALGARVE in southern Portugal.

Távora-Varosa, DOP named after two Douro tributaries immediately south of the DOURO in central-northern Portugal. The surrounding mountains insulate the region from humid Atlantic westerlies and harsh continental influence from the east. With GRANITIC soils and a TEMPERATE climate, the mainstay of production is sparkling wines—the region was Portugal's first to attain classification for *espumante* (TRADITIONAL METHOD) sparkling wines in 1989 (which are made from Portuguese and French varieties). S.A.

tawny, style of FORTIFIED WINES usually associated with extended CASK AGEING. See PORT, for example.

taxation. Wine has attracted the attention of the taxman since ancient times. Its production, sale, and distribution have been so closely regulated by the authorities for one simple reason, whatever their attitude to alcohol: revenue. The civilizations of the ancient Middle East (see ancient EGYPT and MESOPOTAMIA) were the first to recognize this useful attribute. It was carefully regulated in parts of ancient GREECE, but it was the Romans who, in this as in many other aspects of wine history, helped realize its potential.

In ancient ROME tax was paid from the moment the grape appeared on the vine (Roman vine-growers paid a vineyard tax calculated on the quality of the land) to when it was consumed. It was paid either in kind or in cash and represented a huge proportion of state income. Some areas in the empire, CALABRIA, for example, paid its entire tax to Rome in wine, which was then sold or distributed free to the urban masses.

Medieval kings found wine taxation fabulously lucrative. During England's occupation of western France, for example, the crown benefited doubly by receiving DUTIES paid on wine exported from BORDEAUX and then again on the same wine as customs when it entered London. During the early part of the 14th century, when this trade was at its peak, wine duties collected in Bordeaux surpassed the king's total tax revenue in England.

Not surprisingly, taxes on wine have been perceived as a fast, easy way of raising cash, and the state has shown no scruples in doubling or tripling them at times of emergency—often to pay for wars such as the HUNDRED YEARS WAR, the English Civil War, and the Napoleonic Wars.

Although they may complain, in certain circumstances wine merchants have been happy to pay tax because it legitimizes their business. Wine merchants within the Islamic empire of the caliphs (usually Jewish or Christians) viewed their payments as a kind of insurance policy; the state would not outlaw their activities, despite the Qurʾānic ban on alcohol, because the income was so useful (see ISLAM).

Wine taxation has uses beyond mere revenue. Different levels can be used to reward or punish trading partners. For example, throughout the 18th century, French wines attracted twice as much DUTY as Portuguese wines (see METHUEN TREATY). Not surprisingly, trade in French wines suffered and port became the staple English wine (see WAR).

Differential taxation has also been used to manipulate consumer tastes for reasons of health or morality. Gladstone's Act of 1860 reduced the duty on light, less alcoholic wines in an attempt to switch the British palate away from the heavy, FORTIFIED WINES and spirits that earlier taxation had favoured.

Taxation has at times had indirect consequences. During the 18th century, when duties were high and complicated (French wines were subject to 15 separate duties), ADULTERATION AND FRAUD and smuggling increased in England. Grievances against excessive

taxation of wines entering Paris have been recognized as one of the sparks that lit the fire of revolution in 1789.

It was inevitable that, as soon as wine was taxed, certain parties should be exempt. Traditionally these have included the crown, the Church, and sections of the nobility; such exemptions go back at least as far as ancient EGYPT. This privilege has been extended in modern times (so far as customs duties go) to travellers via the system of duty-free allowances.

Taylor's, important independent PORT shipper and a key part of the FLADGATE PARTNERSHIP. The original firm of port shippers was established in 1692 by Job Bearsley, and his son Bartholomew bought Casa dos Alambiques at Salgueiral near Régua, the first known British port shipper's property in the DOURO Valley. Between then and 1844 there were no fewer than 21 name changes. However, with the arrival of Joseph Taylor in 1816, John (later Baron) Fladgate in 1837, and Morgan Yeatman in 1844, the company assumed the name Taylor, Fladgate & Yeatman, or Taylor's for short. See the FLADGATE PARTNERSHIP for more details.

Foulkes, C. (ed.), *A Celebration of Taylor's Port* (1992).

Tazzelenghe, relatively obscure 'tongue-cutting' red grape of Italy's Colli Orientali in FRIULI.

TBA, understandably common abbreviation for TROCKENBEERENAUSLESE. Also for 2,4,6-tribromoanisole, a musty- or dusty-smelling compound which may affect wine produced in a contaminated winery. The cause so far identified is the microbial degradation by fungi in the winery of tribromophenol (TBP) used in wood preservatives or as a flame retardant in paints and plastics. It is therefore only indirectly related to cork, which can act as a 'carrier' of the taint. The perception threshold in red and white wines is approximately 3–4 ng/l, down to 2 ng/l in sparkling wine. Further research is needed to assess the frequency of this fault. It has not so far been possible to distinguish TBA from TCA by tasting.

J.H. & A.L.W.

T-budding, a BUDDING method used extensively in woody horticultural plants, including the grapevine, normally for field GRAFTING on to a ROOTSTOCK. The method entails making a T-shaped cut in the bark of the rootstock, when the bark is slipping, then lifting back the flaps to permit insertion of a shield-shaped piece cut from the SCION with a bud on it. After insertion, the bud is wrapped tightly with budding tape to ensure close contact of the tissues and high humidity around the cuts. T-budding can be done when the bark of the stock lifts freely, during two to three months over midsummer. Scion buds may be taken from stored winter cuttings or green current shoots. As with CHIP BUDDING, T-budding may be used for TOP GRAFTING.

B.G.C.

TCA, or 2,4,6-trichloroanisole, is a potent TAINT compound associated with musty odours and flavours in a range of food and beverages. It is the principal unpleasant-smelling compound most commonly considered responsible for CORK TAINT and is therefore generally encountered by consumers only when a specific cork-sealed bottle is contaminated. The formation of TCA is described under HALOANISOLES.

TCA is extremely potent, with an aroma threshold in wine of 2–5 ng/l in red and white wines but only 1–1.5 ng/l in sparkling wine

because the CARBON DIOXIDE volatilizes taint compounds. Some winemakers now demand TCA testing of all barrels they purchase, as any wood or oak product can and is occasionally contaminated, and winery designers now eschew wood in production areas. See CORK for cork producers' strategies to reduce or eliminate TCA.

J.E.H. & A.L.W.

Tchelistcheff, André (1901–94), consultant oenologist and founding father of the modern California wine industry. Tchelistcheff was born in Moscow, the sickly son of a Russian professor of law. After a brush with death in the army, he trained as an engineer-agronomist in Czechoslovakia then, at the age of 36, decided to study VITICULTURE and OENOLOGY in more detail, in Paris. While working on a farm near Versailles, he became a graduate assistant to the director of the department of viticulture at the National Institute of Agronomy as well as taking a course in wine microbiology at the Institut PASTEUR. An obviously talented student who combined intellectual rigour with a philosophical bent, he worked briefly at MOËT & CHANDON and had already been offered jobs in Chile and China before being introduced to his future employer. Georges de Latour was a Frenchman who had established himself as a highly successful businessman and owner of Beaulieu Vineyard in the Napa Valley, but he was anxious to import a French-trained winemaker for the post-PROHIBITION era.

During his 35-year career at Beaulieu, Tchelistcheff introduced the principles of winery HYGIENE as well as pioneering TEMPERATURE-CONTROLLED fermentation, mastery of MALOLACTIC CONVERSION, and FROST DAMAGE prevention techniques such as the orchard heaters and WIND MACHINES which dominated the Napa Valley for so long. He also made considerable progress in the prevention of various VINE DISEASES and established a reputation as both wine and vineyard CONSULTANT.

From his first years in California, Tchelistcheff established an identity independent of Beaulieu, with his own small laboratory in St Helena advising other Napa and Sonoma wineries and training a younger generation of winemakers such as the young MONDAVI

brothers. He was a consultant to Buena Vista winery, for example (see HARASZTHY), from 1948, and in 1967 he began a long association with Ch Ste Michelle in WASHINGTON State. He was also one of the first to recognize the viticultural potential of the CARNEROS district of northern California. Although he retired from Beaulieu in 1973, four years after it was sold to the Heublein corporation, he continued to be an active consultant to a host of California wineries as well as to Ornellaia of BOLGHERI in Italy (where his son Dimitri subsequently advised). In 1991, however, he was wooed back to Beaulieu by the multinational corporation which by then owned it.

Tchelistcheff was a charter member of the American Society of Enologists and was made a Chevalier de l'Ordre du Mérite Agricole by the French government in 1954, being promoted to Officier in 1979. Tchelistcheff was unique in the wine world for the geographical breadth and historical depth of his singularly acute views on the contemporary wine scene.

TCP. See HALOANISOLES.

TDN, the FLAVOUR COMPOUND norisoprenoid hydrocarbon 1,1,6-trimethyl-1,2-dihydronaphthalene found particularly in RIESLING. TDN formation responds to fruit MICROCLIMATE and is increased by high temperatures and solar radiation. Low-PH wines seem to be more prone to TDN formation, which is also affected by YEAST strain and by the choice of Riesling CLONE and ROOTSTOCKS. At or just above the detection threshold, it adds to the complexity of a bottle-aged wine but at relatively high concentrations, particularly in wines that have been in bottle for two or more years, and in excess TDN can impart an undesirably pronounced kerosene/petrol-like flavour. H.S.

Ziegler, M., et al., 'Impact of rootstock, clonal selection, and berry size of *Vitis vinifera* sp. Riesling on the formation of TDN, vitispiranes, and other volatile compounds', *Journal of Agricultural and Food Chemistry*, 68/12 (2020), 3834–49.

tears (to rhyme with 'ears'), term used to describe the behaviour of the liquid climbing and falling in a glass of relatively strong wine. The wine wets the inside of a clean glass and climbs up a few millimetres or even centimetres. At the upper edge of the thin layer on the inside wall, patches of the film thicken, become more drop-like, and eventually roll back down the inside wall to the liquid surface. These traces of what look like particularly viscous droplets are also sometimes called 'legs' and may give some indication of a wine's ALCOHOLIC STRENGTH. (But note that some of the finest German wines may have only 7 or 8% alcohol but still form very obvious tears.)

James Thomson, a British physicist and engineer, observed in 1855 what he called 'tears of strong wine' and related the phenomenon to surface tension. Unfortunately his work was overlooked, and this relation to surface tension is usually credited to Italian physicist Carlo Marangoni, who published it in 1871. However, the exact physical explanation of the phenomenon was not obtained until 2009.

A few physical relationships are involved in producing tears. The attractive forces between molecules in the liquid–air interface give rise to surface tension forces. A similar type of force also acts between a liquid molecule and the molecules of a solid surface, and yet another intermolecular force acts between the solid and the air molecules. These are called interfacial tensions.

If the interfacial tension between the solid glass and the air is higher than the interfacial tension between the solid and the liquid, then molecules of liquid will adhere to the glass and wet areas higher and higher above the liquid surface. A point is reached at which the weight of the liquid clinging to the wall just balances the force trying to lift more liquid up the wall surface.

Wine is mainly a solution of alcohol and water. While the thin film of wine climbs up the inner wall of the glass, another physical action occurs: the alcohol evaporates faster than the water from the film surface. This changes the composition of the film, increasing its concentration of water and thereby increasing both its air–liquid and solid–liquid surface tensions. This increase in surface tensions, and especially in the solid–liquid surface tension, causes perpetual tears:

the tears keep going down and the wine keeps going up. Eventually the drop becomes so heavy that interfacial tension can no longer hold it to the glass surface. It then runs down the wall, forming a tear or leg.

Dubious readers can convince themselves of this somewhat complicated explanation of an apparently simple phenomenon by observing the lack of tears in glasses of pure water. That evaporation is necessary can be demonstrated by simply covering a glass that previously demonstrated tearing. Tearing ceases, though it will resume upon removal of the cover.

It is often thought that tears are the result of GLYCEROL, but in fact entirely unrelated phenomena are responsible. Tears are *not* a measure of viscosity.

Tears occur in many multicomponent liquid mixtures but not in all. For example, it is most obvious in wines above about 12% alcoholic strength, but at lower concentrations the effect is either small or completely non-existent because the surface tension of the air–solid is no longer higher than that of the liquid–solid.

Tadmor, R., 'Marangoni flow revisited', *Journal of Colloid and Interface Science*, 332 (2009), 451–4.

TeCA, or tetrachloroanisole, more properly 2,3,4,6-tetrachloroanisole, is a musty- or dusty-smelling compound that can taint wine if the concentration is above the perception threshold of around 20 ng/l in red or white wine and 4 ng/l in water. The formation of TeCA is described under HALOANISOLES. PCA or 2,3,4,5,6-pentachloroanisole has a much higher perception threshold, at around 5,000 ng/l, but is nearly always present with TeCA.

teinturier literally means 'dyer' in French, which is the function for which these vines with their red-fleshed grapes were initially grown, notably in the Midi, to add at least apparent depth to the pale wines of the dominant ARAMON in the early years of the 20th century.

The original variety called Teinturier, or sometimes Teinturier du Cher, was probably extremely ancient and was first noted around Orléans in the 17th and 18th centuries, where it imbued the pale-pink wines of the region with valuable colour. DNA PROFILING strongly suggests a parent–offspring relationship with SAVAGNIN.

As long ago as 1824, the Frenchman Louis BOUSCHET decided to try to breed vines with coloured flesh, and the 1828 cross of Aramon × Teinturier du Cher resulted in the popular Petit Bouschet. Henri Bouschet, Louis's son, crossed Petit Bouschet with Grenache to produce the very popular ALICANTE BOUSCHET, a deeply coloured *teinturier*, known as Garnacha Tintorera in Spain, *tintorera* being Spanish for *teinturier*. Other red-fleshed varieties bred by the Bouschet family and used for their 'dyeing' properties at one time include Morrastel Bouschet, Carignan Bouschet, and GRAND NOIR DE LA CALMETTE.

Red-fleshed versions of the lightly coloured GAMAY grape have been widely grown, not just in the Loire but outside France. The Gamay *teinturiers* include Gamay Fréaux, Gamay de Bouze, and Gamay de Chaudenay. Gamay Fréaux and Gamay de Chaudenay are said to be mutations of Gamay de Bouze. Colobel (Seibel 8357) is a *teinturier* FRENCH HYBRID which was the only such variety to be authorized in France.

Germany's useful red-fleshed varieties include Carmina, Deckrot, DUNKELFELDER, Kolor, and Sulmer. ROYALTY 1390, Salvador, and the popular RUBIRED are all California creations, while the important Georgian *teinturier* is SAPERAVI, which is, if not red fleshed, then certainly deep-pink fleshed.

Tejo, DOC and VINHO REGIONAL (called Ribatejo until 2009) in central-southern Portugal. It corresponds to the province of the same name on both sides of the river Tagus (Tejo) inland from the capital Lisbon (see map under PORTUGAL). This new name reflects a desire to distance it from its historic reputation for vast quantities of indifferent wine produced by its CO-OPERATIVES from ultra-high yielding vines grown on the river's fertile floodplains, as does the abolition of six DOC subregions (Almeirim, Cartaxo, Chamusca, Coruche, Santarém, and Tomar) heavily associated with the co-operatives. Today the DOC and Vinho Regional share the same borders; soils, not subregions, tend to define the region's best wines. Large, family-owned agricultural estates, which started to make wine themselves in the 1990s rather than selling to the co-operatives, led the charge in GRUBBING UP vineyards on the fertile alluvial riverbank soils (*campo*), instead concentrating production on less fertile, well-drained sandy soils (*charneca*), calcareous CLAY (*bairro*), and SANDSTONE, with pockets of LIMESTONE and SCHIST in the north. Old-vine CASTELÃO and FERNÃO PIRES from *charneca* soils are among the region's best; with renewed interest, they are being positioned as Tejo's signature varietal wines. Old-vine ALICANTE BOUSCHET, a dark horse, can be very good too, and TOURIGA NACIONAL from northern Portugal and such INTERNATIONAL VARIETIES as Syrah, Cabernet Sauvignon, Sauvigon Blanc, Chardonnay, and Viognier have helped raise Tejo's profile with bargain-hunters abroad. In 2021 three co-operatives still accounted for almost half the region's production (60:40 white/red), but, having almost halved the vineyard area this century, the direction of travel is upwards with a growing number of boutique labels. Temecula Valley , CALIFORNIA high DESERT wine region in Riverside County and AVA inland of the coastal mountain range 56 km/35 miles north of San Diego. Temecula is the viticultural aspect of a large 1960s development called Rancho California, which used vineyards to attract urban escapees from Los Angeles, Orange, and San Diego counties. The warm, dry region credits the Rainbow Gap, a narrow opening in the coastal ridge, for funneling cool marine air into the area. The Cilurzo family created the first commercial winery in 1968, followed by Callaway Winery in 1974 and, six years later, Hart Winery. Steady growth was devastated by PIERCE'S DISEASE in the late 1990s. That disaster inspired a renaissance of viticulture and wine TOURISM, prompting the development of nearly 50 wineries working with 1,012 ha/2,500 acres by 2021. Cabernet Sauvignon, Syrah and Petite Sirah dominate. M.D.K.

temperate climates are generally defined as environments with moderate rainfall spread across the year or over a portion of the year, with sporadic DROUGHT, mild to warm summers, and cool to cold winters. There are two types of temperate climate: MARITIME and CONTINENTAL. G.V.J

temperature is critically important to VITICULTURE, WINEMAKING, wine MATURATION, and wine SERVICE, each in very different ways.

Climate, viticulture, and temperature

Temperature is widely considered the most important climatological factor affecting grapevines, although others such as SUNLIGHT, RAINFALL, HUMIDITY, and WIND are also important. Gladstones comprehensively reviews the role of temperature in viticulture. Temperature records are available from climate recording stations, and modern statistical procedures allow the calculation of temperatures between station locations that may be more representative of actual vineyard sites (see TOPOGRAPHY, MESOCLIMATE, and CLIMATE CHANGE).

Temperatures at particular stages of vine growth or during ripening can have specific effects. During the winter, the risk of killing dormant vines is one basis for defining climatic suitability for viticulture (see WINTER FREEZE). This is the main limiting factor in cool climates with marked CONTINENTALITY. Most fully dormant VITIS VINIFERA vines with well-matured canes can withstand air temperatures down to about −15 °C/5 °F. Native AMERICAN VINE SPECIES are in general hardier, and AMERICAN HYBRIDS intermediate. However, there is considerable variation among VINE VARIETIES.

The winter hardiness of RIESLING, for instance, is almost certainly one of the reasons for its historical success in Germany. The chance of winter killing of vines in Europe increases from south-west to north-east (see RUSSIA, for example). Extensive commercial viticulture without WINTER PROTECTION reaches its limit where the average mean temperature of the coldest month falls below about −1 °C/30 °F.

Air TEMPERATURE VARIABILITY largely determines the risk of FROST DAMAGE after BUDBREAK with temperatures below 0 °C/32 °F adversely affecting the growth of the vegetative parts of the plant and hard freezes (< −2.2 °C/< 28°F) reducing yields significantly. Temperatures around FLOWERING contribute to differences in FRUIT SET (by influencing COULURE, most notably) and to the FRUITFULNESS of the developing new buds which form shoots and bunches the following

year. Both fruit set and bud fruitfulness are favoured by moderately high temperatures. Nearing maturation, early frost or freezes can lead to the splitting of the grapes, which influences disease development and can result in a significant loss of yield. Finally, both average temperature and temperature variability during ripening can have a direct influence on fruit and wine qualities, as discussed under CLIMATE AND WINE QUALITY.

Vines in cool climates start growing in the spring at about the time when the mean air temperature reaches 10 °C/50 °F. The rate of vine growth and development then increases to a maximum at a mean temperature of about 22–25 °C/72–7 °F. Temperature is often discussed in viticulture as mean temperature for the full growing season and for the warmest month, which are often used as a reasonable basis for broad comparisons (see CLIMATE CLASSIFICATION and COOL-CLIMATE VITICULTURE). In the traditional heat-accumulation methods for viticultural climate classification, values are based on excesses of daily or monthly average mean temperatures over 10 °C. Such classifications can at best only approximate the temperatures experienced by the vines. Hourly or shorter time intervals give better results.

Air temperature is not the only kind governing vine growth and fruiting, however. Vines and soils are warmed by sunlight, which has major effects on grape berry temperature, leaf temperature, grape composition, and, subsequently, wine quality. Some evidence now confirms the old belief that soil temperature is also important. This control appears to be mediated by the root-produced hormone CYTOKININ, although soil temperature can also affect vine temperature, especially at night. The composition of the soil, its colour, drainage, and the duration and angle of exposure to the sun are all important factors in this respect. See SOIL COLOUR, STONES AND ROCKS, TOPOGRAPHY, and MESOCLIMATE. G.V.J.

Gladstones, J., *Viticulture and Environment* (1992).

Winemaking and temperature

Temperature and TEMPERATURE CONTROL are of critical importance in making good-quality wine (although great wine may have been made fortuitously, long before the theory of temperature control was understood and temperature was deliberately manipulated). Temperature has direct effects on the rates of the biochemical reactions involved in FERMENTATION and on the slower reactions involved in CLARIFICATION and STABILIZATION of wine. REFRIGERATION slows down the reactions of harmful microorganisms, as well as the reactions involved in AGEING.

In warm regions, therefore, care should be taken to ensure that grapes arrive at the winery in a cool, and relatively undamaged, condition. The harmful effects of microorganisms such as ACETOBACTER and enzymatic OXIDATION are encouraged by high temperatures. Low temperatures are vital if there is any interval between HARVEST and CRUSHING; the potential quality of white wines in particular can be lost through carelessness at this early phase of winemaking. During DESTEMMING and crushing, when the PHENOLICS in grape juice are in direct contact with oxygen, OXIDATION begins at a rate proportional to the temperature. To slow browning of white grape juice, therefore, care is usually taken to keep temperatures as low as possible (see MUST CHILLING). SULFUR DIOXIDE may also be added to the must. Oxidation of red must is less of a problem because its higher phenolic content, including the red colour compounds, can conceal small amounts of amber or brown, although lower temperatures during pre-fermentation processes (around 15 °C/59 °F) allow better control of the fermentation temperature.

If temperature control is desirable prior to fermentation, it is critical during it. At temperatures below 10 °C/50 °F, most yeasts will act very slowly or not at all, while at temperatures above 32 °C/90 °F they are damaged and finally killed. Secondly, higher fermentation temperatures speed up some reactions so that undesirable flavour compounds become apparent. Thirdly, at higher temperatures, there

is a risk that some of the desirable FLAVOUR COMPOUNDS are volatilized in the rapidly evolving stream of carbon dioxide, resulting in a less fruity wine. In the extreme case of temperatures nearing the range at which yeasts are killed, the yeast metabolism produces more VOLATILE ACIDITY and yeast cells secrete compounds which inhibit future yeast growth, thereby making it difficult or impossible to restart this STUCK FERMENTATION even after cooling.

There are yeast strains which grow and ferment very slowly at very low temperatures, only just above freezing. Such strains are particularly useful in cool wine regions such as Switzerland and parts of Germany and also for the production of wines such as CLAIRETTE DE DIE.

White wines are in general fermented at lower temperatures than red, partly in order to conserve the primary grape AROMAS, partly because there is no MACERATION, for which heat may be useful in encouraging the extraction of phenolics and other flavour compounds from the grape skins. Temperatures of 12–17 °C/50–63 °F are common when the aim is to make fruity, well-balanced, light-coloured wines (although see also BARREL FERMENTATION). Grape varieties such as Sauvignon Blanc, Riesling, and Muscat tend to be fermented at higher temperatures than more neutral varieties to encourage the accumulation of secondary fermentation aromas. Old World white wine fermentation temperatures are likely to be 18–20 °C/64–68 °F. The techniques of barrel fermentation and LEES CONTACT, such as are often applied to Chardonnay grapes, often involve slightly higher fermentation temperatures too, although the small size of the barrel (in comparison with the normal stainless-steel tank) helps to control temperature.

Temperature control is also extremely important during RED WINEMAKING. The main concern here is the extraction of sufficient TANNINS, ANTHOCYANINS, and flavour compounds from the grape skins. Temperature is one of the factors governing this extraction, agitation and time being the others. Fermentation temperatures of 25–27 °C/77–81 °F in the must, and therefore 30 °C in the CAP, generally

produce the best flavour and EXTRACTION in red wines, provided other conditions are optimal (and grape variety, agitation, and time all play a part interlinked to temperature in the maceration process). Temperatures higher than this threaten the yeast activity, while temperatures below it limit extraction and favour the production of secondary aromas.

Temperature continues to be an important factor in wine production long after the fermentation phase. Oxidation and loss of fruitiness in white wines can be discouraged by low temperatures, while the bacterial activity that stimulates MALOLACTIC CONVERSION can be positively encouraged by storing the newly fermented wine at 18–20 °C/64–68 °F until this conversion is completed.

Fermentation temperatures govern the types of ESTERS that are formed and accumulate in the wine. Lower temperatures (10–15 °C/50–59 °F) favour both the production and retention of the fruity esters, which have lower molecular weights. Among these are nearly all of those possible by reactions between ACETIC, propionic, isobutyric, and isovaleric acids with ETHANOL, propyl, isobutyl, and FUSEL OIL. These are the esters which give fruits their characteristic flavours (ISOAMYL ACETATE, for example, is the flavour material of ripe bananas). Higher fermentation temperatures (20–25 °C/68–77 °F) result in the production of lower amounts of esters. V.L.

Storage temperature

In the same way that it affects the reactions involved in winemaking, temperature becomes the governing factor in the much slower reactions in bottle that constitute wine AGEING. Interactions among the thousands of natural organic chemicals in the wine during this important phase of its maturation are directly affected by temperature. If the storage temperature is very high, say 30 °C/86 °F, a wine would mature extremely quickly and probably taste cooked or jammy. At a CELLAR temperature of 10 °C/50 °F, a wine would age very slowly, and if a wine is kept at 0 °C/32 °F there would be extremely high deposits of TARTRATES and PHENOLICS. In practice, a reasonable cellar temperature for ageing wines to be drunk within one's own lifetime is somewhere between 10 and 15 °C/50–59 °F. (The cellars of the Swedish state MONOPOLY were so cold that any fine, old wine bought in Sweden would taste markedly different from the same wine aged in the more temperate climate of France, for example.)

Even lower down the temperature scale, wine freezes at a temperature below 0 °C that is roughly half its ALCOHOLIC STRENGTH, so usually somewhere between −5 and −8 °C/23–18 °F. For this reason, in cool climates, care should be taken to insulate wine stored in places such as garden sheds or garages where winter temperatures are not maintained at a level acceptable to humans.

Serving temperature

The temperature at which a wine is served has a profound effect on how it smells and tastes. Different styles of wine deserve to be served at different temperatures to enhance their good points and try to mask any faults or imbalances. The following are some general observations, with suggested guidelines in italics.

The higher the temperature, the more easily the volatile FLAVOUR COMPOUNDS evaporate from the surface of wine in a glass. So, to maximize the impact of a wine's AROMA or BOUQUET, it is sensible to serve it relatively warm, say 16–18 °C/61–64 °F (at temperatures over 20 °C/68 °F the ALCOHOL can begin to evaporate so markedly that it unbalances the wine). *Serve complex and mature wines relatively warm*.

Conversely, the lower the temperature, the fewer volatiles will evaporate; at a serving temperature of about 8 °C/46 °F, all but the most aromatic wines appear to have no smell whatsoever. *The gustatory faults of a low-quality wine can be masked by serving it very cool*.

The higher the temperature, the more sensitive is the PALATE to sweetness, so it makes sense to serve sweet wines which may not have quite enough ACIDITY to counterbalance the sweetness quite cool, say at about 12 °C/54 °F. For the same reason, medium-dry wines served with savoury food will probably taste dry if served well chilled. *In general, chill sweet wines*.

The lower the temperature, the more sensitive the palate to TANNINS and BITTERNESS. Peynaud points out that the same red wine will taste 'hot and thin at 22 °C/72 °F, supple and fluid at 18 °C/64 °F, full and astringent at 10 °C/50 °F'. *Tannic or bitter wines such as many Italian red wines and any young red designed for ageing should be served relatively warm*.

The effect of temperature on apparent acidity is more widely disputed by scientists, but it is generally observable that flabby wines can seem more refreshing if they are served cold, say at 10 °C/50 °F.

(This may be related to the effect of temperature on sweetness described above.) *To increase the refreshment factor of a wine, serve it cool*.

Temperature also has an observable effect on wines containing CARBON DIOXIDE. The higher the temperature, the more gas is released, which means that fizzy wines can be unpleasantly frothy at about 18 °C/64 °F. *Sparkling and lightly sparkling wines are generally best served well chilled*. Since very few wines with a complex bouquet ever have any perceptible gas, this is no great limitation (those who make Australia's extraordinary sparkling Shiraz claim it is best served at room temperature, but these sparkling wines are not particularly fizzy).

General rules are therefore:

Serve tannic red wines relatively warm, 15–18 °C/59–64 °F.
Serve complex dry white wines relatively warm, 12–16 °C/54–61 °F.
Serve soft, lighter red wines for refreshment at 10–12 °C/50–55 °F.
Cool sweet, sparkling, flabby white, and rosé wines, and those with any off-odour, at 6–10 °C/43–50 °F.

Of course wine tends to warm up to match the ambient temperature, so initial serving temperatures at the bottom end of these brackets—or even cooler—are no bad thing, especially in warmer environments. For more details of how to cool and warm bottles, see SERVING WINE.

See also TASTING (as opposed to drinking) for its different requirements of wine temperature.

Peynaud, E., *The Taste of Wine* (2nd edn, 1996).

temperature control during WINEMAKING is crucially important, as outlined in TEMPERATURE. Although it has been widely and systematically practised only since the 1960s and 1970s, its efficacy was appreciated as long ago as Roman times (see DIE). See REFRIGERATION for details of how wine may be cooled at various points in its life. In cool wine regions or during particularly cool years, a

FERMENTATION VESSEL may need to be heated to encourage alcoholic FERMENTATION, most easily by circulating warm water in equipment also designed to carry cooling cold water or, in smaller cellars, simply by closing doors and installing a heater or two. Some form of heating may also be required to encourage MALOLACTIC CONVERSION.

temperature variability, a characteristic of climates referring to the short-term variability of temperature from day to day and week to week. Temperature variability plays an important role in determining the risks of FROST DAMAGE to dormant vines in spring and autumn, as well as those of HEAT STRESS and direct heat damage to the vines and fruit in summer. Such variability is driven by shifts in the circulation of the atmosphere that bring air masses with widely different temperature characteristics to wine regions. Stable temperatures on these time scales are best for grapevine physiology, whereas wide swings in temperatures have distinct viticultural and oenological implications (see TEMPERATURE and CONTINENTAL CLIMATE). This is especially important with extreme heat events (> 40 °C/104 °F) when grapevines will shut down to conserve water and energy, ultimately taking time to recover and return to optimum photosynthetic activity. In cool regions, low temperature variability is important for improved wine quality since it may influence consistent growth characteristics in the vines and the formation of PIGMENT, AROMA, and FLAVOUR in the ripening berries. Under such circumstances, these processes are favoured relative to the mere accumulation of SUGAR IN GRAPES. See also DIURNAL TEMPERATURE RANGE.

G.J.V.

Jones, G.V., et al., 'Climate, grapes, and wine: structure and suitability in a variable and changing climate', in P. Dougherty (ed.), *The Geography of Wine: Regions, Terrior and Techniques* (2012).

Tempranillo has been planted so enthusiastically in Spain that it was the world's third most popular wine grape variety in 2016. In some ways it is Spain's answer to Cabernet Sauvignon, the vine

variety that puts the spine into a high proportion of Spain's most respected red wines, and is increasingly planted elsewhere. Its grapes are thick-skinned and capable of making deep-coloured, long-lasting wines that are, unusually for Spain, not notably high in alcohol. Often replacing GARNACHA, BOBAL, or MONASTRELL, it became the most popular red wine grape in Spain in the early 21st century and by 2021 was planted on a total of 202,917 ha/501,419 acres in virtually all regions except for those in the far south and north-west, overtaking AIRÉN as the country's most planted variety of either colour.

Temprano means 'early' in Spanish, and Tempranillo probably earns its name from its propensity to ripen early, certainly up to two weeks before the GARNACHA with which it is still regularly blended to make RIOJA. This relatively short growing cycle enables it to thrive in the often harsh climate of Rioja's higher, more Atlantic-influenced zones Rioja Alta and Rioja Alavesa, where it constitutes by far the majority of all vines planted. Tempranillo has traditionally been grown in widely spaced bushes here, but this relatively vigorous, upright vine has also responded well to training on WIRES.

Wine made from Tempranillo grown in relatively cool conditions, where its tendency to produce MUSTS slightly low in acidity is a positive advantage, can last well, but the variety does not have a particularly strong flavour identity. Some find strawberries, others spice, leather, and tobacco leaves, but yields and winemaking skill are critical in determining its style.

In Rioja it is traditionally blended with Garnacha, plus a bit of Mazuelo (Carignan), Graciano, and Viura. In PENEDÈS it is known as Ull de Llebre; in VALDEPEÑAS as Cencibel. The variety is ideally suited to the cool conditions of RIBERA DEL DUERO, where, as Tinto Fino, it is by far the principal grape variety, but the seasoning of varieties imported from Bordeaux is a minor but signficant ingredient in that high plateau's most famous wine, VEGA SICILIA. Indeed, throughout Spain, blends of Tempranillo with Cabernet Sauvignon and/or Merlot are common, notably in Navarra and Castilla-La Mancha.

Its Spanish synonyms also include Tinta Madrid, Tinta del País, and Tinta de Toro, where its particularly concentrated form has played a major part in the style and popularity of TORO wines.

Tempranillo is one of relatively few Spanish varieties to have been adopted to a great extent in Portugal, where it is known both as Aragonez and (Tinta) Roriz and, after a dramatic increase in popularity, was the country's single most planted variety. For more, see TINTA RORIZ.

As Tempranillo or Tempranilla and making rather light, possibly over-irrigated reds, it has been important in Argentina's wine industry but lost ground to more marketable varieties in the late 1980s. Plantings stood at 5,430 ha/13,418 acres in 2020, mainly in Mendoza.

There were 359 ha/887 acres in southern France in 2019, most notably in the Aude and used for blending. Thanks to mildly increased interest in the variety and all things Spanish, in 2020 California grew 370 ha/914 acres of Tempranillo, once known there as Valdepeñas. Abacela pioneered fine Tempranillo in southern Oregon, where there were 142 ha/352 acres in 2019, and there has been small-scale enthusiasm for the variety in Washington State.

As vine-growers the world over search for new, recognizably high-quality ALTERNATIVE VARIETIES, Tempranillo is spreading around the globe, notably in Australia, where plantings had reached 844 ha/2,086 acres by 2022.

Italy grows a tiny amount of vines called Tempranillo, but DNA PROFILING unexpectedly showed that some Tempranillo has been grown in Tuscany and Basilicata under the widely applied name Malvasia Nera.

DNA profiling has shown that Tempranillo is a spontaneous cross between the old Spanish light-skinned grape ALBILLO Mayor and the obscure, no longer cultivated, Benedicto from Aragón.

Tempranillo Blanco, a pale-berried MUTATION, has been identified in Rioja, where VARIETAL versions have been made.

tendone, the Italian name for the overhead vine-TRAINING SYSTEM widely used in southern Italy, especially in ABRUZZO. It is also common in South America, where it is used for both TABLE GRAPES and wine grapes and is called *parral* (Argentina) or *parron* (Chile). English terms used include both 'arbour' and 'pergola', although the system is little used in English-speaking countries.

The vines are normally trained with trunks about 2 m/6.5 ft high, and a system of wooden frames and cross wires supports the foliage and fruit. Typically in Abruzzo the vines are planted in a 2.5 × 2.5 m square (up to 3 × 3 m for TREBBIANO), and from each staked vine four shoots are trained in different directions along the wires.

Arbours are normally high enough from the ground to allow tractors and implements to pass underneath, but not so high as to make hand work difficult. The vines are pruned to either canes or spurs (see PRUNING). Because all of the sunlight is captured, the system can be very productive: 30 to 70 tonnes of grapes per hectare (12–28 tons/acre) when water supply is plentiful.

Such training systems are limited in use because of the expense of their construction and the high cost of LABOUR required to manage them. Worker productivity is lower because of fatigue, and, where the vines are vigorous, the leaves form a very dense CANOPY so that the fruit and lower leaves are heavily SHADED. This reduces both YIELD and quality and increases the risk of POWDERY MILDEW.

Furthermore, the ventilation under such canopies is very restricted, and the build-up of humidity favours BOTRYTIS BUNCH ROT. The arbour system is used for table grapes in many parts of the world and has the advantage that the fruit hangs freely and makes access easy. Inclined overhead trellis systems which do not completely cover the ground are often used for table grapes, as in South Africa (where it may be called the verandah system), and occasionally for wine grapes around the borders of fields in the VINHO VERDE region of Portugal. R.E.S.

tendril, coiling, clasping organ that enables the stems of plants to climb (see WILD VINES). In many plants, these organs are modifications of stems, leaves, or leaflets, but in the grapevine they are modified INFLORESCENCES, developing at two of every three consecutive NODES. Tendrils are sensitive to touch (thigmotropic); when sufficiently elongated, they react to pressure on their surface by coiling around the touched object, be it a wire, a part of the vine, or any other adjacent material. Once coiled, the tendrils become lignified, very tough, and difficult to remove. B.G.C.

tent, medieval term for strong red wine from Iberia, mainly Spain (notably deeper in colour that the CLAIRET then still associated with Bordeaux). It is an Anglicized version of the word TINTO, Spanish and Portuguese for 'red'.

tenuta, Italian word for an agricultural holding, estate, or farm, usually larger than, for example, a PODERE.

Teran, Terrano, names for Refosco d'Istria, a member of the REFOSCO group, used, respectively, in CROATIA, the Kras district of SLOVENIA, and the CARSO DOC in the extreme east of Friuli. The Slovenians registered Teran as a geographical entity so that Croatian producers must now specify Hrvatska Istra on the label to make it clear that Teran is the variety not the appellation. Often confused with the distinct REFOSCO DAL PEDUNCOLO ROSSO.

Terlano, or Terlaner in German, long-lived white wines from around the town of Terlano in ALTO ADIGE. It is also the name of a large subzone of the Alto Adige DOC.

Termeno Aromatico. See GEWÜRZTRAMINER.

termites can be pests in older vineyards, where they tunnel into old wood and can weaken it so much that the vine may partially collapse. Very occasionally newly planted cuttings are attacked where growing conditions are poor. M.J.E.

Teroldego, old, well-connected grape variety which makes deep-coloured, seriously lively, fruity wines named Teroldego Rotaliano because they are made almost exclusively in the Campo Rotaliano in TRENTINO, north-east Italy, with suitable tannins for relatively early drinking. Wine made from this variety is rather prone to REDUCTION. From the mid 1980s, Elisabetta Foradori initiated a qualitative revolution, and her wines have become the benchmark for classic, ageworthy Teroldego. The variety was known in the Campo Rotaliano as early as the 15th century, and DNA PROFILING at SAN MICHELE ALL'ADIGE has shown a parent–offspring relationship with LAGREIN from Alto Adige and that the variety is quite closely related, through DUREZA, to Syrah. Total plantings in Italy in 2015 were 730 ha/1,804 acres. Also found in Brazil. See also MARZEMINO.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

terpenes, distinctive FLAVOUR COMPOUNDS associated with the floral and citrus aromas found in wines made from such varieties as Muscat, Gewürztraminer, and Riesling.

terpenoids, an important group of plant chemicals including many essential oils, CAROTENOIDS, plant HORMONES, sterols, and rubber. They contribute much to the unique qualities of the vine. Chemically they are multiples of branched, five-carbon (isoprene) units yielding a variety of compounds with diverse properties: the C10 monoterpenes make an important contribution to floral aromas (see FLAVOUR COMPOUNDS); the C15 sesquiterpenoids include the hormone ABSCISIC

ACID; and the C20 diterpenes include the GIBBERELLIN hormones. Carotenoids, with 40 carbon atoms, contribute to the skin colour of so-called white grapes and are metabolized to norisoprenoid flavour compounds that contribute to non-floral aroma of grapes.

B.G.C. & P.J.W.

Terra Alta, Spanish for 'high land' and a DOP in Spanish CATALUÑA (see map under SPAIN), with 5,820 ha/14,382 acres of vineyards in 2020 at an average ELEVATION of 480 m/1,575 ft. Its development parallels that of neighbouring TARRAGONA, in that growers are following the lead of PRIORAT, notably recovering and relaunching their formerly despised GARNACHA grapes and making some impressive wines. One-third of total worldwide production of GARNACHA BLANCA comes from Terra Alta, and in 2011 the local CONSEJO REGULADOR introduced a special seal for high-quality wines made solely from the grape. Red wines, which make up 70% of production, rely especially on Garnacha Tinta, locally called Vernatxa. F.C.

terraces make work in vineyards planted across sloping land considerably easier and can also help combat SOIL EROSION. Terraces more or less follow the contours of the land, and so row spacing may be irregular. Terraces are created when the hillside is re-formed into a series of horizontal steps between the rows. The world's most famous vineyard terraces are those of the PORT wine region of the DOURO Valley in northern Portugal, where there has been considerable experimentation with different designs, although they are also common in much of SWITZERLAND, the northern RHÔNE, and elsewhere.

In centuries past, such terraces were laboriously constructed by hand and supported by stone walls. For modern vineyards, the cost of laying stones by hand can be prohibitive and skilled craftspeople hard to find. Most modern terraces are formed by bulldozers. Terraces are expensive to create and are therefore justified only for expensive wines.

An alternative to creating terraces is to plant vines up and down the hillsides, as in Germany and other parts of northern Europe. This practice avoids the expense of forming terraces but can lead to soil erosion and worker fatigue, and some slopes are too steep for tractors. See also HILLSIDE VINEYARDS. R.E.S.

Terrano. See TERAN.

Terrantez, Portuguese white wine grape that is practically extinct on the island of MADEIRA but can occasionally be encountered in historic bottles. It is not, as some have suggested, a synonym for GOUVEIO.

terra rossa, strikingly red soil usually associated with the dissolution of LIMESTONE in a MEDITERRANEAN CLIMATE. The colour is due principally to the insoluble residue of CLAYS stained with inert iron oxide and hydroxide minerals such as hematite and goethite. The soils are characterized by a low water-holding capacity, good drainage and aeration, and adequate vine nutrients (see VINE NUTRITION), but their eye-catching colour does not bestow any special benefits on the vine. Examples are found in Coonawarra (SOUTH AUSTRALIA), Istria (CROATIA), LA MANCHA (Spain), and LEBANON's Bekaa Valley. A.J.M.

Terrasses du Larzac, the rising star of the LANGUEDOC which was elevated very rapidly from Languedoc CRU to AOC in 2014. A large and fairly disparate appellation, it is characterized by its myriad soil types and wide DIURNAL TEMPERATURE RANGE—as much as 20 °C/36 °F—due to the Larzac plateau, which rises to almost 1,000 m/3,281 ft to the north. The wines are full-bodied yet crisp reds based on Grenache Noir, Syrah, and Mourvèdre, with small amounts of Cinsaut and Carignan allowed; the iron-rich CLAYS known as *ruffes* can give them a

brimstone edge. The appellation is home to some of the Languedoc's biggest and most famous names, though not all label their wines under the AOC as some contain Cabernet Sauvignon, a variety not permitted under this designation. M.S.

Terret is one of the Languedoc's oldest vine varieties and, like PINOT, has had plenty of time to mutate into different shades of grape (see MUTATION), which may even be found on the same plant. Terret Gris was once by far the most planted white wine variety in the Languedoc, even if it was concentrated in the Hérault *département*. Terret Gris and Terret Blanc, both in decline, can be made into a relatively full-bodied but naturally crisp VARIETAL white. The French vineyard survey of 2019 notes 842 ha/2,081 acres of Terret Blanc, only 40 ha of Terret Gris. Some varietal versions are made, and both are allowed into the white wines of Minervois, Corbières, and the Languedoc.

Terret Noir is the even rarer dark-berried version, one of the permitted varieties in red CHÂTEAUNEUF-DU-PAPE, to which it can add useful STRUCTURE and interest. All Terrets bud usefully late and keep their ACIDITY well.

terroir, much-discussed term for the total natural environment of any viticultural site, sometimes used to refer to the effect of that natural environment on wine quality and TYPICALITY. No precise English equivalent exists for this quintessentially French term and concept. The phrase 'a sense of place' has become popular because terroir links the sensory attributes of a wine to the location in which it was produced. The OIV's 2010 definition of terroir also incorporates the cultural dimension: 'a concept which refers to an area in which collective knowledge of the interactions between the identifiable physical and biological environment and applied vitivinicultural practices develops, providing distinctive characteristics for the products originating from this area'.

Major components of terroir are SOIL (as the word suggests, *terra* being Latin for 'earth' or 'land') and local TOPOGRAPHY, together with their interactions with each other and with MACROCLIMATE, which in turn affects MESOCLIMATE and vine MICROCLIMATE. In each particular location, soil and climate provide a set of resources specific to the place where the vines grow (temperature, light, water, CO_2, nutrients) which influences vine PHENOLOGY, VINE PHYSIOLOGY, and grape RIPENING. Hence, the place where the vines grow influences GRAPE COMPOSITION, which results in specific sensory attributes, as discussed by van Leeuwen et al. (2018).

Major regional CLASSIFICATIONS of European vineyards have been largely founded on the concept of terroir, although these may be based on climate rather than soil. A few decades ago OLD WORLD and NEW WORLD viticulturists, winemakers, and researchers may have argued about the importance of terroir in final wine quality. More recently their views have been converging, and both New World and Old World countries have organized international terroir congresses in the last ten years. However, some authors such as Matthews still consider terroir to be a myth.

It can certainly be argued that modern improvements in vineyard and winery technology have, by raising and unifying standards of wine quality, to some extent obscured differences in both style and quality of wines that in the past were (sometimes wrongly) attributed to terroir in its true sense. But, paradoxically, the same improvements can serve to unmask genuine terroir-related differences. By eliminating extraneous odours and tastes derived from FAULTS IN WINES, they allow a fuller expression of intrinsic grape characteristics which can be related to the vineyard site.

The wines of Burgundy are most often cited as evidence of the reality of the terroir effect. Many growers have different plots which they cultivate in the same way. They then vinify the grapes from these plots in a similar way, yet the wines produced differ significantly in quality and style. GUIGAL's single-vineyard bottlings in Côte Rôtie are one famous example of this approach to terroir, which

is increasingly being followed by producers all around the world who espouse REGIONALITY. Heitz Wine Cellars in the Napa Valley, for example, released its first vineyard-designate wine, Martha's Vineyard, in 1966, and today many other New World producers release single-vineyard wines, for example Catena's Adrianna Vineyard Mundus Bacillus Terrae from Mendoza or Henschke's Hill of Grace in the Eden Valley, Australia. 'Single vineyard' is today a proud statement on many wine labels from all parts of the wine world, even if the vineyard in question may extend over hundreds of hectares.

Both the OIV and Moran argue that terroir also includes human input in the vineyard and winery. Winegrowers choose their plant material (ROOTSTOCK and VINE VARIETY) and adapt their management choices (vineyard floor, TRAINING SYSTEMS, CANOPY MANAGEMENT) to optimize wine quality in each particular environment, which could be described as 'managing terroir' (van Leeuwen et al., 2018).

Many authors have studied specific terroir factors without taking into account the vine, focusing instead on geology (Wilson), geomorphology (Fanet), soil microbiology (Bourguignon), and climate (Tonietto and Carbonneau). The limitation of these approaches is that they remain highly descriptive and do not explain how these factors influence wine quality.

Dr Gérard Seguin, of the University of BORDEAUX, was the first author to conduct multidisciplinary terroir studies, including soil, climate, and the impact of each on vine physiology and grape ripening. He showed that a wide range of soil types are able to produce high-quality wines in Bordeaux. These soils have in common moderate fertility and well-regulated, moderately sufficient water supply to the vines. DRAINAGE was always excellent, so that both waterlogging and sudden increases in water supply to the vines were avoided no matter the amount of rainfall, hence buffering the vintage effect. Renouf et al. established a relationship between soil type and wine quality in hundreds of PARCELS across five vintages at famous Bordeaux wine estates. The highest-quality wine was produced significantly more frequently on specific soil types (in particular GRAVEL and CLAY), while on others (soils with waterlogging, deep

COLLUVIAL soils) the wine produced was more often blended into the second or third wine of the estate. GEOGRAPHICAL INFORMATION SYSTEMS (GIS) and geostatistics have made possible data-driven terroir zoning (see PRECISION VITICULTURE). This approach was successfully implemented by Bramley et al., but the zoning produced needs subsequent validation through sensory analyses.

Van Leeuwen et al. (2004) found that the effect of soil is secondary to that of climate. However, both the climate and the soil effects are mediated through their influence on water supply to the vine (see WATER STRESS). The respective effect of soil and climate may vary: the latter is more likely to dominate on a regional scale, the latter on a smaller scale, as explained by Bramley and Gardiner.

Studies of terroir in Burgundy, cited and illustrated by Johnson and Robinson, show that the best wines are from stony clay-LOAM soils, formed on the middle slopes from MARL (a clay and soft limestone mixture) mixed with SILT and rubble from outcropping hard LIMESTONE further up. These soils combine good drainage with just the right capacity to store and supply water to the vines.

Extensive studies by Carbonneau and colleagues in the Bordeaux region and by Smart and colleagues in Australia and New Zealand have revealed a further common feature of vineyards producing the best wines. All have a high degree of leaf and bunch exposure to direct sunlight, with little complete shading of internal and lower leaves (see further discussion under SUNLIGHT, CANOPY MICROCLIMATE, and CANOPY MANAGEMENT). Variation in this respect is explained by differences in vegetative VIGOUR and vine BALANCE. Best quality is associated with only moderate vigour, which typically results from a somewhat restricted water supply, limited NITROGEN, and (in some cases) appropriate TRAINING SYSTEMS and CANOPY MANAGEMENT. These studies suggest that soil effects on wine quality are indirect (i.e. soil conditions regulating water and nitrogen supply to the vine affect vine vigour, which in turn affects fruit and leaf exposure to sunlight, which in turn affects wine quality). While exposure to sunlight is amenable to management control on soils that are not too fertile,

vine supply of water, in the absence of IRRIGATION, is very largely not. It is therefore a prime contributor, together with local TOPOGRAPHY, to the immutable influence of terroir.

An implication is that GEOLOGY, often cited as a basis of terroir, has in general no more than an indirect role. To varying degrees, parent ROCK materials do contribute to the natures of the soils derived from them; they also shape local topography and therefore MESOCLIMATE. Occasionally the parent materials contribute directly because vine roots can penetrate fissures in them, as in the cases of CHALK subsoils and the SCHISTS of the Douro Valley, contributing to the regulation of water supply. In the broad sense, however, it remains the soil itself and its water relations that play the decisive role.

The effect of terroir on wine quality is now quite well understood: it is mainly mediated through vine water supply by the soil and the climate, although mineral supply (and especially nitrogen supply) can also play a role. This effect of terroir can partly be obtained by good canopy and irrigation management in dry climates. However, the effect of terroir on wine style is just starting to be unravelled. The high quality of Ch AUSONE (limestone), Ch CHEVAL BLANC (gravel and clay), and PETRUS (heavy clay) can be explained by the natural regulation of water supply to the vines. But why do they taste different, and why do they each have their own style, despite very similar viticultural and oenological practices? This aspect of terroir is extremely interesting, because top wines are not only very good but also unique, with their own style. Research into aroma compounds in grapes and wine, reviewed by van Leeuwen et al. (2020), is providing more evidence of the way terroir can shape aromas and TYPICALITY.

Another aspect of terroir is that its clearest expression occurs when grape ripening is relatively slow and therefore late in the season (van Leeuwen and Seguin, 2006). This occurs in cool climates or in warmer climates when varieties are sufficiently late ripening. In all quality wine regions in Europe, growers have chosen varieties that just achieve ripeness under the local climatic conditions. When grapes ripen in August in the northern hemisphere (e.g. Central

Valley, California) or in February in the southern hemisphere (e.g. the Murray river basin, Australia), it is difficult to produce wines with refined aromatic expression. Terroir can only be understood when soil, climate, and vine are taken into account simultaneously. When early-ripening varieties are planted in warm climates, wines are heavy, lacking freshness and aromatic expression (except for aromas produced by winemaking practices). This is the case with warm-climate Chardonnay, for instance. A much better expression is obtained in cool climates (Chardonnay in Chablis, Sauvignon Blanc in New Zealand). Growers in the New World are becoming more aware of this and seeking out cooler regions—for example, Sonoma Coast instead of the Napa Valley for Pinot Noir and Chardonnay, or New Zealand, Tasmania, or high-ELEVATION vineyards in Mendoza, Argentina.

The hierarchy of terroir factors

In the relatively flat topography of Bordeaux, soil and its water relations are major drivers of terroir expression. The situation is clearly different in areas such as Germany's MOSEL region at what was once the cold limit of commercial viticulture (see CLIMATE CHANGE). The topographic differences between individual sites decide whether grapes, particularly varieties such as RIESLING, will ripen fully at all. At high latitudes, topography and mesoclimate are inescapably major components of terroir.

It has also been argued that mesoclimatic differences may not merely govern the degree of ripeness attained but could also affect the more subtle grape and wine qualities commonly attributed to terroir; see CLIMATE AND WINE QUALITY, TEMPERATURE VARIABILITY, and DIURNAL TEMPERATURE RANGE. This is evidenced by Urvieta et al. (2020), who show terroir influence (largely driven by mesoclimatic differences) on phenolic compounds in Mendoza, Argentina. Soil might similarly influence grape and wine qualities through its effect on MICROCLIMATE; see STONES AND ROCKS, SOIL COLOUR, and SOIL AND WINE QUALITY.

All these effects serve to underline terroir as a real concept, not something expressed merely through the relationships between vine vigour, balance, and the vine canopy. The distinction is critical because, to the extent that the latter is true, other approaches might achieve the same end. Two stand out in importance.

1. The use of larger or more complex vine-training systems, such as Carbonneau's LYRE trellis, making it possible to maintain good leaf and fruit exposure on larger and more productive vines. This in turn allows the exploitation of more moist, and possibly more fertile, soils, giving higher yields without any necessary loss of fruit and wine quality.
2. In regions with dry summers, the use of controlled IRRIGATION, especially that made possible by DRIP IRRIGATION. This allows

vegetative vigour to be held at appropriate levels for vine balance but also water to be supplied during ripening as needed. It is an important advance in regions of MEDITERRANEAN CLIMATE as long as water is sustainably available.

It seems inconceivable, however, that these developments will ever totally eliminate the regional and local differences in wine qualities that have been traditionally ascribed to terroir. Differences in MACROCLIMATE, MESOCLIMATE, and soil MICROCLIMATE remain, while there are many conceivable avenues by which differences in soil chemistry —for instance, in trace element balances—might have small effects on wine flavours and aromas which are nevertheless detectable by the sense of TASTE. To the extent that terroirs remain unique (and poorly understood), one can therefore hope that they will continue to help mould the infinite variety and individuality of the best wines, giving the special nuances of character that make wine such a fascinating study for winemaker and consumer alike.

In this book we have chosen to focus on the natural environment as the key determinant of terroir, but the term can also be used to give economic and cultural value to a wine. Charters et al. explore terroir in the wider context of the humanities and social sciences.

tête de cuvée, French term occasionally used for selected top bottlings.

tetrachloroanisole. See TECA.

Texas , south-western state in the United States, currently the country's fifth largest wine-producing state after California, Washington, Oregon, and New York, with about 2,031 ha/5,020 acres planted mainly with VITIS VINIFERA vines in production in 2019. The first vineyard was planted by the Spanish missionaries near what is now El Paso in the mid 1600s. Wine production built to more than 200,000 gal/7,570 hl by 1853. In the 1880s, the famous VITIS taxonomist T. V. MUNSON, from Denison, Texas, shipped native Texas vine species to France and saved the European wine community from devastation by PHYLLOXERA. In the early 20th century, the Texas wine industry was almost eliminated by PROHIBITION. Dr Clint McPherson and Robert Reed of Texas Tech University revived the modern wine industry in 1976 with the creation of Llano Estacado Winery in

Lubbock, experimenting with multiple grape varieties and spurring others to do the same. The industry has grown steadily since. While determining producing wineries in Texas is difficult because the official count of winery permits includes non-producing locations, there were over 500 permits as of 2021, with 300–400 of these belonging to wineries producing wines from Texas grapes.

Texas vines have to combat not just DROUGHT and PIERCE'S DISEASE but also WINTER FREEZE, HAIL, WIND, BLACK ROT, TEXAS ROOT ROT, black berry MOTHS, and CROWN GALL. Texas wineries compensated for these adversities by importing grapes from other states until increased plantings and an industry initiative to improve quality resulted in legislation mandating that wines labelled with vineyard, AVA, or county designations respectively must contain 95%, 85%, and 75% grapes from the designated area, and the remainder must be from 100% Texas grapes.

Like many modern US winegrowers, Texans first planted and vinified the traditional French varieties Cabernet Sauvignon, Merlot, and Chardonnay, often with disappointing results. In recent years, winegrowers have achieved success with Mediterranean grape varieties such as Tempranillo, Sangiovese, Roussanne, Viognier, and Vermentino.

The state had a total of eight AVAs in 2022, spread throughout five main regions.

The Texas High Plains region is located in the north-west portion of the state extending north into the Texas panhandle. The Texas High Plains AVA is the state's second largest AVA at over 3 million ha/8 million acres, although only 1,240 ha/3,000 acres were planted in 2019. The AVA sits atop the Caprock Escarpment, the boundary of which demarcates the Texas High Plains from the lower plains of the Central Texas region to the east. High ELEVATION with fertile red soils, hot days, cool nights, and frigid winters allows full vine DORMANCY. Vineyards are planted at elevations of 915–1,220 m/3,000–4,000 ft, affording plenty of daytime sunshine for ripening and relatively cool night temperatures for acid retention. Drought is the main challenge here. Depending upon vintage, the AVA supplies 75–85% of Texas

wine grapes, though the majority are transported to the Texas Hill Country for fermentation and bottling. The region was initially known for Cabernet Sauvignon and Chardonnay, more recently for Tempranillo, Syrah, Sangiovese, Vermentino, and Roussanne.

The West Texas region is of historical more than commercial significance. It is home to the oldest winery in Texas, Val Verde, which has operated continuously for over a century and is known mainly for sweet FORTIFIED WINES. This arid region encompasses three AVAs: Mesilla Valley, which extends from New Mexico into Texas; Texas Davis Mountains, which produces good Cabernet Sauvignon and a small quantity of Sauvignon Blanc; and the tiny (129 sq km/50 sq mile) Escondido Valley.

To the east is Texas Hill Country AVA, the largest AVA in Texas and the second largest in the US, encompassing 3,884,982 ha/9,600,000 acres but only approximately 1,000 acres of vineyards. Soils vary, with LIMESTONE bedrock found throughout the region. The majority of the state's wineries are located here, with grapes imported from the Texas High Plains AVA to fulfil production needs. Fine *vinifera* wines are produced, mainly in vibrant white and focused red styles. The AVAs of Bell Mountain and Fredericksburg are within the larger Texas Hill Country AVA, with the town of Fredericksburg one of the largest wine-tourism destinations in the US.

The North Texas region is north of Texas Hill Country and east of the High Plains. Humidity makes it difficult to grow *vinifera*, though there has been increased investment in plantings and wineries in recent years due to tourism from nearby Dallas and Fort Worth. The city of Grapevine, which lies between the two, has fashioned itself as a major wine destination. Just under 100 miles north, the Texoma AVA is being developed as another wine tourism destination.

The South-Eastern or Gulf Coast region is located in the south-eastern quadrant of the state, centred on Houston. At 123 ha/305 acres of bearing vines in 2017, the region suffers from both humidity and Pierce's disease. The warm, humid pine forests in its far north-eastern reaches are suitable for HYBRID and non-*vinifera* grapes such as Pierce's disease-resistant Lenoir (Black Spanish), Cynthiana

(NORTON), and Blanc du Bois. One of the state's most respected wines, a Madeira-style FORTIFIED wine made with Blanc du Bois by Haak Vineyards & Winery, is produced here. J.T.

Dupuy, J., *The Wines of the Southwest USA* (2020).

Texas root rot, caused by the fungus *Phymatotrichopsis omnivora*, which lives in the soil. This vine FUNGAL DISEASE can prevent grape-growing on CALCAREOUS soil in parts of the south-western United States. A circular patch of vines can suddenly die in summer. The disease is avoided by planting disease-free material in non-infested soil. The vigorous ROOTSTOCK Dog Ridge can be planted where the fungus is suspected. R.E.S.

texture, the dimension of TASTING that draws together attributes such as smoothness and ASTRINGENCY that produce tactile rather than flavour sensations in the mouth. These sensations are often referred to collectively as MOUTHFEEL. In practice, the sensory perception of texture, experienced through the sense of touch and arising from the trigeminal nerve, is closely intertwined with the senses of taste and smell. Astringency, BODY, VISCOSITY, BITTERNESS, and ACIDITY are among the interrelated factors influencing texture. Because of the complexity of the interactions among the many wine constituents that may be involved, formal sensory studies relating wine composition to texture are limited. Nevertheless, evidence to date indicates that wine TANNINS, PIGMENTED TANNINS, ETHANOL, and POLYSACCHARIDES are all involved with this sensation. TASTING NOTES sometimes try to describe the texture of a wine by comparing it to a type of material such as silk or velvet or by likening it to the texture of a foodstuff (e.g. grainy or chewy). A mouthfeel wheel was developed in Adelaide in Australia

in answer to Davis's AROMA WHEEL (illustrated under MOUTHFEEL). Its purpose was to establish a vocabulary for describing the sensations of texture in red wines. More recent research by Gawel et al. has focused on texture and mouthfeel in white wines. P.J.W. & J.E.H.

Thailand , South East Asian country where viticulture began in the 1960s on the low plain around the capital Bangkok and has flourished, despite the challenges involved in TROPICAL VITICULTURE. Although the early vineyards were developed to produce TABLE GRAPES, the main varieties planted were VITIS VINIFERA, including MALAGA BLANC, MUSCAT OF HAMBURG, Perlette, CARDINAL, and POKDUM. In the mid 1980s, grapes from the so-called 'floating vineyards' in the Chao Phraya delta became the raw material for Spy, a popular wine cooler produced by Siam Winery, a venture established by the man who devised the energy drink Red Bull. The winery remains Thailand's largest, with an upscale label, Monsoon Valley, sourced primarily from vineyards in the hinterland of Hua Hin, south-west of Bangkok, growing predominantly COLOMBARD, CHENIN BLANC, and SYRAH. It also has vineyards in Chang Mai and in the highlands around the Khao Yai National Park north of Bangkok. Situated at 350m/1,148 ft in ELEVATION, Khao Yai has since become home to several wineries, including pioneers PB Valley Khao Yai Winery, started in the mid

1990s by the Boon Rawd Corporation, brewer of Singha beer, and GranMonte Estate, founded in 1999. Chenin Blanc and Syrah are the region's core varieties; GranMonte also grows VIOGNIER, VERDELHO, and DURIF.

The Thai Wine Association has been a cohesive force in setting and maintaining standards for the industry. Some producers in Asia supplement locally grown grapes with imported grapes, GRAPE CONCENTRATE or BULK WINE, but the association requires that its members declare any imported component above 10% clearly on their labels. It also helped launch Thailand's first regional GEOGRAPHICAL INDICATION, for the Khao Yai region, recognized by the Thai government and awaiting EU approval in 2022. D.G.

GranMonte's Chenin Blanc vineyard in the Asoke Valley, Khao Yai, is harvested once a year at the end of THAILAND's winter in February or March. Harvesting at night reduces the amount of energy needed to cool the grapes, minimizes OXIDATION and provides better working conditions for the pickers. © GranMonte

Theophrastus (370–288 BCE), philosopher and botanist from Lesbos who discusses viticulture in his 'plant researches'.

thermal amplitude. See DIURNAL TEMPERATURE RANGE.

Thermenregion, Austrian wine-growing region named for its thermal springs, also unofficially known as the Südbahn for the historical railway south from VIENNA that forms its backbone. In 2021 it encompassed 1,901 ha/4,697 acres of vines or 4.2% of national vine surface. Thermenregion DAC was created in 2023. The northern Thermenregion, especially around GUMPOLDSKIRCHEN, features two white INDIGENOUS VARIETIES seldom encountered anywhere else: ROTGIPFLER produces wines with a striking combination of body and brightness, while ZIERFANDLER (sometimes called Spätrot) recalls CHENIN BLANC in its juxtaposition of opulence with brightness with spiced quince and citrus notes. Weingut Stadlmann's bottling from the Mandel-Höh vineyard demonstrates how profound, seductive, and long-lived Zierfandler can be. But nearly every significant white grape of NIEDERÖSTERREICH shows some success in this same sector.

Red wines from the southern Thermenregion, centred around Baden, once had a major presence in foreign as well as domestic markets as blends of Blauer PORTUGIESER, Pinot Noir (Blauburgunder), and BLAUFRÄNKISCH. Today the overwhelming emphasis is on varietal bottlings of Pinot Noir and ST-LAURENT. D.S.

thermotherapy, a technique to eliminate VIRUS DISEASES from grapevines by growing infected plants at high temperatures (about 38 °C/100 °F) and then propagating from SHOOT TIPS. These shoot tips can produce plants free of virus diseases, but some diseases such as FANLEAF DEGENERATION virus are eliminated much more easily than others—LEAFROLL, for example. Each tip produced must be checked to see whether it is virus-free and then can become registered as a new CLONE. New techniques of TISSUE CULTURE have generally been found more effective at virus elimination. Thermotherapy should not be confused with HOT-WATER TREATMENT.

R.E.S.

thermovinification, process sometimes used in RED WINEMAKING, whereby heat is applied to grapes or MUST before FERMENTATION to increase the speed/extent of extraction of colour from grape skins, treat mouldy grapes, and remove GREEN aromas. Sometimes the term is used specifically to refer to a process that was quite widely adopted in the 1970s, particularly in France, involving one hour or less of heat treatment at around 70 °C/160 °F that liberates coloured must, which is then cooled, pressed, clarified, and fermented much as in traditional WHITE WINEMAKING. However, the term is also used more broadly to refer to a range of techniques entailing the heating of red grapes. Some involve much longer periods of hot skin contact (sometimes referred to as MPC or MACÉRATION PRÉFERMENTAIRE *à chaud*), skin contact for part of the fermentation, and/or coupling heat treatment with other processes such as exposure to a vacuum (see FLASH DÉTENTE). Most of these variations try to address criticisms of some wines made by thermovinification, particularly poor colour stability due to insufficient TANNIN extraction and standardized fruity ESTER flavours that can occur when highly clarified red juices are fermented at lower temperatures. Thermovinification techniques are most commonly used to make everyday wines from grapes low in ANTHOCYANINS or from grapes that are not fully ripe. Used with grapes affected by rot such as BOTRYTIS, the enzyme LACCASE is denatured, thus avoiding OXIDATION of the juice and depletion of red wine colour. Heat treatment also volatilizes ISOBUTYL-METHOXYPYRAZINE and other compounds associated with green aromas. The heating is performed using various types of heat exchangers or immersion systems. Thermovinification is rarely used in making fine wines, however, which almost invariably rely on traditional maceration to extract colour and flavour from the grape skins. S.N.

Nordestgaard, S., 'Pre-fermentation heating of red grapes: a useful tool to manage compressed vintages?', *Australian and New Zealand Grapegrower & Winemaker*, 637 (2017), 54–61.

thiamine. See VITAMINS.

Thiniatiko, red grape occasionally found on the Greek island of Kefalonia making rich wines. According to DNA PROFILING, it is identical to MAVRODAPHNE.

thinning vines. See CROP THINNING and SHOOT THINNING.

thiols, or volatile thiols, are VOLATILE SULFUR COMPOUNDS produced by YEAST during FERMENTATION. They are generally derived from FLAVOUR PRECURSORS in the grapes and are therefore at their maximum levels immediately after fermentation. Although the terms 'thiol' and MERCAPTAN are synonymous, the former is typically used in a positive context when discussing varietal character, for example in SAUVIGNON BLANC wines, the latter in the negative context of FAULTS IN WINE. They have a particularly low perception threshold (ng/l).

Volatile thiols, also known as polyfunctional thiols, for example those described in FLAVOUR COMPOUNDS that bring aromas likened to grapefruit and passion fruit to white wines such as Sauvignon Blanc, are essential for the perception of freshness but can also be responsible for black-fruit flavours in red wines.

So-called age-related thiols such as 2-furfurylthiol (coffee-like) and benzylmercaptan (gun-flint, smoky) are powerful aroma molecules formed by the reaction of HYDROGEN SULFIDE with certain compounds in OAK or grapes. Even at extremely low levels (a few parts per trillion), these compounds contribute to the empyreumatic (charry, smoky) notes in some aged wines. Benzylmercaptan can cause off-odours if present at too high a level. V.F.

third growth. See the CLASSIFICATION of Bordeaux.

Thompson Seedless is the common California name for the seedless white grape variety SULTANA. It acquired this name from an early grower of the variety near Yuba City, one William Thompson. Thompson Seedless is California's most planted grape variety. Almost all of the vines are planted in the hot, dry SAN JOAQUIN VALLEY, with three-quarters in Fresno County, the powerhouse of California RAISIN production. In 1960 almost 70% of all grapes crushed for white wine were Thompson Seedless, clearly indicating what made up the 49% of 'other grapes' then allowed in wines labelled as VARIETALS. In the 1970s, Thompson Seedless was particularly useful to the California wine industry in helping to bulk out inexpensive white JUG WINE blends at a time when demand far outstripped supply of premium white wine grape varieties. Today, however, it is used mainly for raisins, as material for DISTILLATION or for GRAPE CONCENTRATE to sweeten bottled waters or cold tea drinks.

Thongue, Côtes de , IGP in the Hérault between Béziers and Pézenas named for the river that runs through it. Both Bordeaux and Mediterranean varieties make up the IGP's 10,000 ha/24,711 acres of vines.

Thrapsathiri, Cretan vine variety making rich, full-bodied whites. Probably identical to the Cyclades' Begleri and recently identified in

Italy, thanks to DNA PROFILING, under the name Malvasia di Rimini.

J.V.

three-tier system. With the repeal of PROHIBITION, most US states promulgated regulations that made vertical integration of the industry illegal, mandating that it be separated into three 'tiers': producer (or supplier, in the case of imports), wholesaler, and retailer (or restaurant). As a result of the legal protection of the middle tier and the rapid consolidation of wholesalers, notably SOUTHERN GLAZER's, many producers, retailers, and consumers chafe at the lack of a full liberalization of the US wine market. For more, see UNITED STATES, regulation, and DIRECT SHIPPING.

T.C.

thrips, tiny (1–2 mm long) winged insects which readily feed on grapevine flowers and developing bunches, causing scarring and disfigurement of grapes by eating away at the small berries. While thrips are sometimes thought to be the cause of poor FRUIT SET, there is little evidence to support this.

M.J.E. & R.E.S.

Tibouren could almost be said to be *the* Provençal grape variety, but DNA PROFILING has shown it to be identical to ROSSESE di Dolceacqua. It has a long history in south-east France and the ability to produce such quintessentially Provençal wines as earthy rosés with a genuine scent of the GARRIGUE (its wine is not naturally deep in colour). In 2019 total French plantings were a static 451 ha/1,114 acres, almost all in the Var. Tibouren is cultivated by a number of the more quality- and history-conscious producers of Provence, and some of them bottle it as a VARIETAL rosé. Particularly early-budding, it is sensitive to COULURE and therefore yields irregularly. Its original sphere of influence was around St-Tropez, where it is thought by some to have been imported as recently as the end of the 18th century by a naval captain, Antiboul, after whom it was named.

Tierra del Vino de Zamora, DOP just west of TORO with 648 ha/1,601 acres and just nine wineries in 2020. TEMPRANILLO dominates terrain similar to that of its better-known neighbour.

tight spacing, American colloquial expression for closely planted vineyards; see VINE DENSITY.

tillage, the vineyard process of ploughing the soil, normally to kill weeds, also referred to as cultivation. The type of tillage and its frequency vary from region to region around the world. In medieval times, before vines were planted in rows, tillage was by handheld hoes. Animals were subsequently used to pull ploughs. For modern vineyards, tractor-mounted discs or tines disturb the topsoil and kill weeds between the rows. Tillage within the vine row requires a special plough that will avoid trunks. Initially these were manually operated to dodge in and out; later, touch or electronic sensors were used to activate a hydraulic mechanism. Because of root and trunk damage, this practice was replaced from the 1960s onwards by the use of undervine HERBICIDES. However, since the last two decades of the 20th century, growers wishing to avoid the use of AGROCHEMICALS have returned to undervine tillage. This has been assisted by the development of hoes which are more efficient and have more sensitive and accurate 'tripping' mechanisms, thus reducing damage to the vines. Some producers, including those as notable as Ch LATOUR and Leflaive of Puligny-Montrachet, have gone back to using HORSES, which often seem to appear when WINE WRITERS are nearby.

A fastidiously tilled vineyard is still regarded as a sign of good husbandry in some regions, but there is a growing recognition for many vineyards that tillage damages SOIL STRUCTURE and can lead, for example, to problems of water infiltration, SOIL COMPACTION, and SOIL EROSION. The planting of COVER CROPS or allowing volunteer plants to grow is becoming more common. R.E.S.

time and wine. See AGEING.

Timorasso, relatively rare Piemontese vine variety enjoying a renaissance for its aromatic, durable white VARIETALS. There were 123 ha/304 acres reported in Italy in 2015.

tinaja, large earthenware vessel, probably developed from the Roman AMPHORAE, occasionally still used to ferment and store wine in central and southern SPAIN and southern CHILE. Tinajas are used by some producers in LA MANCHA, VALDEPEÑAS, and MONTILLA-MORILES, although modern versions are mostly made from reinforced concrete. They are relatively cheap but have the disadvantages that they are not very efficient in terms of space, are difficult to clean (especially if the neck is narrow), and offer relatively poor TEMPERATURE CONTROL unless they are buried underground like QVEVRI. Increased interest in amphorae in winemaking has led to a certain reprise, however.

tinta, the Spanish and Portuguese feminine adjective for 'red', is therefore the first word of many unrelated Spanish and Portuguese names and synonyms for dark-skinned vine varieties, for example TINTA RORIZ.

Tinta Amarela. See TRINCADEIRA.

Tinta Barroca, common, relatively thick-skinned grape variety planted in Portugal's DOURO Valley, mainly for PORT, and grown on a total of 3,501 ha/8,651 acres in Portugal in 2020, significantly down on 2012's 5,444 ha. It is favoured by growers for yielding large quantities of grapes with exceptionally high levels of sugar and is typically planted on higher or north-facing slopes. However, Barroca is prone to both DOWNY and POWDERY MILDEW, is easily damaged by extreme heat, and has berries which have a tendency to shrivel on

the vine. By no means as highly prized as the other leading port grapes—TOURIGA NACIONAL, Touriga Franca, and Tinta Roriz—Barroca produces reasonably well-structured but slightly jammy, rustic wines which can be useful in a blend. In Portugal Tinta Barroca is rarely used on its own but full-throttle, unfortified, dry, VARIETAL Tinta Barroca (sometimes misspelt and referred to as Tinta Barocca or Tinta das Baroccas) is a speciality in South Africa, where there were 155 ha/383 acres in 2020 and where it is also used in FORTIFIED port-like wines.

Tinta Caiada. See PARRALETA.

Tinta de Toro. See TEMPRANILLO and TORO.

Tinta Francisca, lesser red grape variety used in the production of PORT in Portugal's DOURO Valley. The wine produced can be notably sweet but is not particularly concentrated. Some see similarities with Pinot Noir. It has been planted to a very limited extent in South Africa.

Tinta Miúda, 'small red one', Portuguese wine grape grown traditionally around Lisbon and in the LISBOA region. The vine is low-yielding but can produce seductive and powerful wines. Identical to the GRACIANO of Rioja and MORRASTEL of the Languedoc, it ripens late and is therefore susceptible to ROT in the Atlantic-influenced west of the country, though it is valued by winemakers for the colour and acidity it contributes to a blend. There were 326 ha/806 acres in Portugal in 2017.

Tinta Negra, previously Tinta Negra Mole, name for NEGRAMOLL on the island of MADEIRA, where it is by far the most commonly planted variety. DNA PROFILING has shown it to be identical to the Portuguese

variety Molar. It is therefore indubitably a VITIS VINIFERA variety, unlike many of the vines that replaced the so-called tradtional varieties SERCIAL, VERDELHO, BUAL, and MALVASIA on Madeira after the ravages of POWDERY MILDEW and PHYLLOXERA in the 19th century. It yields relatively high quantities of sweet, pale red wine which turns amber with the madeira production process and then yellow-green with age. Only in the last decade has it been permitted to name the variety on the label.

Tinta Pinheira, former name for the Portuguese grape variety RUFETE.

Tinta Roriz, official name for the Spanish vine variety TEMPRANILLO in northern Portugal. Thanks to recent popularity, it has become Portugal's most planted variety by quite a margin, with total plantings of 20,161 ha/49,819 acres by 2020. It is particularly important in the DOURO Valley, where it vies with TOURIGA FRANCA as the most planted variety in some areas, particularly in the Cima Corgo and Douro Superior. It is relatively easy to grow in the Douro but has a tendency to over-produce and performs best in those years when yields are inherently low. VARIETAL wines are also made in Dão, where it is gaining ground. In the Alentejo, under the name ARAGONEZ, it is often blended with the local TRINCADEIRA.

Tintilla de Rota, Andalucian name for a variety shown by DNA PROFILING to be GRACIANO. Here it can make rather charming sweet FORTIFIED reds.

tinto, Spanish and Portuguese for 'red', so that *vino* (*vinho* in Portuguese) *tinto* is red wine (as opposed to the lighter red CLARETE produced in Spain). This is the origin of the name of the red wine once known in England as TENT.

Like TINTA, 'Tinto' is also the first word of many Spanish and Portuguese names and synonyms for black grape varieties. TEMPRANILLO, for example, is known as Tinto Fino in Ribero del Duero.

Tinto Cão, meaning 'red dog', top-quality black grape variety for the production of PORT. Having almost disappeared from the vineyards of the DOURO Valley in northern Portugal (despite its long history there), it is being planted with greater enthusiasm since it was identified as one of the five finest port varieties, although it is not one of the deepest coloured nor especially productive. It is also grown for TABLE WINES in the DÃO region and has been planted experimentally at DAVIS in California and in Australia.

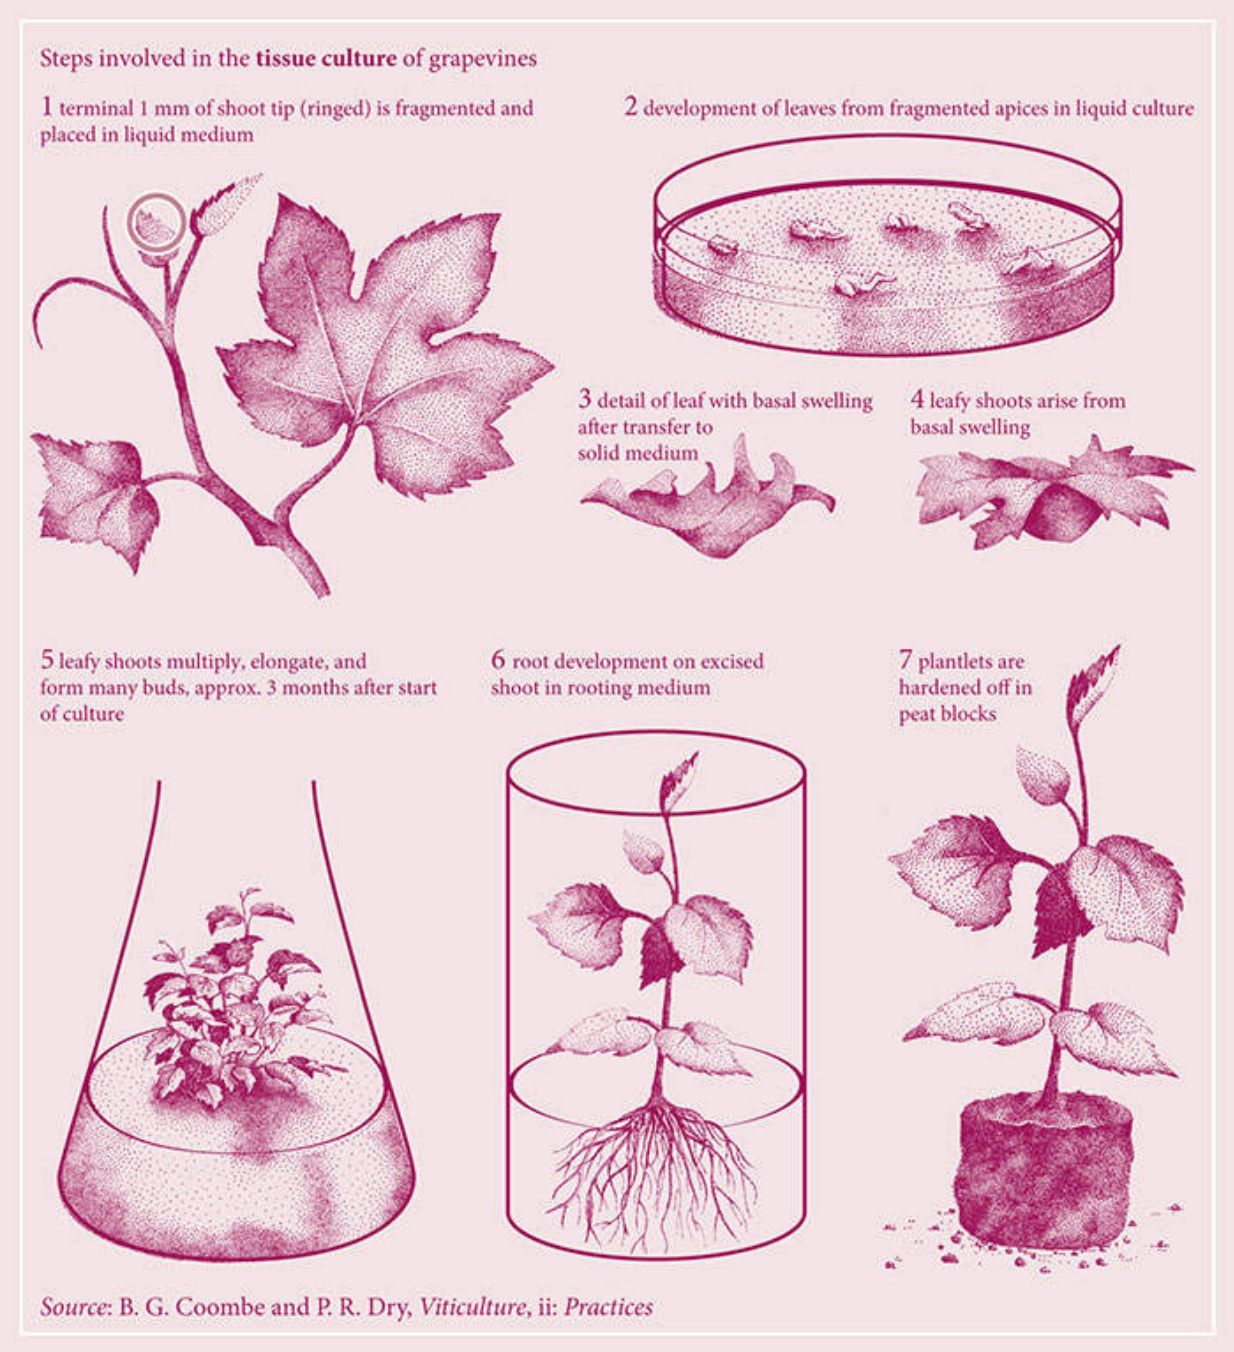
Tinto del País, synonym for TEMPRANILLO, as is Tinto Fino, in RIBERA DEL DUERO.

tipping, the viticultural practice of cutting off SHOOT TIPS at flowering. Normally about 10–20 cm (4–8 in) of shoot tip are removed. This can help reduce the problem of COULURE, or poor FRUIT SET, for some susceptible varieties.

tirage, French for that part of the SPARKLING WINEMAKING process during which sugar and yeast (known in French as the *liqueur de tirage*) are added to the blended base wines in order to provoke a second fermentation, thereby creating CARBON DIOXIDE gas. It is sometimes used to refer to the entire period during which the sparkling wine matures on the LEES of this second fermentation.

tissue culture, the culturing of excised cells, tissues, and organs using artificial media of salts and nutrients, used especially in PROPAGATION and GENETIC MODIFICATION. The techniques can be used to develop vines with particularly useful properties much faster than by

conventional PROPAGATION. Usually a CALLUS develops first, then roots and buds develop within the callus, leading to a new vine that can flower and set seed. The formation of roots or buds is achieved by subtle changes in the ingredients of the culture solution, especially in the relative amounts of the hormones AUXIN and CYTOKININ. Aseptic conditions are essential. Meristem culture, or the culture of the terminal 1 mm of vine shoot, especially after its fragmentation, has permitted the production of large numbers of plantlets in tubes that are free of some VIRUSES and CROWN GALL disease. Large numbers of vine plantlets can be 'micro-propagated' by these methods, which can rapidly build up healthy populations of scarce VINE VARIETIES. See diagram overleaf.



B.G.C.

titratable acidity. See TOTAL ACIDITY.

toast (*chauffe* in French), given to a barrel towards the end of the process of forming it over a heat source, is one of the processes in BARREL MAKING that most obviously affect eventual wine flavour. The

heat source also inevitably toasts the inside of the barrel to a degree that varies according to the heat of the fire and the length of time the barrel is held over it. This heating process dramatically alters the wood's physical and chemical composition. The toasted wood provides a buffer between the ALCOHOL in wine and the TANNINS in wood. In general, the less a barrel is toasted, the more tannins and other wood characteristics will be leached into the wine by the alcohol. Wine matured in lightly toasted barrels therefore tends to taste 'oaky', 'woody', or even 'vegetal', while wine matured in heavily toasted barrels is more likely to taste 'toasty' or 'spicy'. See also OAK FLAVOUR.

Burgundy BARRELS are in general more heavily toasted than Bordeaux BARRIQUES, partly because a heavy toast is better suited to the flavours of Pinot Noir and Chardonnay grapes than to those of Cabernet Sauvignon, Merlot, Sauvignon Blanc, and Sémillon but also because in Burgundy producers tend to put must for white wines or very young red wines into barrel with more LEES, which remove many of the compounds that result from toasting. The following terms are used, although they are imprecise and cannot really be compared between coopers.

White toast: extremely light toast, sufficient to make the barrel stable, achieved by low temperature or by wetting the barrel to decrease the production of compounds during toasting.

Light toast: there is little colour change in the wood. Wines aged in these barrels are usually quite fruity but can be somewhat tannic.

Medium toast: the wood is browner. Wines aged in such barrels are said to smell of vanilla and coffee. They will normally be less tannic than those aged in light-toast barrels and are often described as rounder, smoother, and more persistent.

Heavy toast: the wood is very dark. Wines aged in these barrels are usually marked by aromas of roasted coffee beans, toasted bread, ginger, nutmeg, cloves, and smoked meats. The above flavour descriptions apply to wine aged in French oak barrels.

The word 'char' is usually associated with American whiskey barrels, which are made over steam or natural gas but then set on

fire and burned (charred). Traditionally American oak wine barrels were simply un-charred bourbon barrels, but American cooperages now toast to the customer's specifications.

The higher the toast, the greater the risk of blisters inside the staves. Coopers have recently developed new toast levels using different combinations of temperature and duration.

In addition to the origin of the wood and the way it was seasoned, toast is a crucial factor when ordering a barrel. M.C.K. & A.P.

Tocai, or Tocai Friulano, old Friulan name for SAUVIGNONASSE, now replaced by FRIULANO.

California has limited plantings of the variety they still call Tocai Friulano, which is also produced by Millbrook in the Hudson Valley, NEW YORK.

Tai Rosso is used as a synonym for GRENACHE NOIR in the VENETO.

Togo is a wine hub in West Africa, behind only SOUTH AFRICA in volumes of wine traded. Currently any wine produced in Togo is made from imported juice, but at the end of 2020 the country's first VITIS VINIFERA vineyard was planted, about 1,500 vines of Chardonnay and PINOTAGE rooted into SCHIST and GNEISS soils in the Plateaux region, 150 km/93 m north of the capital, Lomé. This is a private venture with support from Springfontein Wine Estate in South Africa. The vineyard sits at the end of a steep, craggy hiking trail at ELEVATIONS of 720–760 m/2,362–2,493 ft, where the MESOCLIMATE is cooler than the country's otherwise tropical conditions: temperatures range from 10–32 °C /50–90 °F, winds are brisk, and annual rainfall is 1,700 mm/67 in.

Tokaj , town, PDO (*Oltalom alatt álló eredet megjelöléssel* or OEM in Hungarian), and the most famous wine region in HUNGARY. Mount Tokaj is the prominent VOLCANIC cone at the southernmost tip of the region, which includes the foothills of the entire Zemplén Mountains

(which, in turn, form the southern range of the Tokaj-Eperjes Mountains). Hungarians often use the name Tokaj to mean the whole region, but locals refer to themselves as being from the Hegyalja, to emphasize their separateness from the residents of the town of Tokaj itself. However, even they prefer to call their wine Tokaji (the –i suffix indicating place of origin, as with the –er in New Yorker) regardless of any more precise location within the region.

History

The first known occurrence of the name, in the form 'Tokay', is in a 13th-century genealogy and history entitled *Gesta Hungarorum*. The *Gesta*, and many sources after it, refer to the emblematic hill of the region not as Tokaj but as Tarcal, today the name of a village at the western foot of the hill. Remarkably, Tarcal was also the name of the hill in Syrmia far to the south, today known as Fruška Gora in SERBIA, which yielded the most famous wine of medieval Hungary. Records enumerating the administrative units have existed since 1641, but these early sources are rife with gaps and contradictions. Hungarian wine legislation of the time lists 27 communities with a right to label their wines as Tokaj. The vineyards around most of these communities were first CLASSIFIED in the 18th century, in a manner that was rigorous at the time but is not entirely useful today. By the 18th century, this extraordinary wine had been introduced to the French court (see HUNGARY, history) and was subsequently introduced to the Russian imperial court by the Habsburgs. Only CONSTANTIA from the Cape of Good Hope, and to a lesser extent Moldavian COTNARI, rivalled the reputation of this wine, with Tokaji Esszencia regarded as an all-purpose restorative.

During most of the 20th century, Tokaj languished. Its recovery from PHYLLOXERA was slow, and its reputation suffered with the dissolution of the Austro-Hungarian Empire in 1918. Under Soviet domination, quantity rather than quality was encouraged, although a number of individual growers and winemakers continued to uphold traditions and some exceptional wines were made. It potentially encompasses 11,149 ha/27,549 acres, but only 5,946 ha/14,692 acres are planted today. A small portion of the region extends into SLOVAKIA, where wines of a similar style are made.

Geography

Located in north-eastern Hungary, the Zemplén Mountains have a cool climate, as does the entire Tokaj-Eperjes range within the Carpathian volcanic chain. The mean temperature in the foothills is 9–10 °C/48–50 °F annually, 21 °C in July, and −3 °C in January. The favourable south-south-eastern aspect of the foothills contributes to the excellent MESOCLIMATES found on the slopes. The best vineyard sites occupy the southern slopes, where they are sheltered from northern and north-westerly winds by relatively high, forested peaks. Of these, the top sites are open to the east or the west to promote air circulation and to discourage FROSTS. High levels of humidity, due to the location of the vineyards above the confluence of the Bodrog and Tisza rivers, encourage special fungoid flora, including the all-important BOTRYTIS.

The volcanic activity which began 15 million years ago and dominated geological processes here for six million years created a great TOPOGRAPHICAL diversity in the Tokaj-Eperjes range. The spectrum of VOLCANIC rocks that can be found in the area includes rhyolite, rhyodacite, dacite, andesite, and zeolite. These various rock types occur as lavas and differ mainly in terms of silica content. In addition, pyroclastic rocks, most significantly TUFFS, are also found. During and after the principal eruptions, a variety of post-volcanic alterations left their stamp on Tokaj. Volcanic rocks tend to weather faster than other igneous types, and the process is accelerated here by the flow of post-volcanic groundwater and hot springs, which deliver to the surface large quantities of potassium and trace elements, enriching the volcanic detritus.

The major centres of post-volcanic changes are around Mád (sites such as Szent Tamás, Úrágya, Betsek, and Urbán), Erdőbénye, Tolcsva, and Sárospatak. The southern fringes of the range were overlain by LOESS at a much later stage, during the Quaternary period when the region's main soils were developed. On the steeper slopes, the thin soils are typically mixed with weathered andesite and are

quite hard to till. In the low valleys, loess, clay, and glacial deposits evolved. Easily weathered volcanic glass still mingles with the soils today, enriching them in NUTRIENTS that are available to the vines. The most widespread soil type is the clayey *nyirok*, a red soil created by weathering volcanic rocks, particularly stony andesite. When too wet, *nyirok* is so sticky that it adheres to the spade; if it dries out, it will yield to nothing short of a pickaxe. It does not absorb water very well and has low permeability. Its red colour, from ferrous hydroxide, turns darker as its humus content increases (see ORGANIC MATTER). Slightly less common is the soil type known as yellow earth, which forms from LOESS and clayey loess, as well as sandy loess on the Kopasz-hegy near Tokaj and the hills north of Olaszliszka. Loess has good drainage and here has a low LIME content. Szarvas near Tarcal is a famous example of a vineyard with loess soil. Loess is not found in the interior of the Tokaj-Eperjes chain nor in the valleys, but on the south-eastern slope of Mount Tokaj it can be found at ELEVATIONS as high as 405 m/1,330 ft.

A further soil type is the crumbly rock flour that forms from the mechanical weathering of white rhyolite, pumice, and perlite. It does not retain water and has a low heat capacity, so vines planted in it may easily dry out during a DROUGHT or freeze in extreme cold. Rock flour is common in Peres-hegy at Erdőbénye, the Tolcsvai-hegy, and the Oremus vineyard at Sátoraljaújhely.

Nomenclature

The two leading vine varieties, FURMINT and its offspring HÁRSLEVELŰ, have their genetic origin in Tokaj. Both varieties tend to produce dry wines worth AGEING based on ACIDITY, tension, BODY, and BALANCE.

For centuries, the two main categories of Tokaji were *szűrt bor* (filtered wine) and *csinált bor* (made wine). The former were made much the same way as most wine is made today, by simply PRESSING the grapes and fermenting the MUST. The latter were wines produced by the more complicated Aszú process (see below under Sweet wines). Clearly distinct from this noble sweet category was the typically dry *ordinarium*. Even in the old days, a distinction was made between free-run juice and press juice, although they were not necessarily handled separately. *Főbor* (principal wine) was the old name of Szamorodni-style wine, at least insofar as it was made by pressing the harvested fruit as is, without separating BOTRYTIZED berries from grapes unaffected by NOBLE ROT. From 1707 onward, Eszencia, the highest grade of Tokaji, was also increasingly referred to as *legfőbb bor*, meaning 'supreme wine' (*legfőbb* is the superlative of the adjective *fő*).

Dry and semi-dry wines

An increasing proportion of dry wine is made in Tokaj. These are wines matured only briefly. They are typically fermented dry but may contain some RESIDUAL SUGAR (even if at a level well below semi-sweet wines). With a few exceptions, they are fermented in stainless steel and will last three to five years, depending on the vintage.

Matured dry wines These are invariably matured in wood, with a small proportion also fermented in wooden casks, and have a very long cellaring potential. As botrytis is undesirable in these wines, the grapes must come from high-elevation vineyards (about 250 m/820 ft) designed specifically for this purpose. These are mostly SINGLE-VINEYARD and expensive wines.

Szamorodni Made from both botrytized and non-botrytized berries, these wines have a ripeness level comparable to that of BEERENAUSLESE, but they are fermented dry (*száraz*) and subjected to subtle maturation under a FILM-FORMING YEAST. These wines are very like the Jura's VIN JAUNE. More common is a sweet version (see below).

Főbor An old style now extremely rare, Főbor are close to Szamorodni in style without being matured under OXIDATIVE conditions. Főbor can be dry or sweet, depending on the natural proportion of overripe fruit and shrivelled, possibly botrytized, berries.

Sweet wines

Szamorodni Szamorodni wines are typically made in the sweet style (*édes*), when the sugar content of the grapes is so high that the must will not ferment fully dry. Although the minimum RESIDUAL SUGAR is 45 g/l, the average is 80–120 g/l, and some reach 180–200 g/l, taking on a fresh, fruity character and smooth texture that brings them very close to a young Aszú wine in style. This barrel-aged selected botrytized wine is matured for at least six months in oak (and more usually one to two years). It is not necessarily OXIDIZED.

Late Harvest/Cuvée These are mostly sweet wines made in the same way as natural sweet wines in other regions, by a single fermentation of selected bunches, and are ready for release 12–16 months after harvest. This style emerged in the early 21st century in reaction to the substantial time and capital investment required to mature Aszú wines in compliance with regulations. Often marked by a

mineral character (see MINERALITY), they may contain 50–180 g/l residual sugar and (optionally) a proportion of botrytized berries similar to that for Aszú wines. Cuvée wines are generally made from botrytized grapes, but barrel ageing is optional.

Aszú

This is the classic sweet Tokaji, made from hand-selected, shrivelled, botrytized grapes and usually the sweetest wine of any producer. The table shows minimum RESIDUAL SUGAR and EXTRACT required for these designations.

Style	Residual sugar (g/l)	Dry extract (g/l)
Aszú	120	35
Eszencia	450	50

Before pressing, the botrytized grapes are soaked for 16–36 hours in fresh must, *murci* (fermenting wine), or new wine that has completed fermentation. The wine is then matured under oxidative conditions without any FORTIFICATION, including at least one and a half years in barrel (and more likely two to three years). The unique second fermentation gives a special, deeper character to the wines.

The sweetness of Tokaji Aszú wines was classified by *puttonyos* until 2014, from 3 puttonyos (60–90 g/l residual sugar) to 6 puttonyos (150–180 g/l). Now all Tokaji Aszú must have at least 120 g/l residual sugar (although most growers agree that the highest-quality wines have around 180–230 g/l), a minimum of 19% potential alcohol, and a finished alcohol of at least 9%. The maximum yield per hectare for aszú parcels is 10 tonnes (counted in green grapes) and a kilo of aszú berries can produce no more than 2.2 litres of wine.

The following categories of sweet Tokaji are relatively rare:

Eszencia The free-run juice of hand-picked botrytized berries. Residual sugar should be at least 450 g/l; but levels of 800 g/l or more are not unheard of. Eszencia takes years to achieve a modest alcohol level of 4–5%. It is rarely sold commercially, and smaller

wineries will not handle it separately. It is typically used for blending to improve the concentration of Aszú wines.

Fordítás Made by refermenting wine or must poured on Tokaji Aszú 'paste' (marc) left after pressing sweet wines, typically with more than 60 g/l sugar (minimum 45 g/l).

Máslás Rarity made by refermenting new wine or must poured on Tokaji Aszú LEES. These are sweet wines, typically with 50–90 g/l sugar, but no longer an official category.

The Mádi Kör, the local wine authority, has drawn up a rather Burgundian vineyard CLASSIFICATION which means in practice that the member wineries are obliged to follow stricter regulations in vine-growing and winemaking than are required by general Hungarian rules. G.R & G.M.

Tokaj-Hegyaljai Album (1867).

Tokay was the name under which TOKAJ used to travel. It was also the original name of the Australian STICKIE made from raisined Muscadelle grapes that has been renamed TOPAQUE.

Tokay d'Alsace, or simply Tokay, was long the Alsace name for PINOT GRIS, but the term was officially outlawed from 2007.

tonneau, traditional Bordeaux measure of wine volume, once a large wooden cask holding 900 l, or 252 imperial wine gallons, the equivalent of four BARRIQUES. A PARIS tonneau was 800 l, but, because

of the prominence of GASCON merchants in London and English merchants in Bordeaux, the Bordeaux measure became the standard. By the end of the 18th century, tonneaux had been replaced by the easier-to-transport smaller barrique, yet the tonneau, the exact equivalent of 100 CASES of wine, is still the measure in which the Bordeaux wine trade deals.

Such was the importance of wine to medieval trade in general (see BORDEAUX and DUTCH WINE TRADE) that a tonneau, or ton in English, evolved from being the space occupied by a tun of wine to become the unit of measurement for the carrying capacity of any ship, whatever its load.

Topaque and Muscat, extremely sweet FORTIFIED WINES that used to be called Liqueur Tokay and Liqueur Muscat. They taste something like a cross between MADEIRA and traditional dark MÁLAGA, and they are two of AUSTRALIA's great gifts to the world made from, respectively, MUSCADELLE, traditionally known as Tokay in Australia (although the term was officially phased out in 2020), and a very dark-skinned strain of MUSCAT BLANC À PETITS GRAINS, called here Brown Muscat or Muscat à Petits Grains Rouge. The centre of production is a hot north-eastern corner of the state of Victoria around the towns of Rutherglen and Glenrowan. Grapes are semi-raisined on the vine, partially fermented, and then fortified with grape spirit before being subjected to an unusual wood-ageing programme that resembles a cross between a sherry SOLERA and, under many a hot tin roof, a Madeira ESTUFAGEM. The results can be uncannily fine quality, are bottled when they are ready to drink, and do not change with BOTTLE AGE. These wines are quite sweet enough to serve with virtually any dessert. In the late 1990s, the winemakers of Rutherglen joined forces to create a four-tier nomenclature for Muscat (and, by extension, Topaque). At the bottom is Rutherglen Muscat, next is Classic, then Grand, and finally Rare. It is a voluntary, self-regulated system but a very real guarantee of style, which becomes progressively richer and more complex with each tier. Rare is released

in tiny quantities each year, limited by the maintenance of a very old Solera base.

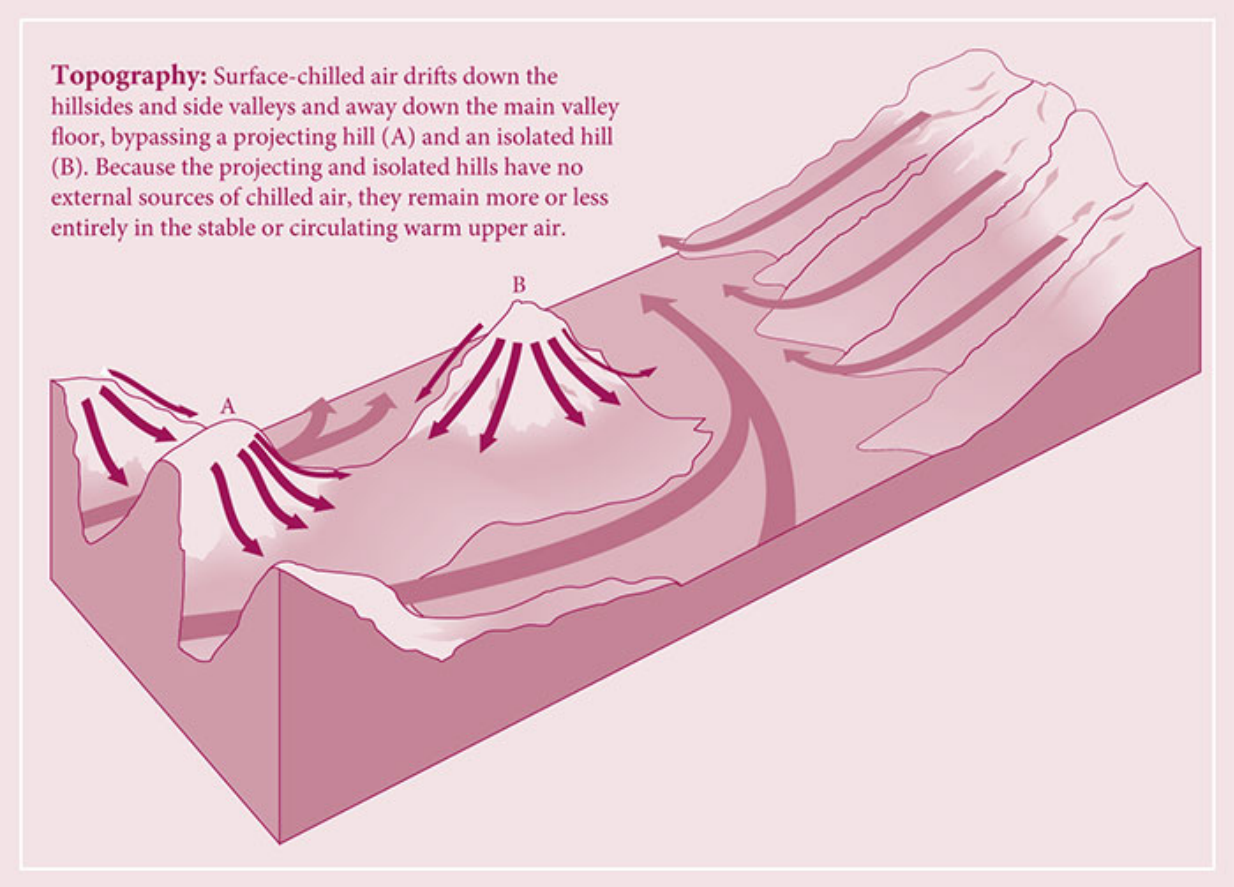
top grafting, or top working, the viticultural operation of changing the fruiting VINE VARIETY of a mature vineyard by inserting a BUD of the selected variety in each vine but retaining the established root system. An array of approaches is available—CLEFT GRAFTING, NOTCH GRAFTING, CHIP BUDDING, or T-BUDDING—usually applied high on the original trunk just below the HEAD. If the operation is done well, only one season's crop is lost. The main risk is that of systemic disease spread from the original planting, especially VIRUS DISEASES to which different varieties and ROOTSTOCKS have different tolerances. B.G.C.

topoclimate, a local climate as determined by TOPOGRAPHY, for instance that of a particular hill, valley or slope. It is commonly subsumed under the broader term MESOCLIMATE.

topography, a term describing the land surface features of any area, which can have considerable implications for local climate (see MESOCLIMATE) and therefore for viticulture. The classic reference work by Geiger gives the most comprehensive general account of topographic effects on local climate. Topographic elements having the most influence on the climate are local ELEVATION; slope; the relative isolation of hills; aspect; and proximity to water masses such as oceans, lakes, and rivers.

Local elevation Other things being equal, temperature falls by about 0.6 °C/1.1 °F per 100 m/330 ft greater elevation. This is known as the lapse rate.

Slope At night, air is chilled by direct contact with a land surface which is rapidly losing heat by radiation. The chilled air, being denser, flows down slopes to the flat land or valleys below and is replaced by warmer air from above the land surface. The turbulent surface air over slopes at moderate elevations is therefore usually warmer at night and in the early morning than that settled over the adjacent flats and valley floors. This band on a hill slope is known as its 'thermal zone', and especially in cool climates it is valued for viticulture because of its enhanced ripening potential and length of frost-free period. The steeper the slope, the more pronounced is its thermal zone. See also HILLSIDE VINEYARDS.



Relative isolation of hills Thermal zones are strongest on isolated and projecting hills or mountains, because these have little or no external source of surface-chilled air. Cooled air from their own surfaces that slips away can be replaced only by totally unchilled air from above. The implications of this are discussed under CLIMATE AND WINE QUALITY; see also TERROIR. Examples of viticulturally famous isolated hills include the hill of Corton at ALOXE-CORTON in Burgundy; the Kaiserstuhl in BADEN; and, on a larger scale, the Montagne de Reims in CHAMPAGNE.

Aspect Slopes which face the sun through much of the day (southerly aspects in the northern hemisphere, northerly aspects in the southern hemisphere) are the warmest, and those facing away from the sun are the coolest. The influence of aspect is modified by other climate parameters. For example, the degree of daytime warming is increased by more sunshine and by protection from wind. Differences in soil temperature are important not only for nutrition of the vine but also for growth and fruiting through export of the growth substance CYTOKININ to the vine tops.

The climatic contrasts among aspects are greatest at high latitudes and in cooler vineyard regions, as well as early and late in the vine-growing season. The steeper the slope, the more aspect will affect its climate.

Easterly aspects of slopes facing the equator have the advantage that they are warmed earliest in the day, when soil and air temperatures are lowest. Notable examples of this are found in the CÔTE D'OR of Burgundy and in the RHINE Valley of Germany and Alsace. West-facing slopes can, however, induce higher daytime air temperatures because absorption of sunlight and warmer air temperatures are complementary. This is important in very cool climates.

Proximity to oceans, lakes, and rivers Water absorbs and stores large quantities of heat, with relatively little change in temperature because of the depth to which the heat penetrates, together with the high specific heat of water compared with rocks or dry soil. Its resulting temperature inertia greatly modifies the temperature regimes of adjacent land. Cool air from over the water is drawn to replace heated air rising over the land in the afternoons, while at night a reverse convection results from chilled air descending from the cold land surface and rising over the now relatively warm water. In some vineyard areas, these breezes may, in fact, be very strong winds if they are funnelled by mountains, as in the Salinas Valley in MONTEREY, California. This daily alternating pattern of air circulation makes the climate adjacent to water bodies significantly more constant than it would otherwise be, in terms of both temperature and humidity. Both factors are important in CLIMATE AND WINE QUALITY. There is also a reduced incidence of spring FROSTS and WINTER FREEZE injury in regions liable to these. Examples of this LAKE EFFECT are found in NEW YORK State, in the vineyards of Ontario in CANADA, and around RUSSIA's Black Sea coast.

The effects of rivers and lakes are normally confined to their immediate valleys, but MARITIME influences can extend considerable distances inland from coasts in the form of land and sea breezes. Notable examples of the latter occur in the BORDEAUX region of France; the NAPA Valley and SONOMA and other near-coastal regions of California; and the HUNTER VALLEY and Swan Valley of Australia's east and west coasts respectively. J.G. & R.E.S.

Geiger, R., *Das Klima der bodennahen Luftschicht* (4th edn, 1961), translated as *The Climate near the Ground* (1966).

topping. See TRIMMING.

topping up, the operation of refilling any sort of wooden container to replace wine lost through EVAPORATION. The container should be kept full or nearly full lest the ubiquitous ACETOBACTER use OXYGEN from the HEAD SPACE to start the process of transforming wine into VINEGAR.

Winemakers differ in what they view as the ideal topping-up regime for various different wines, but modern practice is to top up at least monthly, using wine of the same provenance.

Depending on the amount of evaporation, which is affected by fluctuations in temperature and humidity in the cellar, and the spare time available to the winery staff, topping up is done anything from twice a week during the first months of BARREL AGEING to once every six weeks. The ideal cellar temperature should be about 10–15 °C/50–60 °F: not so cold as to hinder development but not so warm as to encourage bacterial growth. New barrels may also need more frequent topping up since the new oak absorbs up to 5 l of wine. In Bordeaux the BUNG is usually left at the top of the barrel for the first six months, after which some producers roll red-wine barrels to one side so that the bung is in the so-called bung-over position, in which case regular racking provides the opportunity for topping up. However, it is impossible to check levels of SULFUR DIOXIDE or VOLATILE ACIDITY unless the bung is at the top.

See also ULLAGE.

D.D. & V.L.

Torbato, mid- to late-ripening vine variety today most obviously associated with SARDINIA, where VARIETAL dry whites are produced from a grand total of under 10 ha/25 acres, with particular success around Alghero.

It was once quite widely cultivated in ROUSSILLON, where it is known as TOURBAT, or Malvoisie du Roussillon, but was almost abandoned before new and healthier plant material was imported from Sardinia in the 1980s. DNA PROFILING has indicated that it is a natural progeny of Hebén, an old and rare wine and TABLE GRAPE from

Spain, suggesting that it was initally brought to the island when Sardinia was part of the Aragón kingdom. J.V.

Torgiano, small hillside DOC zone between Perugia and Assisi in the central Italian region of UMBRIA. It was considered Umbria's finest red wine in the 1960s and 1970s when the production of bottled wine was almost entirely in the hands of the Lungarotti family, who demonstrated that the SANGIOVESE vine could yield excellent wine outside TUSCANY. Production rules have regrettably been changed to allow VARIETALS based on INTERNATIONAL VARIETIES with no history in the zone such as Pinot Grigio, Chardonnay, and Pinot Noir. Rosso di Torgiano, originally a Sangiovese-based wine, now allows up to 50% Merlot and/or Cabernet Sauvignon. At least 70% Sangiovese is required in DOCG Torgiano Rosso Riserva, but overall the current spirit of Torgiano appears to be marketing-oriented.

torna viagem literally means 'round trip' in Portuguese and is occasionally found on labels of ancient SETÚBAL which have been subjected to lengthy sea voyages for ageing purposes. This is the equivalent of the *vinho da roda* of MADEIRA. José Maria da Fonseca have been experimenting with the genre since 2000.

Toro, revolutionized Spanish red-wine zone in CASTILLA Y LEÓN (see map under SPAIN) whose wines were famous within Spain in medieval times. This wild and remote zone spans the Duero Valley east of Zamora. At an ELEVATION of 600–825 m/2,000–2,800 ft, growing conditions are severe, with cold winters, hot summers, and just 350–400 mm/13–15 in of annual rainfall. The region's principal grape variety, Tinta de Toro, is a local variant of TEMPRANILLO which has adapted to the region's climatic extremes. Left to their own devices, the vines will easily ripen their grapes to a POTENTIAL ALCOHOL level of 16%; with care, the wines average 14.5–15% in ALCOHOLIC STRENGTH. In the late 1990s a number of producers began to move away from

the region's traditional heavy, bulk reds, a move which gained notable momentum when some of top names in Ribera del Duero, Rioja, and even Bordeaux were awakened to the region's potential and launched their own estates, including Vega Sicilia's Pintia, Mauro's San Román, Sierra Cantabria's Numanthia-Termes (subsequently acquired by LVMH), Michel Rolland's Campo Elíseo, and Telmo Rodríguez's Pago La Jara. By 2020 Toro boasted 62 bodegas (up from five in 1987, when it was accorded DO status) and 5,900 ha/14,579 acres of vineyard, including 120 ha of vines more than 110 years old, thanks to the sandy soils that escaped PHYLLOXERA. Since 2021 GARNACHA can be used for a VARIETAL wine, and white wines may include Moscatel (MUSCAT BLANC À PETITS GRAINS) and ALBILLO Real in addition to the previously allowed VERDEJO and Malvasia Castellana (SÍRIA).

V. de la S. & F.C.

Torontel, Chilean white wine grape, also called Moscatel Amarilla, that DNA PROFILING has shown to be one of the numerous natural progenies of Listán Prieto (see PAÍS) and MUSCAT OF ALEXANDRIA. There were still 638 ha/1,577 acres in 2019, mainly BUSH VINES in MAULE.

J.V.

Torres. See FAMILIA TORRES.

Torres Vedras, DOC subregion of LISBOA in western Portugal.

Torrontés, name of many distinct white grape varieties grown in Argentina and Spain, not always named with precision.

Argentina grows at least three different varieties with 'Torrontés' in their name. The most common, planted on 7,659 ha/18,926 acres in 2020, is Torrontés Riojano, a natural cross of MUSCAT OF ALEXANDRIA and CRIOLLA CHICA (California's MISSION grape), as shown by DNA

PROFILING in 2003. It is the most planted white wine grape after the undistinguished Pedro Giménez and is regarded as Argentina's most distinctive white wine grape. See also TORONTEL. Torrontés Sanjuanino, a distinct speciality of San Juan province and another natural cross of Muscat of Alexandria and Criolla Chica, was planted on just 1,628 ha (and, as Moscatel de Austria, 108 ha of Chile), while plantings of Torrontés Mendocino were 563 ha. This third variety is also the result of a natural CROSS of Muscat of Alexandria, but the other parent is so far unknown.

The fragrant Torrontés Riojana is often seen as the Argentine white wine variety with the greatest potential, although some wines can be over-alcoholic and bitter. Carefully grown and vinified, Torrontés Riojana can produce wines that are high in acidity and intriguingly aromatic in a way reminiscent of but not identical to MUSCAT, although much is also used for blending. Grown all over the country and to a limited extent in Uruguay, the variety seems particularly well adapted to the arid growing conditions of Argentina, particularly the high, sandy vineyards of Cafayate where at ELEVATIONS of over 1,600 m/5,250 ft its high natural acidity and assertive flavour are particularly distinguished.

Torrontés Sanjuanino is less aromatic and has bigger berries and more compact clusters. Torrontés Mendocino, also planted mostly in San Juan, lacks Muscat aroma.

DNA PROFILING has shown that the name Torrontés is applied to at least four varieties in Spain: one in Montilla-Moriles, one in Navarra, one in Ribeiro in Galicia (which may be identical to either FERNÃO PIRES or BICAL), and one in Extramadura, where it is a synonym for ALARIJE. Torrontes is also a common synonym for several different varieties in Portugal. Altogether, Torrontes represents an identification minefield on the Iberian peninsula. The situation is much clearer in Argentina, even if the varieties' parents are not the most noble.

Toscana, central Italian region known in English as TUSCANY.

total acidity (TA), measure of the total ACIDITY, both FIXED ACIDS and VOLATILE ACIDS, present in grape juice or wine. With ALCOHOLIC STRENGTH and RESIDUAL SUGAR, total acidity is one of the most common wine measurements involved in any wine ANALYSIS.

It is obtained by a laboratory process called titration (which is why it is also referred to as titratable acidity, although technically they are not exactly the same, according to Boulton), in which very small additions of an alkali of known strength are made to a measured quantity of the grape juice or wine until the amount of added alkali just equals the amount of acids in the sample. The value of these total acids can be calculated and expressed as grams of any number of different acids per litre of juice or wine. By tradition, different wine regions have chosen to express total acidity variously as TARTARIC ACID or sulfuric acid, or milliequivalents.

France and a few other European countries tend to express total acidity as sulfuric, even though the amount of this compound in grapes and wine is minuscule, but most major producers and exporters report acidity as tartaric. A further complication arises with what is termed the end point of the titration, with some countries using pH 7 and others pH 8.2. For many years both the OIV and EU methods of analysis have specified a pH 7 end point, but some countries are slow to change, resulting in confusion in the international wine market.

The total acidity of wines expressed as tartaric acid normally varies between about 4 g/l and 9 g/l and primarily depends on the grape variety and the climate. Warmer-climate wines generally have lower acid levels; some of the highest levels can be found in bottle-fermented SPARKLING WINES and in cool-climate late-harvest wines. The total acidity of ripe grape juice or must should ideally be in the general range of 7 to 10 g/l expressed as tartaric acid, although it may in practice be between 3 and 16 g/l. (Some acid is usually lost during winemaking, as a result of MALOLACTIC CONVERSION and cold STABILIZATION, so one may need to start with a higher acidity than the final level desired.) G.T.

Boulton, R., 'The relationship between total acidity, titratable acidity and pH in wine', *American Journal of Enology and Viticulture*, 31/1 (1980), 76–80.

total dry extract, or TDE. See EXTRACT.

total package oxygen (TPO) is the awkward but efficient neologism used to refer to the total amount of OXYGEN that can and does influence the development, quality, and longevity of a wine once it has been bottled. It includes oxygen that passes through the CLOSURE (see OXYGEN TRANSMISSION RATE), oxygen that diffuses out of the closure itself, oxygen in the HEAD SPACE, and dissolved oxygen in the wine. New methods based on luminescence have enabled the accurate measurement of TPO without opening the bottle. It is clear that if the pick-up of oxygen at BOTTLING is not controlled there can be a dramatic effect on the wine even after just six months in bottle, so there is little point in stoppering the bottle with closures that are highly engineered to control oxygen transmission rate. A.L.W.

Dimkou, E., et al., 'Impact of dissolved oxygen at bottling on sulfur dioxide and sensory properties of a Riesling wine', *American Journal of Enology and Viticulture*, 64/3 (2013), 325–32.

Toul, Côtes de, small AOC (100 ha/247 acres) in the far north-east of France which remains, with the even more northerly French wine region on the MOSELLE, as a reminder of what was once a flourishing Lorraine wine industry. It was subsequently marginalized by industrialization, injudicious replanting after PHYLLOXERA, the First World War, and the delimitation of the nearby CHAMPAGNE region which had once drawn wine from here. Gamay with some Pinot Noir is responsible for the local pale pink speciality VIN GRIS. Pinot Noir is the only ingredient in Toul's relatively light reds. AUXERROIS is the most successful variety for dry whites.

Touraine, a vast, important LOIRE region centred on the town of Tours, second in production to ANJOU. This is 'the garden of France' and Loire château country *par excellence*, enjoyed by France's pre-revolutionary aristocrats and now a UNESCO World Heritage Site. The local TUFFEAU was quarried extensively to build these and more distant châteaux, leaving caves ideal for winemaking and wine maturation.

Touraine's most famous wines are the still red wines from BOURGUEIL, CHINON, and St-Nicolas-de-Bourgueil to the west and its still and sparkling, dry to sweet CHENIN BLANC from VOUVRAY and MONTLOUIS to the east. Wines labelled simply Touraine come from a much larger zone, incorporating about 4,331 ha/10,702 acres of vineyard extending from SAUMUR in the west as far as the city of Blois in the east. The AOC encompasses very varied soils which may include tuffeau, CLAY, SAND, FLINT, and GRAVEL. Viticulture is concentrated on the steep banks of the Loire and its tributaries the Vienne, the Indre, and the Cher. Cereals predominate on the cooler soils of the plateaus between river valleys. The climate of the region is considerably varied, with the most eastern vineyards being distinctly CONTINENTAL and affected by seriously cold winters, while vineyards at the western extreme are tempered by the influence of the Atlantic.

This soil and climate diversity explains the broad range of grape varieties planted. White Touraine, the most important colour, must be made from SAUVIGNON BLANC with only up to 20% Sauvignon Gris allowed as a blending partner. Vinified to be quaffable, the best of these can provide a less expensive alternative to SANCERRE and POUILLY-FUMÉ. Touraine Rouge should be based on Côt (MALBEC) or CABERNET FRANC depending on the location of the vineyard, with the latter favoured in the warmest sector west of Tours. Varietal GAMAY is also allowed within the Touraine appellation, especially for PRIMEUR wines. Rosés have to be blends from among the ten dark-skinned grapes grown in the region.

The Chenin-based Touraine MOUSSEUX production is limited, representing respectively one-quarter and one-tenth of the volume of

the more popular SAUMUR Mousseux and CRÉMANT de loire.

Five communes may attach their name to Touraine. Touraine-Amboise, which encompasses 90 ha/222 acres of vines on both banks of the Loire close to the famous château of Amboise, produces mainly red wines based solely on Côt since 2021 after wineries such as La Grange Tiphaine proved the variety's affinity for the region's flinty LIMESTONE soil. Touraine-Amboise rosé is made with Côt and/or Gamay, while its white wines, dry to MOELLEUX (rarely seen) depending on the year, are made exclusively from the long-lived Chenin Blanc.

Touraine-Azay-le-Rideau comprises just 37 ha/91 acres of vineyard on both banks of the Indre, south of the Loire between Tours and Chinon on flinty, chalky soil. It produces twice as much briny white wine from Chenin Blanc as it does sprightly rosés (mainly from Grolleau). The 83 ha of Touraine-Mesland are dedicated mostly to Gamay-based red and rosé grown on a sandy limestone plateau immediately above the right bank of the Loire between Vouvray and Blois. A little Chenin in all sweetness levels is also made. In the Cher Valley towards the Sologne, Touraine-Chenonceaux (168 ha) and Touraine-Oisly (29 ha) are in Sauvignon Blanc country, the latter for whites only. The Chenonceaux reds depend on Côt with Cabernet Franc.

Touraine-Noble Joué is its own 30-ha appellation just south of Tours for VIN GRIS, a blend made from at least 40% PINOT MEUNIER with Pinots Gris and Noir.

See also LOIRE, including map. P. Le.

Tourbat is the ROUSSILLON name for Sardinia's white grape variety TORBATO. It is alternatively known as Malvoisie du Roussillon and is one of the many varieties allowed into the several VINS DOUX NATURELS of the region and Côtes du Roussillon whites.

Touriga is used as a synonym for TOURIGA NACIONAL, particularly in Australia.

Touriga Franca (formerly known as Touriga Francesa) is the most widely planted grape variety in the DOURO Valley and the second most widely planted variety in Portugal after TINTA RORIZ, with a total of 14,656 ha/36,216 acres in 2020. Despite the name, it has no connection with France and has been shown by DNA PROFILING to be the relatively recent progeny of the Douro varieties TOURIGA NACIONAL and MARUFO. On warmer south-facing slopes it is valued for both PORT and Douro wines and is classified as one of the best port varieties. Although it is more susceptible to ROT and the wine it produces is not as concentrated as that of Touriga Nacional, in hot, dry years it can outperform the latter. Favoured by growers for its consistent yields, it is respected by winemakers for its wines' perfume and persistent fruit. It is also widely planted in TRÁS-OS-MONTES and is spreading to other Portuguese regions such as BEIRAS, TEJO, and the ALENTEJO.

Touriga Nacional, the most famous vine variety for PORT and, increasingly, for fine dry reds, and not just in PORTUGAL. It produces small quantities of very small berries in the DOURO Valley and the Portuguese DÃO region (where it probably originated) which result in deeply coloured, very tannic, concentrated wines, often with a floral aroma in youth. The vine is vigorous and robust but is prone to COULURE and may produce just 300 g/10 oz of fruit per vine, making it unpopular with growers. This almost led to its extinction in the mid 20th century, but considerable work has been done on CLONAL SELECTION so that newer plantings are slightly more productive and average sugar levels even higher. Touriga Nacional has become more important in the Douro than in its native Dão, where it can make fine VARIETAL reds, although the variety is regarded by many as better in a blend. Touriga Nacional plantings have been increasing considerably, not least because it has migrated south into most other Portuguese wine regions. Its total area had reached 13,301 ha/32,867 acres by 2020, making it the country's third most planted variety. Touriga Nacional has also been travelling extensively outside Portugal—

notably to Australia in its capacity as an ALTERNATIVE VARIETY (71 ha/175 acres in 2022), California (121 ha/299 acres in 2020), and South Africa (101 ha/250 acres in 2020). The proliferation of varietal versions from Portugal and its success elsewhere are likely to encourage its worldwide spread. In 2020 it was added to the varieties permitted in Bordeaux AOC, within certain limits, because of its ability to withstand the heat (see VIFA).

tourism. Wine-related tourism continues to be increasingly important to both producers and consumers. For many centuries, not even wine merchants travelled, but today many members of the general public deliberately make forays to explore a wine region or regions. This is partly a reflection of the increased interest in both wine and foreign travel generally but also because most wine regions and many producers' premises are attractive places. VINEYARDS tend to be aesthetically pleasing in any case, and the sort of climate in which wine is generally produced is agreeable at least during the growing season and very possibly for most of the year. Getting to grips with this specialist form of agriculture combines urban dwellers' need to commune with nature with acquiring privileged, and generally admired, specialist knowledge. And then there is the possibility of TASTING and of buying wines direct from the source, which may involve keen prices and/or acquiring rarities. For producers, CELLAR DOOR sales, unmediated by distributors, wholesalers or other retailers, are the most profitable of all.

Wine tourism is certainly not new to Germany. The RHINE has long welcomed tourists, who are encouraged to travel by steamer and stop at wine villages en route, and the MOSEL Valley is surely one of the most photographed in the world. German tourists, on the other hand, have long plundered the Weinstuben of ALSACE and represent an important market for the region's wines.

In France, wine tourism was often accidental. Northern Europeans heading for the sun for decades travelled straight through BURGUNDY and the northern RHÔNE and could hardly fail to notice vineyards and

the odd invitation 'Dégustation–Vente' (tasting–sale). (And it is true that a tasting almost invariably leads to a sale.) Wine producers in the LOIRE have long profited from their location in the midst of châteaux country and within an easy Friday night's drive of Paris.

BORDEAUX was one of the last important French wine regions to realize its potential for wine tourism, although the city itself has determinedly made up for lost time. The village of ST-ÉMILION has had scores of wine shops and restaurants for decades, but it was not until the late 1980s that the MÉDOC, the most famous cluster of wine properties in the world, had a hotel and more than one restaurant suitable for international visitors. Alexis LICHINE was mocked for being virtually the only CLASSED GROWTH proprietor openly to welcome visitors, but there are now others, albeit fewer than one would expect.

Much of southern Europe is simply too hot and too far from suitable resorts to make wine tourism comfortable and feasible, but AGRITURISMO has played an extremely important part in the viticultural economy of Italy.

In various NEW WORLD wine regions, tourism has also become an important aspect of business. The most obvious example is the NAPA Valley, whose main roads in summer are as busy as any rush-hour thoroughfare. Other popular examples, when travel has been allowed, have been SOUTH AFRICAN vineyards within easy reach of Cape Town and offering summer weather with no time difference to visitors from northern European winters; HUNTER VALLEY for visitors to and residents of Sydney; parts of NEW YORK State; and the vineyards of ENGLAND, whose owners depend heavily on income from 'farmgate' sales. There has also been considerable investment in wine tourism facilities in Argentina, China, and New Zealand, but this is one of the growth areas virtually throughout the wine world.

Some tour operators and travel agents specialize in wine tourism, and the number of wine regions without their own special wine route or winery trail is decreasing rapidly. The first annual wine tourism conference was held in 2011.

tourne, wine fault caused by the metabolism of TARTARIC ACID by LACTIC ACID BACTERIA, which affects a wine's colour and flavour.

trade wars. See TARIFFS.

tractor, the most common vineyard machine. Tractor dimensions have had a significant impact on VINEYARD DESIGN. In many parts of Europe where tractors replaced horses, tractor designers obliged by creating either narrow, or row-straddling, tractors (known in France as *tracteurs enjambeurs*). The narrowest vineyard tractors are not much wider than their drivers, about 80 cm/31 in. In the NEW WORLD, however, vineyards were changed to accommodate the tractors, with row spacings of 3–4 m (10–13 ft). Modern ones are much narrower and can fit down rows less than 2 m apart.

The introduction of tractors and other forms of MECHANIZATION to viticulture has had profound economic and sociological effects. Less LABOUR was required, encouraging the population drift to the cities. However, tractors and associated machinery are the major cause of SOIL COMPACTION, and environmentally aware manufacturers and growers prefer tractors with tracks to those with wheels. The most advanced tractors and those that have gone furthest to limit their environmental impact and reduce soil compaction are electric and either driver-operated or autonomous, using both ROBOTICS and ARTIFICIAL INTELLIGENCE. Such vehicles have been pioneered by Monarch in California.

At the opposite end of the spectrum, but with similar motivation, a very few growers have returned to HORSE-drawn ploughs, especially popular among those practising BIODYNAMIC VITICULTURE.

R.E.S. & J.E.H.

The Monarch electric, driver-optional TRACTOR, designed and built in LIVERMORE, California, and launched in 2021, saves LABOUR and reduces SOIL COMPACTION and the overall CARBON FOOTPRINT OF WINE. Here it is being used ROBOTICALLY with a flail mower to cut winter COVER CROPS. One of the four company founders is VITICULTURIST Carlo MONDAVI. © Erik Castro

trade, wine. The world of wine is better known for its sociability than its profitability. What is needed to make a small fortune in the wine business is said to be a large fortune. The wine trade is considerably more appealing, however, than many others. It routinely involves immersion in an often delicious product and travel to some of the more beautiful corners of the world (TOURISM), typically with a MEDITERRANEAN CLIMATE, as well as providing widely admired expertise.

One of the attractions of the wine trade is the people. It has long attracted a wide range of individualists who, if they were not interesting and amusing before they or their visitors have tasted their wares, seem so afterwards. Producers and merchants alike tend to be generous and to appreciate the fact that it is difficult to sell or buy wine without first tasting and sharing it.

Apprenticeship is probably the easiest route into the wine trade, although some form of specialist EDUCATIONAL qualification such as those offered by the WSET can help too. The general areas in which full-time employment may be found include vineyard management, winemaking and quality control, sales and marketing, wholesaling, retailing, and (the job with potentially the most power and perks) buying. There are also the overcrowded fields of WINE WRITING, consulting (in some form), and INVESTMENT. See also wine MERCHANTS.

traditional method, official EU term for the most painstaking way of making wine sparkle, once known as the champagne method. See SPARKLING WINEMAKING for how it works.

Skelton, S., *The Knight Who Invented Champagne* (2021).

traditional terms are words or phrases used on wine labels that enjoy special protection within the EU. They can be phrases such as *appellation d'origine contrôlée* or *vin de pays* which are alternatives to PDO or PGI. They can also be 'the description of a product characteristic' referring to production method (e.g. RANCIO, PASSITO, EISWEIN), ageing method (e.g. SUR LIE, RISERVA, GARRAFEIRA), colour

(e.g. *chiaretto*), place of production (e.g. *château*), or, rather more obscurely, 'a particular event linked to the history of a PDO or PGI wine' (e.g. Liebfraumilch). Terms such as *château*, *sur lie*, vintage, CLASSIC, and so on have been the source of some controversy, as non-EU producers have protested that the EU should not limit the rights of all producers to use words that are purely descriptive or in the public domain. J.P.H.B.

traditionelle Flaschengärung, klassiche Flaschengärung, and traditionelle klassiche Flaschengärung, German terms for SPARKLING WINES made by the traditional method.

Traditionsweingüter Österreich, 'traditional wineries of Austria' in English, is a promotional organization in Austria representing the CARNUNTUM, KAMPTAL, KREMSTAL, THERMENREGION, TRAISENTAL, WAGRAM, and WIEN wine regions. The organization, with 77 winery members in 2022, has developed a CLASSIFICATION of selected vineyard sites (95 as of 2022) under the rubric ERSTE LAGE, pledging not to market wines dedicated to those sites prior to September of the year following their harvest—a restraint that was rare in 1992 when the Traditionsweingüter were organized. In attempting to set an example of model vineyard classification, the Traditionsweingüter invites growers from outside its group to submit candidates for its intensive BLIND TASTINGS, so that in theory all the best sites in the regions it represents will receive their due. An upgrading of selected sites to the status of GROSSE LAGE was in its initial stages in 2022. D.S.

training systems, methods of VINE TRAINING, which vary considerably around the world. Since the grapevine is a true VINE and is not self-supporting like a tree, innumerable training systems for vines have been devised over the millennia of cultivation. Confusion between the terms 'training systems', TRELLIS SYSTEMS, and PRUNING is widespread. In fact they are three distinct, if closely related, entities. A trellis is a physical structure, consisting normally of POSTS, generally made of wood, and WIRES. The word training describes the actions of pruning in winter and TRIMMING in summer, as well as SHOOT and CANE placement, so that the vine's TRUNK, ARMS, and CORDONS and BUDS are appropriately located on the trellis system. Those training systems which involve trellises are often named after the trellis.

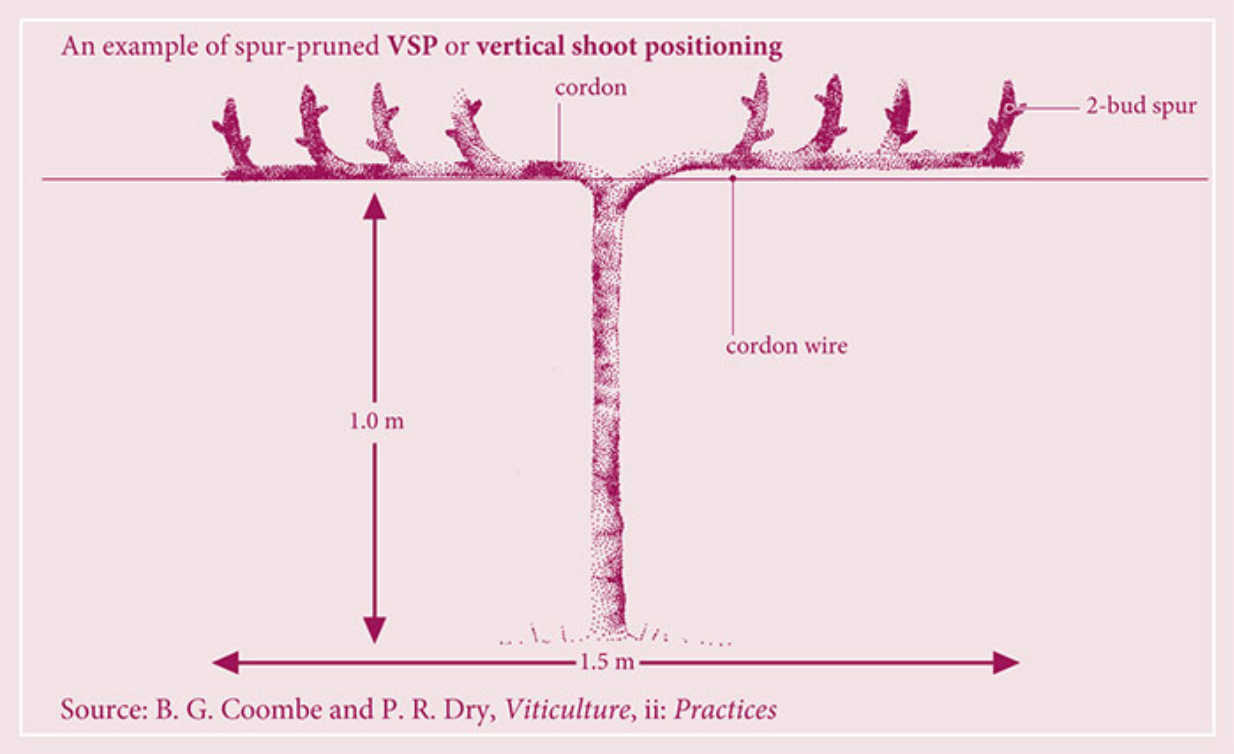
The viticulturist's choice of training system will be affected by the cost of the system, the availability of any materials required, the availability of the skilled LABOUR required to install and manage it, CLIMATE, TOPOGRAPHY, vine VIGOUR, VINE VARIETY, MECHANIZATION requirements, and, in many instances, knowledge of alternative systems. In many places in the world, especially in Europe, little thought is given to using any but the region's traditional system. Outside Europe, more consideration is given to the choice of training system, because research into CANOPY MANAGEMENT has shown substantial benefits in terms of YIELD, wine quality, and disease reduction by adopting newer designs. Training systems may be dictated by requirements for MECHANICAL HARVESTING and MECHANICAL PRUNING.

A basic difference in training systems about which the casual observer may wonder is why some vineyards have trellis systems with wires and others not. While self-supporting GOBELET vines are common in southern Europe, in many countries such vineyards are considered old-fashioned, and WIRES to suspend foliage are used instead. A particular disadvantage of gobelet training is that the yield has to be limited when the vines are young while the trunk and arms grow sufficient girth and strength to be self-supporting. The yield of older gobelet vineyards is reduced by limited SUNLIGHT interception.

The control of vine vigour and VINE DISEASES are the principal reasons for adopting more elaborate systems. Lifting the foliage up and containing it between wires allows trimming and LEAF REMOVAL for better fruit exposure. Both tractor access to the vineyard and airflow within it are also improved by shoot positioning.

The vine is pruned in winter as a means of training the framework to ensure that canes with buds are appropriately positioned to be supported by the trellis system.

A vine-training system should aim to maximize yield and quality and to facilitate cultural operations such as SPRAYING, TILLAGE, HARVESTING, and pruning. In truth, many are designed to minimize the cost of installation or the annual costs of VINEYARD MANAGEMENT. As the degree of mechanization increases, so does the need for the vineyard to be uniform and orderly. For example, mechanical leaf removal and harvesting are made easier by locating the bunches of grapes in a single zone. Similarly, mechanization of trimming and pruning is made easier if the vine shoots and canes all point in the same direction; commonly vertically upwards. The vine framework should ideally be at a convenient waist height for any hand operations.



There are many vine-training systems, ranging from the densely planted (10,000 vines per ha or 4,000 per acre), neatly trimmed vertical hedges of the vineyards of the Médoc to the less common vineyards of a few hundred vines per hectare trained up trees around agricultural fields in the Vinho Verde region of Portugal or vines growing up trees in southern Bolivia (see ARBOREAL VITICULTURE).

Vine-training systems can be classified in a number of ways. In France it is common to classify vines as low-trained (*vignes basses*) or high-trained (*vignes hautes*). For low vines, the trunk is up to 50 cm/20 in high, sometimes shorter. Such training systems are suited to lower-vigour vineyards. Grape RIPENING may benefit from the fruit being closer to the ground, but both harvest and pruning are much less comfortable manual operations, and vines may also be more disease prone. The many examples of low-trained vines in France include the extensive southern areas of gobelet, the CORDON DE ROYAT vines of Burgundy and Champagne, and the double GUYOT of Bordeaux.

High vines are less common in modern France but were certainly known by Roman authors (see AGRICULTURAL TREATISES). Interest in high vines was more recently rekindled by the 1950 publication by the Austrian viticulturist LENZ MOSER. He recommended low-density vineyards with wide rows by trunks about 1.25 m/4 ft high. Higher training does reduce FROST risk but requires thicker and more expensive supports, although vineyard work is made easier. 'High-culture' vines can be trained either cordon or Guyot. Vineyards of the New World have typically used high vine-training systems. Overhead trellises such as Italy's TENDONE are special examples of high vines.

There are other possible ways of classifying vine-training systems, however. The cordons may be classed as short, for example 0.5 m in a closely spaced cordon de Royat, or may be many metres in length as for the Portuguese cruzeta (see below). An alternative classification takes account of whether the foliage is free, as for example in the gobelet vines of the Midi, or SHOOT-POSITIONED or constrained into a plane, such as the vertical systems common in Alsace and Germany in which the foliage is held in place by WIRES and maintained by trimming (or occasionally with the shoots woven into the canopy).

The vine canopies can also be classified by their plane: arbours or tendone-trained vines have horizontal canopies about 2 m above the ground, and most shoot-positioned canopies are vertical. Some canopies have shoots all growing upwards, as in the LYRE trellis, while the GENEVA DOUBLE CURTAIN (GDC) has shoots which are trained downwards, and the SCOTT HENRY and SMART-DYSON systems have shoots trained both upwards and downwards. Vines may have a DIVIDED CANOPY in either the horizontal plane, such as the GDC or lyre trellis, or vertically, as in the Scott Henry or Smart-Dyson. Training systems can be simple, like the free-standing gobelet vines of Rioja, or elaborate, like the Ruakura twin two tier (RT2T) developed for research purposes in New Zealand, which is both horizontally and vertically divided and requires 20 wires per row to support fruit and foliage.

The following list gives brief details of some of the training systems in use around the world, including traditional and some newer ones being used for deliberate canopy management.

alberate, an old form of vine-training system used in parts of Italy where the vines are trained on or between trees. There are local variations, such as those in Bologna, Tuscany, Veneto, and Romagna, with the common feature being that trees are used for support.

alberello, see GOBELET.

aplotaria, a traditional method used on wind-blown Greek Cyclades islands such as Paros. UNGRAFTED VINES sprawl across the ground without any form of trellis or support. The vine is protected from the wind and the berries from the sun. A similar method, known in Spanish as *rasteras*, is used in some old vineyards in the south of Chile, on Spain's La Palma, and in COLARES, Portugal, for example.

arbour, see TENDONE.

arched cane, a variation on many different forms of training systems where canes are arched rather than being tied horizontally; see GUYOT. Alternative names include bow-trained, *arcure* in French, *capovolto*, or Guyot *ad archetto* in Italy. This practice is claimed to lead to better BUDBREAK in the centre of the canes, where buds do not normally burst well (see APICAL DOMINANCE). It can be considered a variation of Guyot training.

ballerina, a form of Smart-Dyson developed in King Valley, VICTORIA, Australia. One vertical and two transverse curtains are created from one or two cordons trained to spurs pointing upwards. Many bilateral cordon training systems can easily be converted to ballerina.

barra, used for monoculture in Vinho Verde whereby vines are trained in one direction along a single wire at shoulder height.

basket training, known as *kouloura* or its taller-trunked variant *kladeftiko* on the Greek island of SANTORINI, often used for free-standing vines where canes are wound one around the other for mutual support. Common for some BUSH VINE systems which are pruned. Typically they are of low vigour.

bush vines, see BUSH VINES and GOBELET.

Casarsa, or Casarsa Friuli, an Italian training system like the SYLVOZ, except the canes are not tied down after pruning.

cassone padavano, a horizontally divided Italian system, pruned like the Sylvoz.

Cazenave, an Italian vine-training system which uses a modified form of Guyot pruning where short arms containing spurs and canes (five to six buds) are arranged along a horizontal CORDON. The canes are tied about vertically to a wire above. Because the pruner is able to leave so many buds per vine, this system is suited to fertile soils.

Château Thierry, a form of GUYOT training where the cane is tied in an arch to a stake beside the free-standing vine.

cordon de Cazenave, an Italian and French system used for fertile soils, with one or more canes left on a CORDON DE ROYAT.

cordon de Royat, see CORDON DE ROYAT.

cordon-trained, term to distinguish a training system using cordons as opposed to a vine head and canes. These are typically horizontal and bilateral but may also be unilateral. They are used in warm to hot regions.

cordon vertical, a vertical cordon with alternating spurs to either side. Not used very commonly as growth tends to be mainly from the top buds.

cruzeta, a system used in the VINHO VERDE area of Portugal where vines are trained to a wide cross arm about 2 m/6 ft off the ground. More sophisticated than *latada* but less so than *barra*.

double header, a system developed by Terry Bennett, a grower in Tasmania, to allow CANE-pruned vines in his COOL-CLIMATE vineyard to achieve BALANCE by pruning to more buds but avoiding shoot crowding. This was achieved by removing each second vine in the row.

duplex, a system developed in California in the 1960s with flexible cross arms to allow for machine harvesting. While the fruiting wires are horizontally divided by 1 m/3 ft, the foliage was not shoot-positioned to create two separate curtains as for the GENEVA DOUBLE

CURTAIN. As a consequence, it is not nearly as beneficial in terms of yield, quality, and disease avoidance and is now little used.

espalier, see ESPALIER.

éventail, French for 'fan', system with multiple arms, each giving rise to a spur or short cane. Originally the form used in Chablis, with the arms lying on the ground, this has been modified to the *taille de Semur* system, where each arm is tied to a lower wire in the one plane.

factory roof system, commonly used for TABLE GRAPES, in South Africa and Israel, for example, where the CANOPY is trained up at an angle to meet in a gable near the row centre. This may also be called a closed, one-arm PERGOLA and provides excellent access to the fruit for any hand work required.

fan-shaped, a training system distantly related to *éventail* that is used in central Europe, particularly Russia, where the vine trunks are spread out in the shape of a fan, which makes it easier to bury vines for WINTER PROTECTION. The Italian version is called *ventagli*.

Flachbogen, the German name for a training system like the Guyot whereby one cane is laid horizontally either side of the head and shoots are trained vertically between foliage wires. The shoots are trimmed at the top. See VERTICAL TRELLIS.

Geneva double curtain (GDC), see GENEVA DOUBLE CURTAIN.

gobelet, see GOBELET.

Guyot, see GUYOT.

Halbbogen, a German training system whereby the vine is pruned to one cane of about 15 buds' length and is arched in the middle over a wire about 25 cm/10 in above the base and end of the cane. Shoots are trained each year vertically between foliage wires and are trimmed at the top. See APICAL DOMINANCE.

head-trained, common term for a vine trained so that spurs and canes arise in one zone, called the head. Such vines may be cane- or spur-pruned.

Hudson River umbrella, a system used in the eastern US whereby canes are arched downwards from a high head.

Isère, a training system much like Château Thierry (see above).

latada, traditional 3-m-high trellis used on Madeira for vines grown around fields of other crops, equivalent to VINHO VERDE's *ramada*.

Lenz Moser, see LENZ MOSER.

lyre, see LYRE.

MPCT, or minimal-pruned cordon-trained, describes the system developed and extensively used in Australia, mainly for BULK WINE production. Young vines are trained to a form of CORDON at about 1.5 m height and, apart from wrapping early cane growth on the wire, receive minimal hand work, including pruning. See MINIMAL PRUNING.

palmette, an Italian training system, with one vine trained to four horizontal canes, one pair above the other.

parral, see TENDONE.

parron, see TENDONE.

Pendelbogen, the German name for the arched-cane training system described above. There is a 50-cm height difference between the end of the cane and the highest point, which is thought to improve BUDBREAK in the middle of the cane. Most of the shoots are trained vertically upright between foliage wires and normally require trimming at the top. Pendelbogen means 'pendulum bow', and there are related training forms: not just Halbbogen ('half bow') but also Rundbogen ('round bow') and Doppelbogen ('double bow'). The name has also been applied to a mid-height Sylvoz system in New Zealand.

pergola, see PERGOLA.

Perold, a South African term for vertical trellis, named after A. I. Perold, the breeder of PINOTAGE.

pyramid, an Italian training system where vine shoots are trained over a group of stakes tied together at the top, forming a pyramid.

ramada, VINHO VERDE name for *latada* above.

raggi Belussi, an Italian overhead training system suspended from above and with two vines planted together and trained in four directions. Pruned like the Sylvoz.

raggiera or raggi, an Italian training system where vines are trained overhead on wires like the spokes of a wheel. One vine may be trained up a central stake or tree and divided into cordons, or several vines may be at the one position with each trained along a different radius.

Scott Henry, see SCOTT HENRY.

shelf, or *tana*, local name for overhead trellis in Japan.

slanting trellis, a system in which the canopy is trained along an inclined support. This trellis can be used for both table- and wine-grape production.

Smart-Dyson trellis, see SMART-DYSON.

Sylvoz, see SYLVOZ.

Te Kauwhata two tier (TK2T), developed at the Te Kauwhata Research Station in New Zealand, a system which is vertically divided, with shoots trained vertically upwards. Limited commercial use in California and New Zealand.

tendone, see TENDONE.

three-wire trellis, another California trellis system with a pair of fixed foliage wires above the cordon. Shoots are not positioned and fall across these wires under their own weight.

traverse trellis, European name for the T trellis.

T trellis, common in Australia, where the vine is trained to two horizontal cordons about 0.5 m apart. It takes its name from the appearance of the vine trunk and cordons. Shoots are not positioned, and so the canopy is not divided. Can be machine pruned and harvested and is widely used in bulk wine-producing areas.

tunnel, an alternative name for a form of overhead vine training where the vines are planted in two rows and trained overhead.

two-wire vertical trellis, common terminology in California, where one wire is occupied by the cordon and the second is a fixed foliage wire. Shoots grow up and over this wire and fall under their own weight to form a bell-shaped canopy. When the vines are vigorous, the canopy is very shaded.

U, an alternative name for the LYRE trellis.

umbrella kniffin, a system used in eastern America, where canes from a mid-height head are trained over a top wire and tied below.

V, a vine-training system in the shape of the letter where shoots are trained upwards into two curtains. This form does not work as well as the LYRE or U system, where the cordons are separated at the base.

vertical cordon, a rare training system as top buds tend to burst first, making it difficult to manage.

vertical trellis, see VERTICAL TRELLIS.

VSP, or vertical shoot positioning, describes a system used throughout the world where annual shoot growth is trained vertically upwards and held in place by foliage wires (typically two pairs). See VERTICAL TRELLIS.

Y, a vine-training system in the shape of the letter and equivalent to the V system except that the trunk of the vine forms the vertical part of the letter.

The above cannot pretend to be a comprehensive list of the multitude of training systems used worldwide, nor of all their local names, nor how patterns of usage are changing, especially in the New World; but it does give some indication of the extraordinary variation in vine-training systems. The greatest complexity of training systems in the world is to be found in Italy, while those used in France tend to be determinedly regional. R.E.S.

Traisental, wine region in AUSTRIA astride a roughly 12 km/7 mile stretch of the Traisen river just before it empties into the right bank of the Danube below KREMS. Inaugurated in 1995, it comprises 851 ha/2,103 vine acres (1.9% of Austria's total) and benefits from a

DIURNAL TEMPERATURE RANGE similar to that of the WACHAU as well as from distinctive and unusual active LIME-rich conglomerate soils (see GEOLOGY) whose efficacy grower Ludwig Neumayer of Inzersdorf demonstrated from the late 1980s with GRÜNER VELTLINER, RIESLING, WEISSBURGUNDER, Sauvignon Blanc, and wine based on an old GEMISCHTER SATZ. Traisental DAC (since 2006) applies to Grüner Veltliner and Riesling, with a DAC Reserve designation stipulating higher minimum alcohol and later release. D.S.

Trajadura, white grape variety used to add body and a certain citrus character to Portugal's VINHO VERDE if it is picked sufficiently early. It was planted on 1,794 ha/4,433 acres of Portugal in 2020, more than the area devoted to TREIXADURA as it is known across the Spanish border in Galicia. It is often blended with LOUREIRO and sometimes with ALVARINHO.

Traminer, name applied to both white-berried and pink-berried non-aromatic BIOTYPES of SAVAGNIN. The more famous, distinctly aromatic, pink-skinned version is known as GEWÜRZTRAMINER or Traminer Aromatico. Traminer Rose, Roter Traminer, and variations on that theme are sometimes used more specifically for the pink-berried form. Traminer was first noted in the village of Tramin or Termeno in what is now the Italian Tyrol (see ALTO ADIGE) in the 13th century. These CLONES are known in various parts of the world, particularly in central and eastern Europe, by names which are derivations of the word Traminer.

Traminette, relatively recent, complex AMERICAN HYBRID showing promise in cooler American states. Its heady whites hint strongly at its GEWÜRZTRAMINER genes.

transfer method, SPARKLING WINEMAKING process, now less common than it was, that involves provoking a second fermentation in bottle and then transferring its contents into a tank, where the wine is separated from the deposit.

translocation, plant physiological process whereby soluble materials such as dissolved salts, organic materials, and growth substances are moved around the vine in the PHLOEM. (The phloem tissue is in the outer part of the trunk or stems, and so it can be disrupted by CINCTURING.) Sucrose is the principal form in which CARBOHYDRATES are moved, and the phloem sap also contains amino acids and organic acids, inorganic nutrients, plant hormones, and alkaloids. Examples of translocation are the movement of inorganic nutrients absorbed by roots from the soil to other parts of the vine, for example POTASSIUM going into the fruit, which may prejudice wine quality. Translocation also includes the important movement of SUCROSE formed by PHOTOSYNTHESIS away from the leaves to the fruit, which will eventually become ALCOHOL in wine. From the point of view of wine, the translocation of sucrose, MALIC ACID, TARTARIC ACID, elements, and compounds containing NITROGEN during RIPENING are crucial to the chemical composition of grapes and thus to eventual wine quality.

Movement of foodstuffs is invariably towards points of need, such as growing shoot tips for the early part of the season, flowers, then developing berries, and also towards the permanent vine parts such as trunks and roots for the accumulation of reserves later in the season. HORMONES such as auxins, cytokinins, and gibberellins play an important role in regulating translocation. The vine is capable of translocating products over long distances and so, even though the shoot supporting a bunch may be shaded, the grapes will still ripen depending on materials imported from other parts of the vine.

Carbonneau, A., et al., *Traité de la Vigne: Physiologie, Terroir, Culture* (3rd edn, 2020).

Keller, M., *The Science of Grapevines* (3rd edn, 2020).

Transmontano, large, mountainous VINHO REGIONAL in north-east Portugal with the same borders as TRÁS-OS-MONTES but which allows a broader range of grape varieties.

transpiration, physiological process whereby water taken up from a vine's roots is evaporated through the leaves, important in preventing the vine from overheating in warm and sunny weather. Water and dissolved elements move in the so-called transpiration stream through the woody part of the vine in tissue called the XYLEM. The xylem fluid also contains relatively large amounts of AMINO ACIDS (especially glutamine), organic acids (especially malic), and small amounts of sugars. Total water loss from a vineyard is called EVAPOTRANSPIRATION, and this includes transpiration from the vines and also any weeds or COVER CROP present, plus EVAPORATION from the soil surface.

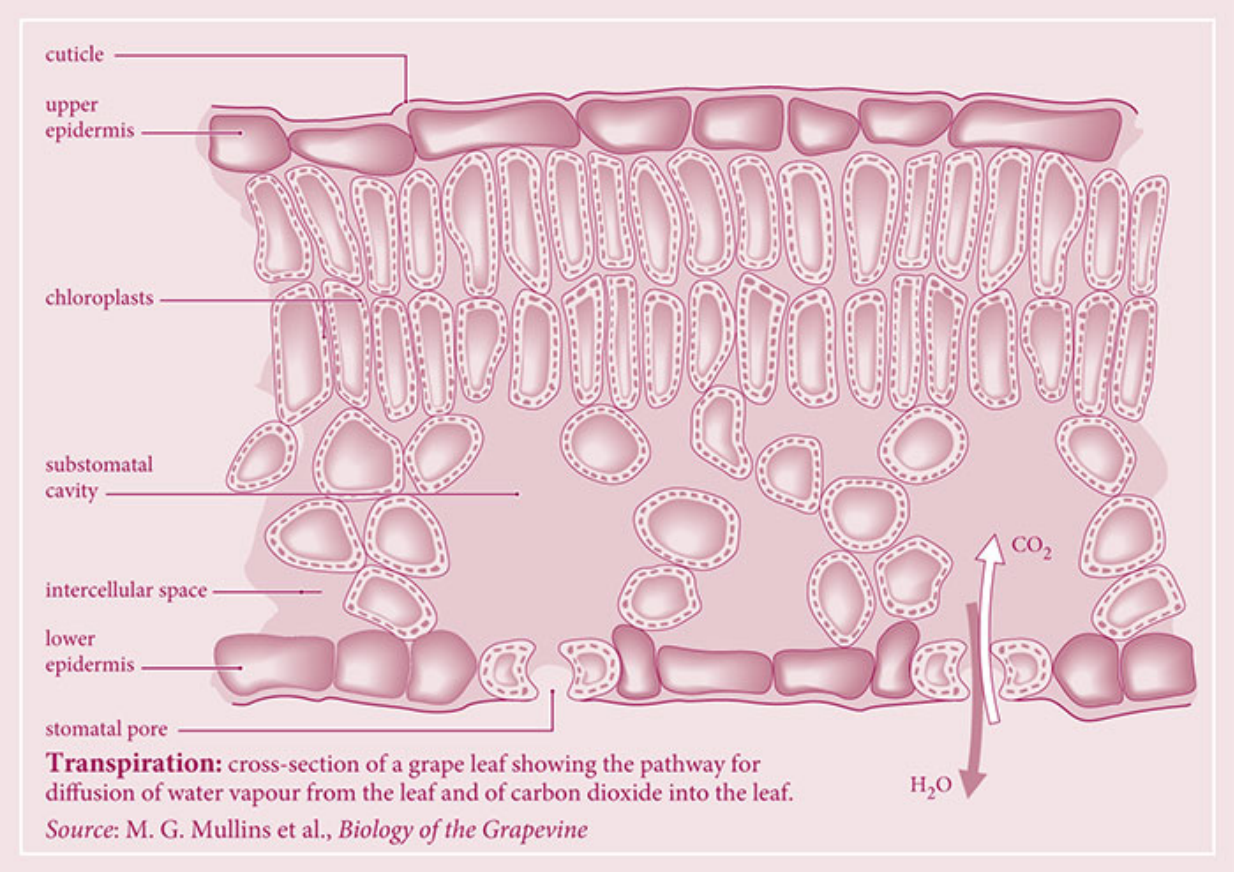
Transpiration is an energy-driven process due to leaves absorbing SUNLIGHT. Water vapour passes from the leaf to the atmosphere via small pores on the underside called STOMATA. Energy is required to provide the latent heat of evaporation for the phase change from liquid (water) to gas (water vapour), which takes place in the cavity below the stomata. The cell walls of the substomatal cavity are wet owing to a long column of water extending from the roots. Provided the vine is well supplied with water, leaves facing the sun will be only 2–3 °C/3–5 °F warmer than the air, while if water supply is limited then this figure can exceed 10 °C/18 °F and the vine will suffer both HEAT STRESS and WATER STRESS.

Transpiration is controlled by both atmospheric and plant factors. High transpiration rates are due to low humidity, high sunshine, high temperature, and high wind speed. Typically during the day, as temperature rises humidity falls, and so transpiration is fastest in the early afternoon. As soils dry, the risk of water stress increases, and so by partially closing stomata the vine is able to regulate its water

status to some extent. However, as stomata close then PHOTOSYNTHESIS stops, as carbon dioxide entry into the leaf is inhibited.

Rates of transpiration vary with the weather and growth stage of the vineyard. For a vineyard in full leaf in the middle of the season, daily evapotranspiration rates may be as high as 40,000 l/ha for a hot, dry, and sunny climate. For a vineyard planted with 2,000 vines per ha, this rate is equivalent to 20 l (4.4 gal) per vine per day. The amount of water transpired is very high relative to both the vine's growth overall and the fruit produced.

Research has shown that, contrary to earlier assumptions, vines transpire at night as well as during the day. This transpiration is driven by a vapour pressure gradient of water, from wet cell walls in the sub-stomatal cavity to the drier atmosphere outside. A study by Rogiers et al. investigated the fact that SÉMILLON is more prone to water stress than many other varieties because its stomata are more open, both day and night, and are slow to shut under water stress.



Transpiration: cross-section of a grape leaf showing the pathway for diffusion of water vapour from the leaf and of carbon dioxide into the leaf.

transport of wine has changed considerably over the ages, but a wide variety of different methods, from tanker to a lone bottle sent by mail, are still used.

Ancient history

Wine was transported in bulk in antiquity in a variety of ways: in huge wineskins or barrels loaded on the backs of two- or four-wheeled carts, but also via waterborne transport, which had a great advantage because of the inefficiency of the harnesses used on animals. For most of the Mediterranean area, wine was carried in large AMPHORAE, which were loaded in the holds of ships. The pottery jars required considerable packing (heather, straw, etc.) to cushion them against breakages. They could be transferred to smaller vessels for transport up inland waterways. A recent discovery has been of wrecks carrying DOLIA, a kind of tanker for the bulk transport of wine. Barrels were widely used in northern Europe (see CELTS) and later in the Mediterranean, although the amphora tradition died out completely only in the medieval period. J.J.P.

The Avontuur, a centenarian 44-metre/144-foot sailing vessel, docking in Shoreham, southern England, having carried wines from the island of PICO in the Azores, thereby reducing the CARBON FOOTPRINT of transportation, which is particularly high for wine GLASS BOTTLES. © Raymond Reynolds

Peacock, D. P. S., and Williams, D. F., *Amphorae and the Roman Economy* (1986).

Modern transport

In the Middle Ages, RIVERS played an important role in transporting wine, and only those wine regions with access to good water transport (by sea and/or river) were likely to develop much trade. In the 19th and early 20th centuries, the advent of a RAILWAY system transformed wine regions as dissimilar as the LANGUEDOC, ROUSSILLON, RIOJA, CHIANTI, and MENDOZA. Today wine is generally transported by road and sea, although some wine is shipped by rail in the US, and a shocking number of special bottles are air-freighted from Europe to billionaires in Asia and the US. Recently, however, several enterprising companies have revived the practice of transporting wine by sailing boat in an effort to lower the CARBON FOOTPRINT of shipping.

For centuries the transport of wine meant BULK TRANSPORT, and the most common container used for transporting wine was the barrel. SHERRY, for example, was still shipped to British bottlers in its special casks, or BUTTS, until well into the 20th century (when the empty butts were used for Scotch whisky maturation). In the latter half of the 20th century, however, container shipment in bulk tankers became the norm, although an increasing proportion of wine is bottled not just in its country or region of origin but actually at the winery (see BOTTLING). However, for both financial and SUSTAINABILITY reasons, the proportion of wine (particularly wine at the lower end of the market) shipped in bulk has risen dramatically this century, and the technology of bulk transport has improved considerably. Unlike wine in bulk, bottles are breakable and can easily be pilfered.

From the consumer's point of view, the most important aspect of the transport of wine is TEMPERATURE. If wine is exposed to high temperatures, it may well deterioriate considerably, even if it has been subject to effective STABILIZATION. Spikes of temperature can also lead to spoilage due to OXIDATION. Conscientious producers try to avoid shipping wine in high summer, while scrupulous wholesalers insist that insulated containers sometimes called reefers are used for shipments in hot weather and/or through the TROPICS, although they

are more expensive. Some shippers of fine wines include temperature sensors in the shipment. Stowing wine below sea level on ships minimizes the temperature variation.

Exposure to light can also be a problem: research indicates that exposure to UV radiation at any point in the distribution chain may damage wine quality (see LIGHTSTRIKE). The risk is reduced by the use of brown rather than clear bottles.

In the US the DIRECT SHIPPING of bottled wine between certain states has been heavily restricted by law.

transversage. See SPARKLING WINEMAKING.

Trás-os-Montes, meaning 'behind the mountains', is a large DOC in north-east Portugal bounded by high mountains on one side and the Spanish frontier on the other (see map of PORTUGAL). The mountains cast a rain shadow over the region, although it becomes progressively more arid towards Spain. With vineyard ELEVATIONS of 350–800 m/1,148–2,625 ft (and another at 1,070 m/3,510 ft, claiming to be Portugal's highest) plus varied mesoclimates and soil types (mostly GRANITE, but also SCHIST and CALCAREOUS soils), Trás-os-Montes has three DOC subregions, from west to east: Chaves, Valpaços, and Planalto Mirandês. Higher vineyards in Planalto Mirandês supply wine for MATEUS Rosé and several imitative brands. Old FIELD BLEND parcels growing in TERROIR similar to neighbouring ARRIBES in Spain are being sought out by winemakers for fresh, characterful, minimal-intervention wines. See also TRANSMONTANO.

S.A.

SEE WEB LINKS

cvrtm.pt

Trbljan, relatively important light-berried vine variety grown particularly on the coast of CROATIA just north of Zadar. Several

hundred hectares are planted. The grape is also sometimes called Kuč.

Treasury Wine Estates, one of the world's biggest wine companies. It was grown out of the first Australo-American wine group and in 2022 had access to more than 12,700 ha/31,382 acres of vineyard around the world. Its brands include PENFOLDS, Wolf Blass, 19 Crimes, Lindeman's, Squealing Pig, Seppelt, Pepperjack, Beaulieu Vineyard, and Stags' Leap Winery. At the heart of the business is TWE's global, multi-regional sourcing model, which includes what they call 'production assets' in the Barossa Valley, the Napa Valley, Marlborough, Bordeaux, and Tuscany. The group also makes a CHAMPAGNE with Thiénot. Winemaker Peter Gago is Treasury's peripatetic public face.

In 2013 the company wrote off US$35 million worth of wine in response to sluggish sales in the US. Exports to the once-dominant Chinese market slumped in 2021 thanks to punitive TARIFFS.

Trebbiano. At least six distinct varieties grown in Italy are known principally as Trebbiano, including Trebbiano Toscano, whose national total of 35,441 ha/87,577 acres in 2015 made it one of the most planted white wine grapes in Italy. Next most planted, largely in Emilia-Romagna, on 19,1059 ha was the remarkably similar Trebbiano Romagnolo. Trebbiano Giallo is found on 2,275 ha, particularly in Lazio, and Trebbiano Spoletino is an Umbrian speciality grown on 121 ha. Trebbiano Modenese is grown on 287 ha and is associated with production of the local vinegar, while Trebbiano Abruzzese (also known as Trebbiano d'Abruzzo although this is actually the name of the wine) is quite unrelated to any other Trebbiano (see ABRUZZO). Meanwhile, many an Italian synonym incorporates the word Trebbiano, most notably Trebbiano di Soave, Trebbiano di Lugana, and Trebbiano Valtenesi, which are all the Marche grape VERDICCHIO. There are almost as many possible histories of Trebbiano as there are different varieties called Trebbiano

(the index of *Wine Grapes* has no fewer than 28 entries for grape names beginning with Trebbiano). The Bolognese agronomist PETRUS DE CRESCENTIIS certainly described a vine called Tribiano as early as 1303, but which one? Today, Trebbiano is planted all over Italy (with the exception of the cool far north), to the extent that it is likely that the great majority of basic *vino bianco* will contain at least some of the variety, if only to add acidity and volume.

The stronghold of Trebbiano Toscano, shown by DNA PROFILING to have a parent–offspring relationship with the GARGANEGA of Soave, is central Italy. It is known as UGNI BLANC and St-Émilion in France, or Tália in Portugal, and is widely planted around the world. Any grape called simply Trebbiano is likely to be Trebbiano Toscano.

See under its most common French name UGNI BLANC for details of Trebbiano in France.

This gold-, even amber-berried grape variety is so productive and is so much planted in both France and Italy (the world's two major wine-producing countries) that it may well still produce more wine than any other vine variety in the world—even though the total area it was planted on appears to have slipped from fifth to ninth place between 1990 and 2016. It is cited in more DOC regulations than any other single variety (about 80) and may well account for more than one-third of Italy's entire DOC white-wine production. Trebbiano Toscano the wine is typically light, crisp, and wet.

Some idea of Trebbiano Toscano's ubiquity is given by listing just some of the wines in which it is an ingredient: VERDICCHIO, ORVIETO, and FRASCATI, together with SOAVE (Trebbiano Toscano was planted in place of Trebbiano di Soave in the 1960s and 1970s, when yield was a more important consideration than quality, but has now been outlawed). The variety has after all had many centuries to adapt itself to local conditions. Between Tuscany and Rome, in UMBRIA, the variety can be known as Procanico, which some agronomists believe is a superior, smaller-berried Trebbiano. Only the fiercely varietal-conscious north-eastern corner of Italy is virtually free of this bland ballast.

Trebbiano's malign influence was most noticeable in central TUSCANY in much of the 20th century, however, where Trebbiano was so well entrenched that CHIANTI and therefore VINO NOBILE DI MONTEPULCIANO laws sanctioned its inclusion in this red wine, thereby diluting its quality as well as its colour and damaging its reputation. Trebbiano is now very much an optional ingredient, however, increasingly spurned by quality-conscious producers. Once Trebbiano fell out of favour with Chianti producers, an attempt was made to transform it into innocuous dry whites. Fortunately the market for these wines has dwindled, and in the 2000s much Trebbiano in Tuscany was GRUBBED UP or used in VIN SANTO.

Trebbiano Toscano has also managed to infiltrate Portugal's fiercely nationalistic vineyards, as Tália or Thalia, and is widely planted in Bulgaria and in parts of Croatia as well as in Greece. As well as being used for Mexico's important brandy production, Trebbiano is well entrenched in the southern hemisphere, where its high yields and high acidity are valued. There were still nearly 1,288 ha/3,183 acres of 'Ugni Blanc' in Argentina in 2020 as well as plantings in Brazil and Uruguay.

South Africa also calls its relatively limited plantings Ugni Blanc but relies more on COLOMBARD for brandy production and cheap, tart, blending material, as does California, whose remaining 42 ha/103 acres of the vine, there called 'St. Emilion', are exclusively in the Central Valley, although interesting VARIETAL versions called Trebbiano are not entirely unknown. Australia, where Colombard is also more important, has limited plantings of Trebbiano, mainly in the irrigated areas, where it provides a usefully tart ingredient in basic blended whites and is also sometimes used by distillers.

The influence of Trebbiano/Ugni Blanc will surely continue to decline as wine drinkers seek flavour with increasing determination.

Trebbiano Romagnolo, along with its almost amber-berried clone Trebbiano della Fiamma, dominates white-wine production in EMILIA-ROMAGNA and results in generally remarkably undistinguished dry whites. The variety is cultivated across a wide swathe of ROMAGNA in

the provinces of Bologna, Forlì, and Ravenna, and only about one-fifth is registered for the production of DOC wines. It is permitted on its own or as a blending component in no fewer than ten Emilia-Romagna DOCs. Permitted yields of almost 100 hl/ha (5.7 tons/acre) do little to assist a grape not known for its striking personality, and most Trebbiano di Romagna is, at best, suitable for a picnic.

Perhaps Italy's most exciting Trebbiano, Trebbiano d'Abruzzese (see ABRUZZO) is not a Trebbiano at all but the BOMBINO BIANCO of Puglia, but this has yet to be proved by DNA PROFILING, which has suggested the variety is related to Trebbiano Spoletino. Trebbiano Spoletino was rescued from extinction by Giampaolo Tabarrini and Paolo Bea, followed by Cantina Novelli in Umbria at the beginning of this century, and has clearly gained ground, with 121 ha in 2015. Trebbiano Giallo and Trebbiano Modenese are, perhaps appropriately, closely associated with vinegar production.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Treixadura, Galician name for Portugal's scented, delicate white TRAJADURA and treated in much the same way. This is the main grape of Ribeiro and may be blended with Galician Torrontés and Lado. It is also grown in the Rías Baixas region, where it is often blended with ALBARIÑO, LOUREIRA, and/or GODELLO. Total Spanish plantings had grown to almost 1,006 ha/2,486 acres by 2020.

trellis systems, support structures for the vine framework required for a given TRAINING SYSTEM. Normally these are constructed, although vines are still very occasionally trained to trees (see ARBOREAL VITICULTURE). The simplest trellis system consists of a STAKE driven beside a vine to which the vine trunk or shoots are tied. Nowadays WIRES are used to support vines and foliage, as POSTS are installed at intervals along the row.

There are several designs of end assemblies, but they are all firmly anchored in the ground so as to support the strain in the wire due to the weight of the crop, the vines, and any WIND stresses. At intervals along the row are intermediate posts, usually made from wood, which also help carry the vine weight. In a well-constructed trellis system, the wires should be strained so tight that the wire does not sag, and this in turn facilitates MECHANIZATION. Details of some common trellis systems and end assemblies are given by Smart and Robinson.

The majority of the world's vineyards, however, have very simple trellis systems. For some, the vines are free-standing (see GOBELET), where the major support for the weight of the vine and crop is from the vine trunk.

For more information on the wide range of trellis systems used in various regions, see TRAINING SYSTEMS. R.E.S.

Smart, R. E., and Robinson, M., *Sunlight into Wine: A Handbook for Winegrape Canopy Management* (1991).

Trentino, the southern and principally Italian-speaking half of Italy's central alpine region of TRENTINO-ALTO ADIGE. Trento is the regional capital. Viticulture is centred in the valley of the Adige and the hills immediately to the east and west of the river and in side valleys such as the Valle dei Laghi and the Val di Cembra. The terrain further east and west into the Dolomites is too rugged and mountainous for viticulture, although CLIMATE CHANGE is an incentive for reviving abandoned plots once considered too marginal for growing grapes. Although the region is on latitude 46° N, the climate is not uniformly cool, as the Dolomites offer protection from cold northern winds and nearby Lake Garda has a moderating effect, so viticulture is by no means confined to early-ripening vine varieties.

Of Trentino's 10,210 ha/25,229 acres in 2020, more than 15% of the vineyards rise over 500 m/1,640 ft in ELEVATION. Three-quarters of Trentino's total wine production is white and geared towards volume, with almost 3,000 ha of PINOT GRIGIO, more than 2,600 ha of

Chardonnay, and 900 ha of MÜLLER-THURGAU. Of the region's total output, 90% is controlled by 15 CO-OPERATIVES and 14 NÉGOCIANTS. This commercial model has led to overproduction of Chardonnay and Pinot Grigio, although the creation of the DELLE VENEZIE DOC, reserved exclusively for Pinot Grigio, has seen volumes shrink and prices rise. Pinot Noir is gaining in interest, in part because the region's high-altitude vineyards are handling the effects of climate change better than BURGUNDY. Riesling might follow.

The region's DOC system has been designed with large-scale production of INTERNATIONAL VARIETIES in mind: the overarching Trentino DOC permits yields up to 15 tonnes/ha as well as innumerable grape varieties. It is, however, subdivided into five subzones with some local focus: Trentino Isera and Trentino Ziresi for MARZEMINO grapes, Trentino Castel Beseno for MOSCATO, Val di Cembra for Müller-Thurgau, and Trentino Sorni for NOSIOLA and SCHIAVA. (Sorni is also home to the local centre of viti-agricultural ACADEME, SAN MICHELE ALL'ADIGE.) The DOC Valdadige covers the same area and varieties as the Trentino DOC and extends into ALTO ADIGE and north-western VENETO.

Trento DOC (for marketing reasons written as TrentoDOC) designates the entire region for production of METODO CLASSICO sparkling wine based on Chardonnay and Pinot Noir. The base wine requires high levels of acidity, guaranteed in grapes coming from elevations of 400–700 m/1,310–2,300 ft. Wines must be aged at least 18 months on the LEES, although Ferrari, the undisputed leader, ages its non-vintage wine for 24 months or longer.

The Teroldego Rotaliano DOC, limited to TEROLDEGO grown on the gravelly Campo Rotaliano, has only a handful of producers, notably Elisabetta Foradori, who has successfully proved that with low yields TEROLDEGO can produce serious wines. Yet because yields can be as high as 17 tonnes/ha, and most production is in the hands of the local co-operative, most quality-conscious producers prefer to label their wines under the more anonymous but less tarnished IGT Vigneti delle Dolomiti. Two other DOCs, Casteller and Lago di Caldaro (the

latter shared with ALTO ADIGE to the north), are devoted almost exclusively to light, pale, Schiava-based reds, although Schiava claims only 204 ha/504 acres in Trentino and is declining fast. W.S.

www.vinideltrentino.com

Trentino-Alto Adige, autonomous, alpine northern Italian region through which flows the Adige river (called Etsch by the region's many German speakers). It is made up of ALTO ADIGE, or the South Tyrol, in the north and TRENTINO in the south (see map under ITALY).

TrentoDOC, TRADITIONAL METHOD sparkling wines from TRENTINO, written thus for marketing reasons.

Trepat, increasingly fashionable indigenous red-skinned wine grape of north-east Spain, particularly in Conca de Barberá and Tarragona. Total plantings were 1,265 ha/3,126 acres in 2020, producing both still and sparkling rosés as well as aromatic light reds.

Tressallier, ST-POURÇAIN synonym for SACY.

Tressot, ancient red grape variety of Burgundy, already described in the 14th century along with PINOT NOIR. Tressot is exclusively cultivated in the Yonne (CHABLIS country), but CLIMATE CHANGE is encouraging Burgundians to re-evaluate its potential. DNA PROFILING has suggested that Tressot is a natural CROSS between DURAS and PETIT VERDOT and that it most likely begat MONDEUSE NOIRE via a natural cross with MONDEUSE BLANCHE. Confusingly, it is also a Burgundian name for the Jura's (unrelated) TROUSSEAU vine. J.V.

tri, French for a sorting process, notably postal, but in a winemaking context it means the selection of suitable grapes. This usually takes the form of a *triage* (see GRAPE SORTING) on reception of the grapes at the winery or cellar, using a sorting table or *table de tri.* However, in the production of BOTRYTIZED wines, a *trie* (note the feminine form), or several *tries*, is made in the vineyard whereby the pickers proceed along the rows selecting only those clusters (and occasionally only those berries) that have been successfully attacked by NOBLE ROT.

tri, table de, French for 'sorting table'. See GRAPE SORTING.

triage, French for GRAPE SORTING.

Tribidrag, earliest known name for ZINFANDEL in its Croatian birthplace.

tribromoanisole. See TBA.

Tricastin, Coteaux du, old name for GRIGNAN-LES-ADHÉMAR.

trichloroanisole. See TCA.

Trimbach, family-run wine producer based at Ribeauvillé in ALSACE. The company was established in 1626. Its wines are characterized by very fine fruit and high, ripe acidity. Riesling constitutes half of production, and even its most basic offering can stand many years' AGEING. Two of its most famous bottlings are Rieslings: the very fine, rare, and long-lived Clos Ste-Hune (in fact from the Alsace Grand Cru Rosacker); and Cuvée Frédéric Émile, named after the 19th-century Trimbach who expanded the business to become an important merchant house as well as vine-grower. The family, including three

members of the 13th generation, works 63 ha/156 acres of vineyards in ten different villages around Ribeauvillé, famous for the diversity of its soils. Recent additions include 2 ha of Alsace Grand Cru Brand from vintage 2018.

trimming, the vineyard operation of removing unwanted SHOOT growth which can cause SHADING and hinder SPRAYING. Although it is usually done with a trimming machine mounted on a tractor, it may also be carried out with a handheld machete or similar device. The operation normally removes the SHOOT TIP and a few leaves below it, or about 30 cm/12 in of growth, thus leaving the shoots trimmed to about 15–25 NODES, or 70–150 cm/31–58 in. Trimming is essential in vineyards with high VINE DENSITY to stop shoots from adjacent rows from growing together. Regrowth may be such as to demand up to six trimmings a year, particularly in vineyards well supplied with water (by rainfall or IRRIGATION) and NITROGEN. If shoots are trimmed too short then there may be insufficient leaf area to ripen the crop properly (see LEAF TO FRUIT RATIO). Resulting wines will be lower in alcohol and of lighter body and colour. Sometimes vineyards are trimmed so neatly on the top and sides that vine rows can look like a recently trimmed hedge, hence the alternative term 'hedging'.

R.E.S.

Trincadeira, sometimes called Trincadeira Preta, or black Trincadeira, is a productive red grape highly valued by winemakers in southern PORTUGAL, in 2020 grown on a total of 7,546 ha/18,647 acres of vineyard all over the country. Known in the DOURO as Tinta Amarela, it is very susceptible to ROT and therefore performs well only in the driest of climates, with better results in the Douro Superior, where it can yield fine, attractively scented wines, than in Baixo Corgo, the coolest and wettest of the Douro's three subregions. Trincadeira is therefore ideally suited to the ALENTEJO, where it can produce deep-coloured, spicy wines in the right conditions but tends to herbaceousness if not picked at the right time. R.J.M.

Trincadeira das Pratas, traditional, minor, but potentially high-quality Portuguese white grape originally known as Tamarez in the Alentejo but not the same as the Tamarez of the Tejo. A likely ALFROCHEIRO × Hebén spontaneous CROSS, it can, but does not always, produce delicate, perfumed dry whites.

Triomphe (d'Alsace), HYBRID bred by Kuhlmann in Alsace from Knipperlé and a *riparia-rupestris* AMERICAN VINE. It has good resistance to POWDERY MILDEW, but the wine produced, however deeply coloured, tastes FOXY. The vine is responsible for some English reds.

trocken German for 'dry', a legally defined term when applied to the wines of AUSTRIA and GERMANY. The term can be applied to a still wine with a maximum of 4 g/l RESIDUAL SUGAR, or up to 9 g/l if the TOTAL ACIDITY is less than the residual sugar by no more than 2 g/l (9 g/l residual sugar and total acidity not less than 7 g/l). Given Riesling's high acidity, the upper limit effectively applies to many Austrian and most German wines from that grape. This legal definition of dryness should not be confused with an organoleptic impression that most tasters would describe as dry, which often applies to Riesling HALBTROCKEN. Confusingly, trocken when applied to SEKT (Austrian or German sparkling wine) designates a decidedly sweet wine containing 17–32 grams of residual sugar, as it corresponds to the similarly sweet category of *sec* in CHAMPAGNE. See also DOSAGE

See also FEINHERB and SWEETNESS. J.R. & D.S.

Trockenbeerenauslese, commonly referred to as TBA, the PRÄDIKAT with the highest MUST WEIGHT defined by Austrian and German wine law. *Trockenbeeren* refers to grapes (*Beeren*) that have shrivelled on the vine, typically under the influence of NOBLE ROT. Other than in Austria's NEUSIEDLERSEE region, TBA was traditionally

confined to rare vintages, but rigorous selection and sorting of fruit (with prestige and high prices as incentives) as well as warmer weather (see CLIMATE CHANGE) have made for considerably increased frequency, especially of tiny lots fermented in glass demijohns. Musts in the upper 200s of OECHSLE, no longer freakishly uncommon, can sometimes take a year or more to ferment to the 5.5% alcohol requisite for wine. A significant share of any TBA is lost to the filter pads in the process of bottling it in stable condition. J.R. & D.S.

Trois Glorieuses, annual weekend devoted to wine and food in and around Beaune. See HOSPICES DE BEAUNE and PAULÉE for more details.

Trollinger, or Blauer Trollinger, is the most common German name for the distinctly ordinary black grape variety known as SCHIAVA Grossa in Italy, VERNATSCH in the Tyrol, and Black Hamburg by many who grow and buy TABLE GRAPES. It almost certainly originated in what is now the Italian Tyrol (see ALTO ADIGE), and its German name is a corruption of Tirolinger. In Germany it is associated exclusively with WÜRTTEMBERG, where it has been cultivated since the 14th century (see GERMAN HISTORY). Total plantings of 2,051 ha/5,068 acres sufficed to sustain the variety's position as Germany's fourth most planted red-wine vine in 2020, a rather astonishing statistic when one considers that virtually all of the resultant pale red is drunk by thirsty Württembergers.

Tronçais is a sort of French OAK named after a forest near NEVERS.

trophy wines, small group of wines more expensive than any others and becoming more so under sustained attack from the world's best-heeled COLLECTORS, INVESTORS, and drinkers. A Bordeaux FIRST GROWTH, PETRUS or LE PIN from a fine VINTAGE is a trophy wine.

The wines of DOMAINE DE LA ROMANÉE-CONTI and Domaines LEROY, Rousseau, and Roumier count, as do the single-vineyard bottlings of GUIGAL, most PRESTIGE CUVÉES from Champagne, VEGA SICILIA, and the rare red-label wines of Bruno Giacosa and Giacomo Conterno Monfortino.

New World trophy wines include PENFOLDS Grange and all the CALIFORNIA CULT wines. The key to identifying trophy wines is their international fame (often determined by a particularly high SCORE) and, especially, PRICE. Their prices rose markedly from the late 1990s because of the dramatic increase, particularly in ASIA, in the number of potential buyers of these 'limited-edition' wines prepared to acquire them at any price—billionaires need billionaires' wines.

tropical viticulture. Although the grapevine is regarded by many as a strictly temperate plant, it is now increasingly grown in the tropics, defined approximately as the region bordered by the tropics of Cancer and Capricorn. Countries in which grapes are cultivated in tropical conditions include AUSTRALIA, BOLIVIA, BRAZIL, CAMBODIA, COLOMBIA, CUBA, ECUADOR, INDIA, INDONESIA, KENYA, Laos, MADAGASCAR, MEXICO, MYANMAR, NAMIBIA, Nigeria, PARAGUAY, the Philippines, SRI LANKA, TAHITI, TANZANIA, THAILAND, TOGO, VENEZUELA, and VIETNAM. About 90% of this tropical vineyard area of around 175,000 ha/432,435 acres produces TABLE GRAPES, but increasing amounts are dried for RAISINS, especially in India, or fermented into wine.

Within the tropics there are many different climates, modified by differences in ELEVATION and RAINFALL. Only those areas with pronounced wet and dry seasons, and those which are virtually arid, are suitable for commercial tropical viticulture. In the lowland areas, grapevines adopt an evergreen growth habit but can be manipulated into cropping two to three times per year, mainly by PRUNING and removal of all remaining leaves at the point chosen as the end of season, and by the application of chemicals such as hydrogen cyanide solution which induce dormant buds to burst uniformly within

one week of application. Other chemicals which retard growth and induce flower buds to form are used mainly for table grapes (see GROWTH REGULATORS).

In areas with pronounced wet (at least 1,800 mm/70 in) and dry seasons, fully ripe wine grapes can be produced only in the dry season. In the Indian 'two season, one crop' system, which has now been adopted in most Asian wine-producing countries, vines are pruned long to produce grapes in the dry season then pruned short (one bud) for only vegetative growth in the rainy season. If IRRIGATION is available in arid regions, then 'two seasons, two crops' is possible.

In some tropical countries, in the interests of both quality and availability, grapes can be ripening as temperatures are rising (35–40 °C/95–104 °F), contrary to most TEMPERATE areas, where ripening proceeds as temperatures fall.

Highland tropical areas with elevations in excess of 1,000 m/3,280 ft to 1,400 m/4,590 ft, depending on the distance from the equator, can have climates that are almost temperate and allow grapevines to follow a climate-controlled growth cycle, including natural LEAF FALL, as for non-tropical areas.

Irrigated grapevines can be very productive in the tropics, giving YIELDS of fresh fruit of 140–280 hl/ha, or 8–16 tons/acre per season, so tropical viticulture can yield relatively inexpensive wine, as in north-east Brazil. In Asian countries, on the other hand, producers are increasingly encouraging vines to produce a single higher-quality crop every 12 months despite the extra costs.

Depending on the climate, tropical grapes can be programmed to reach maturity at times of the year when other fresh fruit is not available or when international prices are very high. For example, north-east Brazil and Maharashtra, India, export table grapes in April/May. W.W.S.

www.tropical-viticulture.com

Trousseau, well-connected and well-travelled red wine grape indigenous to the JURA, where it makes distinctively perfumed, powerful wines that age well and are much more deeply coloured than POULSARD provided yields are controlled. Research in the early 21st century pinpointing the best (warmer) vineyard sites for the variety led to increased plantings: 182 ha/450 acres by 2019. It buds early and may be affected by spring FROSTS, and it is an irregular yielder. In the mid 19th century, the French AMPELOGRAPHER Comte A. Odart maintained that Trousseau was the same as Portugal's BASTARDO, as DNA PROFILING has confirmed. Under the names Bastardo, Maturana Tinta, Merenzao, and Verdejo Tinto, it has been grown in Iberia for at least two centuries, although its journey from eastern France remains a mystery. DNA PROFILING strongly suggests that the variety is a sibling of both CHENIN BLANC and SAUVIGNON BLANC and probably has a parent–offspring relationship with that other Jura variety SAVAGNIN. Grapes called Bastardo are grown in Oregon, Crimea, and Moldova.

Trousseau Gris is a colour mutation that was once known as Gray Riesling in California and is enjoying a small renaissance there.

trunk, the main stem of a tree, from the ground to the first branches or, in the case of a grapevine, to the CORDONS or HEAD. Newly formed vine trunks are pliable and need support (see VINE TRAINING). The height of the trunk of a grapevine is variable, typically from 10 cm/4 in (in BUSH VINES) to more than 10 m/30 ft (in vines growing up trees; see ARBOREAL VITICULTURE), and is determined by the specifications set for each TRAINING SYSTEM and TRELLIS. The trunk height determines the position of the CANOPY relative to the ground. Vine trunks are woody and form part of the bulk needed for storage reserves, especially of CARBOHYDRATES and NITROGEN compounds. In climates with freezing winters, multiple trunks are used to facilitate replacement after winter killing, and in extremely cold climates trunks are buried during the winter (see WINTER PROTECTION).

The trunk of any plant (including the OAK tree, used for COOPERAGE and CORKS) contains a sleeve of conducting tissue with the CAMBIUM in its centre, bark (with PHLOEM) on the outside, and wood (with XYLEM) on the inside. Through these tissues, xylem sap moves upward, carrying water, minerals, and compounds from the roots to the leaves, and phloem sap moves multi-directionally carrying sugars and elaborated molecules from the leaves to the rest of the vine. The downward passage of phloem sap in vines can be interrupted by trunk CINCTURING or girdling. See also TRUNK DISEASES. B.G.C.

trunk diseases, group of FUNGAL DISEASES that infect the wood of the vine and other economically important perennial woody crops such as fruit and nut trees. They are caused by a wide range of Ascomycota and Basidiomycota fungi. Spores from most of these fungi infect grapes through PRUNING wounds, colonizing the vascular system, resulting in symptoms such as wood necrosis, cankers, and/or wood rot. Vascular flow is interrupted over time, causing a progressive death of SPURS, CANES, CORDONS, and TRUNK, leading to the eventual death of the vine. Trunk diseases affect both young and mature vineyards, occur wherever grapes are grown, and are one of the most important biotic factors reducing YIELD, limiting vineyards' lifespan, and increasing production costs.

In young vineyards, BLACK FOOT and PETRI DISEASE are the most prevalent of these diseases, constituting what is known as the young-vine decline complex. Symptoms and negative effects on vine growth can be observed as early as a few months after planting. Though spread of these diseases can occur in the vineyard, it has been well-demonstrated that vine propagation in NURSERIES using infected MOTHER VINES is one of the main sources of infection.

Trunk diseases affecting mature vineyards include ESCA and the canker diseases BOTRYOSPHAERIA DIEBACK, EUTYPA DIEBACK, and PHOMOPSIS dieback. These diseases are caused by airborne spores (conidia or ascospores) under favourable environmental conditions. Studies have also shown that some of the fungi responsible for trunk

diseases can remain latent until the vine is exposed to abiotic and/or biotic stress conditions. Symptoms are characterized by dieback and death of spurs, canes, cordons, and trunks and eventual vine death due to canker formation in the vascular tissue.

Since establishing and maintaining a vineyard is very costly, a long lifespan for vines is essential for economic success, as well as for the widely reported relationship between VINE AGE and wine quality. The decline and death of young and mature vines can cause substantial economic loss to grape-growers. It is therefore imperative that management strategies such as sanitation and pruning-wound protection are implemented from the year of planting. See also TRUNK RENEWAL.

The International Council of Grapevine Trunk Diseases, formed in 1998, meets biannually to coordinate research into tackling these increasing threats

(www.ucanr.edu/sites/ICGTD).

Hrycan, J., et al., 'Grapevine trunk disease fungi: their role as latent pathogens and stress factors that may favor disease development in grapevines', *Phytopathologia Mediterranea*, 59 (2020), 395–424.

trunk renewal, management technique to replace vine TRUNKS injured by WINTER FREEZE or by TRUNK DISEASE. It originated in the north-east of the US and involves removing a disabled trunk and vine framework by cutting below the injury and replacing it by taking a sucker from below the cut and training it upwards. This procedure is one of rejuvenation, as the new trunk and vine are healthy tissue.

R.E.S.

Smart, R., 'Timely trunk renewal to overcome trunk disease', *Practical Winery & Vineyard* (October 2015), 64–70.

Tsaoussi, white grape speciality of the Greek island of Kefalonia, where it may be blended with the more distinctive ROBOLA.

Tsimlyansky Cherny, vine speciality of Rostov in RUSSIA making tannic, characterful reds.

Tsolikouri, relatively important white wine grape of GEORGIA, although only about one-tenth as widely planted there as the popular RKATSITELI. It makes full-bodied semi-sweet and dry wines with moderate acidity and is also used to make sparkling wines.

TTB, acronym for the Alcohol and Tobacco Tax and Trade Bureau, the US regulatory body responsible for AVA approvals, federal taxation, label approvals, and winemaking protocols (although states are permitted to enact more stringent rules than those applied nationally). The TTB is an offshoot of the Bureau of Alcohol, Tobacco, and Firearms (ATF).

Tualatin Hills, northernmost wine region and AVA of the WILLAMETTE VALLEY of Oregon.

tufa, a rock formed by the localized precipitation of calcium carbonate, typically in association with springs, caves, riverbeds, and lake edges. It should not be confused with the marine LIMESTONE of the Loire region known in French as TUFFEAU, nor with the widespread non-calcareous VOLCANIC deposit called TUFF that is much more relevant to viticulture. A.J.M.

tuff is a fine-grained VOLCANIC rock created when fine, ashy material ejected during a volcanic eruption settles, accumulates, and through time becomes progressively hardened. Tuffs vary in composition and colour, depending on the chemistry of the parent volcano, but all

comprise several silicate minerals (see GEOLOGY) and so have plenty of potential nutrients for the vine. Geologically, young tuffs can still be relatively soft and easily weathered. Tuffaceous soils, such as those found in parts of southern Italy and SICILY, can therefore be deep and fertile. The relative softness of young tuff is exploited in places such as TOKAJ, EGER, and Bükk in Hungary for excavating extensive wine cellars. Confusingly, some wine literature refers to tuff as TUFA, which is geologically quite different. In Italy, *tufo* is sometimes used rather inexactly to refer to certain LIMESTONE soils as well as to those of volcanic origin. A.J.M.

tuffeau, a common rock type in the central LOIRE. *Tuffeau blanc* is CALCAREOUS and provides much better DRAINAGE than most LIMESTONES. This is the rock used to build many of the châteaux of the Loire, and remaining hollows in the rock have been adapted for winemaking and storage. The overlying *tuffeau jaune* is more sandy and is particularly suitable for the Cabernet Franc vine, underlying some of the best vineyards in CHINON and SAUMUR-Champigny. It is distinct from both TUFA and TUFF. A.J.M.

Tulbagh, inland wine district in SOUTH AFRICA just east of SWARTLAND that is best-known for its whites but produces some fine reds too.

Tumbarumba , high-ELEVATION, cool Australian wine region in southern NEW SOUTH WALES specializing in Chardonnay and Pinot Noir for sparkling wine and gaining attention for elegant, cool-climate, still Chardonnay wines. Spring FROST is a major threat on these GRANITE-and-BASALT slopes, requiring careful site selection. A.R.P.

Tunisia , North African country with a long heritage of winemaking, likely since the Phoenicians established the city of CARTHAGE on the

coast over 2,500 years ago. Phoenician agronomist MAGO is, in fact, considered to be one of the first authors on viticulture.

Muslim rule curbed wine production from the 7th century until the French occupation in the 1880s. Under the French, Tunisia's vineyard area greatly expanded, and the country became a major exporter of wine and grapes following France's PHYLLOXERA crisis. Its peak winegrowing period was the 1930s when it had 50,000 ha/123,553 acres under vine. Since Tunisia's independence in 1956, vineyard area has fallen dramatically, reaching just 21,702 ha in 2016, just over 9,600 ha of which are for wine production, in the hands of barely a dozen wineries. Annual wine production ranges between 200,000 and 220,000 hl/5,283,441–5,811,785 gal.

Most wine is produced in the region of Cape Bon, on a peninsula about 100 km/62 miles north-east of Tunis. Its MEDITERRANEAN CLIMATE is similar to that of Sicily, with average annual rainfall of 350 mm/13.7 in and an average temperature of 20 °C/68 °F. Red Mediterranean varieties are dominant, with CARIGNAN accounting for over half the vineyard area and Cinsault and Syrah following its lead. Production is focused on full-bodied rosés and rich red wines, although recent improvements in winemaking mean that white wines from Chardonnay, Muscat of Alexandria, Verdejo, and Viognier also sate the growing domestic market. Most Tunisian wines are consumed locally, with a small but growing wine route in Cape Bon and wine clubs in Tunis. A.B.

Türkiye , widely known as Turkey until 2022, has the fifth largest vineyard area in the world, although it is shrinking rapidly. Since 1990, the surface under vines has decreased from 580,000 ha to 419,000 ha/1,035,372 acres in 2021. Only 3% of the 4.2 million tonnes of grapes harvested in 2020 were used for Türkiye's total wine production of 847,000 hl/22.4 million gal. The rest is used in equal amounts for making molasses (an integral part of Turkish cuisine), for TABLE GRAPES, and for RAISINS, of which Türkiye is the world's leading producer.

Wine has long been overlooked by Turks who have developed a drinking culture over the national aniseed-flavoured spirit rakı. It has been gaining popularity among young people since the early 2000s, and the overall quality has improved along with the wine culture. Despite this, domestic per capita consumption is less than a litre, inspiring producers to target exports in order to survive. However, only 2.9% of the annual production is exported.

According to the market regulator Tobacco and Alcohol Department (TADAB) in 2021, there are 185 registered wineries of which 50 have commercial significance. The majority are urban enterprises rather than businesses established by grape-growers.

History

Anatolia, the peninsula where the Asian part of Türkiye is located today, has played an important role in the ORIGINS OF VINICULTURE. South-eastern Anatolia is most likely where the grapevine was first domesticated. Traces of a wine culture in archaeological sites have been traced back to the Neolithic period in the form of wine-related vessels. Anatolia's position as a bridge between Asia and Europe initiated the further spread of viniculture to the rest of the grape-growing world, an argument supported by linguistics, grape genetics, and archaeology.

The ancient civilizations that inhabited Anatolia, from Assyrians and Hittites to the Phrygian Kingdom, Urartians, and Lydians, had cultivated grapes and made wine with their relevant customs, ceremonies, and festivities, continuing through the Classical and Byzantine periods. Alongside its religious attributes, wine was a commodity traded in volume along major river routes and through ports. Between 1650 and 1200 BCE, when the Hittites ruled most of Anatolia, there were laws safeguarding viticultural practices and trade routes, identifying the different types of wine consumed. Hittites used the word *wiyana* for wine, influencing the words used in many modern languages. Numerous artefacts depicting grapes and wine-related rituals in the Museum of Anatolian Civilizations in Ankara reveal the rich heritage of these civilizations.

When Turks settled in ANATOLIA late in the 11th century they had already converted to ISLAM. As their dominance over the region strengthened, they transformed the largely Greek-speaking region into a Turkish-Muslim one. Although alcohol consumption was prohibited for the Muslim population, non-Muslim communities were given concessions to manufacture and trade it. Its consumption was tolerated in order to preserve the multicultural social structure of the empire and to provide a balance between the Islamic influence and pre-Islamic drinking rituals that included even many iron-fisted sultans. The economic return of the alcohol trade was also too great

to ignore. In 1904, 340 million litres of wine were produced, a large portion of which was exported to PHYLLOXERA-hit European markets.

In the aftermath of the First World War and the Turkish War of Independence, the forced migration of Armenian and Greek settlers, who had been responsible for most of the wine production and trade, left Turkish viniculture unattended. Vast vineyards were left unclaimed, and centuries-old knowledge and traditions were lost in an instant. During this period, Türkiye's total wine production decreased to only 2 million litres.

Modern history

After the foundation of the republic in 1923, constructive steps were taken to revive viticulture and winemaking. As a first step, private enterprises were allowed to produce wine alongside the state monopoly. Vine-growers were given technical know-how through agriculture faculties, subsidies for modern winery equipment were provided, and CONSULTANTS were invited from France to determine suitable viticulture areas and vine varieties.

While the earliest established wineries were acquisitions from Greeks, Kemal Atatürk, the founder of the republic, initiated AOÇ Wine Factory in 1925 in the new capital Ankara. At the end of the 1920s, large-scale private sector wineries were initiated by Doluca in Thrace and Kavaklıdere in Ankara. Competition from the state monopoly Tekel and some regional growers encouraged the industry to focus on marketing and sales rather than wine quality and diversity well into the last decade of the 20th century.

A new chapter began in the mid 1990s when Sarafin and Gülor, early boutique wineries in southern Thrace, planted their vineyards with INTERNATIONAL VARIETIES and produced VARIETAL wines. Their success spurred many new producers, equipped with modern technology and often supported by foreign consultant winemakers. Despite protective tax policies, the liberalization of wine imports in 2003 fuelled further interest in wine culture and mediated the improvement of Turkish wine quality, especially under the leadership of female winemakers educated abroad.

Türkiye's restricted local market and the long-serving, Islamist-leaning government's 2013 law banning all forms of alcohol promotion, including on company websites, forced producers to search for new markets. Attempts to promote Turkish wine through tasting events and competitions revealed a need to focus on local grape varieties and winemaking styles in order to find a place in export markets. By 2021 more than 60 INDIGENOUS VARIETIES were in use, helping preserve the country's legacy of old BUSH VINES.

Geography, climate, and grape varieties

Owing to prolonged administrative neglect, the winegrowing regions of Türkiye are not officially designated. Geographically, the country is divided into seven regions with a wide variety of climatic conditions. Türkiye's relatively low latitudes are compensated by the high ELEVATION of most viticulture areas.

More than half of the vineyards dedicated to wine and a large proportion of the registered wineries are in the **Aegean** region. The port city of Izmir is the epicentre of the wine industry and home to Bornova Misketi, a variety related to MUSCAT BLANC À PETITS GRAINS and used for dry, semi-sweet, and DRIED-GRAPE WINES. Dark-skinned local varieties Foça Karası and Urla Karası are being replanted by a group of passionate producers. Cabernet Sauvignon, Merlot, Syrah, and Petit Verdot produce richly structured wines while the fruit of generally older Alicante Bouschet and Carignan vines is used mostly for blending. Chardonnay and Sauvignon Blanc can make fine wines when grown at high elevations, as proven by Sevilen, the region's leading producer. The popular wine route in the Urla district has provided a good model for similar collaborations of regional producers.

The prevailing MEDITERRANEAN CLIMATE of the Aegean coast influences the mountainous interior thanks to the east–west orientation of the mountain ranges. The seedless Sultaniye (SULTANA), Türkiye's most widely cultivated grape, is typically used for drying, and its use in winemaking is gradually decreasing. Inland in Manisa, Kavaklıdere's Pendore vineyards focus mainly on black varieties under the consultancy of Stéphane DERENONCOURT. The high plateau further inland, around Güney in Denizli, has a semi-arid CONTINENTAL CLIMATE with hot, dry summers and cold, snowy winters. At ELEVATIONS reaching up to 900 m/2,950 ft, a wide variety of domestic and INTERNATIONAL VARIETIES are grown, serving many producers in Türkiye. Attention is focused on Syrah and Cabernet Franc, while the local Çalkarası grape is largely used for rosé wines. Pamukkale and

Küp are the region's leading producers, having the experience of more than 60 vintages.

The windy northern Aegean island of Bozcaada is home to some of Türkiye's oldest wineries and vineyards and grows mainly local varieties such as the dark Kuntra and Karalahna and pale Çavuş and Vasilaki, mostly as BUSH VINES. Despite this traditional wine culture, the island was put on the wine map thanks to the efforts of the visionary winery Corvus.

More than 40% of all registered producers in Türkiye are based in the Marmara region in the hinterland of Istanbul. Most of the winemaking activities are in Eastern Thrace, the European territory of Türkiye, surrounded by the Black Sea to the north, the Sea of Marmara to the south, and the Aegean Sea to the west.

In the southern part of **Thrace** around Tekirdağ, the climate is typically Mediterranean. Planted mainly with international varieties, the vineyards enjoy southern exposure along the lower, sandy-clay slopes of the Ganos range facing the Sea of Marmara. Kayra, now part of DIAGEO, won instant recognition for creativity and dynamism after taking over the former state monopoly Tekel in 2005. Further southwest, the Gallipoli peninsula has a mild climate mediated by the surrounding seas and winds that regulate the otherwise humid conditions. CLAY soils yield deep, concentrated reds from Merlot and both Cabernets in the hands of Doluca, long the region's leading winery, and newer estates such as Suvla and Vinero. To the east, in the hilly area across the Dardanelles strait, the Paşaeli winery has revived old plantings of dark Karasakız (Kuntra of Bozcaada) and the white Sıdalan. Adakarası, an aromatic variety grown on the island of Avşa in the Sea of Marmara, is often used for rosé.

The province of Kırklareli in the foothills of Strandja Mountains is close to the Black Sea, which allows for a mild continental climate. Soils are particularly varied and include GRANITE, LIMESTONE, TERRA ROSSA clay, and QUARTZ gravels. The region's late-ripening Papaskarası yields smooth, spicy reds with bright acidity. Some of Türkiye's notable new producers, led by energetic grower Chamlija, are found in this relatively cool climate.

The vineyards in Central Anatolia follow the course of the Kızılırmak, Türkiye's longest river. Kalecik district, north-east of Ankara, is home to the black grape Kalecik Karası, which was saved from extinction in the 1970s. The soft, fragrant examples made in the 1990s by Kavaklıdere encouraged significant plantings. The region's vineyards are at elevations of 650 m/2,132 ft on LOAM and GRAVEL soils. The river and the surrounding mountains moderate what is otherwise a severe continental climate.

Upriver in the south-east, Cappadocia has an elevation of over 1,000 m/3,280 ft, its sandy, VOLCANIC soils planted with bush vines, often UNGRAFTED. The climate is continental and arid, with annual rainfall as low as 350 mm/13.8 in. Winters are very cold and mostly snowy, while summers are hot and dry. Winter and spring FROST can pose problems. For white wines, Emir is the region's most promising grape variety, used in dry and sparkling wines; Narince, Sauvignon Blanc, and Chardonnay have also performed well. Turasan and Kocabağ are the region's oldest producers, while Gelveri makes AMPHORA wines from local varieties grown in old vineyards at the foot of Hasan Mountain in Güzelyurt, near Aksaray.

The climate of Tokat shows Central Anatolian character, though it is geographically part of the damp **Black Sea** region, which is known mostly for growing tea and hazelnuts. The native grape Narince yields full-bodied, perfumed whites, often oak-aged. Most vineyards lie at an average of 400 m/1,310 ft elevatıon and follow the course of the Yeşilırmak River. Established in 1958, Diren is the region's only winery.

The dry, hot summers and mild, wet winters of the **Mediterranean** region's southern shores are not ideal for viticulture, so most vineyards and wineries are nestled on a high plateau in the Taurus Mountains. Likya winery near Antalya has been leading efforts to revive local varieties.

Most of the mountainous **Eastern Anatolia** region lies above 1,000 m. In this markedly continental climate, DIURNAL TEMPERATURE RANGE is wide and annual rainfall can be less than 400 mm/16 in. Vineyards along the Euphrates River in the provinces of Elazığ and Malatya

benefit from the moderating influence of the river and the gigantic dams built on its course. The local variety Öküzgözü, which produces fruity reds, has become so popular that its cultivation has increased significantly throughout Türkiye. Among the few wineries operating in this region, Kayra's facility in Elazığ is the most significant.

South-eastern Anatolia is a major grape-growing region, but most of the produce is used for purposes other than wine. Boğazkere, named after its harsh TANNINS, is its principal grape, harvested from dry-farmed bush vines along the banks of the Tigris river north-west of Diyarbakır. As the climate is extremely hot, the best fruit comes from high-elevation sites around the villages of Çüngüş and Çermik. The local classic blend with Öküzgözü gives balanced reds to match the region's meat dishes. Although long-standing political unrest has made the area unfavourable for wineries, Shiluh winery in Mardin carries the flag of the Syriac Christian community's archaic winemaking traditions. U.C.

www.tarimorman.gov.tr/TADB

www.tuik.gov.tr

Turkmenistan , central Asian republic and former state of the Soviet Union that sprawls between the Caspian Sea, UZBEKISTAN, AFGHANISTAN, and IRAN. Evidence of vine-growing in the country dates back to the 3rd century BCE. Greek and Roman writers report that grapes were cultivated in Marghian (the Murghab Valley) and in Aria (the Tejen Valley). The Kopetdag ravines still have a great diversity of WILD VINES that have served as a basis for many INDIGENOUS VARIETIES. Different wine vessels depicting grape bunches found during excavations of the village of Baghir near the capital Ashkhabad testify to the fact that Turkmenistan has a long history of winemaking.

By 2020, however, most of the country's approximately 19,673 ha/48,613 acres of vineyards were TABLE GRAPES and RAISINS. Vineyards are mainly in the Ashkhabad region with some in Mary and Chardzhou regions. Only a limited selection of wine grapes are grown including Terbash, Tara Uzüm Ashkhabadski, Riesling, Saperavi, Kizil Sapak, and Bayanshira. The vast Karakumy Desert occupies a large part of this hot, dry country. Almost all vineyards need IRRIGATION, but only the north part of the Tashauz region needs WINTER PROTECTION.

Tursan , 320-ha/790-acre AOC in the Landes in SOUTH WEST FRANCE producing wine in all three colours, mainly red and rosé made from CABERNET FRANC and TANNAT grapes with FER and Cabernet Sauvignon. Most wines come from the Geaune CO-OPERATIVE and are sold locally. The white version, a blend focused on the local variety BAROQUE and GROS MANSENG, is more interesting; three-star chef Michel Guérard of Eugénie-lès-Bains sells his oaked version under the name Baron de Bachen. P.S.

Tuscany , the most important region in central ITALY (see map under ITALY), where it is known as Toscana. Today Tuscany is at the centre neither of Italy's economic life nor of its political life, but it is the region which formed Italy's language, its literature, and its art, and thus it has assumed a central place in the country's culture and self-image. The landscape, immortalized in the work of artists from Giotto to Michelangelo and part of every European's cultural baggage, has remained largely unchanged to this day: a succession of hills and valleys covered with cypresses, umbrella pines, and olive groves—and vineyards.

Ancient history

In the ancient world, Tuscany, and at certain points of its history a much larger area, was known as Etruria. See ETRUSCANS for the ancient history of Tuscany.

Medieval history

If we know more about the wines of medieval Tuscany than we do about the wines of other regions of medieval Italy, it is not because they were better or there were more of them: the reason is the region's, and particularly Florence's, economic and political importance.

Viticulture flourished despite the frequent, small-scale civil wars. The region produced more or less equal amounts of oil and wine, but by far the largest crop was wheat. Smallholders were rare in this part of Italy, since the land was mostly owned by monasteries, the local aristocracy, and (increasingly) merchants in the cities. The system of agriculture was often that known as *mezzadria*, sharecropping whereby the landowner would provide the working capital and the land in return for half (*mezzo*, hence the name) the crop. In 1132, for instance, the Badia (Abbey) di Passignano (whose wine is now made and sold by the merchants ANTINORI) leased some of its land to a wealthy cobbler for half his crop of olive oil and wine.

The regional centre for selling wine was the Mercato Vecchio in Florence. The earliest reference to wine retailers in the city dates from 1079, and in 1282 the wine sellers formed a guild, the Arte dei Vinattieri. Giovanni di Piero Antinori, a member of the noble family that continues to make and sell wine in Tuscany today, joined it in 1385. To uphold the profession's reputation, the guild imposed a strict code of practice. The statutes insisted on cleanliness and exact measures; the shop was not to be situated within 100 yards of a church, and it was not to serve children under 15. No cooked food could be sold, and shops were not to shelter ruffians, thieves, or prostitutes. The wine trade was vital to the Florentine economy. Tax records show that more than 300,000 hl/7.9 million gal of wine entered the city every year in the 14th century. The Florentine historian Villani, writing in 1338, estimated that weekly consumption of wine was a gallon a head. Given that Florence had approximately 90,000 inhabitants, this meant that well over 90% was sold elsewhere, to the surrounding country or other Tuscan cities, some

overseas via the port of Pisa, mainly to Flanders, PARIS, and Marseilles.

By no means would all this wine have been Tuscan: a lot came from CRETE (Candia), CORSICA, or NAPLES. Tuscany itself produced red wine, which was usually called simply *vino vermihlio*, but occasionally names appear. The reds of MONTEPULCIANO and Cortona were heavy, those of Casentino lighter. In the late 14th century, we find Montalcino referred to as BRUNELLO. The most important of Tuscany's white wines were called 'Vernaccia' and 'Trebbiano', probably named after their respective grape varieties VERNACCIA and TREBBIANO, but neither was an exclusively Tuscan wine. Of the two, Vernaccia was the more highly reputed. In its sweet form it was associated primarily with LIGURIA, although sweet Vernaccia was also made in Tuscany. The dry style of Vernaccia, made in San Gimignano (but also elsewhere) and not found before the 14th century, was not exported overseas, because only the sweet version could survive the long sea voyage to France, Flanders, or England. Trebbiano, too, could be dry or sweet. The first recorded mention of CHIANTI is in the correspondence of the Tuscan merchant Francesco di Marco Datini in 1398, and it is a *white* wine. Datini was fond of it: in 1404 Amadeo Gherardini of Vignamaggio, which is still a well-known estate, wrote to Datini and sent him half a barrel of his personal stock. Another of Datini's favourites was (red) CARMIGNANO.

Datini's letters give us an idea of what a rich merchant bought for his own consumption. He had MALMSEY sent to him from Venice and Genoa, and, more exotically, the equally strong, sweet wine of Tyre from Venice. These foreign wines were luxury items. Another expensive wine from outside Tuscany that Datini loved was Greco. It was grown in PUGLIA, and so highly prized was it that in the 14th century the commune of San Gimignano abandoned its tradition of giving distinguished visitors a few ounces of saffron and instead made them a present of the precious Greco.

Dante and Boccaccio both mention Vernaccia, a byword for luxury. No Tuscan author wrote exclusively about the wines of the region

until Francesco Redi. His *Bacco in Toscana* ('Bacchus in Toscana'), published in 1685, is subtitled *ditirambo*, the Greek dithyramb being a choral lyric in praise of DIONYSUS. Redi's poem, however, has little to do with the classical genre and is no more than an excuse for showing off his learning to fellow members of the Accademia della Crusca: he provides 228 pages of unhelpful and pretentious notes to deluge 980 lines of verse. Neither the poem nor the notes contains anything interesting or new about Tuscan wine and viticulture, and the notes Leigh Hunt wrote to his translation (1825) of *Bacco in Toscana* are a good deal more amusing (although of more use to the historian of language than to the historian of wine). The only wines Redi mentions, and praises, are VERNACCIA, CHIANTI, CARMIGNANO, and, finally, MONTEPULCIANO, which he regards as the king of all wines.

Modern history

Tuscan viticulture was dominated historically by large estates owned by wealthy local families, most of them of noble origin, and tilled by a workforce of sharecroppers. The demise of this system in the 1950s and 1960s led to a hiatus in investment or even ordinary maintenance, plummeting wine quality, and eventual sale of the properties to new owners. A wave of winegrowers from Milan, Rome, and Genoa—joined in the 1980s by a sizeable contingent of foreigners—has shown both a commendable commitment to quality and an equally commendable openness to new and more cosmopolitan ideas. See also ANTINORI, FRESCOBALDI, and RICASOLI, local noble families with considerable wine interests.

Geography and vine varieties

Tuscany produces wines in a wide variety of ELEVATIONS, ASPECTS, and SOILS. Vineyards spread from the plains of the MAREMMA on the Tuscan coast and steep hillsides as high as 550 m/1,800 ft above sea level in Gaiole-in-Chianti and Lamole in Greve-in-Chianti. A mere 8% of the land is flat, and HILLSIDE VINEYARDS, at elevations of 150–600 m/500–1,968 ft, supply the vast majority of the better-quality wines. The SANGIOVESE vine, the backbone of the region's production, seems to require the concentration of SUNLIGHT that slopes can provide to ripen well in these latitudes, as well as the less fertile soils on the hills. Growers also value the significant DIURNAL TEMPERATURE RANGE as an important factor in developing its aromatic qualities.

Sangiovese, covering more than 36,000 ha/88,957 acres in 2020, is by far Tuscany's most planted grape variety. The second most planted, with 2,400 ha, is the insipid white TREBBIANO Toscano, though it has been rapidly losing ground to VERMENTINO (1,741 ha) since it lost its once mandatory role as ingredient in many of the region's Sangiovese-based wines. In the past enormous yields were demanded from both varieties, and the DOCs that were generously demarcated in the 1960s encouraged large-scale plantings of high-yielding CLONES with scant attention to site suitability, giving Sangiovese an undeserved reputation as a mediocre grape variety. As the DOC laws did nothing to encourage the production of good-quality wines, many producers enthusiastically embraced INTERNATIONAL VARIETIES, especially Merlot and Cabernet Sauvignon, which they aged in French BARRIQUES and sold at high prices. Except for the most famous wines, the popularity of these SUPERTUSCANS is now in decline. Several iconic producers persevered with Sangiovese, devoting their best sites to it and drastically lowering YIELDS. As they refused to blend Trebbiano Toscano with Sangiovese, they also had to resort to the lowly VINO DA TAVOLA category. The situation has since been redressed, especially in CHIANTI CLASSICO where at the end of the

1980s intensive research in clonal material, rootstocks, and site specifics led to a noticeable increase in quality, while the creation of the IGT Toscana brought the Supertuscan rebels back into the fold of a slightly higher denomination. Merlot is still regularly a blending partner (up to 20% varieties other than Sangiovese is allowed), but the trend is for varietal Sangiovese wines, regularly from single vineyards. Many ferment with AMBIENT YEAST and age their wines in traditional large oak CASKS rather than small French BARRELS.

BRUNELLO DI MONTALCINO, a 100% Sangiovese wine by law, and despite the lapse in credibility caused by a blending scandal in 2008, has long shown that Sangiovese can produce world-class, long-lived wines. Its neighbour VINO NOBILE DI MONTEPULCIANO has been more reluctant to embrace Sangiovese fully; since 2010 the production rules allow for 30% international varieties. This has been partially redressed by the introduction of an official system of subzones, which may appear on labels only if the wine is 85% Sangiovese with the balance indigenous varieties only.

BOLGHERI has been Tuscany's hotspot for Bordeaux varieties (see SASSICAIA) although many of the wines contain a portion of Sangiovese to add acidity to Cabernet and Merlot, which can be too ripe when grown on the hot Maremma plains. Further inland and higher up in the hills where a cooler climate prevails, the DOC Montecucco has attracted newcomers who regularly produce wines on a par with the best from Chianti Classico. DOC Monteregio di Massa Marittima seems equally promising for fine wine, especially when vineyards are planted on elevations above 300 m/984 ft. Neighbouring Montalcino, Orcia DOC might compete with Monteregio di Massa Marittima if newcomers persist with Sangiovese rather than international varieties. Valdarno di Sopra, near Arezzo, is set to become Italy's first DOC to be 100% organic as per its legally binding production rules.

Not all the myriad DOCs and DOCGs in Tuscany (63 in total in 2022) are either significant or particularly different from the supposedly lower IGT category. Producers therefore often prefer to label their wines with the more widely recognized IGT Toscana. Of

Tuscany's 60,000 ha, 99% are registered for the production of DOC and DOCG wine, with stricter production rules than for basic table wine. While the Chianti DOCG continues to supply the mass market with distinctly modest wines, most of Tuscany's wine regions are now focused on high quality. While the trend for indigenous varieties seems unstoppable, international varieties remain dominant in several areas, notably in CARMIGNANO, Bolgheri, Suvereto, and, for Syrah, Cortona. Most of Tuscany seems too warm to produce truly great white wines (although an increasing number of *rosato*, or rosé, wines compensates). VERMENTINO, a relative newcomer in central Tuscany, seems to be the most credible indigenous answer, while the minerally and elegant VERNACCIA di San Gimignano deserves a comeback.

For more details of specific Tuscan wines, see BOLGHERI, BRUNELLO DI MONTALCINO, CARMIGNANO, CHIANTI, CHIANTI CLASSICO, CHIANTI RUFINA, ELBA, GALESTRO, VERNACCIA, VINO DA TAVOLA, VINO NOBILE DI MONTEPULCIANO, and VIN SANTO. W.S.

Belfrage, N., *Brunello to Zibibbo: The Wines of Tuscany, Central and Southern Italy* (2nd edn, 2003).

Txakoli, usually white wine made in Spain's BASQUE country, known as Chacolí in Castilian. Like VINHO VERDE it is strongly Atlantic-influenced and is usually sold young, very slightly sparkling, and low in alcohol. A century ago over 1,000 ha/2,471 acres of vines stretched from Bayonne to Bilbao, but after PHYLLOXERA ravaged the region few vineyards were replanted. With cool summers and annual RAINFALL of 1,500 mm/58 in, this is challenging grape-growing country. DOWNY MILDEW can be a problem.

The high-trained HONDARRABI Zuri and Hondarrabi Zuri Zerratia (PETIT COURBU) white grape varieties account for 85% of Txakoli. Mune Mahatsa (FOLLE BLANCHE), RIESLING, Iskiriota Zuri Handia (GROS MANSENG), and Iskiriota Zuri Tipia (PETIT MANSENG) play minor parts. The 2% of Txacoli wines that are not white are light reds from Hondarrabi Beltza.

There are three DOPs for Txacoli. Getariako Txakolina, extending in 2021 to 433 ha/1,070 acres around San Sebastian in the province of Guipuzcoa (see map under SPAIN), is the appellation responsible for the classic low-alcohol, herbal, spritzy style of Txacoli.

A richer, fuller style comes from Bizkaiko Txakolina DOP, which covers 428 ha/1,058 acres of vineyards in the Vizcaya province, whose capital is Bilbao. DOP **Arabako Txakolina**, or Txacoli de Álava, covers 100 ha in the Álava province and produces wines similar to those from Bizkaiko Txakolina.

In both DOPs, the embrace of LEES CONTACT to increase depth and texture in the wines creates a richer style reminiscent of the wines of Galicia. In November 2021, three designations were introduced: Txacoli Bereziak, indicating a wine that has been aged at least five months in barrel and on lees; Apardunak, for sparkling wines produced by the MÉTHODE ANCESTRALE; and Apartak, meaning 'singular' and indicating a wine made using non-traditional methods such as SKIN CONTACT or AMPHORA ageing. F.C.

typicality, English word dating back to the 17th century though now often replaced by the neologism typicity to translate the French wine-tasting term *typicité* (and Italian *tipicità*), coined in the late 1970s and promoted by agronomist Jean Salette as a way to accentuate the importance of CONTROLLED APPELLATIONS and counter the international competition that French wines were increasingly facing. The term refers to a wine's quality of being typical of its type, geographical provenance, and even its VINTAGE year, and it is perhaps because typicality is a SUBJECTIVE notion, rather than a physical attribute that can be measured by ANALYSIS, that it is so much discussed and that individual tasters are likely to differ as to what they consider typical of a particular wine.

Typicality may be of less concern to most wine drinkers than how good a wine tastes, but it becomes important in wine JUDGING if the wine has been entered into a particular class. It is also important to professional wine buyers, particularly when choosing wines to

represent a GENERIC style. The notion of typicality may also be a source of contention when producers submit their wines to the tasting panel of a controlled appellation in order to obtain the *agrément*, permission to put the name of the appellation on the label. For example, a producer in Alsace who is making a high-quality skin-fermented Pinot Gris may fall foul of the tasting panel if they consider the wine too tannic or oxidative and therefore atypical.

Typicality demands a specific set of characteristics for every wine type. For example, a deep white wine of modest ACIDITY and relatively high ALCOHOLIC STRENGTH, smelling strongly of ALDEHYDES, would be extremely atypical of Chablis but would display the typicality of a FINO style of SHERRY. Similarly, a very young red wine smelling strongly of CARBONIC MACERATION would be typical of many a young BEAUJOLAIS but very unlike a young BORDEAUX.

As winemakers increasingly travel between wine regions, absorbing and applying different techniques, some distinctions between wine 'archetypes' are being eroded, and there is more disagreement than ever as to what constitutes typicality. See also REGIONALITY.

Baudouin, P., 'AOC: originalité ou typicité?', *Revue des Œnologues*, 102 (2003).

typicity. See TYPICALITY.

Tyrian. Australian NEW VARIETY, a cross of SUMOLL and CABERNET SAUVIGNON. See CIENNA.

Tyrol . Hardly any wine is made in this western part of Austria, but considerable quantities are made in that part of the Tyrol ceded to Italy after the First World War, now known as the South Tyrol, Südtirol in German, or ALTO ADIGE in Italian.

U

Uclés, promising Spanish DOP in the Cuenca province of CASTILLA-LA MANCHA.

UGA, *unità geografica aggiuntiva*, meaning 'additional geographical unit', the term used for any one of the 11 named COMMUNES within CHIANTI CLASSICO that may appear on the label as a suffix to the DOC name (e.g. Chianti Classico Radda). It is also used to refer to the 33 named single vineyards within the SOAVE DOC. In VINO NOBILE DI MONTEPULCIANO, UGAs are 12 vineyard areas identified on the basis of geological research. Since these largely and fortunately coincide with the historic boundaries of 12 parishes already registered in the 18th century, they are known as *pievi* (plural of *pieve*, or 'parish'). See also the slightly different MGA, as well as France's DÉNOMINATION GÉOGRAPHIQUE COMPLÉMENTAIRE.

Uganda , East African country that has a small wine industry pioneered by the Mukaira Foundation, which started growing wine grapes in 2006 and bottles under the Valley Wines label. Most vineyards are in the south-west of the country.

Ugni Blanc (which is in fact Italy's ubiquitous TREBBIANO Toscano) is France's most planted white grape variety by far, with more than twice as much French vineyard devoted to it than to Chardonnay, and yet it is rarely seen on a wine label. Just as AIRÉN, Spain's most planted white variety, supplies that country's voracious brandy stills, so the copious, thin, acid wine of Ugni Blanc washes through

armagnac and, especially, cognac stills. In Charentes it is often known as St-Émilion.

But despite EU encouragement to pull up poorer-quality vines, as well as a distinctly sluggish market for brandy, France's total plantings of Ugni Blanc fell by little more than 10% between the late 1980s and 2019, to 92,514 ha/228,607 acres, and actually went up in the last decade.

Ugni Blanc supplanted the FOLLE BLANCHE that was pre-PHYLLOXERA the main ingredient in French brandy production because of its good resistance to POWDERY MILDEW and GREY ROT. It was probably imported from Italy during the 14th century when the papal court was established at Avignon. Other Italian varieties were presumably similarly transported, but Trebbiano Toscano's extraordinarily high YIELDS and high ACIDITY may have helped establish it in southern France, where it is still grown widely today. It is still grown in Provence, the southern Rhône, and in and around Bordeaux, but the great majority of plantings are in the Charentes. It is, like most copiously produced wines, low in EXTRACT and character, relatively low in alcohol, but usefully high in acidity. This exceptionally vigorous vine buds late, thereby avoiding most spring FROST damage, which makes it popular with growers. Yields can easily reach 150 hl/ha (8.5 tons/acre). Because it ripens relatively late, there is a natural geographical limit on its cultivation, but in areas such as Charentes it is simply picked before it is fully ripe.

For more details of this variety, see TREBBIANO Toscano (although it is usually known throughout South America, where it is widely planted, as Ugni Blanc).

Uhudler, wine speciality of SÜDBURGENLAND in Austria—usually pink, sometimes white—made from the several AMERICAN HYBRIDS introduced post-PHYLLOXERA to this region (as to so many others in Europe, though very seldom with such lasting influence). Long legally contentious and maligned for its dependence on American

hybrids, it was eventually banned; it did not regain recognition until 1992. D.S.

Ukraine is the second largest country in Europe, its southern borders washed by the waters of the Black and Azov seas. The history of winemaking on its shores dates to the 4th century BCE, when ancient Greeks settled the area. The roots of the modern-day industry date to the 11th and 12th centuries, when MONKS AND MONASTERIES introduced viticulture to northern Ukraine.

Wine production has since waxed and waned as this part of the world has suffered much political upheaval. In 1913 its total vineyard area was 54,000 ha/133,000 acres, but owing to the effects of the First World War and PHYLLOXERA it had shrunk to 13,000 ha/32,124 acres by 1919. Holdings then mushroomed to 103,000 ha by 1940, only to be decimated by the Second World War, when total plantings dropped to 68,000 ha.

In the post-war Soviet period, state farms specializing in viticulture were established and were subsequently amalgamated into specialized trusts and large companies. Nurseries were also established to meet the need for PROPAGATION material. By the time the CRIMEA was ceded to Ukraine by the Soviet Union in 1954, the national total vineyard area was boosted to an estimated 400,000 ha/988,421 acres.

Since then there has been a steady and significant decline, exacerbated by Russia's annexation of Crimea in early 2014. By 2020 vineyards covered 39,100 ha/96,618 acres, supplying 134 licensed wineries. Of these, 80% are large wineries, but there is a growing interest in smaller artisan productions, and tastes are changing from sweet to dry-style wines. In 2022 Ukraine was again under attack from Russia, which mounted a full-scale invasion in February of that year. While the Transcarpathian wine region appeared to be stable, wineries in and around Kyiv, Kherson, Chernihiv, Mykolaiv, and Odesa have suffered, with some under occupation and other parts under constant enemy fire. The future fate of wineries in the

occupied territories, such as Prince Trubetsky, Tavria, and Bilozerka, is unknown. Several wineries have been bombed, and the Gostomel glass factory in Kyiv, which supplied bottles for many local producers, was destroyed. However, Ukrainian winemakers who can continue to make wine are persevering, producing wine with a focus on exports while the domestic market is in decline.

Geography and climate

Ukraine's landscape is diverse, from plains and steppes in the south to hilly areas in the centre to the Carpathian Mountains in the west. The climate is predominantly CONTINENTAL, favourable for viticulture in most regions, although the north-east can get quite cool, requiring WINTER PROTECTION for the vines. Since most vineyards are located in dry zones, IRRIGATION plays a major part, with DRIP IRRIGATION employed for some higher-quality wines.

The vast majority of vineyards are concentrated in the Odesa region (23,700 ha/58,564 acres), where three out of four of the country's proposed CONTROLLED APPELLATIONS are located: PDO Yalpuh, PDO Chabag, and PGI Prydunaiska Bessarabia. The other, PGI Zakarpattia, is in Transcarpathia, near the borders with Hungary, Slovakia, and Romania.

Vine varieties

Vineyards are planted mostly to VITIS VINIFERA varieties grafted on to phylloxera-resistant ROOTSTOCKS. The most planted grape variety was long RKATSITELI, which has accounted for as much as 40% of all plantings in some regions, but INTERNATIONAL VARIETIES such as Chardonnay, Pinot Noir, Cabernet Sauvignon, Merlot, and others have taken over some of its share. The 61 recognized varieties listed in the Ukrainian State Register in 2021 also include Eastern European varieties such as FURMINT, KÉKFRANKOS, and SAPERAVI as well as INDIGENOUS VARIETIES such as Cevat Kara, Kefessyia, and Telti Kuruk.

For much of the 20th century, viticultural and oenological research in Ukraine was carried out by the famous centre of wine ACADEME in the former Soviet Union, the Institute for Vine and Wine MAGARACH, founded in 1828 in Yalta in the Crimea. Today its importance has been usurped by the Tairov Institute for Viticulture and Oenology, which has bred 150 varieties since its founding in Odesa in 1905. O.P.-T.

ullage, which derives from the French *ouillage*, has had a variety of meanings and uses in the English-speaking wine trade. It can mean the process of EVAPORATION of wine held in wooden containers such as a BARREL. The HEAD SPACE left in the container is also called the ullage, or ullage space, and the wine in that state is said to be on ullage. The word 'ullage' is also used for any space in a stoppered wine bottle not occupied by wine (see FILL LEVEL). And a bottle or barrel not entirely full is said to be ullaged. The ullage space in a barrel is not empty but contains water and alcohol vapours together with some CARBON DIOXIDE previously dissolved in the wine. See TOPPING UP for the measures undertaken to avoid the risks of ullage.

Ull de Llebre, meaning 'hare's eye', is the Catalan name for TEMPRANILLO.

ultrafiltration, a form of cross-flow FILTRATION which can be used for ALCOHOL REDUCTION and, more controversially, for TANNIN removal or for CONCENTRATION. It is looser than REVERSE OSMOSIS but tighter than sterile filtration. It can also be used to separate COLLOIDS from their solution and is used as an alternative to FINING. Proponents suggest it is also useful for removal of browning and for reducing tannins in PRESS WINES, but it is subject to strict regulation.

Smith, C., 'The new filtrations', in *Postmodern Winemaking* (2013), 202–18.

Wollan, D., 'Membrane and other techniques for the management of wine composition', in A. G. Reynolds (ed.), *Managing Wine Quality 2: Oenology and Wine Quality* (2nd edn, 2021), 183–212.

ultraviolet radiation, or UV radiation, radiation of shorter wavelength (< 400 nm) than so-called visible SUNLIGHT, which is very damaging to all life because of its mutation-inducing properties. PHENOLIC compounds absorb ultraviolet radiation, and levels of QUERCETIN in grape berries are related to ultraviolet exposure. It is proven that ultraviolet exposure increases levels of phenolics and therefore COLOUR in red wines, which can be an advantage of vineyards at high ELEVATION and of those closer to the 'ozone hole' over the Antarctic. It also increases RESVERATROL levels.

umami, Japanese term derived from two words meaning 'delicious' and 'essence' and used to refer to what some consider to be the fifth primary taste (see TASTING). More a quality than a specific flavour, it is variously described as 'savoury' or 'meaty' and is found in high levels in foods such as soy sauce, Parmesan, fresh tomato juice, tuna, and seaweed. Umami levels in other foods are increased by the addition of monosodium glutamate (MSG).

Eastern thinking has for many centuries recognized five primary tastes, but it was not until 1907 that Professor Ikeda of Tokyo Imperial University identified and isolated the AMINO ACID glutamate, or glutamic acid, as the source of the flavour he named 'umami'. He subsequently developed the seasoning monosodium glutamate so that umami levels in other foods might be increased. Recent research identifying the receptors on the tongue that detect amino acids gives further credibility to the existence of this fifth taste.

The level of amino acids in wine is thought to be affected by the RIPENESS of the grapes and the process of FERMENTATION. However, it is extremely difficult to isolate the taste of umami in wine because of the way it interacts with the other four primary tastes.

Proponents of umami suggest that its presence brings a 'completeness' to the flavour of a wine but warn that it may increase the BITTERNESS and ASTRINGENCY of some tannic reds.

Umbria, fourth smallest of ITALY's 20 regions, in terms of both physical size and population, and one of the country's very few landlocked regions (see map under ITALY). It shares many geological and climatic similarities with neighbouring TUSCANY, which produced six times as much wine in 2020. Umbria's DOCs seem repetitive at best, obstructive of the distinction of different TERROIRS at worst.

Most of its 13 DOCs are similar in terms of GRAPE VARIETIES, YIELDS, and minimum ALCOHOLIC STRENGTH, with a strong bias towards INTERNATIONAL VARIETIES. SANGIOVESE, with a total of 2,204 ha/5,446 acres planted in 2020, is Umbria's most important red wine grape, followed by Merlot (1,158 ha), the indigenous SAGRANTINO (837 ha), and Cabernet Sauvignon (560 ha). Of white wine grapes, the lacklustre Tuscan import TREBBIANO Toscano (also called Procanico in Umbria) comes first with 2,041 ha, followed by the superior GRECHETTO (1,444 ha) and Chardonnay (447 ha). Almost all of these varieties are either allowed or an obligatory component in every DOC's production regulations, regardless of their suitability for the local conditions.

Regrettably, Trebbiano Toscano dominates in Umbria's most important white DOC, ORVIETO. The blend must include at least 60% Trebbiano and/or Grechetto. Orvieto's terroir is very suitable for the production of high-quality whites, and in the 1980s the region attracted Tuscan wine producers and CONSULTANTS keen to broaden their portfolio with a white from a nearby location. But instead of working with local varieties, they planted Chardonnay and Sauvignon Blanc, which may have promised a higher return but have done little to increase Orvieto's reputation. Although quality has undoubtedly improved, currently most Orvieto wines are made with one or more international white varieties and contain RESIDUAL SUGAR. Spoleto, Umbria's other all-white DOC, relies on the more characterful Trebbiano Spoletino, requiring at least 50% in the Bianco and 85% in VARIETAL bottlings. The Montefalco DOC also requires at least 50% Trebbiano Spoletino in its Bianco; Montefalco Grechetto must include a minimum of 85% Grechetto.

In Umbrian red wines, Sangiovese gives pleasant, if not memorable, wines in the Colli Altotiberini, Colli Amerini, Colli Martani, Colli Perugini, and Colli del Trasimeno DOCs, often blended with Merlot and Cabernet Sauvignon. The best Umbrian Sangioveses have been produced by Lungarotti (see TORGIANO). It is also the basis for Rosso di Montefalco, made in the HILLSIDE VINEYARDS of the

Montefalco DOC zone between Assisi and Terni. Here it is blended with a small percentage of the local Sagrantino, a grape that comes into its own in the DOCG Montefalco Sagrantino. Already documented in the 16th century, this ancient variety was almost extinct by the 1960s. Thanks to a flowering of interest in it in the 1990s, total plantings in the DOC were 837 ha/2,068 acres in 2020. Traditionally used for PASSITO sweet wines, it is now more often made into full-bodied, OAK AGED, concentrated dry reds which, by law, must be aged for at least 33 months. Regularly compared with BRUNELLO in its aromatics and with BAROLO in its tannic grip, Montefalco Sagrantino quenched international thirst for high-octane wines at the time, although some are simply too oaky and alcoholic. Research into sites that can provide an extended ripening season and into the best CLONES should help. W.S.

Belfrage, N., *Brunello to Zibibbo: The Wines of Tuscany, Central and Southern Italy* (2nd edn, 2003).

underwater ageing. Inspired by the quest for the perfect environment for AGEING wines and by the example of champagne preserved for nearly two centuries on the floor of the Baltic Sea, in the last two decades wine producers have been experimenting with underwater ageing of their wines, both still and sparkling, generally in bottle but occasionally in cask or AMPHORA, mostly under the sea, at a range of depths, but also in water-filled tanks in the winery. One producer on the south-west coast of France is even fermenting wines underwater in specially devised CONCRETE tanks: a submarine winery.

Several factors may affect the way a wine ages underwater, depending on the type of wine, the location, and the water depth. These include temperature, darkness, pressure, salinity, movement of the tides, and, for bottled wines, reduced oxygen ingress. This last could well be the most influential factor, since esterification of alcohols and acids is unchanged (see ESTERS) and other reactions

that are normally triggered by OXYGEN are slowed so that the wine remains in a REDUCTIVE state. If a bottled sparkling wine is submerged with its LEES, then pressure and tides may have a significant impact because of the greater interaction between the lees and the wine. The influence of underwater pressure is unclear (at −40 m under the sea, the pressure is typically 4.5 bar compared with 6 bar in a bottle of fully sparkling wine; at −60 m, it is 7 bar), although trials have shown not only very little oxygen ingress but also no escape of CARBON DIOXIDE.

While these experiments have been well publicized, often accompanied by photos of barnacled bottles, much of the evidence remains anecdotal, with producers and tasters generally agreeing that the wines do taste different from their exact counterparts aged in a cellar, often fresher and more youthful in both colour and aroma. However, one four-year experiment conducted by Gaia Wines at −20 m off the coast of SANTORINI showed distinct differences between pairs of wines in terms of the number and concentration of aromatic compounds, suggesting that it is the reduced-oxygen environment that has the greatest impact on still wines in particular. Analysis at DIJON of still and sparkling wines aged for a year off the western tip of Brittany has shown that wines age more slowly, that the level of SULFUR DIOXIDE remains constant, and that red wines retain their red colour.

These bottles of Champagne Drappier's Brut Nature spent 646 days, post-DISGORGEMENT, in protective cages at a depth of 31 m/102 ft and a TEMPERATURE of 8–13 °C/46–55°F in the Bay of Lannion off the coast of BRITTANY. UNDERWATER AGEING conditions have been shown to have a significant effect on the AGEING of wine. © Champagne Drappier

ungrafted vine, also known as an own-rooted or self-rooted vine, is a vine which has not been grafted to a ROOTSTOCK (see GRAFTING). Ungrafted vines grow perfectly well, although some varieties (e.g. SÉMILLON) are known to produce weak root systems, while SYRAH, for example, produces strong ones. The terms *pie franco*, *pe franco*, *piede franco*, *franc de pied*, and *würzelecht* are occasionally used on labels in Spain, Portugal, Italy, France, and Germany respectively. See also PHYLLOXERA. R.E.S.

unicorn wine, a wine that is so rare it is almost mythical. The term was originally coined in the 2010s by FASHION-conscious American SOMMELIERS boasting of their drinking exploits on SOCIAL MEDIA.

unità geografica aggiuntiva. See UGA.

United Kingdom . See Great BRITAIN for general matters, and see ENGLAND and WALES for wine produced there.

United States of America has become a juggernaut in the wine world in a relatively short time. Since its first and mostly doomed attempts at winemaking in the 1600s, the country has become not only the largest wine consumer in the world, averaging over 32 million hl/845 million gallons of wine per year by 2021 according to OIV estimates, but also the globe's fourth-largest producer of wine.

Vines now cover some 400,000 ha/988,422 acres, making the country sixth in vineyard surface area globally. Some of this goes into the production of RAISINS, an important crop in California, but the majority is used by the more than 11,300 wineries coast to coast.

The country is a major exporter, shipping 338.4 million l/89.4 million gal of wine in 2021, and has become a significant importer as

well, behind only Germany in terms of volume and number one in terms of value according to OIV data, at €6.2 billion in 2021.

CALIFORNIA is by far the most important wine-producing state in both volume and prestige, contributing 81% of the country's total production of 24.1 million hl/637 million gal of wine in 2021, followed by WASHINGTON, OREGON, and NEW YORK, but all 50 states in the Union now produce wine, most of them from locally grown grapes.

wineamerica.org/impact/

History

European settlement in what is now the US goes back to the late 16th century (see also VÍNLAND) but it was two centuries later that wine was first successfully produced there. The long delay was not for lack of trying. The abundant native AMERICAN VINE SPECIES immediately drew the attention of the first settlers; winemaking was an official aim of the VIRGINIA and Carolina colonies, and it was encouraged and repeatedly tried in all of the American colonies.

However, the colonists found wine made from the INDIGENOUS VARIETIES unpalatable, and began to import cuttings of VITIS VINIFERA vines from Europe to Virginia. The experiment was frequently repeated over the whole length of the Atlantic seaboard with vines from every great European wine region, but the result was uniform failure. The vines were destroyed by extremes of climate, by native PESTS, and by previously unknown VINE DISEASES. The facts were not clearly understood for more than two centuries, since the trials were isolated and uncoordinated, and no adequate knowledge of plant pathology existed. The cycle of hopeful experiment followed by complete failure went on in profitless repetition (see Thomas JEFFERSON, for example).

All Europe took part in the effort. French VIGNERONS were imported along with French vines by the Virginia Company in 1619, and French expertise continued to be sought thereafter: Huguenot exiles were employed in Carolina in 1680, in Virginia in 1700, and in Pennsylvania in 1683. Germans attempted winegrowing at Germantown in Pennsylvania; in Florida a colony of Greeks, Italians, Frenchmen, and Spaniards tried vine-growing in 1767. All of these, and innumerable other efforts, were based on *vinifera* varieties and failed (see PHYLLOXERA and FUNGAL DISEASES).

A new direction was taken through the discovery of a chance HYBRID—the combination of a native VITIS LABRUSCA and an unknown *vinifera*—called the Alexander grape, in PENNSYLVANIA, not far from

where William Penn had planted *vinifera* in 1683. Its hybrid character was unrecognized for many years, but it in fact showed the way in which vine-growing in the eastern United States would be developed. The variety became the basis for the first successful commercial wine production in the US—that of Jean Jacques Dufour in what is now INDIANA around 1806.

Thereafter, many new AMERICAN HYBRIDS of American vine species—either with each other or with a European *vinifera* variety, and formed almost invariably by chance—were introduced and contributed to the possibilities of winemaking in the US. The most important were CATAWBA, DELAWARE, ISABELLA, and NORTON, all introduced in the first half of the 19th century. With the exception of Norton, most were better adapted to white-wine production than to red, and most had more or less of the so-called FOXY aroma.

Dufour's efforts—and his 1826 book *The American Vinedresser's Guide,* the first book on vine-growing published in the US—inspired Nicholas Longworth to try his hand at winegrowing in OHIO, where his international success with Catawba inspired wine industries in neighbouring NEW YORK and MICHIGAN. Other winemaking centres sprung up wherever European wine-drinking emigrants landed: around Hermann, MISSOURI; Altus, ARKANSAS; along the Delaware River in NEW JERSEY; and further afield.

In the south, before the Civil War broke out in the 1860s, scattered vineyards growing American native or hybrid vines and small wineries could be found throughout the Carolinas and Georgia and extended to the frontiers of TEXAS and Kansas. The federal government supported vine-growing through plant exploration, the distribution of plants, and experimental work in the analysis of grapes and wines. In the decade before the Civil War, interest in vine-growing burgeoned and many new hybrid varieties were introduced, some of them now the outcome of controlled rather than accidental hybridizing.

The most important single result of this activity was CONCORD, a vine with good resistance to pests and diseases, well adapted to the

extreme growing conditions of the area that then constituted the United States, but whose extremely FOXY grapes were largely unsuitable for wine (or at least wine as most wine drinkers know it). The ubiquity of Concord has had a large part in establishing a taste for GRAPE JUICE among Americans.

Meanwhile, although the fact was quite unknown in the US, *vinifera* grapes were successfully grown and wine made in the Spanish settlements on the Rio Grande in New Mexico (beginning around 1629) and Texas (mid 1600s) and in the Franciscan missions of California (beginning around 1779). The Mexican–American War of 1846–8, followed by the GOLD RUSH of 1849, brought the *vinifera*-growing regions of the south-west into the US. At the time, the vine was already grown on a small but commercial scale in Los Angeles. Plantings thereafter spread over the state, and production grew rapidly from a few hundred thousand gallons in 1860 to more than 30 million gal/1.1 million hl by the end of the century.

The first *vinifera* variety grown in New Mexico and California was MISSION. Importations and trials of many other *vinifera* varieties quickly began. Among the most interesting is ZINFANDEL, long associated specifically with California, where it is still widely grown.

On the east coast, vine-growing continued to develop, such that New York became the second-largest wine producer in the US by 1890, surpassing Ohio, Illinois, and Pennsylvania. In 1919, the last year before national PROHIBITION was enforced, the US produced 55 million gal of wine. During the Prohibition years, some commercial wine production was allowed, for SACRAMENTAL and 'medicinal' purposes, and HOME WINEMAKING became more popular than ever before, resulting in an increase in total vine acreage thanks to demand for GRAPE CONCENTRATE, but the industry was largely destroyed.

Upon Repeal (from 1934), the US industry had to reconstitute itself. Some of the old firms reappeared, and many new firms were founded. But it took time to put things right: the country was in the lowest depths of economic depression, and wine was an unfamiliar

luxury. High-alcohol sweet wines became the mainstay of the trade and remained so for the next generation. The federal government failed to re-establish its research programmes for wine, but important OENOLOGICAL and VITICULTURAL research was carried out by the state universities of California at DAVIS and CORNELL UNIVERSITY in New York. Promotional work was largely in the hands of the Wine Institute of California, founded in 1934.

The Second World War, by cutting off European supplies, brought new prosperity to US industry but new instability as well. Large distilling companies bought up established wineries in order to have a product to sell. A seller's market prevailed until, after the war, the artificially stimulated demand collapsed. The distillers departed from the wine trade, which fell into somnolence. Little effort was made to develop new markets; wineries typically sold their wines in BULK to wholesalers who often bottled wines under GENERIC names such as Burgundy, Chablis, Sherry, and Champagne, from a severely limited range of grape varieties.

In the east, especially, the decline was marked; in Ohio, for example, the 149 wineries of 1940 had dwindled to 47 by 1960. One valuable new development was the introduction, by Philip WAGNER, of hybrid grape varieties developed in France (see FRENCH HYBRIDS) such as SEYVAL, SEIBEL, and BACO into the eastern vineyards; these gave larger yields and made more attractive and interesting wines than did the old American hybrids. Another innovation was the effective introduction of VARIETAL labelling by the American merchant Frank SCHOONMAKER, a practice that was to become standard.

Beginning around 1970, wine production in the US took on a new energy and glamour. New wineries, large and small, were started in California: there were 240 wineries in 1970, 770 in 1989, almost 1,700 in 2004, and 4,807 by 2022, comprising 43% of the total number of wineries in the country. New vineyards were planted, and winegrowers made unprecedented efforts to find the best matches between grape variety and location, aspiring to new levels of quality and complexity. Innovation in technology was eagerly sought, at the

same time as traditional European methods were introduced and adapted. Large-scale foreign investment from Japanese, British, French, Spanish, Swiss, and German companies was attracted to the American wine industry, notably a number of French CHAMPAGNE firms who invested, some of them briefly, in California sparkling wine production in the 1980s.

The explosion of new activity in the industry was matched by consumer developments: wine classes, wine societies, wine publications, and, eventually, internet sales and websites proliferated to exploit the interest and anxieties of a public long ignorant and indifferent but now eager to learn. Consumption of wine—now dominated by TABLE WINE—rose from 10 million hl/267 million gal in 1970 to 33 million hl in 2021.

Outside California the boom in wine was, proportionately, even greater. The old regions—New York and Ohio especially—began to sprout new enterprises after a long quiescence. The vineyards were transformed by the introduction not only of hybrids developed in France, such as Seyval and Seibel, but of *vinifera* varieties—now, thanks to modern understanding of plant pathology and the availability of PESTICIDES and FUNGICIDES, at last able to be grown successfully in the eastern US after more than three centuries of failure. States such as Maryland, New Jersey, Pennsylvania, and Virginia which had once supported viticulture on only a modest scale now saw the growth of a renewed and expanded industry. Centres of wine research and education such as Cornell University in NY, BROCK UNIVERSITY just across the NY border in ONTARIO, and VIRGINIA TECH helped develop better understanding of COOL-CLIMATE VITICULTURE. By the late 2010s, the east coast, from the Great Lakes to the Atlantic coast, had the fastest winery growth in the US and accounted for 25% of the total number of wineries by 2021. New York, Pennsylvania, and Virginia claimed more than one-third of that number, but even cold Maine boasted 38 wineries and Rhode Island, the smallest state in the Union, another 18.

TEXAS and NEW MEXICO, sites of very old but very small-scale *vinifera* winemaking, now boasted large viticultural developments. ARIZONA developed a robust wine industry with a specialty in sparkling wine. The wine industry in WASHINGTON grew to become the third largest by volume in the US (just after California and New York), and OREGON was right behind. Michigan embraced Riesling and other aromatic varieties suited to its cold winters, and Minnesota, Wisconsin, and the Midwest cultivated an industry with cold-climate HYBRIDS such as La Crescent, Frontenac, and Marquette developed by the University of Minnesota. Mid-South states such as Arkansas and Missouri look to the University of Arkansas for new hybrids that can withstand the region's cold winters and humid summers; the University of Florida has created varieties such as Blanc du Bois that are resistant to PIERCE'S DISEASE, a serious issue in the deep south.

Many obstacles to the production and sale of wine still exist, however, some of them natural, such as climate, and some of them political, such as the complex web of taxes and restrictions imposed by the different states. The spirit of Prohibition is still vigorous in some states, whether it takes the old form of moral disapproval or the protectionism of alcohol beverage MONOPOLIES. Since 1989 the federal government has required warning labels on all bottles of wine sold in the US (see LABELLING INFORMATION). And in the late 1990s, further, sometimes severe restrictions were placed on the shipment of wine between states, making it even more difficult for consumers to buy wine direct from wineries (see Regulations, below).

But, on any view, the US wine industry in the latter half of the 20th century underwent a remarkable development from the ruins left after Prohibition, renewing old activities, spreading into new regions, expanding production, developing new methods in viticulture and winemaking, and reaching new levels of quality.

Regulations

Following repeal of Prohibition in 1933, each of the 48 (now 50) states was allowed to set its own regulations governing the sale and distribution of alcoholic beverages. As a result, an arcane, confusing regulatory environment involving in effect 50 separate countries has evolved. (Within some of them there still exist 'dry' counties which prohibit the sale of any alcohol.) The prevailing THREE-TIER SYSTEM is, however, under increasing economic and legal pressures. The consistent theme throughout the rules is that no enterprise can act as supplier, wholesaler (distributor), and retailer. A chief exception to this rule is California, where wineries can circumvent this structure. In many states, boutique (farm) wineries can sell their wines directly to consumers, but most sell them to wholesalers, which then sell to retailers and restaurateurs. After a series of aggressive acquisitions, the number of wholesalers dramatically shrunk between 1985 and 2005, each enjoying what is effectively a state-sanctioned monopoly on alcohol sales and profits. An actual state MONOPOLY operates in Pennsylvania and New Hampshire.

A 2005 US Supreme Court ruling gave all states a choice: either allow inside-the-state and into-the-state shipping by wineries or prohibit both. Such shipments would enable consumers interested in DIRECT SHIPPING to bypass the three-tier system. The effects were gradual, but by 2022, 47 states had opened up to winery-direct shipping, although most states require wineries to obtain a shipping licence and impose a limit on the number of cases that can be shipped per person or per address per year. The same freedom does not apply to retailers, however: only 13 states allow shipments from out-of-state retailers. But the three-tier system has not disintegrated, because all but the smallest producers need wholesalers to display and to distribute their wares across the immense continent and to keep restaurants supplied with their bottles. Seeking to protect their privileges, wholesalers have amassed clout in state legislatures nationwide by giving sizeable contributions to officeholders' fundraising campaigns.

For details on regulations governing wine labelling, see AVA, the US version of a CONTROLLED APPELLATION system. Label approval, AVAs, and federal taxation are overseen by the TTB. D.F. & T.C.

Viticulture and winemaking

US wine law specifies only geographical boundaries for its AVAs. It sets no limitations on what sorts of vine varieties may be used or how they are farmed. It also does not prescribe how a wine is made, save to require that any ADDITIVES be 'GRAS' or 'generally recognized as safe' as determined by the FDA (Food and Drug Administration), and it sets maximum limits on these additives.

Lacking any historical ties between grape variety and place, the US has long led the movement towards VARIETAL wines, focusing on variety instead of place. The vast majority of these wines are made from INTERNATIONAL VARIETIES, with Chardonnay and Cabernet Sauvignon leading the way and Pinot Noir, Merlot, Pinot Grigio, and Sauvignon Blanc following. However, their grip on the market is loosening. Widespread concern about CLIMATE CHANGE and water availability in warm-climate regions has instigated increased interest in Mediterranean varieties such as SYRAH, GRENACHE, and TEMPRANILLO and redirected attention to old DRY-FARMED vineyards planted to varieties such as MATARO, PETITE SIRAH, and CARIGNAN. (See HISTORIC VINEYARD SOCIETY.) Meanwhile winegrowers in MARGINAL CLIMATES are increasingly looking towards cold-hardy, DISEASE-RESISTANT hybrid varieties that will allow for less use of AGROCHEMICALS in the vineyard. There are more than 350 wine-grape varieties grown in the US today, and consumers are encouraging exploration with their increased openness to and desire for unique local wines.

That said, BRANDS are big business in the US. Just 50 companies supply 90% of US wine, most of them based in California but also including CONSTELLATION BRANDS (based in New York) and Ste Michelle Wine Estates and Precept Brands (located in Washington State). Economies of scale dictate that most wines sold in the US come from conventionally farmed, IRRIGATED vineyards that rely on some degree of MECHANIZATION for vine maintenance and harvesting. This has gained the US a reputation for the sorts of wines often referred to as

NEW WORLD style: clean, robust flavours focused on fruit, often created by scrupulously clean, technical winemaking.

In the 1990s and 2000s, this often meant big, rich, high-alcohol wines, as winegrowers strove for ever more RIPENESS, more EXTRACTION, and more flavour, often using a robust battery of tools to reach those ends, including additives such OENOLOGICAL TANNINS and ACIDS, cultured YEASTS and yeast NUTRIENTS, GRAPE CONCENTRATE, OAK CHIPS, and many other tricks of the trade. As alcohols rose, so did the practice of HUMIDIFICATION or removing alcohol using REVERSE OSMOSIS or SPINNING CONES.

These and many other technological tricks are still widely deployed, but there has since been a backlash, fuelled in part by WINE WRITERS who have publicized the amount of MANIPULATION and AMELIORATION that can happen in winemaking and have championed LOW INTERVENTION WINES and in part by ever more savvy consumers with greater access to a wider variety of wine than ever before, along with a deeper interest in how wine is made and where it comes from.

Winemakers, for their part, responding not only to the market but also to rising temperatures, water shortages, WILDFIRES, and concerns for the SUSTAINABILITY of their land and community, have increasingly been looking towards ORGANIC, BIODYNAMIC, and REGENERATIVE VITICULTURE and LOW-INPUT VITICULTURE. This century has also seen a marked increase in attention to matching variety to place in pursuit of making wines with a sense of TERROIR. So while the US remains dominated by clean, fruity, reliable wines made in the cellar, there are also plenty of wines with ample personality, from PET-NATS to PIQUETTES and ORANGE WINES that employ SPONTANEOUS FERMENTATION and extended SKIN CONTACT sometimes even in AMPHORAE. The vagueness of the US AVA system can also be its advantage: it allows for endless experimentation.

Upper Goulburn, hilly, cool, high-ELEVATION wine region in Australia's Central Victoria Zone, between the snowfields of Mt Buller on one extremity and Strathbogie Ranges on the other. Chardonnay is the foremost variety. See VICTORIA.

urban wineries, a 21st-century phenomenon that introduced city-dwellers from London to Hong Kong to WINEMAKING. Wine was long made in unglamorous warehouses on the outskirts of American cities, and much of the wine produced in the Soviet era was finished in urban processing plants close to centres of consumption. But the first of this new era of self-consciously artisanal urban wineries was probably Edmunds St John, established in the San Francisco Bay Area in 1985, vinifying grapes grown in nearby California wine country. The Bay Area still has one of the greatest concentrations of the several hundred urban wineries located in North American cities, including New York, with the advantage of having thousands of

potential customers on their doorstep. Some urban wineries fulfil an educational role, and an increasing number offer hospitality in some form.

Urgestein, literally 'primordial rock', amorphous term used in AUSTRIA and sometimes in GERMANY to refer to especially ancient VOLCANIC or metamorphic rocks of crystalline structure underlying a vineyard. The term has no standing among geologists (see GEOLOGY).

D.S.

Uruguay is South America's fourth most important wine-producing country with an area under vines of just under 6,000 ha/14,826 acres, of which more than 95% is for wine production. In a good year, Uruguay produces over a million litres (264,172 gal) of wine, although it can fall to almost half that in a poorer vintage.

The history of winemaking in the country is linked to its independence, officially starting in the 19th century although there are reports of Jesuit MISSIONARIES bringing vines more than a century before. Vineyards were largely planted by immigrants, mainly Basque and Italian families. This tradition of family smallholdings continues, with the average vineyard being no more than 5 ha/12 acres. In all there are over 1,200 growers but fewer than 160 wineries, and only about one-quarter of those focus on higher quality and export. Wine was initially produced for local consumption and, with one-third of the population of the country living in the capital Montevideo, four-fifths of the vineyards are in the immediately neighbouring *departmentos*, especially in Canelones. Most other vineyards are in the west, close to the Río de la Plata (River Plate), which forms the border with Argentina, or further east in the coastal region of Maldonado near to Brazil. Domestic wine consumption is high, standing at 20 l/4 gal per person per year in 2021.

With the formation of Mercosur, announced at the end of the 1980s, the Uruguayans realized that they would have to protect their wine industry from Chilean and Argentine wine, which benefited

from lower production costs. To achieve this, the Uruguayan National Institute for Vitiviniculture (INAVI) embarked on a three-pronged campaign. Firstly, encouragement was given to growers to plant VITIS VINIFERA varieties, rather than the AMERICAN VINES and HYBRIDS that then dominated. Secondly, the Uruguayans were urged to be proud of their own wines, with stress being laid on their purity and SUSTAINABILITY. (In an American report published at the 2004 World Economic Forum, Uruguay was ranked as the third most environmentally sustainable country in the world after Finland and Norway.) Finally efforts were made to conquer export markets despite limited promotional resources. BRAZIL, because of a shortage of domestic red wine, is the most important export market, accounting for two-thirds of the total, but Uruguay exports to some 51 countries today.

Wines are divided into two classes, VCP (*Vino de calidad preferente*) and VC (*Vino Común*). VCP wines must be made from *vinifera* grapes and be sold in 75 cl, or smaller, bottles. VC wine, which is sold widely in demijohns and tetrapacks (see CARTONS), is predominantly rosé based on MUSCAT OF HAMBURG grapes, although this variety is in sharp decline thanks to increasing demand for *vinifera* wines.

For better-quality wines the dominant grape variety is TANNAT, introduced to Uruguay by Basque settlers and made with increasing enthusiasm and expertise. It accounts for over one-quarter of all plantings of wine grapes and over 1,600 ha/3,954 acres. Other important red wine grapes are Merlot, Cabernet Sauvignon, and Cabernet Franc. White wines (around one-quarter of total production) tend to be made from Sauvignon Blanc and Chardonnay, although Albariño is on the rise.

Most of the vineyards lie on deep CLAY soils on gently rolling hills to the north of Montevideo, but those in the Cerro Chapeu region on the Brazilian border and in El Carmen in the centre of the country are on sandier soils; Sierra de Mahoma has poor SCHIST soils; and vines in Colonia are planted on river GRAVELS. The most explosive

growth has been in Maldonado, on the eastern coast, where over 400 ha/988 acres are grown on mainly GRANITE soils; the region has become notable for crisp white wines and focused reds.

The climate in Uruguay is influenced by the Atlantic and often compared with that of Bordeaux or Galicia, averaging over 1,000 mm/39 in of rain each year. Humidity can be excessive even though the climate seems to be getting warmer and drier, so the ESPALIER training system is popular, gradually replacing the once-widespread LYRE. Vintages are variable in Uruguay, with drier, warmer vintages such as 2018 seen as the best.

International interest in Uruguayan wine is seen not only in its growing market but also in significant new investments taking place within the country. Cerro del Toro is a new Japanese investment; Viña Edén is owned by a Brazilian investor; and Argentine billionaire Alejandro Bulgheroni's Garzón Winery remains one of the biggest 21st-century wine investments in South America. Uruguayan families are also pushing new boundaries. Familia Deicas continues to invest in ever-more-extreme vineyards; the Bouza family have moved beyond traditional Canelones to pioneer wine regions around Maldonado; and there are a clutch of new Uruguayan wineries including Bodega Oceánica José Ignacio just inland from the popular José Ignacio beach town. US . See UNITED STATES of America.

USSR . See SOVIET UNION.

Utiel-Requena, Spanish DOP with some 34,000 ha/84,016 acres of vines producing sturdy reds and mostly rosés, in the hills inland from VALENCIA in south-east Spain (see map under SPAIN). At about 700 m/2,300 ft in ELEVATION, Utiel-Requena is the coolest of Valencia's three DOPs and was once famous for its heavy DOBLE PASTA reds. Consequently the region is dominated by the sweet, dark BOBAL grape variety, although the TEMPRANILLO vine has become important this century. White grapes MACABEO, MERSEGUERA, and Tardana are also grown for still and sparkling wines. F.C.

Uva Abruzzese, occasional name for the red MONTEPULCIANO grape.

Uva di Troia, old name for NERO DI TROIA.

Uva Rara, red wine grape variety too widely grown in north-west Italy to justify its Italian name, whose literal translation is 'rare grape'. In the Novara hills it is often used to soften the SPANNA grapes grown here in a range of scented red wines.

Uzbekistan , independent central Asian republic with Tashkent as its capital. The most prolific grower of grapes among the former Soviet republics, it is a major supplier of TABLE GRAPES and has since the mid 2000s embarked on an effort to reinvigorate its wine industry. By 2020 the country had 112,298 ha/277,494 acres of vineyard according to OIV figures.

History

The grapes and wines of Uzbekistan have long been famous beyond its own frontiers. Between the 6th and 2nd centuries BCE, people in the Fergana Valley grew wheat, barley, and grapes using IRRIGATION, and Fergana grapes were prized in CHINA to the east.

It is thought that some central Asian VINE VARIETIES originated as the wild subspecies VITIS *silvestris* C.C. Gmel as a result of long-term selection. Some varieties were brought to Uzbekistan from IRAN between the 6th and 4th centuries BCE; others were brought by Greeks and Arabs in the 7th and 8th centuries CE.

Viticulture and winemaking flourished in Uzbekistan until the end of the 7th century, when, as a result of the Arab conquest of central Asia, wine grape varieties gave way to TABLE GRAPE and RAISIN varieties (see ISLAM).

After central Asia was annexed to RUSSIA in the second half of the 19th century, demand for table grape varieties rose, and European wine varieties from MOLDOVA, CRIMEA, and other regions were also imported into Uzbekistan. In 1917 Uzbekistan had 37,000 ha/91,000 acres of vineyards, mainly owned by individual smallholders. The first specialized Soviet state farms were established in the 1920s. Prior to the widespread GRUBBING UP of vineyards due to the anti-alcohol measures of Mikhail GORBACHEV in the mid 1980s, Uzbekistan was producing 13.6 million decaliters of wine annually.

Modern viticulture

Uzbekistan, in the very heart of central Asia, is on the same latitude as Italy. The country's relief varies considerably, with the Tian-Shan and the Pamir and Alai spines in the east, and mountains account for about 30% of the total area of the country. The climate of Uzbekistan is very CONTINENTAL. The average January temperature ranges from 3 to −3 °C/37–22 °F and that of July is 26–32 °C/79–89 °F. Late spring and early autumn FROSTS are commonplace. The active temperature summation (see CLIMATE CLASSIFICATION) is 4000–4500 °C. The annual rainfall is 100 mm/4 in in the lowlands, with 1,000 mm in the mountains.

The leading viticultural zones, accounting for about 75% of vines, are the Samarkand, Surkandaria, Namandan, Tashkent, Bukhara, and Kashkadaria regions. About 90% of vines need WINTER PROTECTION. Only the mountain vineyards at ELEVATIONS of at least 800 m/2,600 ft do not require IRRIGATION.

The country's assortment of vines, all UNGRAFTED, still has features typical of the viticulture of central Asia. Table-grape varieties predominate; wine-grape varieties include those brought in during Soviet times such as SAPERAVI, RKATSITELI, Tavkveri, Bayanshira, Khindogni, MUSCAT, and ALEATICO, as well as INDIGENOUS VARIETIES such as Soyaki and INTERNATIONAL VARIETIES such as CABERNET SAUVIGNON, MERLOT, PINOT NOIR, and RIESLING. Sparkling wines are especially popular, and there is a long history of sweet and semi-sweet reds.

The Scientific Research Institute of Horticulture, Viticulture, and Winemaking, named after academician Makhmud Mirzaev, is Uzbekistan's centre of wine ACADEME and sole vine NURSERY.

V

Vaccarèse, rare, relatively light red grape variety permitted in CHÂTEAUNEUF-DU-PAPE producing wines similar to CINSAUT. Also known as Brun Argenté and Camarèse.

Vacqueyras, after GIGONDAS, the second of the Côtes du Rhône villages (see RHÔNE) to be awarded its own appellation, in 1990. Although it is next to Gigondas, much of the TERROIR is very different. The body of the appellation consists of a large deposit of old ALLUVIUM from the Ouvèze river since overlaid with CLAY and LIMESTONE, situated to the south-west of the Dentelles de Montmirail. Called the Garrigues Plateau, it is flat, sits at around 100 m/328 ft in ELEVATION, and is open to the sun and the mistral. Further north, a small section of the appellation near the village of Vacqueyras climbs into the foothills of the Dentelles. There are also significant outcrops of SAND that skirt around the western, eastern, and southern edges of the Garrigues.

In 2020 Vacqueyras was produced from 1,452 ha/3,588 acres of vineyards, and 94% of this was red. The style is typically highly concentrated and STRUCTURED, and TANNINS are prone to rusticity in hot, dry years. Reds must be majority Grenache and include some Syrah and/or Mourvèdre; they may include small amounts of several minor varieties. Whites must be a blend of two or more of the permitted varieties (Bourboulenc, Clairette, Grenache Blanc, Marsanne, Roussanne, and Viognier). Whites made up 5% of total volume in 2020, but plantings of white varieties are on the increase. Rosé makes up just 1%. Vacqueyras is the only CRU on the east bank of the Rhône permitted to make red, white, and rosé wines.

M.C.W.

vacuole, the central compartment of plant CELLS, separated from cytoplasm by a membrane. In grape berries, vacuoles within flesh cells contain the solution that forms GRAPE JUICE. B.G.C.

vacuum evaporation. See CONCENTRATION.

Valdadige, or Etschtaler in German, basic DOC of the Adige (Etsch) Valley that, unusually, extends across three regions, though is used principally by producers in TRENTINO and also by some in north-western VENETO. Vineyards in ALTO ADIGE theoretically qualify, but the Alto Adige DOC is usually used instead.

Val de Loire , one of six massive regional IGPs in France, sprawling across 14 *départements*, from the Atlantic coast inland to Puy-de-Dôme. White wines dominate, particularly from SAUVIGNON BLANC; reds and rosés are made from a range of varieties, from GAMAY and CABERNET FRANC to PINEAU D'AUNIS.

Valdeorras, easternmost DOP in GALICIA in north-west Spain (see map under SPAIN). Steeply terraced vineyards are planted predominantly with inappropriate but productive vine varieties such as Garnacha Tintorera (ALICANTE BOUSCHET) and the white PALOMINO. The indigenous white GODELLO, which had all but disappeared from Galicia in the wake of PHYLLOXERA, is being aggressively replanted. This moderately productive variety is susceptible to disease, but Valdeorras is protected from the Atlantic by mountains immediately to the west. If carefully vinified, it can produce an aromatic wine with an ALCOHOLIC STRENGTH of 12–13% and a glycerine content that gives it a particularly creamy and umami-rich aspect. In the late 1990s, some of Spain's most acclaimed BARREL-FERMENTED whites were Godello wines from Valdeorras made by the Guitián family, who

pioneered this style. The MENCÍA grape, which makes fruity reds, is similarly respected by a new wave of producers in Valdeorras.

Valdepeñas, wine region in CASTILLA-LA MANCHA in south-central Spain producing soft, ripe red wines. The sea of rolling vineyards that is Valdepeñas is really an extension of LA MANCHA (see map under SPAIN), but Valdepeñas has developed a reputation for quality over and above its larger neighbour and has consequently earned a separate DOP. Physical conditions in Valdepeñas are similar to those in La Mancha. The Sierra Morena dividing CASTILE from ANDALUCÍA immediately to the south is a barrier to the moderating influence of the Mediterranean. At an ELEVATION of 700 m/2,300 ft, Valdepeñas shares the arid CONTINENTAL conditions that prevail through much of central Spain.

As in La Mancha, the white, DROUGHT-resistant AIRÉN is the dominant grape variety, but the red Cencibel, as the TEMPRANILLO of Rioja is known here, has been gaining ground in Valdepeñas' 22,000 ha/54,363 acres of vineyard. Much of the 'red' wine made in the region is a blend of red and white grapes somewhat lacking in colour and BODY. The best red wines, however, are made of Cencibel, which has the capacity to age well in OAK, and increasingly they include Cabernet Sauvignon, Merlot, Syrah, and even Petit Verdot. The best wines have the soft, smooth, vanilla character, although not the price tag nor the COMPLEXITY, of a well-aged RIOJA. V. de la S. & F.S.

Val di Cornia. See MAREMMA.

Valdiguié, sometimes called Gros Auxerrois, enjoyed its finest hour in late 19th-century France, when, as a dark-berried grape variety from the Lot, it was valued for its productivity and its resistance to POWDERY MILDEW. In the early 20th century, it was known as 'the ARAMON of the south-west' for its emphasis on quantity at the

expense of quality. It has now been all but eradicated from France, where just 88 ha/217 acres remained in 2018, mainly in the Tarn *département*.

In 1980 French ampelographer Pierre GALET visited the US and identified the variety then sold rather successfully as Napa Gamay as none other than this undistinguished vine from south-west France, of which there were then 1,600 ha/4,000 acres planted in California. By 2020 the area had shrunk to 232 acres, but it occasionally turns up on the label of a fruity VARIETAL wine.

Galet, P., *Dictionnaire encyclopédique des cépages* (2nd edn, 2015).

Valdobbiadene . See CONEGLIANO-VALDOBBIADENE.

Valençay, small, cool AOC region on the south bank of the Cher tributary of the LOIRE in northern France with about 155 ha/383 acres in production by 2019. LIMESTONE, FLINT, and SILT are planted with a wide range of LOIRE grape varieties. Reds make up slightly more than half the production, relying predominantly on Gamay, with Pinot Noir, Côt, and Cabernets Franc and Sauvignon allowed in the blend. The few rosés produced use the same grape varieties with the possibility of up to 30% PINEAU D'AUNIS. The crisp, citrusy whites must be at least 70% Sauvignon Blanc (Valençay is only about 20 miles/30 km from QUINCY and REUILLY) and can incorporate MENU PINEAU, SAUVIGNON GRIS, and/or more rarely Chardonnay.

Valencia , Spain's biggest port and third-largest city, also lends its name to an autonomous region and one of three wine denominations (see DOP) in the Comunidad Valenciana region (see map under SPAIN). It includes four VINO DE PAGO (Chozas Carrascal, El Terrerazo, Los Balagueses, and Vera de Estenas) and the promising IGP Castelló, with some interesting red wines from the MONASTRELL grape.

The vineyards of the appellation are well away from the city, inland from the fertile market gardens and paddy fields bordering the Mediterranean. Production of white wine exceeds red. There are four subzones: Alto Turia in the north-west, where MERSEGUERA and MACABEO dominate on slopes at 700–1,100 m/2,297–3,609 ft in ELEVATION; Valentino in the centre (growing, among others, Merseguera, MALVASIA, PEDRO XIMÉNEZ, GARNACHA, and TEMPRANILLO); and Claraiano in the south, where white varieties dominate near the sea and red varieties including MONASTRELL and INTERNATIONAL VARIETIES Cabernet Sauvignon and Merlot take over inland. The Moscatel de Valencia subregion is nested within the Valentino subzone and is devoted entirely to MISTELAS made from Moscatel Romano (MUSCAT OF ALEXANDRIA). F.C.

Valle d'Aosta. See AOSTA.

Valle de Güimar, DOP with 635 ha/1,569 acres of vineyard in 2020 at up to 1,400 m/4,593 ft in ELEVATION occupying a valley in the dry south-eastern part of Tenerife in the Spanish CANARY ISLANDS. A few tiny wineries, improved technically with EU subsidies, make distinguished wines from the white LISTÁN Blanco grape.

Valle de la Orotava, DOP with just 216 ha/534 acres of vines registered in 2021 on the lush northern flanks of Mt Teide on Tenerife in the Spanish CANARY ISLANDS. LISTÁN Blanco and LISTÁN NEGRO dominate plantings on these high VOLCANIC slopes, much of it UNGRAFTED and trained in *cordon trenzado* ('braided cordon'), a unique, traditional TRELLIS SYSTEM. V. de la S.

Vallée du Paradis, IGP for still red, rosé, and white wines, and VIN GRIS in the AUDE *département* and in the commune of Rivesaltes in the Pyrénées-Orientales *département* of southern France. The

designation is often used for wines falling outside the regulations for CORBIÈRES or FITOU and for varietally labelled wines from Mediterranean and INTERNATIONAL VARIETIES. The name references a legend about an epidemic that decimated the region's cattle save for those in this valley.

Valle Isarco, or Eisacktaler in German, source of pure, dry white wines from the upper reaches of ALTO ADIGE.

Valles de Benavente, VINO DE CALIDAD in Castilla y León in Spain, just south of LEÓN and producing wines of similar style. PRIETO PICUDO is the main grape variety. F.C.

Valpaços, DOC subregion of TRÁS-OS-MONTES in north-east Portugal.

Valpolicella, lively red wine from the VENETO region in north-east Italy. Vines are grown in three distinct zones formed by a series of adjacent valleys descending from the pre-alpine Lissini Mountains north of Verona down to the plains in the south. The Fumane, Marano, and Negrar valleys, with vineyards on hillsides rising to 400 m/1,312 ft, form the historic nucleus and have their own DOC, Valpolicella Classico, with 3,500 ha/8,648 acres of vines. Between the Classico zone and the plains to the east lie the 433 ha of Valpantena vineyards on both hillsides and plains. The total area of vineyard given over to regular DOC Valpolicella in the valleys of Illasi, Tramigna, and Mezzane is 4,500 ha. Valpolicella, like a number of other historic areas of Italy, saw its production zone greatly enlarged when it achieved DOC status in 1968. It was extended eastward as far as the boundary of the SOAVE white-wine zone, as well as south on to the fertile plains on the northern edge of the Po Valley. Although the total Valpolicella zone is large and varied, in general soils are more CALCAREOUS and temperatures lower in the north and on the HILLSIDES, in the Classico area, while soils on the plains are distinctly

heavier and deeper and temperatures higher. Most quality-conscious producers' vineyards are to be found on hillsides only.

The name Valpolicella is derived from a mixture of Latin and Greek, meaning 'the valley of many cellars'. CORVINA has historically been regarded as the best grape of Valpolicella, being used to produce a wide range of styles, all from the same hills. The youthful wines resemble a good BEAUJOLAIS in that they can be enjoyed chilled and have, at their best, a delicious sour-cherry character. The fuller wines come from better sites on the hills, as do the RECIOTO and AMARONE wines made from dried grapes.

By the late 1960s, when the DOC regulations were drawn up, any pretence of quality wine production seemed to have been abandoned. Lesser grape varieties MOLINARA and RONDINELLA were allowed as part of the blend, and excessive YIELDS were permitted. As a result, quality fell almost as quickly as the prices paid to growers for their grapes. By the late 1980s, many of the vineyards on the hills in the Classico zone were abandoned as viticulture there became less and less profitable. Only those growers on the plains, where yields were several times higher than those from the hills, were able to make money. Consequently, the grapes from these prolific vineyards made most Valpolicella, and these were the wines that shaped—one might say tarnished—the image of the wine.

Hillside viticulture was salvaged by Amarone, a wine once considered a 'faulty' Recioto that had fermented to complete dryness and only commercially produced since the 1960s. As described in the AMARONE entry, there has been an explosion in total production this century. As the price paid for Amarone grapes is about three times that paid for regular Valpolicella grapes, the denomination's total surface area increased by 30% in the decade preceeding 2020 to almost 8,500 ha/21,000 acres. To prevent overproduction of Amarone, the total amount of grapes coming from a single estate that may be dried has been reduced from 70% to 50%, and further plantings have been blocked until at least 2023.

The commercial success of Amarone reduced average annual production of regular Valpolicella from 41 to 18 million bottles

between 2005 and 2020. Meanwhile the production of Valpolicella RIPASSO, a normal Valpolicella run over Amarone skins, adding alcohol and EXTRACT to the wine, has soared from 7 million bottles in 2007 to more than 30 million bottles in 2020. Ripasso's rapid growth is a direct result of Amarone's popularity: the volume of Ripasso obtained by this method may be double the volume of the Amarone that has been racked off before (see RACKING), while 10–15% of Amarone must be added to improve its quality as well as diminish the total volume of Amarone. With falling prices for Amarone and the Ripasso marketed as a cheaper alternative, this policy may prove toxic in the long run.

Faced with the continuous threat of overproduction, not least due to the enormous size of CO-OPERATIVES here, and the embarrassment that the wine the denomination is named after has been reduced to mere supermarket fodder over the last decades, the CONSORZIO has launched a campaign to encourage producers to increase the production of Valpolicella Superiore without resorting to Ripasso or dried grapes, in the hope that more wines with a clear expression of origin will emerge. W.S.

Masnaghetti, A., *Valpolicella, Amarone: The Vineyards* (2013) (map).

www.consorziovalpolicella.it

Valtellina, Italy's northernmost wine zone, is a narrow valley formed by the river Adda as it flows west into Lake Como in the alpine far north of LOMBARDY where the NEBBIOLO grape (here called Chiavennasca) is cultivated. Despite its 46° N latitude, the valley—protected to the north by the Alpi Retiche and to the south by the Alpi Orbie—has a relatively privileged MESOCLIMATE (not unlike the warmer wine regions across the border in SWITZERLAND) with a high percentage of sunny days and moderate rains evenly spread

throughout the year. The steep, terraced vineyards optimize solar radiation for grape RIPENING as daytime heat is stored by the stone walls of the TERRACES and the very rocky soils of the vineyards and released during the cooler hours of the evening and night. All of this helps compensate for lower median temperatures than in Nebbiolo's classic areas in PIEMONTE to the south-west and contributes to the sleek, perfumed, long-lived wines produced in the area.

Although Nebbiolo is well adapted to Valtellina, it arrived relatively recently: the detailed works of Francesco Saverio Quadrio in the 17th century make no mention of the grape. Its cultivation in Valtellina appears to date from the early 19th century, when more than 6,000 ha/15,000 acres of vineyards were registered here, more than one-third planted with Nebbiolo. In 2020 the region had just 890 ha/2,200 acres of vineyards planted on a thin 45-km/28-mile strip of terraces on the right bank of the Adda, with 814 ha planted to Nebbiolo. This isolated zone has been classified as DOC Valtellina Rosso, whose maximum yield of 10 tonnes/ha is unlikely to be achieved in practice. A step up is Valtellina Superiore DOCG (215 ha), from separate demarcated areas where yields are restricted to 8 tonnes/ha and the wine must be aged for at least 24 months (36 for Riserva). At the pinnacle of quality are five subzones within the Superiore area, each with a distinct style of Nebbiolo: delicate Maroggio (25 ha); elegant and mineral Sassella (114 ha); harmoniously precocious Grumello (78 ha); earthy and powerful Inferno (55 ha); and fresh and FRUIT-DRIVEN Valgella (137 ha). All these DOCs must contain at least 90% Nebbiolo. The handful of INTERNATIONAL VARIETIES planted here, among them Pinot Noir and Sauvignon Blanc, may be sold as IGT Alpi Retiche. The zone's only other DOCG is reserved for the SFORZATO di Valtellina (or Sfurzat in local dialect), a full-bodied, dry red made from Nebbiolo grapes that have been dried for three months and which must be aged for at least 20 months, including 12 months in BARREL.

Until recently the vineyard area had declined significantly because of the increasing cost of working the narrow TERRACES which are impossible to mechanize. The region's vineyards are extremely

fragmented with many small smallholders; their produce was traditionally bought and bottled by NÉGOCIANTS, who, together with the four local CO-OPERATIVES, were long the dominant economic force in the zone. However, today négociants play a more active role in grape-growing, and more producers are bottling their own wines, often from single vineyards. Ar.Pe.Pe, founded in 1984, has achieved virtual cult status, while other notable producers include Rainoldi, Fay, the négociant Nino Negri, and Mamete Prevostini, and it is becoming difficult to find a mediocre bottle of wine from Valtellina. Valtiendas, VINO DE CALIDAD in CASTILLA Y LEÓN in Spain producing TEMPRANILLO-based red wines similar in style to those of neighbouring RIBERA DEL DUERO but lighter thanks to ELEVATIONS of 900 m/2,953 ft and CALCAREOUS soils. Established in 2007, the region had seven wineries and 170 ha/420 acres of vines in 2021. F.C.

vandalism has long affected wine production, but as wine prices have risen so has the cost of wine vandalism, which can now be publicized easily. Disgruntled ex-employees, commercial rivals, and pranksters are the usual culprits. Perhaps the most famous instance was the loss of six vintages of BRUNELLO DI MONTALCINO in the cellars of its most famous producer, Gianfranco Soldera of Case Basse in 2012. A former employee went to jail for opening the taps on every cask. The year before the cellars of lauded PRIORAT producer Terroir Al Limit were broken into and tank taps opened, with bleach added to contaminate various casks. Foreign ownership may have been a factor here, as at Domaine Jones in FITOU, where wine was destroyed

in early 2013. Moana Park in Hawke's Bay, NEW ZEALAND, was the next victim.

Vineyards are generally more public but much more accessible. In 2010 someone threatened to poison the venerable vines of DOMAINE DE LA ROMANÉE-CONTI unless a substantial ransom was paid. In the same year, protesters against GENETIC MODIFICATION vandalized a trial planting of GM vines in Alsace.

Van Duzer Corridor, wine region and AVA within the WILLAMETTE VALLEY of Oregon defined by regular and strong ocean breezes funnelled through a break in the Coast Range.

vanillin, a phenolic ALDEHYDE that is a component of the lignin structure of OAK wood and is responsible for the vanilla note in wines. It is especially extracted from barrel wood. If new oak casks are used for wine maturation, this vanillin adds complexity to the flavour (see OAK FLAVOUR). Vanillin levels tend to be higher in American than in French oak.

Var, *département* and large IGP in PROVENCE reaching from the Mediterranean Sea north to the Alpes de Haute-Provence. While the IGP allows for still and sparkling wines of all colours, since the 2000s it has specialized in rosé wines, encouraged by the Centre du Rosé, a research institute founded in 1999 in Vidauban. Nearly three-quarters of IGP wines are rosé, made mainly from GRENACHE, CINSAUT, CARIGNAN, SYRAH, and MOURVÈDRE. White wines are mainly Rolle (VERMENTINO), Viognier, and Chardonnay. Three subregions may appear on labels: Argens, Coteaux du Verdon, and Ste-Baume.

varietal, adjective used to describe a wine named after the dominant grape variety from which it is made. The word is also used casually as a noun as shorthand for 'varietal wine', but it is

increasingly misused as a noun in place of VINE VARIETY. A varietal wine is distinct from a wine named after its own geographical provenance (as the great majority of European wines are) and a GENERIC wine, one named after a supposed style, often haphazardly borrowed from European geography, such as 'Chablis' and 'Burgundy'. Varietal wines are most closely associated with the NEW WORLD, where they constitute the great majority of wines produced. The concept was nurtured by Maynard AMERINE at the University of California at DAVIS in the wake of PROHIBITION as a means of encouraging growers to plant worthy vine varieties. It was advocated with particular enthusiasm by Frank SCHOONMAKER in the 1950s and 1960s and was embraced during the CALIFORNIA wine boom of the 1970s to distinguish the more ambitious wines, often made from Cabernet Sauvignon and, increasingly, Chardonnay, from the lacklustre generics of old. Varietal labelling was also adopted, for a similar purpose, in AUSTRALIA, SOUTH AFRICA, NEW ZEALAND, and elsewhere.

Originally, when the United States' acreage of classic vine varieties was relatively limited, a varietal needed only 51% of that variety in the blend to be so labelled. In 1973 this requirement was increased to 75% (although some particularly strongly flavoured NEW YORK State vine varieties were exempted from this increased requirement; see FOXY). See also LABELLING INFORMATION.

The French INAO authorities are not proponents of varietal labelling, understanding that they have nothing to gain and much to lose by entering into this commonwealth of nomenclature. Within France, varietal wines (typically IGP) are called *vins de cépage* and are often regarded as of lower rank than AOC wines.

Italian authorities, in their attempts to reformulate the DOC system and wine-quality categories in the 1990s, were equally keen to emphasize uniqueness and place over grape variety whenever possible. Such attitudes are understandable and, in the long term, may pay dividends, but there is little doubt that an important factor in the success of many New World wines has been the ease with which consumers can grasp the concept of varietal labelling. In the 1980s,

Chardonnay and Cabernet Sauvignon became the most recognizable names in the world of wine.

Varietal blends made from two or even three different varieties—and with those varieties clearly stated on the label—have become increasingly common. Popular varietal blends include Sauvignon/Sémillon among white wines and Cabernet/Merlot, Cabernet/Shiraz, and Grenache/Shiraz/Mourvèdre (GSM) among reds. It is usual to list the varieties on the label in declining order of importance in the blend.

Thanks to changes in EU rules, WINES WITHOUT GEOGRAPHICAL INDICATION may now also state the variety and vintage on the label, although this is sometimes constrained at a national level. In theory this should help consumers and enable such wines to compete with varietal wines from New World.

variety of vine or grape. See VINE VARIETIES.

Varois-en-Provence, Coteaux, enclave within the Côtes de PROVENCE appellation which takes its name from the Var *département*. More than 90% of the wines from its 2,900 ha/7,166 acres of vines are rosé. The wooded hills around Brignoles are based on LIMESTONE and are so buffered from warming MARITIME influence by the hills of Ste-Baume that vines will not ripen their fruit at all reliably at ELEVATIONS of more than about 350 m/1,100 ft.

Reds and rosés may incorporate a wide array of grape varieties: Grenache and Cinsaut primarily but also Syrah and Mourvèdre (which will ripen only in the warmest sites), while Cabernet Sauvignon, Carignan, and the Provençal speciality TIBOUREN are allowed a minor role. For white wines, Grenache Blanc is added to those varieties permitted for Côtes de Provence Blanc (see PROVENCE), although Vermentino is increasingly appreciated.

Varro, Marcus Terentius (116–27 BCE), was a prolific Roman writer who wrote on subjects as diverse as grammar, geography, history, law, science, philosophy, and education; the rhetorician Quintilian called him 'the most learned man among the Romans' (*Institutio oratoria* 10. 1. 95). Yet the only one of his works to survive in its entirety is his manual of agriculture, *De re rustica*. Varro started it in his 80th year and addressed it to his wife, who had bought a farm. Varro was a man of letters; unlike CATO's treatise, from which he borrows occasionally, his own is a literary exercise, written in a highly wrought style. *De re rustica* is full of antiquarian learning as well as practical advice, and Varro often looks back to the time when the inhabitants of Italy were all hard-working honest farmers, with none of the decadence that prevails among the city dwellers of his day. The treatise is divided into three books, each of which is a dialogue; most of the material on wine comes in the first book. He defines old wine as at least a year old; some wine goes off before that, but some, like FALERNIAN, becomes the more valuable the longer it is kept. Varro's work was used by later writers such as VIRGIL, PLINY, COLUMELLA, and PALLADIUS. Varro's own chief authority, by his own admission, is Mago of CARTHAGE, about whom nothing is known and of whose work nothing survives. Among the many Greek authors he mentions as his sources are Aristotle, Xenophon, and Theophrastus.

vat, large CONTAINER for STORING wine and/or ÉLEVAGE. A vat may also be used as a FERMENTATION VESSEL. In English-speaking countries, they may also be known as tanks; in France they are called CUVES.

For many centuries WOOD was the most common material, but in the mid to late 20th century inert materials such as CONCRETE, enamel, epoxy resin, and STAINLESS STEEL replaced wood except in

particularly traditional or traditionalist areas. At the start of the 21st century, wooden fermentation vats once again became more fashionable though they are very expensive.

For details of wine maturation in wooden vats, see CASK AGEING.

vat size varies enormously. FERMENTATION VESSELS in large commercial wineries contain, typically, between 50 and 300 hl (1,320–8,000 gal), although smaller enterprises may use much smaller wooden or CONCRETE vats. The ratio of height to width has implications for red winemaking in determining the area of the CAP. Blending tanks in large commercial wineries usually hold around 3,500 hl (92,000 gal) and may contain up to 10,000 hl. Grupo Peñaflor, Argentina's largest wine company, boasts the largest wine vat in the world, made from concrete and with a capacity of about 53,000 hl—large enough to hold a dinner party for several hundred inside—and still used for wine storage.

Vaucluse, *département* in inland PROVENCE between the Drôme and Bouches-du-Rhône. The IGP covers a vast area, including ALLUVIAL plains as well as slopes in the Luberon mountains, and allows more than 200 grape varieties, although most wines are made from traditional southern French varieties such as SYRAH and GRENACHE or from INTERNATIONAL VARIETIES. 'Aigues' may be appended to wines made in any of 59 villages in the Luberon. 'Principauté d'Orange' may be used for wines from around Orange, an area that includes AOCs such as CHÂTEAUNEUF-DU-PAPE and RASTEAU.

VDN, abbreviation for VIN DOUX NATUREL.

VDP, or the Verband Deutscher Prädikatsweingüter, officially registered as the Verband Deutscher Prädikatsweingüter but marketing itself under the title VDP.Die Prädikatsweingüter, German growers' association, in 2001 incorporating 200 wine estates in

GERMANY whose influence and prestige far exceeds the less than 4% share of German vineyard surface controlled by its members. In 1910, just two years after consolidating the top MOSEL estates into the GROSSER RING, the mayor of Trier persuaded like-minded organizations in the RHEINGAU and PFALZ to band together to form a national association for the purpose of selling its members' wines at AUCTION. Over the years, other regional groups joined what was until 1972 known as the Verband Deutscher Naturweinversteigerer to signify its auctioning (*Versteigerung*) of wine from unchaptalized (see CHAPTALIZATION), undiluted MUSTS (NATURWEIN). By the late 1990s its membership included estates in all of Germany's 13 winegrowing regions.

In their effort at promoting and preserving German wine culture, the national and regional branches of the VDP still maintain their tradition of wine auctions, although today bottles rather than casks of wine are on offer, and prices, prestige notwithstanding, have little bearing on market prices. The VDP's contribution to the image of fine and rare German wines is based on its members' disciplined dedication to standards going far beyond those mandated by law as regards maximum YIELDS, minimum MUST WEIGHTS, environmental SUSTAINABILITY, and commitment to varieties traditionally associated with each region. Both the release of individual wines and membership in the VDP are subject to regular internal inspection. Members' labels and capsules carry the VDP name and logo, an eagle and grape cluster. The VDP's efforts at vineyard classification and QUALITY CONTROL as well as its LABELLING practices have been influential beyond its membership, most notably on a 2001 German wine law.

See also GROSSES GEWÄCHS and GERMANY, labelling. D.S.

VDQS, or Vin Délimité de Qualité Supérieure, was France's minuscule interim wine quality designation between VIN DE PAYS and AOC, which accounted for less than 1% of the nation's wine

production. The VDQS category was scrapped after the 2010 vintage, and most have been promoted to AOC.

Vega Sicilia, concentrated and notably long-lived red wine that is Spain's undisputed equivalent of a FIRST GROWTH, made on a single property now incorporated into the RIBERA DEL DUERO denomination. This 1,000-ha/2,500-acre farm either side of the main road east of Valladolid has been making wine in its present form since 1864, when Eloy Lecanda planted vines from Bordeaux alongside Tinto Fino, also known as Tinta del País (a local strain of TEMPRANILLO). Until 1927 it was the only wine estate in what is now Ribera del Duero. The current style was defined around 1910, when the winery was leased by Cosme Palacio, a Rioja grower. A succession of different owners has since managed to maintain the quality and reputation of Vega Sicilia as Spain's finest red wine. However, Vega Sicilia fell on lean times at several junctures and was able to make a substantial leap in quality and, more importantly, in consistency after being bought by the Álvarez family in 1982.

The more than 200 ha/500 acres of vineyard on varied soils but mainly marl with some gypsum overlooking the river Duero are planted mainly with Tinto Fino, supplemented by varying, small proportions of Cabernet Sauvignon.

Bodegas Vega Sicilia produces three wines, all red and aged in American and French oak coopered on the estate. Valbuena is released at five years old while the most famous wine, Unico, made only in the best VINTAGES, is generally released after spending about ten years in a combination of wooden tanks; small, new BARRIQUES; large, old barrels; and bottles. The rare Reserva Especial is a blend of three vintages of Unico and can last for decades.

In 1991 Bodegas Vega Sicilia acquired the nearby Liceo winery and created the immediately acclaimed Bodegas Alión, which makes much more modern reds from 150 ha of 100% Tempranillo grapes, aged in 90% French oak.

Vega Sicilia established Oremus in TOKAJ in 1993; and in 2001 Pintia, Vega Sicilia's bodega in the TORO region, produced its first vintage. Then, in a JOINT VENTURE with Benjamin de ROTHSCHILD, Vega Sicilia created the Macán estate in Rioja, first vintage 2009. A new winery in Rías Baixas, Deiva, was scheduled to produce its first vintage in 2023. The entire portfolio has been branded Tempos.

As Vega Sicilia celebrated its 150th anniversary in 2014, tensions between different members of the Álvarez family were widely publicized. V. de la S. & J.R.

Peñín, J., *Vega Sicilia: Journey to the Heart of a Legend* (2002).

vegetarian and vegan wines are increasingly popular. The main area of concern is the use of animal-based products for FINING and STABILIZING wine (although some producers are now using plant-based fining agents). Of the most common agents, only BENTONITE is suitable for vegans as well as vegetarians; CASEIN and albumin (see EGG WHITES) are acceptable to most vegetarians; ISINGLASS and GELATIN would be unacceptable to most vegetarians and vegans. Although such materials are PROCESSING AIDS rather than ADDITIVES, it is impossible to guarantee that there is absolutely no residue in the wine, and some wine drinkers may object to the use of an animal-derived product at any stage—even the use of HORSES in vineyards. An increasing number of wine producers and retailers make this information available on the bottle or at the point of sale. See also LABELLING INFORMATION and INGREDIENT LABELLING.

vegetative propagation, reproduction of a plant by asexual means. In viticulture, CUTTINGS on which both roots and shoots will grow are used. In those limited locations where PHYLLOXERA and other root pests are not present and ROOTSTOCKS are not used, LAYERING can be used to replace missing vines. Micropropagation (see TISSUE CULTURE) is a modern application in which small amounts of a MOTHER

VINE may be propagated in large numbers rapidly. Unlike SEXUAL PROPAGATION, the progeny of vegetative propagation is genetically identical, unless MUTATION intervenes. B.G.C.

vein banding, vine disease. See FANLEAF DEGENERATION.

Veltliner, Valtlin Zelene, Veltlinske Zelené, Veltini, common Eastern European names for the four distinct Austrian grape varieties mistakenly thought to originate from VALTELLINA in Lombardy (northern Italy): GRÜNER VELTLINER, ROTER VELTLINER, FRÜHROTER VELTLINER, and occasionally Brauner Veltliner. J.V.

vendange, French word for HARVEST. A *vendangeur* is a grape-picker, and a temporary lodging for grape-pickers may be called a *vendangeoir*.

Vendanges Tardives means literally 'late harvests' and in France is restricted to ALSACE, JURANÇON, and GAILLAC. Strict regulations cover its production. Although all Alsace Vendanges Tardives wines are made from ripe grapes and without the aid of CHAPTALIZATION, the wines themselves vary considerably in how sweet they are, with some of them tasting rich but almost bone dry. Beginning with the 2021 vintage, all Alsace wine labels must indicate the wine's sweetness level using a standardized scale—a helpful guide when it comes to FOOD-AND-WINE MATCHING. SÉLECTION DE GRAINS NOBLES is Alsace's even riper category. See also AUSLESE and BEERENAUSLESE, their counterparts in Germany, and LUXEMBOURG.

vendange verte. See CROP THINNING.

vendemmia, Italian for VINTAGE YEAR or HARVEST. Vendimia is Spanish for 'harvest'.

Vendômois, Coteaux du, AOC of 120 ha/297 acres in 2019 producing a wide range of light wines between the Coteaux du LOIR and the city of Vendôme in the northern LOIRE Valley. The wines are necessarily crisp in this cool, often damp climate (annual rainfall averages 680 mm/27 in), but a pale pink VIN GRIS from the PINEAU D'AUNIS grape can be an attractive local speciality. Pineau d'Aunis must also constitute at least half of any blend for the reds, the make-up being Cabernet Franc, Pinot Noir, and/or Gamay. The few white wines that are made rely on Chenin Blanc, often aided by up to 20% Chardonnay.

See also LOIRE, including map.

Veneto, Italy's most productive wine region, encompassing 80,000 ha/197,684 acres of vines in the north-east (see map under ITALY). It stretches westward to Lake Garda and northward to the Alps and the Austrian border from the Terraferma behind the lagoons and city of VENICE, an important power in the wine trade of the Middle Ages whose legacy has shaped some wines in the Veneto and along the Adriatic. In the mid 1990s the volume of wine produced in the Veneto overtook that of PUGLIA and SICILY; and in 2020 it was more than 11 million hl/241 million gal. Initially much of this growth was due to the runaway success of PINOT GRIGIO, now overtaken by that of PROSECCO.

In theory, a significant proportion of Veneto wine is of good quality, with 29 DOCs and 14 DOCGs representing well over half the total. The reality is somewhat different. This proportion has been artificially inflated both by drastic enlargements of the DOC zones (to plains which were cereal-growing areas prior to the Second World War) and/or by sanctioning extremely generous YIELDS. The resulting wines, although nominally of DOC level, are too frequently characterless or leaning too heavily on Bordeaux varieties. Good

bottles of BARDOLINO, VALPOLICELLA, SOAVE, and CONEGLIANO-VALDOBBIADENE Prosecco are not difficult to find, however; and the CORVINA vine variety, which forms the basis of Valpolicella and Bardolino, and GARGANEGA, the basis of Soave, are capable of making seriously interesting wines if grown in the right place (i.e. the hills on the LATITUDE 45.30° N which run eastward from Lake Garda to the north of the fertile Adige river plain). Other HILLSIDE zones of real potential include the Colli Berici to the south, especially for Tai Rosso (GRENACHE) and CARMENÈRE; Breganze to the north of Vicenza, especially for both Cabernets; the Colli Euganei south-west of Padua for BORDEAUX BLENDS and Serprino, akin to Prosecco FRIZZANTE; and the hillside part of the Piave DOC zone for the high-acid RABOSO, which used to freshen up many an AMARONE. Native varieties such as Friulano, Garganega, and Verduzzo are cultivated in these zones, as are imports such as Merlot and Cabernet, mainly Franc (brought to the area in the wake of the Napoleonic invasion in the early 19th century). The Garganega-based Bianco di Custoza and Gambellara, two country cousins of Soave, the sparkling Prosecco of Conegliano, and the Fior d'Arancio of the Colli Euganei (a fuller-bodied answer to MOSCATO D'ASTI) round out the regional picture, one characterized by large quantities of pleasant, easy-drinking wines. Producers throughout the region provide exceptions, especially those who show an interest in TERROIR rather than volume. The small Lessini DOC, producing TRADITIONAL METHOD sparkling wine from the Durella grape, and the revived Custoza DOC are two bright spots.

Veneto's centre of ACADEME is the experimental viticultural institute at CONEGLIANO.

For details of notable specific wines, see AMARONE, BARDOLINO, BREGANZE, CUSTOZA, GAMBELLARA, LISON-PRAMAGGIORE, PIAVE, PROSECCO, RECIOTO, SOAVE, and VALPOLICELLA. W.S.

www.uvive.it

Venezuela is a minor South American wine producer, and consumer, but TROPICAL VITICULTURE has been practised here since the arrival of European immigrants at the end of the 19th century—although there is evidence that Jesuit MISSIONARIES first planted vines at Cumana in the 16th century and that vine-growers emigrated here from BADEN, Germany, in the early 19th century. Situated between latitudes 9° and 11° N, the country has an average temperature of 27 °C/81 °F, making vine DORMANCY impossible, and the rainy seasons dictate the two harvests per year. ELEVATION varies from 30 to 643 m/100–2,110 ft, with the best vineyards at the higher end of that range.

Many producers use GRAPE CONCENTRATE or import BULK WINE to make products that range from LAMBRUSCO-like blends to base wines for SANGRÍA. But by 2021 Venezuela had around 450 ha/1,112 acres planted to wine grapes, mainly Tempranillo, Syrah, Petit Verdot, Chenin Blanc, Macabeo, and Malvazíja Istarska. Seventy per cent of the plantations are in Zulia, north-western Venezuela; the rest, including Bodegas Pomar, the country's leading producer, are mainly in Lara, east of and adjacent to Zulia, in the arid, hilly Segovia Highlands. E.M.G.

Goldstein, E., *Wines of South America* (2014).

Venice , overarching DOC created in the early 2010s stretching from the hills of CONEGLIANO-VALDOBBIADENE to the Venetian lagoon in an attempt to capitalize on the name of this world-famous city which was the cultural and, once, commercial centre of north-east Italy.

In its time Venice exerted considerable and sometimes lasting influence on the wines of the world. Medieval Venice had no agriculture or viticulture and obtained its wine and grain from

LOMBARDY to the west; Venice's importance was in its trade. In 840 a treaty, known as the Pactum Lotharii, between CHARLEMAGNE's grandson Lothair and the doge of Venice protected Venice's neutrality and guaranteed its security from the mainland. This treaty made Venice independent from the west and from Byzantium. Thus Venice became the most important of the Italo-Byzantine ports, and its position was strengthened when the Byzantines discovered that Venice's rivals Amalfi, NAPLES, and Gaeta had been collaborating with the Saracens. Initially Venice owed its wealth to its trade, acquiring possession of Crete, Modon, and Coron in the Aegean and being granted exemptions from the TAXATION in Constantinople that was to ruin the Byzantine economy (see GREECE, medieval history). The Crusades only strengthened Venice's position at the frontier between northern Europe and the eastern Mediterranean.

With its eastern expansion came the trade in sweet wines, so much more esteemed by northern Europeans than their own thinner ferments. Most of these were from CRETE, known then as Candia. Many of them carried the name of the Greek port from which they were shipped, Monemvasia (hence MALVASIA di Candia and MALMSEY). Some of these wines were sold in Constantinople; others were taken to Venice for redistribution, either overland to Florence (via Ferrara) or by sea to Paris, England, and Flanders. In addition to buying and selling Aegean wines, Venice also dealt in Italian wines, from Trevi, the northern Adriatic, and the MARCHE, and in the even richer wines of Tyre (in modern LEBANON), which was owned by the Venetians for most of the 13th century.

However, in trade with Syria and Palestine, Venice came second to GENOA, and the rivalry extended to trade with northern Europe: Genoa led the way there, and Venice, which was less well placed, did not start shipping wine to northern Europe until the early 14th century. By that time Genoa had already won the battle: at the end of the 13th century, Venice had ceased to be the richest and most important port in Italy, but not before it had imported the Greek techniques of increasing sugar and alcohol content by deliberately

making DRIED-GRAPE WINES. Johnson suggests a direct link between such practices, employed on the islands along the Dalmatian coast, and those subsequently (indeed currently) used by some in the VENETO hinterland of Venice to make RECIOTO versions of VALPOLICELLA and SOAVE.

Venice was also to become the centre of GLASS production and therefore played an important, if indirect, role in the history of wine.

Ventoux, one of the largest appellations in France, covers some 5,675 ha/14,023 acres of vineyards on the south-eastern fringes of the southern RHÔNE between GRIGNAN-LES-ADHÉMAR and the LUBERON. It takes its name from Mont Ventoux, a peak rising 1,912 m/6,273 ft high that dominates the region. The communes entitled to the appellation are on its western and southern flanks and some of the surrounding flat land. Much of the best TERROIR is found in the foothills of the western flank. Historically Ventoux has produced TABLE GRAPES along with other tree fruits such as cherries, and until the 1970s wine production was dominated by CO-OPERATIVES. In the 1990s, the establishment of domaines producing significantly superior wines such as Ch Pesquié and Domaine de Fondrèche generated more interest in the area. By 2020 it was one of the most dynamic appellations in the Rhône Valley, with more than 130 estates. Reds and rosés make up the bulk of production, blended from a wide

variety of southern Rhône grapes. Clairette, Bourboulenc, and Grenache Blanc are the principal varieties for the little white produced. M.C.W.

veraison, word used in viticulture for that intermediate stage of grape-berry development which marks the beginning of RIPENING. It is derived from the French term *véraison*. At the beginning of veraison, the berries are hard, green, and about half their final size. During veraison, the berries change skin colour and soften, SUGARS and volume increase, and ACIDITY decreases. The colour of the grape before veraison is due to green chlorophyll, and at veraison berry skins change colour to red-black (see ANTHOCYANINS) or yellow-green (see CAROTENOIDS), depending on the variety.

The inception of veraison is rapid and dramatic, but not all berries on a vine, nor indeed in a bunch, show veraison simultaneously. This is because of variation in time of FLOWERING. About six days after colour change, the berries soften, begin to accumulate GLUCOSE and FRUCTOSE, and start to enlarge. The first to soften are those which are exposed and in warmer MICROCLIMATES (on the west-facing part of exposed bunches or near a POST, for example); the last berries to undergo veraison are those in the CANOPY shade and on short shoots. It is difficult therefore to be precise about the single date of veraison; more commonly a date is recorded when, say, 50% of the berries on a vine show veraison. At about the same time as veraison occurs, CANE RIPENING begins.

The onset of veraison (and cane ripening) is controlled by both plant and environmental factors. Exposed grapes on vines which have a high LEAF TO FRUIT RATIO and which are experiencing mild WATER STRESS (and hence no active shoot growth) undergo veraison first. By contrast, veraison is delayed in vines with large crops, in those with many actively growing shoot tips, and for shaded fruit (see SHADE). Veraison is observably early in vineyards producing high-quality fruit, with both veraison and cane ripening developing quickly.

Environmental factors associated with the early onset of veraison are warm, sunny, and dry weather. R.E.S.

Keller, M., 'Phenology and growth cycle', in *The Science of Grapevines* (3rd edn, 2020).

Verdea, ancient Tuscan light-berried vine now a speciality of the Colli Piacentini in north-central Italy.

Verdeca, Puglia's most popular light-berried vine producing neutral wine suitable for the VERMOUTH industry and declining in popularity, with 912 ha/2,254 acres remaining in 2015. DNA PROFILING has shown that it is a parent, with TRIBIDRAG (Zinfandel), of the widespread Dalmatian variety PLAVINA, indicating an ancient viticultural bridge across the Adriatic Sea. More recently, Verdeca has been shown to be identical to the much more highly regarded Greek variety LAGORTHI and to have a parent–offspring relationship with MALVASIA Bianca Lunga. J.V.

Verdejo, characterful grape so FASHIONABLE in Spain that its total plantings increased more than fourfold between 2004 and 2020 to 25,504 ha/63,022 acres. With its distinctive blue-green BLOOM, which presumably inspired its name, the variety is RUEDA's pride and joy (and helped stave off a challenge for primacy from imported SAUVIGNON BLANC, with which it is often blended). The variety ripens relatively early but is very susceptible to POWDERY MILDEW. DNA PROFILING has shown that Verdejo and GODELLO (under its Portuguese name Gouveio) are siblings and that Verdejo is a natural SAVAGNIN × Castellana Blanca cross, the latter an old variety from Huesca in northern Aragón. Wines produced are aromatic, HERBACEOUS (somewhat reminiscent of laurel), but with great substance and EXTRACT, capable of AGEING well into an almost nutty character. J.V.

Verdelho, name once given to several Portuguese white grape varieties and most closely associated with the island of MADEIRA, where the Verdelho vine became increasingly rare in the post-PHYLLOXERA era, but the name was long used to denote a medium-dry style of wine somewhere between SERCIAL and BUAL levels of richness. Of the original four VITIS VINIFERA varieties that were traditionally grown on Madeira, Verdelho is the most planted today, with 58 ha/143 acres in 2018. A further 452 ha of Verdelho was recorded on the Portuguese mainland in 2020, mainly in the ALENTEJO. Musts have moderate levels of sugar and notably high ACIDITY. The Verdelho found on Madeira is the same as that found growing in the AZORES, and this Verdelho, CUTTINGS of which were presumably picked up on one of these Atlantic islands en route to the Antipodes, was extremely important in 19th-century Australia. Planted on 1,061 ha/2,622 acres in 2022, it has had notable success in vibrant, tangy, full-bodied TABLE WINES in more recent times, particularly in the Hunter Valley of New South Wales, Victoria, and some of the hotter regions of Western Australia. See AUSTRALIA for more details. Verdelho has been planted to a very limited extent in SAVENNIÈRES in the Loire for just as long and makes some interesting varietal wine there. It is also grown in New Zealand, California, and Argentina.

A quite distinct variety once called Verdelho or Verdelho do Dão in Portugal is now officially known as Gouveio and has been identified as Spain's GODELLO.

Verdelho Roxo is a red-berried colour MUTATION of Verdelho (while the now virtually extinct Verdelho Tinto of the MINHO is unrelated).

Verdello, white Umbrian grape variety once prized for its ACIDITY. Just 179 ha/442 acres remained in 2015.

Verdesse, revived white grape of SAVOIE and ISÈRE in eastern France whose wine can be powerful and highly aromatic.

Verdicchio, one of central Italy's classic and potentially finest white wines, produced since at least the 14th century. It is made from the Verdicchio grape (see below) in two DOC zones of its home territory of the MARCHE: Verdicchio dei Castelli di Jesi, to the west of Ancona and a mere 30 km/20 miles from the Adriatic Sea; and the Verdicchio di Matelica zone, considerably further inland and at higher ELEVATIONS, close to the border with UMBRIA.

At 2,000 ha/4,942 acres, Castelli di Jesi is Marche's largest DOC and one which makes no distinction between vineyards on plains and those on the hills, with the exception of the much smaller historic Classico zone in the hills near the town of Cupramontana. Here several small producers make complex wines, often from single vineyards. Under their initiative a start was made in the early 2010s to identify subzones based on ASPECT, ELEVATION, and SOIL TYPES.

An overwhelming majority of the production of the Castelli di Jesi DOC is controlled by CO-OPERATIVES and NÉGOCIANT houses. The wine's fame was largely due to the efforts of Fazi-Battaglia, a large négociant firm which introduced the amphora-shaped bottle and scroll-shaped label, initially a positive factor in gaining recognition for the wine but later responsible for the image of kitsch and frivolity with which Verdicchio has been saddled. It did not help that, in its heyday in the 1970s, the wine was flash-pasteurised (see PASTEURIZATION) to make it stable for travel, negatively impacting quality.

While most Verdicchio is made in a modern style, without SKIN CONTACT and with TEMPERATURE CONTROLLED fermentations, quite a few herald a return to traditional methods, using SKIN FERMENTATION to give the wines a certain fullness and authority. The best wines are cool with mandarin fruit, lifted lemony acidity, MINERALITY, and a slight chew on the finish. The finest can age ten or more years.

Verdicchio di Matelica, a much smaller zone of 200 ha/494 acres with marginally lower yields and better exposed HILLSIDE VINEYARDS, was long supposed to produce fuller, more characterful wine, but this

is no longer a given, since many quality-oriented producers in Castelli di Jesi have voluntarily decreased yields.

Two DOCGs were created in 2011: Castelli di Jesi Verdicchio Riserva and Verdicchio di Matelica Riserva, for wines aged for at least 18 months before release.

Perhaps partly because of its high natural acidity, Verdicchio can also produce fine PASSITO wines. It was also one of the first Italian SPUMANTES, with a tradition which can be traced back to the middle of the 19th century and which remains an integral part of DOC production.

Verdicchio, the grape

The Verdicchio grape has been in the Marche for centuries. but DNA PROFILING has recently established that it is identical to TREBBIANO di Soave, Trebbiano di Lugana, and Trebbiano Valtenesi. In SOAVE it can add perfume to the steely GARGANEGA, while further west, on its own in a warmer zone, it gives full-bodied LUGANA of real interest.

Most of Italy's Verdicchio, some 2,762 ha/6,825 acres, is planted in the Marche. W.S.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Verdiso, revived grape speciality in Conegliano in the VENETO region of north-east Italy making lively, varied whites.

Verdot. See PETIT VERDOT and GROS VERDOT.

Verduzzo, wine made from VERDUZZO FRIULANO and/or VERDUZZO TREVIGIANO, principally in FRIULI and in the PIAVE DOC in the bordering province of Treviso in the Veneto in seven DOC zones, although only Friuli Grave and Friuli Colli Orientali produce significant quantities and the latter is qualitatively far superior due to its HILLSIDE VINEYARDS. The wine exists in a dry, occasionally sparkling, and regularly sweet version, although the last, obtained either by LATE HARVESTING or by raisining the grapes (see DRIED-GRAPE WINES), can frequently be more medium dry than lusciously sweet. Sweet Verduzzo, less common than dry Verduzzo, is the more interesting wine, golden in colour, and often with delightful density and honeyed aromas, even if it lacks the COMPLEXITY of an outstanding dessert wine. The grapes' TANNINS can impart a certain astringency, which is more noticeable when it has been fermented dry.

Ramandolo, to the north of Udine, is considered the classic zone for fine sweet Verduzzo, but the Friuli Colli Orientali DOC, when first established, permitted the use of the name Ramandolo for any sweet Verduzzo in the production zone, converting, as it were, a place name into a generic name. This anomaly has been corrected with the establishment of a Ramandolo DOCG for generally sweet wines, with maximum yields of 8 tonnes/ha (as opposed to 11 tonnes/ha permitted for Colli Orientali Verduzzo) from two villages, Nimis and Tarcento. W.S.

Verduzzo Friulano, also known as Verduzzo di Ramandolo, white grape variety recorded as early as 1409 in north-east Italy. Total plantings of 687 ha/1,698 acres were recorded in 2015.

Verduzzo Trevigiano makes much duller wine than the distinct VERDUZZO FRIULANO. It was planted on around 531 ha/1,312 acres in 2015, mainly in the provinces of Treviso and Venezia.

verjus, or verjuice, the tart, apple-flavoured juice of unripe grapes, has many variations and many culinary uses, especially in dressings and sauces. It adds ACIDITY to a dish but unlike VINEGAR does not clash with wine. Traditional in many countries of the world, it is made from underripe grapes cut during CROP THINNING or from second-crop berries that are unripe at harvest. One method is to press the grapes then preserve the partially fermented but highly VOLATILE juice with salt. Alternatively, the grapes may be boiled before PRESSING to kill the YEAST and prevent fermentation but must then be used immediately or frozen. Most commercial producers gently press the grapes, cold settle, and filter the juice before packaging, in which case STERILE BOTTLING is essential to prevent the verjus from fermenting.

Vermeille, Côte , IGP for wines falling outside the regulations of BANYULS or COLLIOURE in the foothills of the Pyrenees in southern

France. Red wines dominate, although still wines of all colours are allowed, as are sweet and RANCIO styles.

Vermentino, attractive, aromatic white grape variety widely grown in north-western Italy, on Sardinia, to a limited extent on Corsica (as Vermentinu), and in southern France. DNA PROFILING has shown it to be identical to the Ligurian PIGATO and the Piemonte variety FAVORITA. However, Ligurians have distinguished between their Pigato and their Vermentino, and the two may well be different CLONES of the same variety. Vermentino has long been considered identical to the ROLLE of Provence, the synonym which an EU regulation of 2019 obliges French producers to use on their labels because Vermentino forms part of several Italian DOC/DOCG names.

France has the world's greatest area planted with Vermentino/Rolle: 7,023 ha/17,354 acres in 2019, considerably boosted by recent plantings in the Languedoc, fuelled by varietal FASHION. The Var *département* grows about 2,203 ha/5,444 acres, about the same as the entire Languedoc and Roussillon, and it is both the southern Rhône's and Corsica's most planted white grape variety, dominating the island's white AOC wines. The wines vary from floral to citrus but are almost always refreshing.

There were 6,703 ha/16,563 acres of Vermentino Bianco in Italy in 2015. On Sardinia, Vermentino is the most planted white wine grape and is often picked deliberately early to retain acid levels but still manages to produce lively wines of character, although examples of a richer, fuller style are increasing, especially in the Vermentino di Gallura DOCG. The interest in white INDIGENOUS VARIETIES has been a boon for those growers along the Tuscan coast who had either the foresight or good fortune to plant Vermentino, which is the fastest-growing variety in the MAREMMA, reaching 914 ha/2,259 acres in 2022.

Some Vermentino is also grown on Malta, in California, in Texas, and in North Carolina, but of the non-European wine producers the land of ALTERNATIVE VARIETIES, Australia, has been quickest to embrace this popular variety with plantings in many different regions.

Vermentino Nero is a minor, unrelated Tuscan red wine grape once almost extinct.

Vermont , state in the north-east United States, bordering Canada, distinguished by the Green Mountains running its length from north to south. Attempts at vine cultivation date to the earliest colonial settlers, but not until the 1990s did a craft-scale commercial wine industry take root.

The central mountains are bounded by the Lake Champlain Valley to the west and the Connecticut River Valley to the east. A longitudinally oriented, complex LIMESTONE bedrock contributes to regional SOIL FERTILITY. Fossils from Earth's oldest coral reef, estimated at 450 million years of age, line the north-western border, and the eastern rift valley is eroded VOLCANIC material. The mixed surficial GEOLOGY shows the impact of repeated glaciation: both eastern and western valleys were massive glacial lakes in the last ice age, adding rich CLAY deposits to upper strata.

Warm, humid summers, late spring FROSTS, and short growing seasons with extreme winter temperatures make Vermont inhospitable to VITIS VINIFERA, while HYBRIDS bred to resist both disease and extreme cold thrive. Early vineyards employed FRENCH HYBRIDS including SEYVAL BLANC and LÉON MILLOT; they have been joined by hardier AMERICAN HYBRIDS such as MARQUETTE, LA CRESCENT, FRONTENAC (Noir, Gris, and Blanc), and multiple selections from private breeders.

By 2021 there were 60 ha/200 acres under vine and two dozen commercial wineries producing still and sparkling wines (both TRADITIONAL METHOD and MÉTHODE ANCESTRALE) at artisanal scales. The Lake Champlain basin hosts most vineyards, but numerous regional MESOCLIMATES can support vines. Vermont has gained notoriety for its engagement with REGENERATIVE VITICULTURE practices and LOW-INTERVENTION approaches in the wineries, as well as for its distinctive wines, with some having gained international acclaim. T.T.

vermouth, herb-flavoured FORTIFIED WINE available in many styles and qualities. The practice of adding flavouring to wines dates as far back as Neolithic times (see FLAVOURED WINES, history), though modern vermouth owes more to the styles popular in 18th-century Europe, flavoured in particular with wormwood (*wermut* or *vermut*) or *artemesia absinthum*, which was thought to have curative powers for gastric ills. These aromatized wines enjoyed a certain success in French royal circles and subsequently became known as *vermutwein* and, in Anglicized form, vermouth. Modern large-scale vermouth production dates from 18th-century PIEMONTE, close to the Alps which could supply the necessary herbs. By the 19th century, BRANDS such as Cinzano, Martini, and the French Noilly Prat threw off any pretence of curative powers and became extremely popular during the cocktail age as mixers.

After the Second World War, vermouth had become a wan, lacklustre drink made in industrial quantities, often flavoured by the addition of a concentrate designed for consistency. There was little interest in the category until the cocktail renaissance of the 1990s. By the 2000s, a rash of small-production vermouths, often made from high-quality wine and flavoured with intensely local ingredients, gave vermouth back some of the respect it had lost. Today, so many herbs and spices are used to flavour fortified wines that the definition of vermouth is necessarily elastic. Wines can be almost dry, with the strong aroma of wormwood and other bitter alpine herbs, or sweet, red, and more vaguely herbal. French styles tend to be the most delicately alpine, such as those from Chambéry, which once boasted an AOC; Italian versions are bolder and traditionally red; Italy also has the only geographically protected vermouth designation, IGT Vermouth di Torino. Spain has its own unique tradition, including SOLERA-aged examples, but there are vermouths coming from nearly every wine-producing country. In the best cases, the new vermouths are another window into a region's TERROIR, flavoured with local ingredients and to local tastes.

Wondrich, D. (ed), *The Oxford Companion to Spirits and Cocktails* (2022).

Vernaccia, name used for several, unrelated Italian grape varieties, mainly white but sometimes red, *vernaculus* meaning 'native' or 'indigenous' in Latin. These vary from the extreme north of the country (VERNATSCH being merely a Germanic version of Vernaccia) to the fizzy red Vernaccia di Serrapetrona of the MARCHE made from the vine variety known locally and in Umbria as Vernaccia Nera (a central-Italian synonym for GRENACHE), Vernaccia di Pergola (a southern-Italian synonym for ALEATICO), and VERNACCIA DI ORISTANO, a unique variety famous on the island of SARDINIA. The most highly regarded form is the dry white Tuscan varietal VERNACCIA DI SAN GIMIGNANO. Wines called Vernaccia, or sometimes vernage, are often cited in the records of London wine merchants in the Middle Ages, but the term could have been used for virtually any sort of wine, Latin being the common language then. Vernaccia was a particularly common product of LIGURIA in north-west Italy and Tuscany. For more details of medieval trade in Vernaccia, see GENOA, ITALY, and TUSCANY.

Vernaccia di Oristano, distinct variety (see VERNACCIA) grown almost exclusively on 232 ha/573 acres of western SARDINIA in 2015, making a wide range of white wines with varying SWEETNESS levels and sometimes fortified and SHERRY-like.

Vernaccia di San Gimignano, potentially distinctive dry white wine made from the historic local vine variety of the same name, probably unrelated to any other Vernaccia, cultivated in the sandstone-based soils around the famous towers of San Gimignano in the province of Siena in TUSCANY in central Italy. There are references to Vernaccia in the archives of San Gimignano as early as 1276. The wine was the first ever awarded DOC status, in 1966, and was

elevated to DOCG status in 1993 in recognition of its unquestioned superiority over the standard bland Tuscan white blend of Trebbiano Toscano and Malvasia.

In the late 20th century, Vernaccia di San Gimignano enjoyed some export success and producers were encouraged to make crisp, refreshing wines. Demand for them has since declined, despite attempts to create COMPLEXITY via small BARREL MATURATION. Since the beginning of this century the CONSORZIO has promoted SUSTAINABLE VITICULTURE, and some producers have adopted ORGANIC VITICULTURE. Some are also experimenting with SKIN-FERMENTED Vernaccia in AMPHORAE. The best examples have a 'minerally', salty impact on the palate and gain both complexity and notes of ripe yellow fruit and beeswax with age.

By 2010 total plantings of Vernaccia had declined to 500 ha/1,236 acres, perhaps because of sales success with red wines based on SANGIOVESE (which has always been grown around San Gimignano) and because it was usurped by an influx of INTERNATIONAL VARIETIES. However, by 2020 the tide had been stemmed, with 730 ha registered for the production of Vernaccia. W.S.

www.vernaccia.it

Vernatsch, German name for the generally undistinguished light-red grape variety SCHIAVA.

Veronelli, Luigi (1926–2004), Italy's most influential food and wine critic from 1956, when he founded the magazine *Il Gastronomo* and began to collaborate with Italy's major daily newspapers, news weeklies, and the national television network RAI-TV, until his death. Born into an affluent cosmopolitan Milanese family, Veronelli was an unabashed Francophile and a frank admirer of the French AOC system, in particular of its designated CRUS, a CLASSIFICATION which he

attempted to apply to Italian vineyards and their products in his many books on his country's wines. Polemical in character and a romantic anarchist in his political convictions, Veronelli long championed the cause of the small peasant proprietor and was a particularly bitter opponent of Italy's DOC systems, which he considered rigged in favour of the country's large commercial wineries. A trip to California in the early 1980s turned him into a promulgator of the BARRIQUE, then almost unknown in Italy, and his writing was extremely influential in spreading the use of small oak barrels in Italy. He can be credited with the discovery and identification of many of the country's better producers in the late 20th century, a role which won him a group of devoted friends and an equally large group of sworn enemies.

Belfrage, N., *Life beyond Lambrusco* (1984).

vers de la grappe, insect pest and an important cause of BOTRYTIS BUNCH ROT. This French term is generally used to refer to the European grapevine moth and the vine moth (see MOTHS).

vertical trellis, a vine-TRAINING SYSTEM widely used throughout the world in which the shoots are trained vertically upwards in summer. The system is commonly called vertical shoot positioning, or VSP. The shoots are held in place by foliage wires which, in turn, are attached to vineyard POSTS. In many vineyards there are two pairs of foliage wires, and commonly the vines are subjected to TRIMMING at the top and sides to maintain a neat, hedge-like appearance. Both SPUR PRUNING and CANE PRUNING are possible. This trellis system is widely used in Alsace, Germany, eastern Europe, the United States, South America, Australia, and New Zealand, with high vines (TRUNKS of about 1 m/3 ft) and relatively low-density plantings. The vineyards of Bordeaux, Burgundy, and Champagne are also vertically shoot-positioned, although the vines are planted closer together and the trunks are much shorter. R.E.S.

verticillium wilt, FUNGAL DISEASE which causes apparently healthy vines to collapse suddenly. The fungus *Verticillium dahliae* lives in the soil and can attack new vineyards. Young vines are usually affected, and often the vine recovers. There is no control apart from avoiding planting on sites where the fungus exists. Fortunately it is uncommon. R.E.S.

Vespaiola, white wine grape speciality of Vicenza in the VENETO region of north-east Italy, said to take its name from the wasps (*vespe*) attracted by the sugar levels of its ripe grapes. Its most famous product is the Torcolato sweet wine of BREGANZE. As a dry white wine, Vespaiolo (*sic*) is typically acidic and neutral if the grapes are not fully ripe, but a number of more complex examples are now appearing. Total plantings were just 9 ha/222 acres in 2015. It may have a parent–offspring relationship with VERNACCIA DI ORISTANO.

Vespolina, low-yielding red grape variety known almost exclusively in, and probably native to, the area around GATTINARA in the PIEMONTE region of north-west Italy. Commonly blended with its close relative NEBBIOLO, it was planted on just 88 ha/217 acres in 2015, occasionally in the OLTREPÒ PAVESE zone across the border in LOMBARDY, where it is known as Ughetta.

Veuve Clicquot, Champagne house as famous for its eponymous leader, the great champagne widow (*veuve* in French), as for its wines. Nicole Barbe Ponsardin (1777–1866) married François Clicquot, the son of the house's founder, in 1798. After the premature death of her husband in 1805, the 27-year-old widow took over the reins of the company, which she renamed Veuve Clicquot Ponsardin. Despite her youth, she steered the house carefully through the turbulent years of the First and Second Empires, defying Napoleon's blockades to ship the wine to Russia and finding an export market in virtually every European court. 'La grande dame de la Champagne' is

credited with inventing the RIDDLING process and adapting a piece of her own furniture into the first riddling table for that purpose. In 1818 she was first to elaborate a rosé champagne by addition of red wine from Bouzy. On her death, the company passed to her former chief partner, another shrewd operator, Édouard Werlé, who introduced the famous yellow label, still used for the NON-VINTAGE wine, and the house remained in the hands of the Werlé family until in 1987 it became part of the Moët Hennessy-Louis Vuitton group (see LVMH). The house style is based on Pinot Noir grapes and, in particular, those grown at Bouzy, where the house has large holdings. La Grande Dame is Clicquot's PRESTIGE CUVÉE, named, of course, after the widow. In 1990, the Champagne house purchased a majority stake in the WESTERN AUSTRALIAN winery Cape Mentelle and its New Zealand subsidiary CLOUDY BAY, completing the purchase in 2000.

Crestin-Billet, F., *Veuve Clicquot: La grande dame de la Champagne* (1992).

Vézelay, recently promoted (2017) Burgundy AOC near Avallon, south-west of Auxerre and CHABLIS, for white wines made from Chardonnay. The also attractive Pinot Noir vineyards remain as BOURGOGNE. J.T.C.M.

Victoria , third most important wine state in Australia in terms of volume of wine produced. From its nadir in the mid 1950s, when there were fewer than 30 wineries in operation, Victoria has recovered to the point where its viticultural map once again resembles that of the 19th century, populated by some 800 wine producers, more than any other state. A swing among local tastemakers towards subtler, lighter wines than was the Australian stereotype—with Chardonnay and Pinot Noir especially in FASHION—has thrust Victoria and its cooler regions into the spotlight in recent decades. But even these cooler spots are on notice, with CLIMATE

CHANGE prompting a widespread rethink of suitable sites and VINE VARIETIES.

Hubert de Castella came to Victoria in 1854 from his native Switzerland and was a leading figure in the golden age of Victorian viticulture up to 1890 (when it produced half the wine made in Australia). He wrote several books, the most famous entitled *John Bull's Vineyard*, a eulogy suggesting Victoria could supply England with all the wine it might ever need. Instead, a combination of PHYLLOXERA, changing land use, changing consumption patterns, the removal of inter-state duties, and the First World War saw the end of the hundreds of vineyards and wineries spread across the very cool southern half of the state.

What is now the North East Victoria Zone, with Rutherglen as its epicentre, became the focus of winemaking, producing a range of FORTIFIED WINES and red TABLE WINES, some of the latter almost indistinguishable from some of the former. Foremost among the former are the super-sweet TOPAQUES AND MUSCATS, fortified wines of unique style and extraordinary concentration of flavour. Rutherglen and Glenrowan to its south also produce rich, full-bodied dry reds (from mainly SHIRAZ and DURIF), as well as a range of other, less convincing, table wines, but with their very warm summer and autumn days (and cold nights) they are best suited to fortified wines.

The North East Victoria Zone also includes King Valley, Alpine Valleys, and Beechworth. Alpine Valleys and Beechworth provide a total contrast to Rutherglen and Glenrowan. Their ELEVATION (the highest King Valley vines are above 800 m/2,625 ft) creates a significantly cooler climate eminently suited to table wines, albeit with a wide spectrum of varieties. King Valley is the state's largest grape-growing region outside the Murray Darling/Swan Hill area and is an incubator for VARIETAL wines of every hue: Prosecco (GLERA), ARNEIS, VERDUZZO, GRACIANO, MARZEMINO, MONDEUSE, PETIT MANSENG, SAGRANTINO, SANGIOVESE, and TANNAT.

The Port Phillip Zone has five regions clustered around Melbourne: Yarra Valley, Mornington Peninsula, Geelong, Sunbury, and Macedon

Ranges. Well over 300 wineries here enjoy a range of climatic conditions all cooler than those of BORDEAUX, variously cooled by ELEVATION or MARITIME influences. Pinot Noir and Chardonnay are the dominant varieties, capable of producing wines of world class, with the Yarra Valley, Mornington Peninsula, Geelong, and the southern part of Gippsland leading the way.

Shiraz is sometimes seen as a newcomer in these parts, but in fact Craiglee (at Sunbury) has long made superb examples, evidenced by a cache of 1872 discovered almost 100 years later buried in the then defunct winery. Yarra Yering has been producing its No. 2 Dry Red for over 50 years, quietly using a little VIOGNIER—a move widely mimicked in recent decades, notably in Geelong and the Yarra Valley. In keeping with local drinking trends, a cooler articulation of Shiraz (often styled SYRAH to signal an elegant, medium-weight rendition) is on the rise in parts of the Port Phillip Zone. Both Cabernet Sauvignon and Merlot can be superb, too, especially with warmer vintages and appropriate VINEYARD SITE SELECTION. Pinot Gris remains extremely significant in many Victorian wine regions.

Heathcote is the darling of the Central Victoria Zone. The TEMPERATE climate and 500-million-year-old Cambrian soils—decompressed igneous greenstone which has become a vivid red-brown with age—produces some of Australia's most striking Shiraz, deeply coloured and velvety rich. Here, too, alcohol levels have become more moderate and Heathcote has seen a diversifying of its vineyard towards Mediterranean varieties including SANGIOVESE and TEMPRANILLO. Bendigo, which once included Heathcote, is likewise red-wine country, with Cabernet Sauvignon also excellent.

Goulburn Valley is the oldest Victorian region with a continuous history of viticulture thanks to Tahbilk, which still makes an iconic Shiraz exclusively from vines planted in 1860. Marsanne grows alongside Shiraz, Cabernet Sauvignon, and, of course, the ever-present Chardonnay. The newcomers, planted in 1990, are ROUSSANNE and VIOGNIER.

Upper Goulburn and Strathbogie Ranges are the cooler customers of Central Victoria on account of elevations rising to some 700 m/2,297 ft, although it is not enough to inhibit generous flavours and MOUTHFEEL in the Pinot Noir, Shiraz, and Cabernet Sauvignon of the Strathbogie Ranges. Riesling, Gewürztraminer, Pinot Gris, Chardonnay, and Viognier are the dominant white varieties.

The red-wine dominance continues into the Western Victoria Zone. The Pyrenees on the eastern side can provide Shiraz and Cabernet Sauvignon as sumptuous as that of Heathcote or Bendigo, but as you move west into the Grampians (with Great Western registered as a subregion in 2007), the subtly cooler climate yields more elegant wines with pepper, spice, and EUCALYPT flavours alongside vibrant red fruit.

Sparsely populated Henty in the far south-west is dramatically cooler; indeed on some criteria it is the coolest region on the Australian mainland. That's why grapes for sparkling wines initially made a home here, latterly joined by ultra-fine and intense Riesling, Semillon, Sauvignon Blanc, Chardonnays, and micro-quantities of Pinot Noir.

The North West Victoria Zone takes in the Murray Darling and Swan Hill regions on the Murray river as it meanders for 500 km/305 miles marking the border between New South Wales and Victoria before moving through South Australia's Riverland. The story is no different: modified hydroponics in desert sand with historically unlimited WATER provide sky-high YIELDS of at times surprisingly good-quality grapes. But recent DROUGHTS and increasing SALINITY have encouraged both more effective water usage and an increase in Mediterranean vine varieties suitable for dry climates.

J.H. & E.N.H.M.

SEE WEB LINKS

www.winevictoria.org.au

Vidal, white grape variety and a FRENCH HYBRID more properly known as Vidal Blanc or Vidal 256 and widely grown in CANADA, where

it is particularly valued for its winter hardiness. Grown to a limited extent in the Midwest and eastern UNITED STATES, particularly NEW YORK State, it is a hybrid of UGNI BLANC and one of the Seibel parents of SEYVAL BLANC. The wine produced, like Seyval's, has no obviously FOXY character and can smell attractively of currant bushes or leaves. Its slow, steady ripening and thick skins make it particularly suitable for sweet, LATE HARVEST (non-BOTRYTIZED) wines and ICE WINE, for which it, with RIESLING, is famous in Canada. Vidal-based wines do not have the longevity of fine Rieslings, however.

Vidiano, Greek light-skinned variety enjoying a revival on its homeland of CRETE, where it was grown on 195 ha/482 acres in 2021. Wines are richly fruited and fresh, sometimes blended with a more aromatic variety such as Muscat or Sauvignon Blanc. More concentrated examples are amenable to BARREL FERMENTATION.

Vidigueira , DOC subregion of the ALENTEJO in southern Portugal which marks the border between the upper and lower (hotter) parts of the region. However, Vidigueira's relative proximity to the coast and cold air descending from the Serra de Portel escarpment tempers the heat, hence the region's tradition of making white wine from ANTÃO VAZ. White wines (and old FIELD BLENDS of varieties such as Perrum, Diagalves, and Mateúdo) have received strong impetus from the revival of TALHA wines, of which Vidigueira is the heartland. They offer the spicy, textural appeal of ORANGE WINES, with mellow honeyed fruit. Modern red wines are well-structured; standout varieties include ALICANTE BOUSCHET and Tinta Grossa from Portugal's few remaining hectares. S.A.

vieilles vignes, French for OLD VINES.

Vien de Nus, red grape variety grown on 9 ha/22 acres in 2015, and mainly blended, around the town of Nus in Italy's Valle d'AOSTA.

Vienna , capital city of Austria and, unusually, a wine region in its own right. See WIEN.

Vietnam , South East Asian country with a history of viticulture dating from French colonial times. Recent attempts to revive viticultural traditions and make wine have had mixed results. The most suitable locations for conventional viticulture in this hot, humid country are in the highlands—on the slopes of Ba Vi Mountain west of Hanoi, for example, where VITIS VINIFERA vines were grown by French colonists about a century ago, or on the upper slopes of the central highlands. Contrarily, however, Vietnam's first commercial grape winemaking venture, the Thien Thai Winery, was established on the steamy southern coastal plain at Phan Rang, in Ninh Thuan province, 350 km/210 miles north-east of Ho Chi Minh City. The attraction was the existence of established vineyards producing substantial quantities of TABLE GRAPES, mostly from red-berried CARDINAL vines grown on PERGOLAS. The first wines, both still and sparkling, were released in 1995, but the winery was mothballed in 2002. Subsequently, two of Vietnam's largest food and beverage companies began drawing on grapes grown in Ninh Thuan for still and sparkling grape wines. Hanoi-based Thang Long Liquor uses primarily Cardinal, Shiraz, and Sauvignon Blanc for its grape wines; Lam Dong Foodstuffs, through its beverage subsidiary Vang Đàlạt and upmarket Chateau Dalat label, also grows Cabernet Sauvignon, Merlot, and Chardonnay. While many domestic wine labels rely on imported BULK WINE bottled locally, there are now a number of small-scale operations in Ninh Thuan committed to local grape wines. Under natural conditions, the southern vines bear almost continuously (see TROPICAL VITICULTURE). Systematic PRUNING has been adopted in some wine-grape vineyards, however, to induce three output peaks ('vintages').

D.G.

VIFA stands for variété d'intérêt à fin d'adaptation, literally 'variety of interest for adaptation' (i.e. grape varieties that might be suitable for a changing climate and environment). This term was introduced by the INAO in 2021 to allow the regulatory body of a PDO in France to apply for permission to plant, on an experimental basis for at least 10 years and within specific limits, up to 20 varieties (10 red and 10 white) that they believe might be suitable to overcome specific viticultural problems such as increased incidence of FUNGAL DISEASES, high temperatures, or DROUGHT. These may include both VITIS VINIFERA and authorized HYBRIDS. See also NEW VARIETIES and DISEASE-RESISTANT VARIETIES.

vigna is Italian for VINEYARD, while a vignaiolo is a vine-grower.

vigne is French for a VINE, and sometimes VINEYARD. Vigneron is French for a vine-grower, or for someone who is both grower and winemaker, whereas a viticulteur merely grows vines. The term vigneron is now used widely outside France for a wide range of people engaged in wine production.

A vignoble is French for a vineyard, although the term *vignoble* can be used more broadly, as in 'the entire French *vignoble*'.

Vignoles, also known as Ravat 51, late-budding, early-ripening FRENCH HYBRID popular in cooler wine regions in the Midwest and eastern UNITED STATES. It can make fresh, delicate white wine and is particularly well suited to sweet-wine production.

vigour in a viticultural sense is the amount of vegetative growth, an important aspect of any vine. This may seem of unlikely interest to wine drinkers, but it has significant effect on wine quality. Very low-vigour vines do not always have sufficient leaf area to ripen grapes properly, while high-vigour vines typically produce thin, pale wines, sometimes low in alcohol, wrongly thought to result from

OVERCROPPING. Vigour changes through a vine's lifetime, as discussed in VINE AGE.

High-vigour vines show a lack of BALANCE between shoot and fruit growth. Vigorous vineyards show rapid shoot growth in the spring, and shoots continue to grow late into the growing season. Shoots on vigorous vines have long INTERNODES, thick stems, large leaves, and many, usually long, LATERAL SHOOTS. Vigorous vineyards are generally, but not necessarily, associated with high YIELDS. Rank vegetative growth may produce so much SHADE that FRUITFULNESS declines, leading to even more vegetative growth and a loss of varietal character, colour, body, and general wine quality.

Vine vigour is easy to quantify using PRUNING WEIGHTS and other vine measurements as outlined by Smart and Robinson, and these approaches, along with SCORING, can be used as a form of quality control. For an alternative approach to the assessment of vine vigour using REMOTE SENSING, see NORMALIZED DIFFERENCE VEGETATION INDEX.

The vigour of a vineyard is essentially dependent on two features: the size and health of the root system; and the pruning level. First, what grows above ground is some sort of mirror of what grows below. A vine with a large and healthy root system will have the substantial reserves of CARBOHYDRATES and balance of HORMONES to support considerable vigorous shoot growth. On the other hand, a vine with a small and/or unhealthy root system, be it due to shallow soil, DROUGHT, root pests such as PHYLLOXERA, or diseases such as TRUNK DISEASE or ARMILLARIA ROOT ROT, will support only low-vigour growth.

Vines should be pruned to bud numbers relative to the amount of early shoot growth they can support. This is the concept of BALANCED PRUNING, and one criterion used is to retain at winter PRUNING about 25–30 buds per kg of pruning weight. Use of this sort of rule means that the subsequent shoot growth will be in balance with the vine's carbohydrate reserves, ensuring balance between shoot and fruit growth, as well as moderate vigour.

High vigour is a common problem of modern vineyards, for many and varied reasons. The vines may be planted in a region with a benign climate on too deep a soil, which is well supplied with water (from rainfall and/or IRRIGATION) and nutrients, especially NITROGEN (from natural fertility or FERTILIZERS or added COMPOST). Such soils are said to have high SOIL POTENTIAL in that they promote excessive vine vigour. Modern control methods can also keep vines free of stress associated with weeds, pests, and diseases. CANOPY MANAGEMENT techniques are used to maintain yield and wine quality in such situations.

An alternative approach is to devigorate the vines, most commonly by controlling the water supply, which is of course easier to do when irrigating in an arid climate than when vineyards are supplied by rainfall alone. COVER CROPS that compete for the available water are another useful tool. Other techniques include nutrient stressing, increasing crop load by leaving more buds at winter pruning or by growing shoots downwards as in the GENEVA DOUBLE CURTAIN training system. R.E.S.

Smart, R. E., and Robinson, M., *Sunlight into Wine: A Handbook for Winegrape Canopy Management* (1991).

Vijariego (also known as Bujariego and Vijiriega), white grape variety from the CANARY ISLANDS which produces distinctive dry wines there on vineyards totalling 167 ha/413 acres in 2020. A little is also planted in Andalucía.

Vilana, white grape variety that is native to and the most widely grown on the island of CRETE, with total Greek plantings of 546 ha/1,349 acres in 2021. It is solely responsible for the delicate spicy dry white Peza PDO, and is blended with THRAPSATHIRI for Sitia PDO.

Vila Nova de Gaia , or Gaia New Town, a city on the south side of the DOURO estuary from the Portuguese city of OPORTO where PORT is traditionally aged. Rising from the waterfront, long, single-storey buildings called LODGES line the narrow, cobbled streets. Under the clay-tiled roofs, shippers mature their stocks of port, as well as TASTING, BLENDING, BOTTLING, and selling it. Until 1986 the law required that all port destined for export had to be shipped from within the strictly defined area of the Gaia entrepôt. Port may now be shipped from anywhere within the demarcated Douro region so that export markets are open to small firms, QUINTAS, and CO-OPERATIVES without premises in Vila Nova de Gaia. R.J.M.

Villages, common suffix of an AOC name for a French wine. Generally speaking, an X-Villages wine must be made from one or several of a selection of communes whose produce is known to be superior to that of the rest of the X zone. See, for example, BEAUJOLAIS, MÂCON, and Côtes du RHÔNE.

village wine is a term used particularly in BURGUNDY for a wine which qualifies for an AOC that coincides with the name of the village or commune in which the wine is made. It contrasts with a lesser GENERIC wine, which takes the name of a region, and wines from PREMIER CRU and GRAND CRU vineyards.

Villány , wine region and PDO in HUNGARY extending over 2,390 ha/5,906 acres on the terraced southern and eastern slopes of the Villány Mountains. These mountains protect the vineyards from cold northern influences resulting in a special sub-MEDITERRANEAN CLIMATE. The soils consist of CALCAREOUS rocks deposited in the marine basins of the Mesozoic. Dolomite, MARL, and LIMESTONE are covered with sandy LOESS. This layer is sometimes mixed with limestone debris, having a higher concentration of CALCIUM. This is the cropland of more acidic wines, while the purely loess soil produces softer wines. Villány

is mostly known for its red BORDEAUX BLENDS, sometimes rather heavy and tannic but with good AGEING potential. Cabernet Franc grows well here, with the top VARIETAL examples labeled Villányi Franc. The everyday drinking wine is the softer PORTUGIESER, and KÉKFRANKOS is often used in blends. Some white wines are also made, mostly from Olaszrizling (WELSCHRIESLING), Chardonnay, and HÁRSLEVELŰ. G.M.

Villard is the common French name for a great French viticultural secret, their most widely planted HYBRIDS. Most are members of the vast SEYVE-VILLARD group.

In France, Villard Noir is Seyve-Villard 18.315 while Villard Blanc is Seyve-Villard 12.375. Villard Noir was planted all over France, from the northern Rhône to Bordeaux, and was treasured for its resistance to DOWNY MILDEW and ROT. Villard Blanc made slightly more palatable wine (though the must can be difficult to process). Both varieties yield prodigiously and for that attribute were so beloved by growers that in 1968 there were 30,375 ha/75,058 acres of Villard Noir and 21,397 ha of Villard Blanc in France (making them the fifth and third most planted black and white grape varieties respectively).

To the great credit of the authorities, and thanks to not inconsiderable bribes for GRUBBING UP, by 1998 these respective totals had been shaved to 3,245 ha and 1,129 ha, mainly in the Tarn and the Ardèche. In 2019 Villard Noir plantings were down to 986 ha, while Villard Blanc, now planted to a very limited extent in several American states, is grown on only 133 ha in France.

vin, French for 'wine' and therefore a much-used term (see below). Vin blanc is white wine, vin rosé is pink, vin rouge is red wine, vin mousseux is sparkling wine, and so on. For vin ordinaire, see VIN DE FRANCE. For vin biologique, see ORGANIC WINE. For vin blanc cassis, see KIR.

viña, viñedo, Spanish word for VINEYARD.

Vin de France, category created in 2009 for the most basic French wine, formerly called *vin de table*, known in the EU as WINE WITHOUT GEOGRAPHICAL INDICATION and in France as VSIG. Unlike the old *vin de table*, a Vin de France may be labelled with a vintage and/or vine variety, a change designed to make it more competitive with inexpensive VARIETAL wine produced outside Europe. On average this category accounts for less than 8% of all French wine, but it includes an increasing number of superior-quality wines made outside the tighter strictures of AOC/AOP and IGP regulations. See also FRANCE.

vin de liqueur, strong, sweet drink made by adding neutral grape spirit or eau de vie to GRAPE JUICE or MUST, so-called MUTAGE, either before or during FERMENTATION. The resulting liquids have an ALCOHOLIC STRENGTH of 16–22% but no secondary products of fermentation such as GLYCEROL or SUCCINIC ACID. Confusingly, the term is also used by the EU to refer to all FORTIFIED WINES. See LIQUEUR WINE.

The principal members of this special category of French specialities, known as *mistelles* (see MISTELA) if the fortification takes place before fermentation has started, are the PINEAU DES CHARENTES of Cognac country, its Armagnac counterpart FLOC DE GASCOGNE, MACVIN DU JURA (made from local MARC added to grape juice and tasting strongly of the former), and CLAIRETTE DU LANGUEDOC. Most vins de liqueur are pale gold, but soft, fruity rosé versions of both Pineau and Floc can be found in the regions of production. Vin de liqueur differs from VIN DOUX NATUREL in that the alcohol is generally added earlier, and the resulting drinks therefore tend to be, and taste, more spirit-dominated. Some Muscat de FRONTIGNAN may also qualify. Many wine regions have their own versions of this easy-to-make strong, sweet APERITIF: Champagne has its Ratafia, while the Languedoc has Cartagène. Where there are no regulations governing their production, they are sometimes made further along the scale towards vins doux naturels. Like vins doux naturels, these sweet wines can be

enhanced by serving them cool, and the wine in an opened bottle should retain its appeal for well over a week.

vin de paille is French for 'straw wine' (STROHWEIN in German), a small group of necessarily expensive but often quite delicious, long-lived, sweet white wines. These are essentially a subgroup of DRIED-GRAPE WINES made from grapes traditionally dried on straw. Cyrus REDDING's catalogue of wines produced in the early 19th century makes it clear that *vins de paille* were much more common then and, although he was most enthusiastic about 'Ermitage-paille' (from HERMITAGE vines), he found *vins de paille* in the JURA, ALSACE, and Corrèze. At about the same time some producers in RUST in Austria were also using the technique.

For much of the 20th century, no *vin de paille* was made in Hermitage, but Gérard Chave revived the practice with healthy, not late-picked, MARSANNE grapes in 1974, dried on straw in the attic, and has since been followed by CHAPOUTIER, Jaboulet, and others.

Average yields are minuscule once the grapes have been raisined, but the results, invariably sold in half-bottles, can be luscious in the extreme.

Less than 1% of Jura's wine production is of *vin de paille* from ARBOIS, L'ÉTOILE, and Côtes du JURA made mainly from SAVAGNIN, POULSARD, and/or Chardonnay grapes picked relatively early and typically dried in boxes in a ventilated loft for at least six weeks. The minimum POTENTIAL ALCOHOL allowed is 19% (14% in Hermitage). Jura producers must age their *vins de paille* for at least three years, including a minimum of 18 months in cask. The wines must have a natural ALCOHOLIC STRENGTH of at least 14% and tend to be less intensely sweet than in the Rhône, where the minimum alcohol level is just 12.5%. Some have an oxidative note (see OXIDATION) and all are capable of long AGEING. Many Jura producers avoid these appellation rules, making a lower-alcohol version or one with less OAK AGEING and labelled VIN DE FRANCE.

See also ALSACE and LUXEMBOURG.

Livingstone-Learmonth, J., *The Wines of the Northern Rhône* (2005).

Lorch, W., *Jura Wine* (2014).

Vin de Pays, French expression meaning 'country wine' which was adopted for an intermediate category of wines created in France in 1973, and formalized in 1979, to recognize and encourage the production of wines between VIN DE TABLE and AOC in quality. This category has been superseded by IGP wines.

vin de presse, French for PRESS WINE.

Vin de Savoie. See SAVOIE.

Vin des Glaciers, also known as Vin du Glacier, or Gletscherwein in German, 'glacier wine', is a local speciality in the Val d'Anniviers near Sierre in the Valais in Switzerland. The white wine, traditionally made of the now obscure RÈZE vine, comes from communally cultivated vines and is stored at high ELEVATIONS in casks refilled just once a year in a SOLERA system. The resultant product is deliberately MADERIZED and valued for its rarity.

vin de table, the old name for France's most basic level of wine, which, having been a copious embarrassment, has dwindled to a relative trickle. It has been replaced by VIN DE FRANCE.

vin doux naturel translates directly from French as 'a wine that is naturally sweet' but is a term used to describe a French wine speciality that might well be considered *un*naturally sweet. Nature's

sweetest wines contain so much grape sugar that the yeasts eventually give up the FERMENTATION process of converting sugar into alcohol, leaving a residue of natural sugars in a stable wine of normal alcoholic strength (see SWEET WINEMAKING). Vins doux naturels, on the other hand, are made by MUTAGE, by artificially arresting the conversion of grape sugar to alcohol by adding spirit before fermentation is complete, thereby incapacitating yeasts with alcohol and making a particularly strong, sweet half-wine in which grape flavours dominate wine flavours. They are normally made of the grape varieties MUSCAT and GRENACHE and should have an ALCOHOLIC STRENGTH of 15–18% and a POTENTIAL ALCOHOL of at least 21.5%. The minimum RESIDUAL SUGAR level varies from 45 g/l for Rasteau and Banyuls to 100 g/l for the various Muscat de Somethings.

The Greeks, happily ignorant of DISTILLATION, already knew how to make a sweet wine by adding concentrated MUST. Almost as soon as the techniques of distillation were introduced into western Europe, it was discovered that distilled wine, or alcoholic spirit, had the power to stop fermentation, thereby reliably retaining the sweetness so prized by our forebears. The Catalan alchemist ARNALDUS DE VILLANOVA (Arnaud de Villeneuve) of Montpellier University's then flourishing medical school perfected the process and in 1299 was granted a patent from the king of Majorca, then ruler of ROUSSILLON, which was to become the world's centre of vin doux naturel production.

This is essentially how PORT as we know it, created nearly 400 years later, is made strong and sweet, and the technique is also used in the production of MADEIRA and MÁLAGA. In each case, spirit is added when the fermenting must has reached about 6% alcohol, except that whereas the added spirit constitutes 5–10% of the final volume of a vin doux naturel, typically resulting in an alcoholic strength of just over 15%, the added spirit usually represents 20% of the final volume of port, whose alcoholic strength is closer to 20%. The spirit added to vins doux naturels is considerably stronger than that added to port, however: about 95% alcohol as opposed to the traditional 77% used in port FORTIFICATION. Nowadays, however, the spirit may

well come from exactly the same source, one of France's larger distilleries.

A young vin doux naturel therefore, like young port, tastes relatively simply of grapes, sugar, and alcohol (although, since some fermentation has usually taken place, it may contain a more interesting array of fermentation products than most VINS DE LIQUEUR, which are made by adding spirit before fermentation or just as fermentation is starting). Naturally aromatic MUSCAT BLANC À PETITS GRAINS grapes are therefore particularly well suited to the production of vins doux naturels designed to be drunk young (and, usually, chilled to offset the sugar and alcohol). The best known of these golden sweet liquids made from this Muscat vine variety was historically Muscat de FRONTIGNAN. The Languedoc has three other AOC vins doux naturels, however: Muscats de LUNEL, MIREVAL, and ST-JEAN-DE-MINERVOIS; and CORSICA has its Muscat du Cap Corse. The Muscat vin doux naturel made in the Côtes du Rhône village of BEAUMES-DE-VENISE is probably easier for non-locals to appreciate than the southern Rhône's other vin doux naturel appellation of RASTEAU, whose Grenache-based heady red and tawny sweet wines, some of them deliberately made RANCIO, have more in common with the vins doux naturels of Roussillon. The best of these tend to come from BANYULS and, like the best ports, owe their complex flavours to ageing, whether in cask, BONBONNE, or, occasionally, bottle. MAURY is a smaller appellation in the mountains with enormous (and occasionally realized) potential, although most wine made there now is dry TABLE WINE, while the extensive coastal RIVESALTES and Muscat de Rivesaltes appellations are much more varied. Grand Roussillon is a largely theoretical vin doux naturel appellation designed as a lesser Rivesaltes.

Non-vintage-dated vins doux naturels are common, particularly among the Languedoc Muscats into which a little of the previous year's output may be blended so as to smooth out vintage differences. In Roussillon, however, it is common to find indications of age and vintage dates, although most vins doux naturels are ready to

drink as soon as they are sold. Many, particularly the Muscats, benefit from being served young and chilled, but the alcohol preserves the freshness of wine in an opened bottle for at least a week.

vine, the plant, often known as the grapevine, whose fruit is transformed into wine.

A vine in its broadest sense is any plant with a weak stem which supports itself by climbing on neighbouring plants, walls, or other supports. Of this group of plants, the grapevine is the most famous and the most commercially important. (In this book the word 'vine' is used to mean the grapevine.) There are various forms of climbing vines which rely on different mechanisms for attachment. The so-called ramblers rest on each other, and some, as for roses, have spines to help adhesion. The grapevine is one of the so-called tendril climbers with TENDRILS on the stem; the garden pea has leaf tendrils.

Because the vine is unable to support itself, it is generally grown on TRELLIS SYSTEMS. Some TRAINING SYSTEMS still use trees for support, for example the *alberate* of Italy (see also ARBOREAL VITICULTURE). However, most vineyards of the world are trained to some combination of POSTS and wires. Vines can be trained so that they are free-standing, but this requires special PRUNING and TRAINING to keep the trunk short, otherwise the vine will fall over. The GOBELET of the Mediterranean region is the most widespread of the free-standing forms.

Most of the world's wine is made from VITIS VINIFERA, the *vinifera* species of the *Vitis* genus (see BOTANICAL CLASSIFICATION for a more detailed explanation of where the vine fits into the world of plants).

Grapevines are the world's most important fruit crop, with about 7.3 million ha/18.04 million acres of vineyards producing around 258 million hl/6,816 million gal of wine in 2022, as well as GRAPE JUICE, TABLE GRAPES, RAISINS, GRAPE CONCENTRATE, RECTIFIED GRAPE MUST, and limited industrial products. Wine production accounts for 70% of all vineyard output.

The grapevine is grown on all continents except Antarctica, but most of the world's vineyards are in Europe. Spain had nearly 1 million ha/2.4 million acres of vineyards in 2022, France just over 0.8 million ha, and Italy more than 0.7 million; between them these three countries produced more than half of the world's wine in 2022, Italy more than 19%, and France 17.7%. China has nearly 11% of the world vineyard area but produced only 1.6% of world wine in 2022.

Vinifera cannot tolerate extreme winter cold. Requiring warm summers for fruit maturation, the vine is grown approximately between the 10 and 20 °C isotherm in both hemispheres, or about between latitudes 30º N and 50º N, and 30–40º S, although CLIMATE CHANGE has seen the vine planted ever closer to the poles (see map of WORLD PRODUCTION, page 842). Principally in order to minimize the damage associated with FUNGAL DISEASES, the grapevine has traditionally been grown in MEDITERRANEAN CLIMATES with warm, dry summers and mild, wet winters. The ready availability of AGROCHEMICALS, and to a lesser extent disease-tolerant varieties, has allowed this range to be extended, especially since the Second World War. Winter DORMANCY is essential for vine longevity, and the hot and humid climates nearer the equator are not conducive to either grape production or wine quality (although see TROPICAL VITICULTURE).

Most of the world's vineyards are planted with traditional VINE VARIETIES, which have been perpetuated for centuries by vegetative PROPAGATION. Different CLONES of these varieties may also be distinguished.

Many viticultural practices are very traditional, especially in Europe, where in many cases they are prescribed by law. Cultural operations and the reasoning behind them are introduced under VITICULTURE, VINE PHYSIOLOGY, VINE DISEASES, and VINE PESTS. The effects of climate and soils are also discussed in, respectively, CLIMATE AND WINE QUALITY and SOIL AND WINE QUALITY.

See VINE MORPHOLOGY for discussion of the parts of the vine and VINE PHYSIOLOGY for details of how the vine functions. See also VINE

GROWTH CYCLE and, for a historical perspective, ORIGINS OF VINICULTURE.

Keller, M., *The Science of Grapevines* (3rd edn, 2020).

vine age, often observable by the size of a vine or the girth of its TRUNK. Vine age is widely considered a factor that can affect wine quality; many believe that, in general, older vines make better wine. Although there is no agreement and no legislation as to what constitutes 'old', vines more than 50 years old could justifiably be described as such. AOC legislation in many cases specifically excludes the produce of vines less than two or three years old, although this probably represents a bias against the fruit of very young vines rather than an affirmation of the qualities of older ones, and it is unusual for vines to crop before their third year. Some French producers deliberately exclude wine from vines under a certain age from their top bottlings and put it into SECOND WINES. The concept that older vines make better wine is much used in marketing wine in Europe (see OLD VINES) and has more recently been adopted by producers in regions as diverse as California, Chile, South Africa, and Australia, where the BAROSSA wine region is home to UNGRAFTED VINES which remain alive and producing, some after more than a century and a half. Conversely, some winemakers observe that young vineyards produce their highest-quality wine when relatively young. For example, in the world-famous JUDGMENT OF PARIS blind tasting in 1976, which first pitted California Cabernets and Chardonnays against top-quality red bordeaux and white burgundies, Stag's Leap Wine Cellars S.L.V. Cabernet Sauvignon 1973 came out on top, scoring more highly than Ch MOUTON ROTHSCHILD 1970 and Ch HAUT-BRION 1970, even though this was the first vintage of this Napa Valley red and the vines were only three years old. Both of these apparently opposed viewpoints may be correct, as will be discussed below.

After planting, conventional VINE TRAINING takes two to three years to form the vine framework. Bunches formed in these early years are often discarded in favour of vegetative growth. Once a vine is allowed to produce fruit and is about three to six years of age, it usually fills its allotted growing space above ground, then the YIELD and annual shoot growth normally stabilize, changing only with a major alteration to management or growing conditions. Vineyards which are protected from stresses, pests, and diseases; in a hospitable soil; and free from an excess or deficit of water (see WATER STRESS) or mineral nutrients (see VINE NUTRITION) can be very long-lived. An outstanding example is the famous vine at Hampton Court Palace near London, which is still producing large crops of MUSCAT grapes (under glass) despite having been planted in 1768. Another example is a vine reported to be over 400 years of age in the town of Maribor, SLOVENIA, which is still producing an annual crop of grapes that are vinified in celebration.

The VIGOUR and yield of many commercial vineyards may begin to decline after 20–30 years, and by 50 years many vineyards are yielding at such a low level as to be considered uneconomic, sooner if the wood is diseased (see TRUNK DISEASES) or has suffered physical damage from aggressive PRUNING or rough MECHANIZATION resulting in missing vines.

Below ground, however, the picture can be different. Champagnol defines three stages of ROOT GROWTH. During the first stage, the root system colonizes available space, and this takes until the seventh to tenth years, taking longer in poor soils and with low VINE DENSITY. In the so-called adult stage, there is little change in the volume of soil exploited, but in the final, senescent stage there is a supposed reduction in root activity. This can be from the effects of DROUGHT, from SOIL COMPACTION by machinery and TILLAGE or from lack of oxygen at depth. It has also been noted that root pests and diseases may weaken the root system, especially in the case of UNGRAFTED VINES infested with PHYLLOXERA. Long-term application of some fertilizers and spray materials can increase SOIL ACIDITY while

application of poor-quality IRRIGATION water can load the soil with salts, reducing root, soil, and vine health.

Grapevines are climbing plants that usually require external support. In cultivation, this is in the form of a TRELLIS SYSTEM, which may be complex, with numerous posts and wires, or simple, like the BUSH VINES which are the mainstay of many old vineyards. The above-ground framework of the vine may weaken with age due to the increased size and weight of the branches or via pathogen attack or mechanical damage. Annual winter PRUNING may weaken vines over time; the increasing number of pruning wounds can accumulate over years, allowing wood-rotting pathogens to invade (see TRUNK DISEASES) or restricting sap flow via dessication. While some pathogens can kill a vine within a few years, many are ever-present in vineyards and can be slow to cause obvious visible symptoms. Other less common pathogens that may cause rapid vine decline, preventing old age, are often under quarantine control or regional treatment to limit their spread, for example phylloxera, *Xylella fastidiosa* (see PIERCE'S DISEASE) or FLAVESCENCE DORÉE. The large amount of living wood and stored CARBOHYDRATES above and below ground in the structure of many old vines is thought to increase resilience to stress. Dead wood that is the result of pruning cuts or vine age can be decomposed by TERMITES or microbes, weakening the permanent structure of the vine.

The conventional explanation for improved quality with vine age is because of reduction in yield, and indeed for many celebrated vineyards the two go hand in hand. However, since older vines are often lower in vegetative vigour and physically large in size, there may be more balanced growth resulting in a more desirable MICROCLIMATE. This may in turn offer an indirect but plausible explanation for the effect of increasing vine age on wine quality.

This BALANCE between vegetative growth and fruit can also explain the apparent paradox that some vineyards seem to produce their best quality when very young, often with the first few crops. Such vines have very open CANOPIES and so in the first fruiting year there is

a favourable LEAF TO FRUIT RATIO. Commonly the vine is more vigorous in subsequent years, the shoots grow longer, and quality may be reduced because of increasing SHADE. Such vineyards can produce premium quality for the first few crops, then quality may decline until the vine is older and vigour is reduced. However, appropriate CANOPY MANAGEMENT can improve wine quality in these in-between years.

Vinea Wachau, full title Vinea Wachau Nobilis Districtus, is an organization representing most wine estates (nearly 200) in Austria's WACHAU region, called into existence in 1983 by a quartet including the late Josef Jamek, who helped define the styles of dry, unchaptalized wine (see CHAPTALIZATION) that came to characterize this region and eventually the wines of NIEDERÖSTERREICH as a whole. The Vinea Wachau established three stylistic tiers—STEINFEDER, FEDERSPIEL, and SMARAGD—imposing them on the region in the aftermath of Austria's 1985 wine scandal. In the 1990s, a Vinea Wachau executive board that featured Toni Bodenstein of Weingut Prager, Franz Hirtzberger, Emmerich Knoll, and F. X. Pichler was instrumental in achieving prestige for Austrian wine on export markets. In 2006 the Vinea Wachau strengthened its founding principles by publishing a Wachau Codex, unusual for the number of cellar procedures—including any form of must CONCENTRATION or separation (such as DEALCOHOLIZATION)—that it proscribes, as well as for its explicit rejection of any new WOOD flavours.

D.S.

vine breeding, the crossing of one vine variety or species with another to produce a new variety. Grapevines are highly heterozygous outcrossers and do not breed true from seed, which is the reason for their universal vegetative PROPAGATION. If both parent varieties belong to the same species (in practice, usually the European VITIS VINIFERA) of the VITIS genus, then the result is commonly called a CROSS (occasionally crossing), while the results of crossing varieties from more than one species (typically, a *vinifera* variety and a member of an AMERICAN VINE SPECIES) are commonly called HYBRIDS.

These NEW VARIETIES are traditionally created by dusting POLLEN from the male parent on to the receptive stigma of the female parent (see FLOWERS, VINE) and then germinating the seed from the berry which subsequently grows (although see GENETIC MODIFICATION for more recent techniques). There is a relatively low probability that any one seedling will become a useful variety, and extensive testing, probably over more than ten years, for viticultural and winemaking suitability is required before any new variety is released.

The convention is to express the female parent first, thus KERNER is a Schiava Grossa × Riesling cross, while BACO 22A is a Folle Blanche × Noah hybrid (Noah itself being an AMERICAN HYBRID).

Vine breeding was particularly important in the early 20th century, notably in France, Germany, and Romania, as a European response to controlling the spread of the PHYLLOXERA pest (see HYBRIDS and FRENCH HYBRIDS). Breeding of new varieties which combine high yields with good wine quality and resistance to pests and diseases has been an important activity in such German centres as Geilweilerhof and GEISENHEIM.

A main emphasis of grape breeding has been to combine the pest and disease resistance that exists in wild grape species with the high-quality fruit from *vinifera* varieties. For instance, VITIS AMURENSIS and VITIS RIPARIA contain genes for winter hardiness, and *vinifera* and *Vitis berlandieri* for lime soil tolerance (see CHLOROSIS). Among various *Vitis*

species can be found genetic resistance to the fungal diseases DOWNY MILDEW, POWDERY MILDEW, and BOTRYTIS BUNCH ROT; the bacterial diseases of CROWN GALL and PIERCE'S DISEASE; and the soil pests of PHYLLOXERA and NEMATODES. A desire to minimize the use of AGROCHEMICALS has encouraged breeding DISEASE-RESISTANT VARIETIES to combine these natural resistances, notably in Germany and the United States.

Because of increasing emphasis on a few familiar VINE VARIETIES and also the lingering suspicion of hybrids caused by the poor wine performance of the early French hybrids, some consumers view the results of breeding programmes with suspicion. Yet such programmes can offer the opportunity of an improved range of flavours and styles produced from vineyards which do not require any other means of pest and disease protection.

vine density is a measure of how closely spaced vines are in the vineyard, both within the row and between rows. The choice of vine spacing is one of the most fundamental decisions in PLANTING a vineyard, and between, even within, the world's wine regions there is enormous variation in spacing. The traditional vineyards of France's Bordeaux, Burgundy, and Champagne regions have about 10,000 plants per ha (4,050 per acre) and sometimes more, with vines spaced typically 1 m apart both within and between the rows. In many NEW WORLD vineyards, on the other hand, a spacing of 2.5 m/8

ft between vines along the row and 3.7 m/12 ft between rows, or 1,080 vines per ha, is quite common. Probably the most widely spaced vineyards of the world are those of the Vinho Verde region in Portugal, La Mancha in Spain, and some parts of Chile, Japan, and Italy (see TENDONE), with spacings as wide as 4 m by 4 m, or just 625 vines per ha.

Some argue that high vine densities lead to improved wine quality. It is true that many of the world's most famous vineyards, almost invariably in Europe, have very narrow spacings, and therefore high densities, but it is difficult to argue that this is a prerequisite for quality production. Narrow spacings are indeed appropriate to vineyards of moderate VIGOUR, which is a feature of the low SOIL POTENTIAL of these vineyards (see TERROIR and SOIL AND WINE QUALITY). Some New World winegrowers have been encouraged to plant high-density vineyards on fertile vineyard soils in expectation of matching the quality of famous European vineyards. The theory is that such dense planting will cause root competition and substantial devigoration, but this has infrequently, if ever, been demonstrated, and the result is often a high-vigour vineyard which is very difficult to manage and where SHADE reduces both quality and quantity. The outcome of this endeavour depends ultimately on SOIL WATER available to the vine. If well-supplied with water, high-density plantings do not lead to devigoration.

The belief that 'tight spacing' encourages wine quality was widely promulgated in the 1980s and 1990s in California. Despite many commercial experiments, it remains to be demonstrated that wine quality is automatically increased, while the costs of establishing and running such a high-density vineyard certainly are. Research and commercial experience in Europe indicate that close row and vine spacings are suited only to vineyards of low soil potential. In high-vigour situations, some New World vine-growers have responded by removing one vine in two down the row, and sometimes two in three. This has been found to restore vine BALANCE, and yield and quality have subsequently improved.

High-density vineyards are the traditional form of viticulture in many parts of the world, as spacing need only be sufficient to allow the workers unhindered access. Some very early vineyards were not even planted in rows but were haphazardly arranged. Before PHYLLOXERA invaded Europe, unhealthy plants could be replaced by LAYERING a cane from an adjacent vine. These considerations, and the fact that vines then were generally less vigorous, encouraged high-density vineyards, and densities were as high as 40,000 plants per ha, or just one-quarter of a square metre per plant. Once GRAFTING to ROOTSTOCKS developed as a response to phylloxera, however, then the additional cost of each plant encouraged lower vine densities. The introduction of first draught animals and then TRACTORS led to the planting of vineyards in rows with a further reduction in vine density.

Many New World vineyards were planted after the introduction of tractors, necessitating row spacings of about 3 m/10 ft or more for early and wide tractors, although over the last few decades tractor width has decreased to less than 2 m/6.5 ft. Over this period vine vigour has also increased, but this has not necessarily affected vine density since the modern tendency is to train shoots vertically upwards on a VERTICAL TRELLIS rather than allow them to sprawl into the row. By contrast, most European vine-growers have chosen to persist with narrow rows and to develop either narrow tractors or over-row tractors, known in France as *tracteurs enjambeurs*.

Vineyard density is a major consideration affecting the vineyard's yield, quality, cost of establishment and maintenance, and therefore profitability. Planting costs are proportional to the number of plants used; costs for TRELLIS SYSTEMS and DRIP IRRIGATION are higher with narrower row spacings. The time taken to till and spray is also greater when rows are closer together.

Under most circumstances, the YIELD of densely planted vineyards is higher, especially in the first years of the vineyard's life and with vines planted on low soil potential. R.E.S.

vine diseases. Diseases caused by microbes can limit the distribution of vines and affect both yield and quality. See BACTERIAL DISEASES, FUNGAL DISEASES, TRUNK DISEASES, VIRUS DISEASES, PHYTOPLASMA diseases, and the names of individual diseases. See also CLIMATE EFFECTS ON VINE DISEASES.

vine foliage lifter, machine which lifts vine foliage in the growing season. Once the foliage is vertical, it can be secured by WIRES and is then well placed for TRIMMING to maintain a constant CANOPY outline. This is a particular aid to CANOPY MANAGEMENT. See also SHOOT POSITIONING.

vinegar, sour liquid condiment that depends etymologically, and often materially, on wine. The French word for it, composed of *vin* (wine) and *aigre* (sour), is a direct descendant of its Latin equivalent. Not just wine but any solution containing a low concentration (less than 15%) of ETHANOL will turn to vinegar if exposed to OXYGEN. The ethanol is oxidized first into an ALDEHYDE and then to ACETIC ACID by the oxygen in the atmosphere. Winemakers over the centuries have learnt to shelter wine from the action of atmospheric oxygen, and nowadays they will do all they can to prevent their wines turning to vinegar, 'vinegary' being a tasting term of great disapprobation (while 'winey' is quite a compliment when applied to a vinegar). Once the VOLATILE ACIDS in a wine have reached a certain point, however, it can have a future only as wine vinegar.

The OXIDATION of any dilute aqueous alcohol solution is greatly hastened by the action of a group of bacteria known as ACETOBACTER from the environment. These bacteria also hasten the reaction of some of the alcohol with some of the newly produced acetic acid to form the ESTER known as ETHYL ACETATE. This compound, when added to the tart taste of acetic acid, gives the complex character to a good wine vinegar.

The everyday vinegar of the marketplace varies geographically. In southern Europe wine vinegar is the norm, for example, while in northern Europe malt, cider, and distilled vinegars predominate, and in the Far East rice vinegar is most usual.

Today a wide range of vinegars are produced, many flavoured with herbs and fruits, some, such as Italian balsamic vinegar, given BARREL AGEING according to rules as strict as those governing AOC wine production. The most powerful vinegars are so strong in ethyl acetate that their flavour can overpower that of a subtle wine. In foods served with subtle wines, wine itself can be used as a condiment, contributing the same sort of ACIDITY as a vinegar would have done. See also VERJUS.

A domestic vinegar SOLERA is one solution for LEFTOVER WINE.

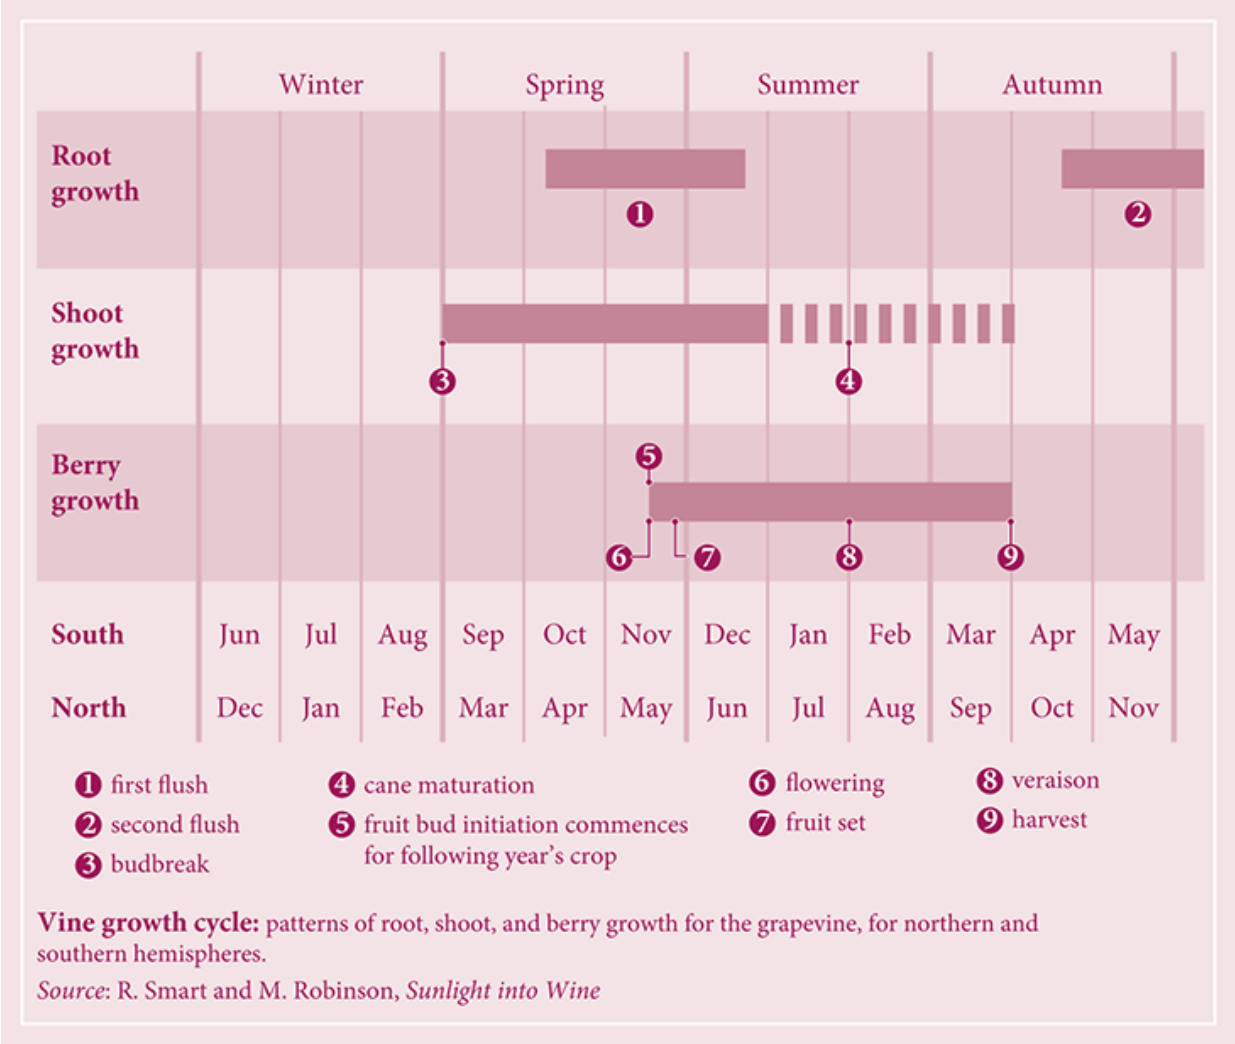
vinegar fly. See DROSOPHILA.

vine growth cycle, the annual march of the vine's development, which begins at budbreak in the spring and concludes at leaf fall in the autumn. There are distinct developmental stages along the way (see PHENOLOGY), the principal ones being BUDBREAK, FLOWERING, FRUIT SET, VERAISON, RIPENING, HARVEST when the grapes are mature, and LEAF FALL. The pace of development between these phenological stages varies greatly with vine variety. Very early varieties, such as MADELEINE ANGEVINE, go through the stages up to ripeness in a short time and can therefore ripen in regions with a short growing season and relatively cool temperatures. In late varieties, such as MOURVÈDRE, CARIGNAN, and CLAIRETTE, all stages are prolonged, and much more heat and time are needed to bring them to maturity. The length of the growth cycle also depends on climate, especially temperature. In hot regions, the period from budbreak to harvest may be as short as 130 days for early varieties, but in cooler regions this period can be over 200 days.



Vine growth cycle: patterns of root, shoot, and berry growth for the grapevine, for northern and southern hemispheres.

Source: R. Smart and M. Robinson, *Sunlight into Wine*

The vine often begins to grow later in the spring than most other deciduous plants, when the average air temperature is normally about 10 °C/50 °F in cool climates. The first sign of impending growth is vines BLEEDING as the soil warms, then the BUDS swell, and eventually the first tinges of green are seen in the vineyards as the SHOOT TIPS burst from the buds. The young shoots grow very slowly at first, producing small leaves on each side of the shoot. This early shoot growth depends on the reserves of CARBOHYDRATES stored in the vine, but soon the leaves are old enough for PHOTOSYNTHESIS and to produce the carbohydrates which become the tissue of further shoot growth.

After about four weeks in warm climates, the principal period of most rapid shoot growth begins. Shoots may grow more than 3 cm/1 in a day, and differences in shoot length can be observed from day to day. Shoot growth slackens at flowering, 40–80 days after budbreak depending on TEMPERATURE, but can continue to the end of the season under conditions of mild temperatures and over-generous supplies of water and NITROGEN. More commonly, especially for DRY-FARMED vines, WATER STRESS reduces shoot growth between flowering and veraison, and it may cease altogether later in the season. The shoot tips are sometimes TRIMMED but will often grow again from lateral buds.

Small flower clusters are apparent on the young shoots as buttons, and in the few weeks before flowering the STEMS and the individual flowers are obvious. Flowering takes place when the average daily temperatures are about 15–20 °C/59–68 °F and is followed by the so-called fruit-set process.

The next significant stage is that of veraison, about 40–50 days after fruit set, when the green, hard berries, which have grown to about half their final size and contain low concentrations of SUGARS but are high in organic ACIDS, soften and change colour to either red-black or yellow-green, depending on the variety. The berries begin rapidly to build up sugar and accumulate carbohydrate reserves in the roots, trunk, and ARMS. (See RIPENING.)

The most appropriate date of harvest depends on the desired stage of RIPENESS for WINEMAKING. It is earliest for sparkling wines, intermediate for TABLE WINES, and delayed for DESSERT WINES and FORTIFIED WINES. Harvest date may also be influenced by weather conditions and by disease levels (see BUNCH ROTS). Fruit ripening normally proceeds quickly in hot areas, with rapid increases in sugars and PH and a decline in ACIDITY, especially MALIC ACID. In cooler regions the rate of ripening is slower, and the fruit typically has lower sugars and higher acidity. Rainfall near harvest can cause problems due to berry splitting, BOTRYTIS, and other bunch-rotting fungi (see ROT). After rain, there is normally a rush to harvest grapes while they are still sound.

Leaf fall, the least precisely marked of all the developmental stages, indicates the end of the season. Some leaves may fall off during the growing season, especially if the vine comes under stress, for example from DROUGHT, disease, or SHADE. A significant proportion of the leaves may also be removed by MECHANICAL HARVESTING. With continued warm and sunny weather following harvest, the leaves remain healthy and are photosynthetically active in replacing carbohydrate reserves in the vine trunk and roots. Once these levels are built up, the vines often lose their green chlorophyll colour and turn yellow. The first FROST or the low temperatures of the winter season usually cause leaf fall, and the vines are then in a dormant state. After PRUNING in winter, the vines are ready for the growth cycle to begin again.

vine guards, plastic tubes which became popular internationally in the 1980s and 1990s to protect young vines. As well as protecting vines from WIND, they also protect from HERBICIDES and vineyard PESTS, especially rabbits, and reduce vine-training costs, although in warmer wine regions they can create an excessively hot MICROCLIMATE around the young plant. The guards are normally in place for one year, sometimes two. Wine tourists now witness coloured vine guards as the most obvious feature of new plantings. R.E.S.

vine identification. See AMPELOGRAPHY and DNA PROFILING for details of these two very different methods of identifying different VINE VARIETIES.

vine improvement, a group of practices designed to improve vine planting material for the benefit of vineyard YIELD and the quality of the fruit and wine produced. This is currently focused on eliminating harmful VIRUS DISEASES and also on genetic improvement by CLONAL SELECTION. Some virus diseases such as LEAFROLL can have dramatic effects on yield and wine quality and are transmitted by infected planting material. More recently there has been concern about fungal TRUNK DISEASE infections, also spread by PROPAGATION. Clonal selection is a technique which, by identifying and selecting high-performance vines for propagation, can achieve both elimination of disease and genetic improvement. See also VINE BREEDING.

Although virus diseases had affected European vines since the end of the 19th century, it took some time for preventive action to be taken on a national scale. The first attempt at controlling the quality of planting material in France was made in 1944, when the Section de Contrôle des Bois et Plantes de Vigne was formed (its functions now subsumed within FranceAgriMer, the intermediary body between the French ministry of agriculture and the grape and wine sectors), charged with avoiding the spread of virus diseases and also with ensuring that all rootstocks used had sufficient resistance to PHYLLOXERA. Previously, NURSERIES had been free to propagate whichever vines they chose, with sometimes disastrous effects for their clients; instead they were encouraged to take healthy CUTTINGS from specially planted and disease-free MOTHER VINES.

In Germany there has been a high regard for the health of buds and ROOTSTOCK for GRAFTING, and rigorous clonal selection programmes and registration of CLONES has ensured high-quality planting material. Similar schemes operate in other European countries.

In non-European countries there has also been an awareness of the importance of quality control of propagation material. After the Second World War, the California wine industry created a model system for improving the quality of planting material. Research at the University of California at DAVIS had demonstrated the importance of

virus diseases and had shown how they might be detected. A so-called 'clean rootstock program' was developed which aimed to distribute only virus-free cuttings to nurseries, using THERMOTHERAPY and INDEXING in particular to produce virus-free plants. This has subsequently become known as FOUNDATION PLANT SERVICES (FPS) and has distributed high-health vines, now produced by TISSUE CULTURE and improved virus testing, all around the world. Vine improvement began in Australia in the 1970s and in New Zealand in the 1980s, with such schemes becoming less centralized over time. In New Zealand, the Bragato Research Institute in Marlborough has adopted this role. R.E.S.

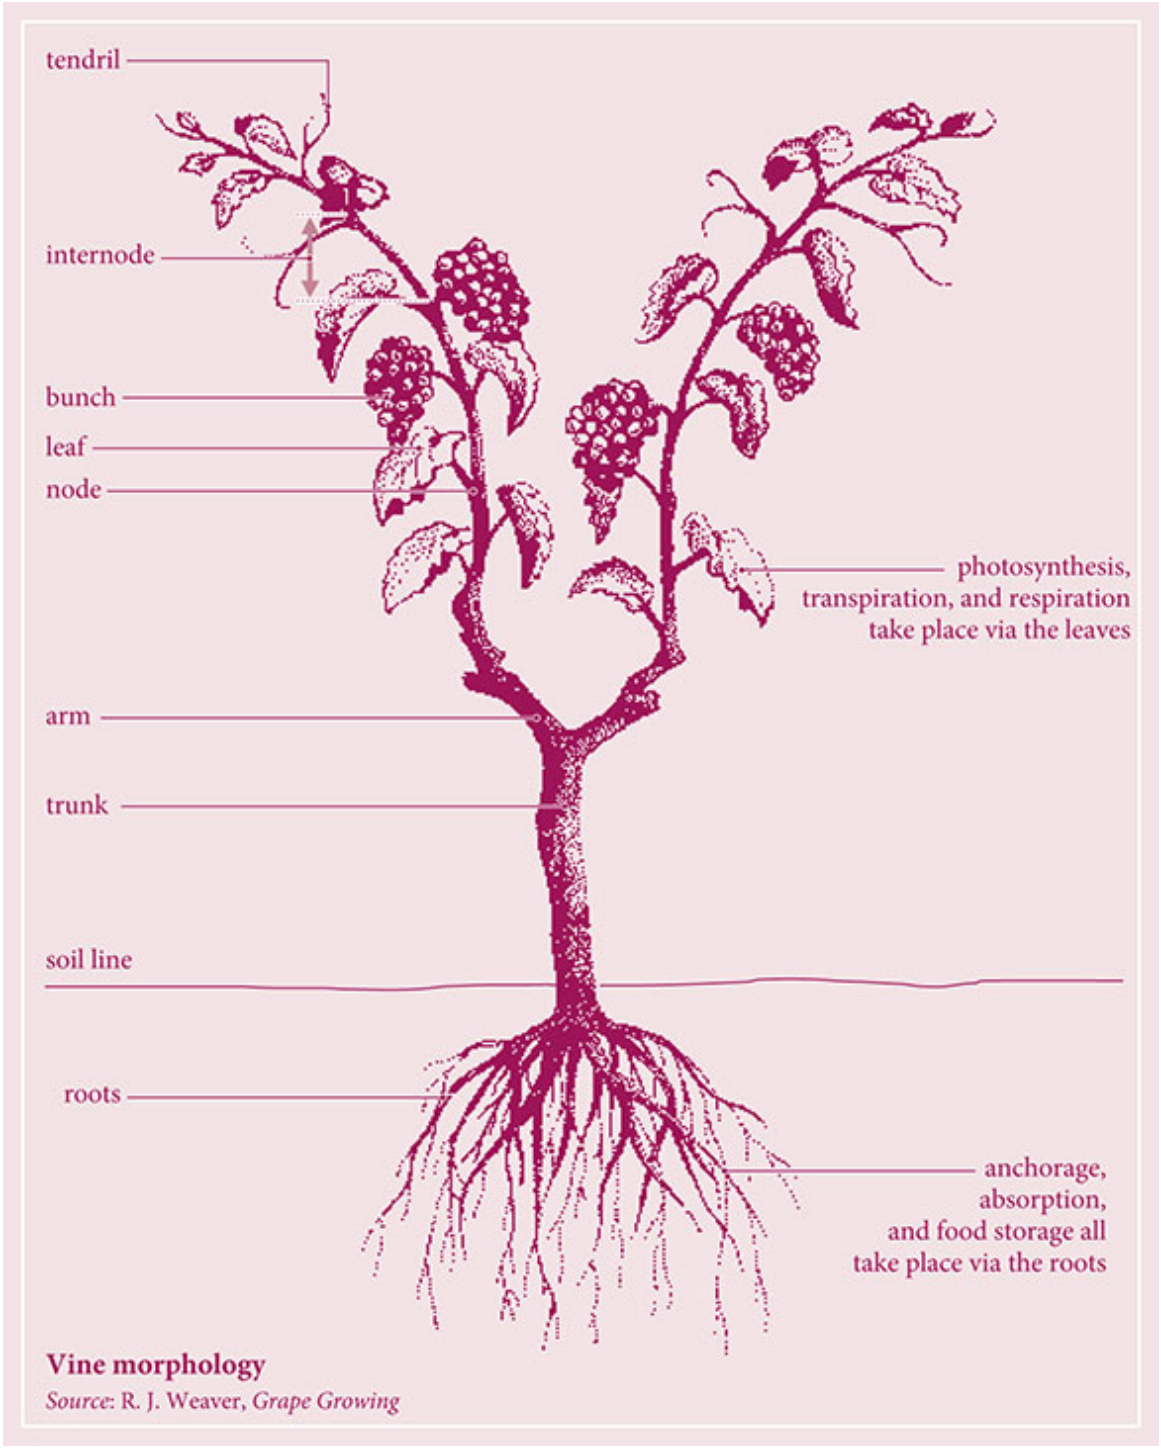
vine management, a term embracing all management practices in the vineyard, including especially SOIL PREPARATION and DRAINAGE; PRUNING and CANOPY MANAGEMENT; use of FERTILIZERS, MULCHES, and COVER CROPS; TILLAGE and WEED CONTROL; use of FUNGICIDES and PESTICIDES; IRRIGATION; vine TRIMMING and LEAF REMOVAL; CROP THINNING to control YIELD; and HARVEST methods. See also VINEYARD MANAGEMENT COMPANY.

vine morphology is the study of the form and structure of the vine plant, as distinct from VINE PHYSIOLOGY, which is the study of its function. See ANTHER, ARM, BEARER, BERRY, BRUSH, BUD, BUNCH, CALYPTRA, CAMBIUM, CANE, CELL, CORDON, FLOWERS, GRAPE, HEAD, INFLORESCENCE, INTERNODE, LATERAL SHOOT, LEAF, NODE, OVARY, PEDICEL, PERICARP, PETIOLE, PHLOEM, POLLEN, PULP, ROOT, SHOOT, SPUR, STAMEN, STEM, STOMATA, TENDRIL, TRUNK, VINE, WATER SHOOT, and XYLEM.



B.G.C.

vine nutrition, the supply of inorganic nutrients (also called mineral nutrients or nutrient elements) to the vine. Vines, like other plants, require the essential macronutrients NITROGEN, PHOSPHORUS, POTASSIUM, SULFUR, CALCIUM, MAGNESIUM, and chlorine (at

concentrations greater than 1,000 ppm in their tissues), as well as the micronutrients MANGANESE, IRON, ZINC, COPPER, MOLYBDENUM, and BORON (at concentrations less than 1,000 ppm in their tissues). See MINERALS.

Among horticultural plants, the vine is regarded as having low nutrition requirements. A common but conservative recommendation for vineyards, depending on the soil and the grower's objectives for the wine to be made, would be 0–50 kg/ha nitrogen, 0–25 kg/ha phosphorus, and 0 to 100 kg/ha potassium. These low requirements reflect the low levels of nutrients that are removed from the vineyard each year by the grape HARVEST. (See SOIL NUTRIENTS.)

Measurements have been made in many countries of the amounts of elements contained in the grapes picked and also in the leaf litter and winter prunings. These values vary with region, variety, and yield but are in the range of 12–24 kg/ha of nitrogen, 3–6 kg/ha of phosphorus, and 25–40 kg/ha of potassium for a 10 t/ha crop. A general recommendation therefore would be to apply this amount of fertilizer if there were any doubt that the vineyard soil would be able to supply it. In general, SOIL TESTING before PLANTING can indicate any likely deficiencies. In mature vineyards, the standard procedure is to test either the leaves or the leaf stalks (PETIOLES) for their nutrient content and apply fertilizers only as the need is indicated. Grapevine leaves can show distinctive symptoms of some nutrient deficiencies, but for others an experienced eye is necessary. For many crops, an annual addition of fertilizer will do little harm if it is not needed. For vines, however, such an addition is likely to be unnecessary and even wasteful since their needs are low, and there is always the danger of over-fertilization, especially with nitrogen, which can directly and indirectly reduce wine quality. Furthermore, repeated applications of nitrogen as ammonium-based or urea fertilizers leads to acidification of the soil over time. Similarly, high levels of potassium in soils can reduce wine quality because of increased wine PH.

Continued use of the same PARCEL of land for viticulture over extended periods of time reduces the levels of nutrients. Studies of old vineyard soils in Bordeaux have shown that fertility can be

restored by heavy applications of ORGANIC MATTER, LIME, phosphorus, and potassium. Organic matter such as MULCHES, COMPOST, and animal manures can be used to fertilize vineyards, but they are typically lower in nutrient content and may be more expensive. However, they often improve SOIL STRUCTURE by their organic-matter content. Such forms of fertilizer are favoured for ORGANIC VITICULTURE.

Although research shows little connection between nutrition of the vine and a wine's quality or specific character, other than through influences on vine VIGOUR, there is a perception that soil directly affects wine character by giving wines a special chemical signature that is unique to the site. Recent studies in Canada and elsewhere have shown that the vineyard origin may be determined by analysis of a wine's trace elements, but there is not necessarily any relationship to wine character. See MINERALS for more explanation; see also SOIL AND WINE QUALITY and TERROIR. R.E.S. & R.E.W.

vine pests can make viticulture uneconomic and can have drastic effects on wine quality unless controlled. They include ANIMALS, INSECTS, and NEMATODES (while VINE DISEASES include the microorganisms BACTERIA, FUNGI, PHYTOPLASMA, VIROIDS, and VIRUSES).

The principal commercial wine grape VITIS VINIFERA is indigenous to Eurasia, while the majority of severe vine pests and diseases come principally from east and south-east North America. Their accidental introduction to Europe from the 1850s onwards had dramatic consequences for local viticulture. The fungal disease POWDERY MILDEW was bad enough, but fortunately a control was soon at hand; the insect pest PHYLLOXERA was not so easy to control, and for a period following its introduction in 1863 the entire French wine industry was

threatened. Fortunately it was solved by GRAFTING *vinifera* vines on to ROOTSTOCKS derived from AMERICAN VINE SPECIES, which have natural resistance to phylloxera. This practice is now used worldwide.

In general, vine pests are easier to control than diseases, although the AGROCHEMICALS used to control insects (PESTICIDES) are among the most potent used in viticulture. The modern tendency is to depend less on pesticides and to develop strategies such as INTEGRATED PEST MANAGEMENT (see also BIOLOGICALS). Phylloxera is a threat to only a small proportion of the world's vineyards, as an overwhelming majority are grafted to rootstocks considered resistant. However, at present there is only limited chemical control of the insect pest MARGARODES, which is currently confined to a few vineyard regions of the southern hemisphere.

Vine pests can have dramatic effects on wine quality. At one end of the spectrum are the pests causing severe vine stress, as for example with root damage due to NEMATODES or phylloxera. This effect is frequently transient as it is a prelude to death and/or vine removal (see GRUBBING UP).

The following are some examples of how some pests can affect vines and reduce wine quality. Leaf area removal by ANTS, BEETLES, deer, kangaroos, LOCUSTS, MOTHS, rabbits, and SNAILS can jeopardize PHOTOSYNTHESIS and grape RIPENING. Leaves can also be damaged and photosynthesis reduced by LEAFHOPPERS and MITES. Vine growth and yield are reduced by attacks on roots from gophers, badgers, phylloxera, margarodes, nematodes, and squirrels, as well as by destruction of the trunk and arms by BORERS and TERMITES. Monkeys can cause significant damage to shoots, leaves, and fruit in JAPAN, as can elephants in Thailand. Damage to the grapes themselves by insects and BIRDS can lead to BUNCH ROTS, which can be spread by FRUIT FLY. Some pests can taint grapes, as for example the LADYBUG, or the honeydew of MEALYBUGS and SCALE. Last but not least is the very important role of pests in carrying (vectoring) diseases. The dreaded and lethal bacterial PIERCE'S DISEASE is spread by leafhoppers,

as is the phytoplasma disease FLAVESCENCE DORÉE. Important VIRUS DISEASES that can substantially reduce wine quality and yield are spread by nematodes and mealybugs.

For more detail, see major entries under ANIMALS, BEETLES, BIRDS, DROSOPHILA, INSECT PESTS, MITES, NEMATODES, and PHYLLOXERA; other entries are to be found under the pests' common names. R.E.S.

vine physiological status, term often used to describe the condition of the vine. How the vine is responding to its environment is a most important consideration for the production of premium-quality wine, especially during the fruit RIPENING period, but its status during the preceding year may also affect YIELD. R.E.S.

vine physiology, the science of the function of the VINE, including the growth and development of the vine shoot and root systems, its fruiting, and the major physiological processes such as PHOTOSYNTHESIS, TRANSLOCATION, and TRANSPIRATION. Physiology is also concerned with controls on plant growth and development, including both environmental and internal control by HORMONES. Both VINE NUTRITION and degree of WATER STRESS are affected by the vineyard soil, and TEMPERATURE and SUNLIGHT are the most important climate influences.

The vine's physiology can be manipulated by vineyard management techniques to alter growth, yield, and quality. For example, decisions on TRAINING SYSTEMS and PRUNING levels will alter the light incident on leaves, thus affecting photosynthesis and sugar supply to the grapes during RIPENING. IRRIGATION is another important form of manipulation. The term VINE PHYSIOLOGICAL STATUS is often used to describe the condition of the vine, as for example the degree of water stress it is experiencing. Manipulating such conditions is the aim of the vineyard manager intent on maximizing yield and/or wine quality. R.E.S.

vine products, the range of products produced from the vine. The GRAPEVINE is the world's most important fruit crop, and WINE and its brandy distillates are by far the most important of its products. Other products include RAISINS, TABLE GRAPES, GRAPE JUICE, GRAPE CONCENTRATE, VINEGAR, VERJUS, grapeseed oil, and RECTIFIED GRAPE MUST. There are other minor products: grapevine cuttings can be used for PROPAGATION or even occasionally for barbecue firewood; vine leaves are used in Middle Eastern and Greek cuisine and for wrapping certain cheeses; cosmetics based on grapevine products have been developed; and pharmaceutical companies have even started selling grape-derived RESVERATROL tablets with supposed HEALTH benefits.

R.E.S. & J.E.H.

vine-pull schemes have been instituted in various parts of the world at different times, generally in response to a perceived wine SURPLUS.

In the late 1980s and early 1990s, smallholders in the south of France and Italy in particular took advantage of substantial financial inducements to abandon viticulture on all or part of their land in an effort to drain the European WINE LAKE. About 300,000 ha/741,000 acres of French vineyard and about 400,000 ha of Italian vineyard were ripped out between the late 1970s and 1991. France's total vineyard was reduced by a further 80,000 ha and Italy's by about 150,000 ha between 1991 and 1996, while a further 284,000 ha were ripped out in Spain and 126,000 ha in Portugal. In the following decade, the uptake was greatly reduced, with just 30,000 ha grubbed up, mainly in France.

As a result of the EU reforms of 2008, there were further financial incentives to grub up vines in much of Europe, but this time farmers

were able to apply directly to the EU. As a consequence, 161,164 ha/398,244 acres of vines were grubbed up between 2008 and 2011, equivalent to 10% of the European vineyard area. During the same period, 111,364 ha/275,186 acres were grubbed up without the inducement of a subsidy. However, this has not necessarily resulted in a reduction in wine production. In SPAIN, for example, vineyard restructuring has increased yields despite the ripping out of 150,000 ha of vines.

Such schemes are not exclusive to the EU. An even more comprehensive vine-pull scheme was enacted within a single country, the Soviet Union, as part of GORBACHEV's attempts to curb alcohol consumption. Between 1985 and 1990, the total area under vine in the old USSR fell from more than 1.3 million ha/3.21 million acres to 880,000 ha/2.2 million acres.

Other national vine-pull schemes may be directed at particular types of vine in an effort to reduce production of certain wine types—in recent history usually wine of the most basic sort. Such schemes were applied in both ARGENTINA and NEW ZEALAND in the late 1980s, for example.

For details of the mechanics of pulling out vines and why a grower might do so, see GRUBBING UP.

vine removal. See GRUBBING UP.

vine spacing. See VINE DENSITY.

vine training, the process of establishing a vine framework in the required shape. It may begin in summer by tying down and TRIMMING growing shoots, followed by suitable winter PRUNING. Normally vines are trained to a supporting structure which may be as simple as a STAKE in the ground or a more complex TRELLIS SYSTEM made from wire and wood, metal, or concrete posts. Training is normally complete within the first two or three years of a vine's life and is well

established before grape production begins. It will, however, take longer where vines are planted at wide distances apart and with complex trellis systems such as the TENDONE. Training normally consists of forming the TRUNK, the CORDONS or HEAD, and any ARMS required.

See under TRAINING SYSTEMS for more details of individual forms.

R.E.S.

vine-training systems. See TRAINING SYSTEMS.

vine varieties, distinct types of vine within one species of the vine genus VITIS (see also BOTANICAL CLASSIFICATION). Different vine varieties produce different varieties of grape, so that the terms 'vine variety' and 'grape variety' are used almost interchangeably. Each variety of vine, or grape, may produce distinct and identifiable styles and flavours of wine. 'Vine variety' is *cépage* in French, *cepa* in Spanish, *Rebsorte* in German, *vitigno* in Italian, and *casta* in Portuguese. Professional botanists favour the term grapevine CULTIVARS.

All of the vine varieties we know today initially originated from WILD VINES. Domestication was made possible by propagating the best vines (see ORIGINS OF VINICULTURE) either by CUTTINGS or LAYERING (see PROPAGATION), thus producing genetically identical new plants. Afterwards, new vine varieties could originate from natural CROSSES between the vine varieties that had been selected, or between vine varieties and wild vines, or by selecting other wild vines.

Most important vine varieties used to produce wine are of the European vine species VITIS VINIFERA. A number of varieties of AMERICAN VINE SPECIES and their AMERICAN HYBRIDS have also been used to make wine, however, although many suffer a bad reputation because of the resultant wines' FOXY character (the dark-skinned NORTON is a notable exception). American species are also used as ROOTSTOCKS. Wine has also been made from a range of Asian vine varieties and from the FRENCH HYBRIDS.

It is clear that specific vine varieties were recognized in ancient GREECE and ROME, since some are already described in CLASSICAL TEXTS such as those of Pliny and Columella (see ANCIENT VINE VARIETIES). The extent to which the vine varieties of Europe originate from wild vines or were introduced is not known. Also, with the fall of the Roman Empire, cultivated vineyards were abandoned, and such varieties as were deliberately cultivated presumably interbred with local wild vines and native *vinifera*. The result of this intermixing over time is that many European regions have developed their own INDIGENOUS VARIETIES.

There are between 5,000 and 10,000 known varieties of *vinifera*. Ampelographers Pierre Viala and Victor Vermorel listed about 5,000 different varieties in their great seven-volume AMPELOGRAPHY published between 1901 and 1910. Many of these were synonyms, and Robinson, Harding, and Vouillamoz proposed a total of 1,368 varieties cultivated around the world for commercial wine production in 2012, although another 200 or so could now be added to that total. Thousands of other varieties exist in grape germplasm collections, but they are not cultivated for commercial bottling and sale. VINE IDENTIFICATION and the study of individual varieties' characteristics and aptitudes is a scientific activity known as ampelography, recently supplemented by DNA PROFILING.

Vine varieties are often named for the colour of their berries, with many French varieties, for example, coming in *noir* (black), *rouge* (red), *violet*, *rose* (pink), *gris* (grey-pink), *jaune* (yellow), *vert* (green), and *blanc* (white) hues. This book uses the convention of adopting a capital letter for each word in a vine variety's name (except prepositions), without quotation marks, even though 'Pinot Noir' would be botanically more correct for a cultivar name. Examples of MUTATIONS are Pinot Blanc and Pinot Gris, while Sauvignon Vert is a quite different variety from Sauvignon Blanc. See individual variety names for more details.

Varieties were classified and grouped into families by Levadoux, but DNA profiling is now shedding light on the true origin for many varieties and being harnessed to yield the pedigrees of both

traditional and modern vine varieties. Varieties can be broadly grouped into three major botanical categories called PROLES, which are related to their geographical origins and to some extent their end use. Varieties can also be classified in more detail by their country or region of origin, although as some varieties have been planted widely throughout the world (see INTERNATIONAL VARIETIES) this distinction is becoming unclear.

Another classification is by end-product use, and so vine varieties may be described as being for wine, TABLE GRAPES, RAISINS, GRAPE JUICE, or ROOTSTOCKS (although some varieties, such as SULTANA, are in practice used for several of these). Among wine vine varieties, some are particularly well suited to different styles of wine: sparkling, fortified, sweet, or dry still wine, for example. Within each group there are varieties more likely to make notable, ageworthy wines and those suitable only for lower-value products.

Varieties themselves are often subdivided into various CLONES. While particular clones of many varieties have been selected through performance evaluation by CLONAL SELECTION, in many cases they cannot be separated by appearance.

See also NEW VARIETIES.

Most widely planted varieties

Of all vine varieties, remarkably few have achieved an international reputation, and most of these are French. Obvious examples of these international varieties include Cabernet Sauvignon, Pinot Noir, Syrah/Shiraz, Merlot, Chardonnay, Sauvignon Blanc, and Riesling. As an increasing proportion of all wine is labelled VARIETALLY, there has been an increasing correlation between these most famous varieties and those which cover the greatest total area of vineyard land. Nevertheless an OIV report in 2017 shows that more of the Earth's surface is devoted to the TABLE GRAPE Kyoho than to any well-known wine grape.

The table shows the changing fortunes of the 20 most planted wine grape varieties in the world over a 20-year period, based on Kym Anderson's 2020 research.

	Global area 1990		Global area 2000		Global area 2010		Global area 2016

Choice of variety

Vine-growers are rarely free to choose which vine variety to plant in a given vineyard. They may have acquired a planted vineyard in full production and cannot afford the crop loss involved in changing variety either by GRUBBING UP established vines or by FIELD GRAFTING a new variety on to the trunk and root system of the old one. Different varieties need different conditions of soil and climate. Cabernet Sauvignon simply will not ripen regularly in cool regions, for example.

In much of Europe, the varieties permitted are likely to be regulated. In France, for example, some of these restrictions can be traced back to the Middle Ages (see PINOT NOIR), but formalization took place from 1935 with the AOC laws which authorize only specified varieties for each CONTROLLED APPELLATION, distinguishing between principal and secondary varieties (see Appendix 1 for details). Similarly, some varieties were completely banned. For the production of more basic VIN DE TABLE, l'Institut des Vins de Consommation Courante decreed in 1953 for each viticultural region three classifications of varieties: recommended, authorized, and tolerated until eventual removal. These laws and those in other European countries have subsequently been overtaken by EU laws with the similar intent of allowing only specified varieties in regions or appellations. For discussion of these restrictions, see VINE VARIETIES, EFFECT ON WINE.

In the NEW WORLD, the choice of vine variety or varieties is often in practice determined by the style of wine that is eventually desired, many of them involving just one vine variety, typically sold as a VARIETAL wine. Mono-varietal PDO wines within Europe such as Beaujolais (Gamay), Sancerre (Sauvignon Blanc), and Barolo (Nebbiolo) are much less likely to state the variety on the label. Two or more complementary varieties are often blended, such as the productive and full-bodied Marsanne mixed with the lighter, rarer Roussanne for white HERMITAGE, or Sémillon, Sauvignon Blanc, and Muscadelle in SAUTERNES, and Pinot Noir, Chardonnay, and Pinot

Meunier in CHAMPAGNE. Even more complex blends of varieties are common in CHÂTEAUNEUF-DU-PAPE. However, blends are also widely produced in many other wine regions but without the constraints of regulation and with more freedom to experiment.

vine varieties, effect on wine. Of all the factors such as SOIL, CLIMATE, VITICULTURE, and detailed WINEMAKING techniques which have an effect on wine quality, vine variety is probably the easiest to detect in a BLIND TASTING. The colour of the grapes' skin determines what COLOUR of wine can be produced: red wine can be produced only from dark-skinned grapes. Only grape varieties which ripen readily and/or are prone to NOBLE ROT are likely to produce good

SWEET WINES, while only those with high levels of natural ACIDITY are likely to produce good SPARKLING WINES. But, even more important for blind tasting, individual grape varieties tend to produce wines with identifiably different flavours. In very general terms, it is a mark of quality in a vine variety that it is capable of producing wines with distinguished and distinctive flavours, even if those flavours are heavily influenced by weather, TERROIR, vineyard practices, and winemaking. Lesser vine varieties tend to produce wines that are neutral and undistinguished, however promising the vineyard site. However, some more neutral varieties are better able to reveal other influences such as their place of origin or TERROIR or aspects of WINEMAKING (e.g. LEES AGEING), or they may be distinguished by their TEXTURE or STRUCTURE.

When more than one vine variety is used to produce a single wine, it is important that the wines produced by those varieties are complementary. Cabernet Sauvignon tends to blend well with wines that have more luscious fruit such as Merlot or warm-climate Syrah/Shiraz, for example, while the weight of Sémillon is a good foil for the aroma and acidity of Sauvignon Blanc. Another French example widely copied elsewhere is Grenache with Syrah and, possibly, Mourvèdre.

Wine quality is maximized if the vine variety or vine varieties are well suited to the site, in terms of climate, soil, ROOTSTOCK, VINE DENSITY, TRAINING SYSTEM, PRUNING regime, and other viticultural methods. When a new vineyard is planted in a region where the choice of variety is not regulated by local wine laws, the variety is often selected on the basis of climatic similarity with an existing wine region (see HOMOCLIMES), taking soil and TOPOGRAPHY into consideration, although combinations such as Coonawarra for Cabernet Sauvignon or Oregon for Pinot Noir are now well established. In parts of Europe, on the other hand, the matching of vine variety to site, or even whole regions, is so entrenched (see VINE VARIETIES above) as to be restrictive, particularly at a time when

CLIMATE CHANGE may well require the planting of more heat- and drought-tolerant varieties.

In BORDEAUX, for example, where Merlot and Cabernet Sauvignon have long dominated, permission was granted by the INAO in late 2020 to plant six new varieties predicted to be more resilient to the challenges of climate change: two white varieties, ALVARINHO and LILIORILA; and four reds, ARINARNOA, CASTETS, MARSELAN, and TOURIGA NACIONAL. These recommendations follow ten years of trials with 52 varieties from seven countries, and there are strict limits on their use. (See VIFA for more detail.)

Varieties vary in the range of environments they can tolerate. Chardonnay, for example, is extremely versatile and can produce good wine in climates which vary from the coolness of Chablis to the hot interior valleys of California. Varieties such as Pinot Noir and Nebbiolo, on the other hand, appear to be extremely fastidious. See also CLIMATE AND WINE QUALITY.

European regulations for CONTROLLED APPELLATIONS, which typically disapprove of citing vine varieties on the label, are predicated on the belief that for every appellation there is an ideal vine variety or blend of varieties, or that the character of the appellation is stronger than that of any vine variety. While this is an attractive proposition (and it is certainly true that, for example, the appellation of a red bordeaux or a white Alsace wine is often more strongly identifiable than any single vine variety), it seems questionable for most wine regions.

vineyard, name given to the agricultural field where grapevines are grown.

The contrast in connotations between the words ‘vineyard’ and ‘field’ illustrates something of the special nature of vines as a crop. This may be partly connected with the symbolism of, and pleasures

associated with, wine, but it is also a function of the aesthetic appeal of vineyards in all seasons, whether the increasingly luxuriant green CANOPY of spring and summer, the flame-coloured leaves of autumn (even if these invariably indicate the presence of VIRUS DISEASE or some other stress), or the rows of poignant black stumps in winter. The beauty of vineyards and vines plays an important part in wine TOURISM; it is difficult to imagine substantial numbers of people making a pilgrimage to a region famous for any other agricultural crop.

In most parts of the world, the vineyard is a well-defined entity, generally demarcated by the borders of the straight rows. *Vignoble* is a common French term for a vineyard at all quality levels. In Bordeaux, and elsewhere, CRU may be used synonymously with a top-quality, often classified, vineyard, while in Burgundy the terms CLIMAT or, in the case of a walled vineyard, CLOS are more common. In Italy the terms cru, VIGNA, SORÌ, and RONCO are all used. Recognition of single vineyards is less developed in Spain although VINO DE PAGO is a classification for single-estate wines.

In an agricultural sense, vineyards are typically monocultures, with vines the only plants growing apart from COVER CROPS and WEEDS. Less frequently, however, vineyards are grown intermingled with other crops, the so-called *coltura promiscua* that was once the norm in much of central Italy. In the VINHO VERDE region of northern Portugal, vines are still occasionally grown as borders around other fields which may contain field crops or orchards. Originally trained to wires attached to bordering trees, the vines of Vinho Verde are nowadays more commonly trained on wooden or metal supports, known as *ramada*, although they may still surround fields in which other crops are grown. There is growing interest worldwide in finding ways to increase vineyard biodiversity and protect wildlife. In addition to cover crops, trees and hedges may be planted around, occasionally within, vineyards, an approach sometimes referred to as agroforestry. Trees may provide a crop; they may help protect vines from heat or

FROST; and they can contribute significantly to the vineyard ECOSYSTEM. See also ARBOREAL VITICULTURE.

Any one vineyard may be made up of smaller units, PARCELS, or blocks, which may contain different vine varieties, CLONES, ROOTSTOCKS, or vines of different ages. Sometimes fields are separated by headlands, hedges or drainage ditches, for example, or they may be contiguous. Even relatively small vineyards are rarely homogeneous in terms of SOIL and TOPOGRAPHY. Soils in particular may vary considerably within one single vineyard (see VOUGEOT or MONTRACHET, for example).

Vineyards vary in size, depending on many factors. Owing to fragmentation of vineyards by inheritance, some vineyard owners in BURGUNDY may lay claim to only a few rows often indistinguishable to outsiders from the adjacent vines. At the other end of the scale in the NEW WORLD, there are often large corporate vineyards. One of the world's largest vineyards is the 2,800-ha/6,920-acre San Bernabe ranch in the Salinas Valley of MONTEREY in California. While relatively rare, such extensive vineyards are also found in Europe, for example Plantaze's 2,300-ha/5,700-acre vineyard in MONTENEGRO.

Some vineyards are particularly famous for their wine because of their specific combination of VINE VARIETY, clone, rootstock, and climate conditions, which can be distinguished at the various levels of MACROCLIMATE, MESOCLIMATE, and MICROCLIMATE. Of particular importance are the soil conditions, which, together with TOPOGRAPHY, mesoclimate, and CANOPY MICROCLIMATE, constitute what the French (and others) call TERROIR. See under each of these entries for a discussion of their relative contribution. For example, a feature of the famous Bordeaux PREMIERS CRUS is that, as well as producing great wine in good years, they are able to do well in acknowledged low-quality years because the terroir allows the vine to ripen the fruit adequately when other, less exalted vineyards cannot.

See also HILLSIDE VINEYARDS, PLANTING, VINEYARD ANNUAL CYCLE, and VINEYARD SITE SELECTION. J.E.H. & R.E.S.

vineyard annual cycle. The march of the seasons through the year dictates the work to be done in vineyards (see VINE GROWTH CYCLE). Spring is the time of BUDBREAK, and early TILLAGE and SPRAYING must be done. Early spring is also the common time for PLANTING vineyards, once the danger of FROST is past. As the temperatures rise, the vine shoots grow more rapidly, and FLOWERING takes place in early summer. This can be a busy period, as often FUNGICIDE sprays are to be applied and the first SHOOT POSITIONING is carried out. Soon after FRUIT SET is the time for the second shoot positioning. In those vineyards of the world where IRRIGATION is practised, the first applications of water are often made around this time and may continue up to the time of harvest. About this period the NURSERIES are busy BENCH GRAFTING, and it is also the time for FIELD GRAFTING. As the summer progresses, TRIMMING is carried out, typically before VERAISON. Many vine-growers are involved with further spraying of AGROCHEMICALS and often continued tillage and mowing (see COVER CROPS). Depending on the vine variety and region, the HARVEST may be in early, mid, or late summer or sometimes in the autumn. Whenever it occurs, it is one of the busiest periods in the vineyard, often involving SAMPLING to test grape RIPENESS before the harvest itself. Depending on the spread of varieties, the harvest may be brief or protracted, but few other jobs are attended to in the vineyard at this time. The period immediately following harvest is busy in the wineries but not so in the vineyards, and vineyard workers and viticulturists often take their annual leave then. This is also the common time for soil RIPPING and for maintenance of machinery and TRELLIS SYSTEMS. Once the leaves fall, the serious business of PRUNING begins; depending on the scale of operations, this may continue right up until budbreak. This is also the time when CUTTINGS are taken for PROPAGATION. R.E.S.

vineyard design, important component of vineyard planning before vineyard planting (except in traditional European wine regions

where VINE SPACING, VINE VARIETY, and ROOTSTOCK may well be prescribed). In a new vineyard, normally the first step is a topographic survey, followed by a soil survey and SOIL MAPPING, today in some instances using GLOBAL NAVIGATION SATELLITE SYSTEM technology. Based on this important information, block layout and IRRIGATION design proceeds, and finally on a block-by-block basis decisions are made about variety, CLONE, rootstock, row and vine spacing, and TRAINING SYSTEM. In this way, the vineyard will optimize use of local resources and the potential of the site. R.E.S.

vineyard management company, a business which executes all viticultural operations, from land development and VINE MANAGEMENT to fruit sales, and which can provide all necessary equipment, machinery, and LABOUR. What would become the first such company began in the Napa Valley in 1945 as a general agricultural management company for orchards. Since then, vineyard management companies have become specialized and often employ trained viticulturists to implement up-to-date best practices for pest and disease management, nutrient applications (see VINE NUTRITION), IRRIGATION solutions, and CANOPY MANAGEMENT. These companies are particularly important in the US, especially where people outside of the wine trade invest in vineyard land. Examples of this increasingly important business structure can also be found in both Australia and New Zealand. S.C.-J.

vineyard site selection can be the single most important aspect of grape production, even if it is not always appreciated as such. If, for example, the new vineyard is in a cool region, then the TOPOGRAPHY of the site may be a critical factor in avoiding FROST DAMAGE, and the ASPECT chosen may be vital to ensure adequate warmth for RIPENING (see HILLSIDE VINEYARDS). In those parts of Europe where vineyards have been in existence for centuries, another

important consideration may be whether or not it qualifies for a certain CONTROLLED APPELLATION.

Vineyard site selection embraces more than just choosing the vineyard location, as the decision will affect the vineyard's YIELD, the quality of the wine produced, and therefore the vineyard's long-term profitability. The site's regional climate, or MACROCLIMATE, for example, determines by virtue primarily of temperature and sunshine hours which VINE VARIETIES should be grown and the resulting likely wine style and quality. For example, lower temperatures produce more delicately flavoured wines, and hot climates produce wines relatively high in alcohol. (Such effects are discussed under CLIMATE AND WINE QUALITY.) Vineyards are often planted at higher ELEVATIONS to take advantage of lower temperatures, increasingly so in regions affected by CLIMATE CHANGE. The site selection process might include evaluating climatic data from distinguished wine regions either locally or internationally in an attempt to locate similar climates, or HOMOCLIMES, as has been done with considerable success in Australia. With its enormous range of LATITUDE and elevation, Chile has a greater opportunity than most countries to match climates.

Modern science is creating new methods of vineyard site selection, especially based on GEOGRAPHICAL INFORMATION SYSTEMS (GIS) and digitized databases. Researchers at VIRGINIA TECH in the US, for example, identified sites with the greatest potential by overlaying maps of the same area according to different selection criteria such as elevation and land use, slope and aspect, and WINTER FREEZE risk. Such approaches provide a useful alternative to the more expensive trial-and-error method more usually employed.

Similarly, rainfall and humidity affect the likelihood of many VINE DISEASES, especially important fungal diseases such as POWDERY MILDEW, DOWNY MILDEW, and BOTRYTIS BUNCH ROT. The likelihood of these diseases can be estimated by reference to climate records. In addition, the threat of NEMATODES may be evaluated by knowledge of indigenous types or of the previous crops grown on the site. It may even be possible to avoid the introduction of PHYLLOXERA and other

pests and diseases by creating a local QUARANTINE. If phylloxera and nematodes are considered a likely problem, the appropriate ROOTSTOCKS can be used.

The site climate, or MESOCLIMATE, affects, for example, the extent to which cold air drains away and the likelihood of spring and autumn FROST. A site's proximity to bodies of water such as lakes (see LAKE EFFECT) can be important in providing protection from injury due to particularly low temperatures, as in NEW YORK State and SWITZERLAND. These attributes depend on local TOPOGRAPHY.

The balance between RAINFALL and EVAPORATION indicates the likelihood of DROUGHT and, for some regions at least, whether IRRIGATION is desirable and the amount of water required. In many parts of the world, availability of high-quality water for irrigation is an essential factor in site selection. This may involve locating vineyards near streams or rivers; with access to underground (artesian) water; or on sites with opportunities to build dams or reservoirs.

SOIL conditions present at the site will determine vineyard VIGOUR, with deep, fertile soils, for example, leading to vigorous growth, the possibility of high YIELDS, and the concomitant need to manage the problems this creates (see CANOPY MANAGEMENT). Premium-quality vineyards are typically found on soils with low water-holding capacity and low SOIL FERTILITY. Site selection normally involves a process of SOIL MAPPING and physical and chemical analysis of soil samples. This allows potential problems such as poor DRAINAGE or SOIL ACIDITY to be treated appropriately before the vineyard is planted. Knowledge of soil depth indicates likely vine vigour.

Vegetation growing at the site (and the productivity and quality of other agricultural crops grown in the region) can be used as an indicator of the vineyard performance. The types of trees present give guidance as to the soil properties, and their size for their age indicates soil fertility and water supply.

Not all the important features of potential vineyard sites are natural ones. Frontage to busy roads is essential if retail sales are

expected from the vineyard site. Good communications with markets and proximity to a supply of LABOUR can also be significant. The performance and reputation of other vineyards in the area are also commercially important. R.E.S.

Smart, R. E., and Dry, P. R., 'Vineyard site selection', in Dry, P. R., and Coombe, B. G. (eds), *Viticulture*, i: *Resources* (2nd edn, 2004).

www.grapes.extension.org/vineyard-site-selection/

vineyard weather stations contain a number of electronic instruments to measure the climate within a vineyard. Normally they comprise sensors for sunshine, air and soil temperatures, wind speed and direction, humidity, rainfall, leaf wetness, and occasionally EVAPORATION. Data are stored in a data logger which may be downloaded to a laptop or phone or remotely interrogated by a computer via the internet. Such weather stations are used primarily for disease prediction, especially for fungal diseases such as DOWNY MILDEW and POWDERY MILDEW, and also for predicting vine PHENOLOGY. R.E.S.

vin gris is not, happily, a grey wine but a pink wine that is usually decidedly paler than most ROSÉ, made exactly as a white wine from dark-skinned grapes and therefore without any MACERATION. No rules govern the term *vin gris*, but a wine labelled gris de gris must be made from lightly tinted grape varieties described as *gris* such as GRENACHE GRIS or Grolleau Gris.

In France, where it is a speciality of the Côtes de TOUL in the north-east and in certain parts of the LOIRE, *vin gris* is usually made from PRESSING, but not macerating, dark-skinned grapes, often Gamay, which rarely ripen sufficiently to produce a deeply coloured red. It is also made in the Midi, notably by Castel beside the saltpans of the Camargue, where care is needed to tint rather than dye the

resultant wine. The term is also occasionally encountered outside Europe—although BLUSH wines are extremely similar to, if almost invariably sweeter than, *gris* wines. See also SCHILLERWEIN and other German light pinks.

The style is particularly popular in Morocco, which produces gris with an orangey-pink hue, mainly from traditional varieties such as Cinsaut and Grenache Gris but also from Merlot and Cabernet Sauvignon. Moroccan Gris de Boulaouane is one of CASTEL's French supermarket staples.

Vinhão, official Portuguese and local MINHO name of the dark-skinned grape SOUSÃO.

vinho, Portuguese for 'wine', vinho is how Portugal's WINE WITHOUT GEOGRAPHICAL INDICATION is described on the label.

Vinho de Talha, introduced in 2010 for new-wave bottled wines from the ALENTEJO made in TALHA, fermentation vessels typically made of clay, sometimes CONCRETE. Grapes must be destemmed and wines must remain in talha on skins until at least 11 November (St Martin's Day in the year of harvest, when talhas were traditionally first tapped). Grapes must be sourced from (and permitted by) Alentejo's eight DOC subregions. In 2020 Vinho de Talha DOC wines represented 0.1% of Alentejo's production. S.A.

White, P.J., *Talha Tales: Portugal's Ancient Answer to Amphora Wines* (2022).

vinhodetalha.vinhosdoalentejo.pt

Vinho Regional, second tier of designated wine regions in Portugal. Although the new term Indicação Geográfica Protegida (IGP), sometimes shortened to Indicação Geográfica (IG), meaning Protected Geographical Indication (PGI), has been introduced since the EU wine market reforms of 2008, most Portuguese regions have chosen to keep the old denomination Vinho Regional (VR).

These large regions covering entire provinces—MINHO, TRANSMONTANO, DURIENSE, Beira Atlântico, Terras da Beira (see BEIRAS), Terras do DÃO, TEJO, LISBOA, Alentejano for ALENTEJO, PENÍNSULA DE SETÚBAL, ALGARVE, and Terras Madeirenses for MADEIRA—allow greater flexibility in terms of permitted grape varieties, YIELDS, and ageing requirements. The Vinho Regional denomination is therefore popular with innovative winemakers wishing to bottle relatively young wines or blend Portuguese and INTERNATIONAL VARIETIES. In the centre and south of the country (Lisboa, Tejo, Península de Setúbal, and the Alentejo), producers are largely ignoring the DOCs in favour of Vinho Regional. S.A.

Vinho Verde, large DOC in north-west PORTUGAL known for its distinctively light, fresh wines and some gastronomic top-tier whites. Vinho Verde originated as a rough-and-ready local wine on a domestic scale. Following fermentation in open stone LAGARES, the wine would be run off into CASK where the secondary MALOLACTIC CONVERSION produced carbon dioxide. This was retained in the wine, giving it a slight sparkle. Huge-volume BRANDS are typically widely sourced, slightly sweet, spritzy (carbonated), NON-VINTAGE blends for early consumption (*vinho verde* means 'green wine', a reference to the youthful state in which wines were customarily sold). However, since the 1980s a shift towards better viticultural practices and more PROTECTIVE WINEMAKING has challenged the old stereotype, resulting in a middle tier of fruitier wines and a top tier of dry, complex wines (the latter typically subregional VARIETAL wines). The region's verdant coastal strip (known as the Costa Verde or Green Coast) extends

from Vale da Cambra south of the river DOURO to the river Minho that forms the frontier with Spain over 130 km/80 miles to the north (see PORTUGAL map). The big brands represent most of production where rain-bearing westerly winds from the Atlantic support intensive cultivation on its GRANITIC soils. These fertile soils extend inland, along the rivers which criss-cross the region and act as conduits for tempering ocean winds.

In 2019/20, 16,000 growers (including 600 bottling their own wines) cultivated 16,232 ha/40,100 acres under vine for DOC production totalling 787,948 hl/20,815,384 gal (83% white, 12% red, 5% rosé). Some growers' plots are little bigger than a suburban back garden. To make the most of these small plots, vines were traditionally grown high above the ground around stakes or trees (known as *uveira* or *vinha de enforcado*) or on PERGOLAS (known as *ramadas* or *latadas*) built on stout granite posts up to 4 m/13 ft high, leaving space for other crops underneath. Similarly, farmers trained vines on pergolas around the perimeters of fields planted to corn (once the region's biggest crop). These high-trained vines also helped to reduce the risk of GREY ROT, which is endemic during the warm, damp growing season; average annual RAINFALL is as high as 1,500 mm/59 in. However, this tradition of polyculture, which remained embedded well into the last century, was conducive neither to MECHANIZATION nor to quality, both of which had become critical to making economically viable wine once the Portuguese wine industry entered a more competitive phase following the country's accession to the EU. Vineyards planted (or restructured) since the 1990s are on lower TRAINING SYSTEMS, resulting in riper, healthier grapes. At the same time, with ruthless CANOPY MANAGEMENT and grape selection a handful of young guns are making interesting small-batch wines from vines trained the old-fashioned way. Increased professionalism in the vineyard has been mirrored in winemaking. Since the 1980s, the average ALCOHOLIC STRENGTH has increased from 9–10% to 11–12% without sacrificing the region's signature freshness.

The Vinho Verde DOC is officially divided into nine subregions: Amarante, Ave, Baião, Basto, Cávado, LIMA, MONÇÃO E MELGAÇO, Paiva, and Sousa. Monção e Melgaço on the Spanish border produces one of the best but least typical Vinhos Verdes from the ALVARINHO grape, the wines up to 13% alcohol. Further south along the river Lima around the towns of Braga, Barcelos, and Guimarães, the dominant grape varieties are LOUREIRO (which thrives in the LIMA subregion), TRAJADURA, and Pedernã (ARINTO). Inland, in Amarante, AZAL shows promise, while in the Baião subregion bordering the Douro AVESSO is gaining ground, producing a slightly fuller style of wine in a warmer, drier climate.

Basic Vinhos Verdes must be 8–11.5% alcohol so more potent basic wines are sold as VINHO REGIONAL MINHO. Vinho Verde labelled with a single variety, subregion, or quality level (Escolha, Grande Escolha, Superior, Colheita Selecionada) have different (generally higher) minimum alcohol levels and are subject only to a maximum POTENTIAL ALCOHOL of 14%. Since 1999 the DOC includes sparkling wines (labelled ESPUMANTE) made by the TRADITIONAL METHOD and bottled-aged for at least nine months.

Until the 1980s, Vinho Verde was predominantly red, made in a naturally fizzy, acidic, bone-dry style from red grapes such as Vinhão, Alvarelhão, and Espadeiro. Examples still exist and are prized locally, but little leaves northern Portugal. Ambitious estates have pushed the boundaries with Vinhão, making deeper-fruited, still reds, sometimes OAK-AGED or even blended with Alvarinho to tame the TANNINS. Rosés (on the increase) and modish GLOU-GLOU styles made from a wider range of grape varieties seem a better fit for the TERROIR.

viniculture. While some use this term interchangeably with VITICULTURE, this book uses it to denote both vine-growing and a culture of wine drinking.

vinifera. See VITIS VINIFERA.

vinification, the practical art of transforming grapes into wine. In its widest sense, it is synonymous with WINEMAKING, but strictly speaking it encompasses only those processes which take place in the winery up to the point at which the ÉLEVAGE of the new wine begins. See also OENOLOGY.

vin jaune, meaning literally 'yellow wine' in French (not to be confused with ORANGE WINE), extraordinary style of wine made in France, mainly in the JURA region, using a technique similar to that used for SHERRY but without FORTIFICATION.

All Jura areas make a *vin jaune*, but the most famous is CHÂTEAU-CHALON. The wine must be made from the signature local white grape variety SAVAGNIN, grown ideally on grey MARL. The grapes are picked well ripened, ideally at not more than 13.5% POTENTIAL ALCOHOL, to allow for an increase during the ageing process, and are fermented as normal. The wine is then put into old 228-l/60-gal casks usually not quite filled so that the local benevolent FILM-FORMING YEAST, called here the *voile* or veil, can develop on the surface. It is similar to the FLOR which is responsible for FINO sherries but can develop at a lower

ALCOHOLIC STRENGTH, and a much thinner layer, coloured grey, is considered the best. The ageing 'cellars' (which may be above or below ground) are ventilated deliberately to allow temperature fluctuations during which the activity of the *voile* will change. The presence of the veil prevents severe OXIDATION, but the important factor in making *vin jaune* is that the wine is left in cask for at least five years, untouched other than to allow regular sampling to check the amount of ETHANAL (a crucial compound for the taste of *vin jaune*) and for a dangerous rise in VOLATILE ACIDS. It may not be bottled for a full six years and three months after the harvest. Inoculation or seeding of yeasts to form the *voile* for Savagnin wines was introduced in the 1970s, and today this is used by some producers but is disapproved of by purists who believe that natural methods produce a better wine and are reliable if 'cellar' conditions are right and barrels have previously held wine aged under the *voile*.

The finest *vin jaune* from the best vintages will last for 50 years or more in its distinctive 62-cl *clavelin* bottle (the amount of wine left after keeping a litre in a cask for six years, supposedly). Research in the 1990s showed that the compound SOTOLON develops in bottle, providing the distinct spicy, fenugreek or light 'curry' flavours in *vin jaune*. The wine should be served at cellar temperature or warmer, and the bottle should be opened well in advance. The wine may be drunk with all sorts of savoury dishes, particularly chicken cooked in the wine itself, a classic dish, and the local Comté cheese.

A similar wine, called *vin de voile*, is made by at least one producer in GAILLAC. Other isolated French producers are also experimenting, as are some Australian producers growing Savagnin.

W.L.

Vínland. Driven westward by overpopulation in the second half of the 9th century, the Scandinavians colonized Iceland, then Greenland, then finally, a century later as some sources tell us, Vínland, 'Wine Land', which must have been on the east coast of America.

Two sagas—Grenlinga Saga, the 'Saga of the Greenlanders', composed in the late 12th century, and Eirik's Saga, dated mid 13th

century—give accounts of the discovery of Vínland, where wild vines, wheat, grassland, and game are found.

Scholars do not agree on the precise location of Vínland. The sagas do not give clues, and, although archaeologists have found what appear to be traces of Norse settlements on the east coast of America, the evidence is inconclusive. Besides, the climate was warmer around 1000 CE than now (hence the colonization of Greenland; see CLIMATE CHANGE) so that vines could survive further north.

The sagas were written from oral accounts many generations after the actual events. Even though the stories told in the sagas differ in some respects, they are not fantasy. An earlier and unrelated source supports the existence of Vínland. Around 1075 Adam of Bremen wrote a history of the archbishopric of Bremen and Hamburg, which until 1104 included the Scandinavian countries. Adam travelled to the royal court of Denmark, where King Svein Ulfsson, nephew of King Canute, tells him that Vínland has wild vines, which make excellent wine. So were the first winemakers in America Norse colonists? If they were, the wine must have been made not from the European VITIS VINIFERA but from native AMERICAN VINE SPECIES, almost certainly VITIS LABRUSCA, which grows wild on the eastern coast of the United States. H.M.W.

vin muté, wine that has undergone MUTAGE.

vino, Italian and Spanish for 'wine' and, colloquially and unfairly, an English name for basic quaffing wine, or PLONK. In Italy and Spain, the term has replaced VINO DA TAVOLA and VINO DE MESA respectively as the most basic level of wine, WINE WITHOUT GEOGRAPHICAL INDICATION.

vino da meditazione, unofficial Italian category of wines considered too complex (see COMPLEXITY) but often simply too alcoholic and/or sweet to drink with food. Such wines, many of them extra strong and/or sweet because they are DRIED-GRAPE WINES, are probably best sipped meditatively after a meal.

vino da tavola, Italian for TABLE WINE, was the official EU category denoting the lowest of the vinous low until 2009 when it was replaced with VINO. It also played a key role in the transformation of Italian wines in the late 20th century. Historically the great majority of each Italian wine harvest qualified as basic Vino da Tavola, but the designation was for a period worn as a badge of honour by some of the finest, and most expensive, wines produced in Italy but that did not conform to the DOC laws of the time.

These new vini da tavola were born in the early 1970s with the commercial debut of Tignanello and SASSICAIA, both marketed by the Florentine house of ANTINORI. Although the wines were produced in different geographical zones (CHIANTI CLASSICO and BOLGHERI respectively) and from different grape varieties (a predominance of Sangiovese and Cabernet Sauvignon respectively), they shared four significant characteristics that were to mark the evolution of this category of wines. They both represented an attempt to give more BODY, intensity, and longevity to Tuscan red wines. Unlike the prevailing Tuscan red-wine norm, these blends excluded white grapes. Non-traditional, non-Italian varieties were used in both blends (from 1975 when Tignanello substituted Cabernet Sauvignon for the native CANAIOLO). And, in a move that was to delight French

COOPERS, small oak barrels, principally of French origin, were used for the BARREL AGEING of both wines. This latter innovation was a radical break with the traditional practice of using large casks of Slavonian oak and marked a general movement towards an international style. The move was not welcomed by all in the domestic market and forced Antinori to seek a wider international public for the wines.

The *vini da tavola* were born out of frustration with the DOC laws that came into practice in the late 1960s. These laws enshrined the practices of low quality and high quantity that prevailed in Italy in the post-war years, so producers trying to pursue a quality route found their way blocked by absurd regulations. In Chianti, for instance, producers were compelled by DOC laws to add at least 10% white grapes to their blend. Any producer wishing to produce a superior red wine had to ignore this stipulation. Rather than do battle, they stepped outside the legal framework at the urging of Italian wine journalist Luigi VERONELLI, a vehement opponent of the mediocrity of the DOC laws.

INTERNATIONAL VARIETIES were enthusiastically planted, and other Cabernet Sauvignon-based wines began to appear in the image of Sassicaia, particularly after the mid 1980s. The native Sangiovese grape was hardly neglected, however, and a substantial number of BARRIQUE-aged, 100% Sangiovese wines were also launched, as *vini da tavola*, in the 1980s, following in the path of Montevertine's Le Pergole Torte, whose first vintage was 1977.

Experiments with earlier-maturing varieties SYRAH and, with notable success, MERLOT became increasingly common in the late 1980s, both for blending with Sangiovese and for VARIETAL wines. Some non-traditional white varieties were also planted, notably CHARDONNAY and SAUVIGNON BLANC, and various OAK treatments essayed with variable success.

Sassicaia was a pioneering wine, not only in its use of Cabernet but also in its revaluation of a zone never known for producing fine or even commercial wine. When first offered commercially, Sassicaia had to be sold as a *vino da tavola*, not because, as with Tignanello, it

eschewed the legal constraints of the area but because there was no DOC for BOLGHERI reds at the time. Its example was rapidly followed by other peripheral areas of Tuscany. Such wines, with their ambitious price tags, came to be known as SUPERTUSCANS.

Inspired by these highly priced Tuscan 'outlaws', ambitious producers in other regions were quick to launch their own *vini da tavola*, in some instances even when they could have qualified as DOC wines. Some of these wines returned to the DOC fold in the 1990s, partly as a result of the greater prestige and credibility now accorded to the wines of their zones and regions. In 1992 Giovanni Goria, the then Minister of Agriculture, introduced the IGT designation to allow producers to add more information to their wine labels, but some important wines are still deliberately sold simply as VINO.

See also SUPERTUSCAN.

vino de aguja, Spanish for a wine that is PÉTILLANT. In Catalan, *vi d'agulla*.

Vino de Calidad (con indicación geográfica), transitory Spanish denomination between VINO DE LA TIERRA and DOP, of which there were seven in 2022. It identified wines 'produced and vinified in a specific area or place, with grapes of the same origin' with some degree of recognition and quality. Eventually this denomination is to be merged, with DO, into DOP.

Vino de la Tierra, wines from legally designated zones in Spain which have not qualified for DOP status. With changes to EU denominations (see PGI), this category is now known as *Indicación Geográfica Protegida* (IGP), a term which can also be found on Spanish labels and which may eventually replace it. Of the 42 Vinos de la Tierra in 2022, Cádiz, Valdejalón, Bajo Aragón, Castilla, Castilla y León, Extremadura, Ibiza, Valles del Sadacia, 3 Riberas, and Castelló are regions to watch. F.C.

Vino de Mesa, old Spanish term for TABLE WINE, the most basic category of wine now known in EU terms as WINE WITHOUT GEOGRAPHICAL INDICATION. See VINO.

Vino de Pago, special Spanish category of supposedly exceptionally high-quality, single-estate wines, granted their own appellation. In 2022 there were 24, 12 of them in CASTILLA-LA MANCHA, where Dominio de Valdepusa was the first to be created. See also PAGO.

Vino de Tea, a traditional specialty of LA PALMA in Spain's Canary Islands, is a blend of mainly NEGRAMOLL aged in barrels made from the Canary pine (*Pinus canariensis*) to take on a resinous flavour. F.C.

Vino Nobile di Montepulciano, potentially important red wine based on SANGIOVESE, known locally as Prugnolo Gentile, made exclusively in the township of Montepulciano 120 km/75 miles south-east of Florence in the hills of TUSCANY in central Italy. Vino Nobile has an illustrious history, having been lauded as a 'perfect wine' by the cellarmaster of Pope Paul III in 1549 and 'the king of wines' by Francesco Redi in his 'Bacchus in Toscana' of 1685, while the first record of the name dates from 1787 when it was listed in the expense accounts of Giovan Filippo Neri for a trip to Siena. After the introduction of the DOC in 1966, the total vineyard area rose from fewer than 150 ha/370 acres in 1970 to 1,377 ha in 2020.

Vino Nobile di Montepulciano was one of the first four DOCGs conferred in 1980. Traditionally producers would have blended in Canaiolo, Mammolo, and Trebbiano, but since the mid 1980s Sangiovese has come to the fore as the principal variety. Since 1999 DOCG regulations require at least 70% Sangiovese in the blend; in 2009 the production regulations were changed to allow up to 30% of varieties such as Cabernet Sauvignon, Merlot, and Syrah, reflecting

an already common practice. This amendment was criticized widely as the 'internationalization' of a historic Tuscan wine.

Vines are planted on east- to south-east-facing slopes at ELEVATIONS of 250–600 m/2,000 ft; vineyards on the plain do not qualify as Vino Nobile. Soils are generally higher in CLAY than in either Montalcino or Chianti Classico. The region consists of two distinct zones: the hills around the township of Montepulciano and, about 10 km west and separated by the Val di Chiana plain, the hills around the township of Valiano, the latter dominated by extensive holdings. It is further divided into 20 subzones, but these are practically obsolete since the creation in 2020 of the *unità geografica aggiuntiva* (UGA), here called a *pieve*, or parish. Twelve *pievi* (plural for *pieve*) have been identified on the basis of geological research, which also largely coincided with the boundaries of 12 parishes registered in the 18th century. The *pieve* name may appear on labels from 2024, with the obligatory addition of the word 'Toscana' to distinguish the wines from Montepulciano d'Abruzzo.

Vino Nobile must be aged for two years, at least one of them in BARREL; Riservas require three years of ageing, with 12 months in barrel. The DOC Rosso di Montepulciano, which allows the wines to be released in March following the vintage, was created for earlier-maturing wines but, because it is much less profitable than Vino Nobile, is used for smaller volumes of wine.

Stylistically Vino Nobile sits between CHIANTI CLASSICO and BRUNELLO DI MONTALCINO, combining the elegance of the first with the firm STRUCTURE of the second. The wines tend to fall into two camps: a traditional style using Sangiovese either on its own or blended with CANAIOLO and aged in large casks of Slavonian oak and generally requiring prolonged ageing; or a more modern approach in which Sangiovese is blended with INTERNATIONAL VARIETIES and aged in new French oak. This modern style, although still dominant, has been losing ground because it results in wines that are less recognizably Vino Nobile. W.S.

Vino Santo. See VIN SANTO.

Vin Santo, 'holy wine', TUSCANY's classic amber-coloured dessert wine, is produced throughout this central Italian region. It is made traditionally from the local white grape varieties TREBBIANO Toscano and MALVASIA (although the red SANGIOVESE is also used to produce a wine called Occhio di Pernice, or 'eye of the partridge') which have been dried on straw mats under the rafters, in the hottest and best-ventilated part of the peasant home (see DRIED-GRAPE WINES). The grapes were normally crushed between the end of November and the end of March, depending on the desired RESIDUAL SUGAR level in the wine (the longer the drying process, the greater the evaporation and the sweeter the MUST), and then aged in small barrels (50–300 l/13–79 gal). These barrels, often bought second-hand from the south of Italy, were frequently made of chestnut, but the 1980s saw a decisive turn towards OAK. The barrels themselves are sealed and never TOPPED UP, resulting in ULLAGE and OXIDATION, which gives the wine a RANCIO-like aroma and its characteristic amber colour. Some producers believe in using a *madre*, or starter culture, comprised of yeast cells from previous batches of Vin Santo, in order to help the fermentation and to add COMPLEXITY to the blend. Others, in true Tuscan fashion, view the *madre* as a throwback to the time when all Vin Santo was marred by FAULTS and refuse to countenance its use.

The wine can range from ultra-sweet to a bone-dry version which more closely resembles a dry FINO sherry than a dessert wine. The practice of keeping the barrels under the roof in a space called the *vinsantaia* encouraged refermentation each year when warm weather arrived and tended to exhaust the unfermented sugars that had remained in the wine. Today, most producers keep their Vin Santo in a cellar with a more constant temperature to retain a degree of freshness in the finished wines.

Pre-1990s, most Vin Santo was sold as a VINO DA TAVOLA, simply because the authorities had struggled to codify the bewildering array of styles contained within the many localized traditions. The DOCs under which Vin Santo is now produced include Chianti, Chianti Classico, Chianti Rufina, Carmignano, Montepulciano, Colli dell'Etruria Centrale, and Val d'Arbia.

The quality of the wine itself varies wildly, not only as a result of variation in grape composition, RESIDUAL SUGAR, and winemaking competence but because the land is divided between so many smallholders, all of whom seem to feel obliged to produce Vin Santo as an obeisance to the tradition of offering this wine to guests as a gesture of esteem. Although some delicious Vin Santo is made, a considerable proportion have serious wine faults, particularly an excess of VOLATILITY, usually a direct consequence of lengthy BARREL AGEING. DOC rules insist the wine is matured for at least three years, and the better producers rarely release their Vin Santo before five years. Cask maturation, without RACKING, may last for up to ten years for the most traditionally made wines.

Vin Santo is also made in Gambellara in the VENETO, and TRENTINO produces a version called Vino Santo, made from the NOSIOLA grape and a decisively sweet DRIED-GRAPE WINE. D.C.G. & W.S.

Vinsanto is the official term for the sweet wines of SANTORINI.

Tachis, G., *Il libro del Vin Santo* (1988).

Vinsobres, the most northerly of the nine CRUS of the southern RHÔNE, dedicated to red wines from 531 ha/1,312 acres of vineyards in 2020. Grenache must dominate a blend with Syrah and/or Mourvèdre (it may also contain a further 17 varieties). The commune is situated on a south-east-facing slope of a large hill. Soils are mixed: largely CLAY and SAND north-east of the village, clay and pebbles north-west of the village, and clay, sand, pebbles, and LIMESTONE directly south of the village. Relatively high-ELEVATION

vineyards (up to 450 m/1,476 ft) and a northerly situation make for a cooler climate than most other southern Rhône crus, as does the pontias, a cool easterly air current that follows the Aigues, a tributary of the Rhône that skirts around the foot of the hill. The style is concentrated but fresh, with a bold tannic structure. M.C.W.

vintage can either mean the physical process of grape-picking and winemaking, for which see HARVEST, or it can mean the year or growing season which produced a particular wine, for which see VINTAGE YEAR. A vintage wine is one made from the produce of a single year.

vintage assessment is important enough to have an immediate effect on PRICE but is also notoriously difficult because quality and character can vary so much between producers and properties. A vintage is often assessed at the most difficult stage in its life, its infancy, for reasons of commerce and curiosity. Wine MERCHANTS and WINE WRITERS habitually taste wines from the most recent vintage in a wine region important for INVESTMENT when they are just a few months old and are still in cask (see EN PRIMEUR). Quite apart from the fact that the wines are at this stage still being made (see ÉLEVAGE), samples may give a misleading impression because they have been specially chosen and groomed to show particularly well at this early stage, or because too long has elapsed since they were drawn from cask (OXIDATION is a common problem), or, if they are tasted directly from cask, because they are undergoing a distorting treatment such as FINING. Furthermore, this sort of vintage assessment may be before the ASSEMBLAGE process and provides only a snapshot of embryonic wine from a small proportion of the total number of barrels produced.

This sort of comparative tasting can usually give some indication as to which are the most and least successful wines of a given vintage, but it can be difficult to stand back from the individual

samples, accurately remember exactly how the same wines from previous vintages tasted at the same stage, and make any reliable assessment of the likely characteristics and potential of the young vintage as a whole. Vintages of which the collective assessment at this young stage was subsequently agreed to have been too enthusiastic include 1975 in Bordeaux and 1983 and 1996 in Burgundy, but other examples abound. (Wine merchants have proved themselves much less likely to err on the side of caution, although 2001 Bordeaux and 2011 Burgundy are generally agreed to have been underestimated.)

The assessment of a mature vintage is a much less hazardous process that is usually undertaken in the form of a horizontal TASTING, although of course SUBJECTIVITY plays its part as it does in all tasting.

Broadbent, M., *Great Vintage Wine Book II* (1991).

Broadbent, M., *Wine Vintages* (1998).

vintage charts are both useful and notoriously fallible, partly because young VINTAGE ASSESSMENT is so fraught with difficulty and partly because of the difficulty of generalizing about a district in which there may be hundreds of different producers, each with a different vineyard regime, winemaking policy, and style of wine.

The most useful vintage charts are the most detailed but also those that are regularly updated on the basis of continuous and relevant tasting. The INTERNATIONAL WINE & FOOD SOCIETY was one of the first to issue a vintage chart, in 1935. The Society has since then published one annually, updated by a committee expressly charged with this task.

vintage port. See PORT.

vintage year, the year in which a wine was produced. Most, but not all, of a vintage's characteristics result from the particular

WEATHER conditions experienced in that year, which makes CLIMATE CHANGE so significant for the style and quality of many wine regions. In the southern hemisphere, a vintage-dated wine invariably carries the year in which the grapes were picked, even though much of the VINE GROWTH CYCLE was actually in the previous year. In the northern hemisphere, vintage-dated wines carry the year in which both the vine growth occurred and the grapes were picked (with the exception of those rare examples of EISWEIN picked in early January, which are dated with the year whose vine growth produced the wine). The expression 'vintage year' is also sometimes used of a year producing particularly high-quality wines.

In a literal sense, all newly fermented wine is vintage wine, being from a single year. Only at the BLENDING stage may wine of a recent year, or vintage, be mixed with older wines into an undated blend. Many everyday wines—such as the JUG WINES of the US and CASK WINE in Australia—are not vintage dated. Some top-quality CHAMPAGNE, most SHERRY, and many other FORTIFIED WINES are NON-VINTAGE too. In most other circumstances, however, a non-vintage wine is inferior to a vintage-dated one. For wines designated within the EU as WINE WITHOUT GEOGRAPHICAL INDICATION, stating the vintage date on the label is now optional (having previously been prohibited), depending on local wine regulations.

The vintage year printed on a wine label can help the consumer decide when to open a particular bottle, being especially relevant to wine meant for AGEING (others, the great majority of wines, should simply be drunk as young as possible). Since the capacity of a wine to improve with age is one obvious test of its quality, a vintage's status is only fully established in retrospect (whatever those charged with selling it may say; see VINTAGE ASSESSMENT).

The concept of vintage year has a long history. OPIMIAN wine, made in the consular year of Lucius Opimius, 121 BCE, was celebrated for decades afterwards as a particularly fine vintage. The celebrated RHINE Steinwein of 1540 CE, last drunk in 1961, was made in a freak

year so hot and dry that the Rhine dried up and people could walk across its bed.

Vintage years did not become a normal commercial consideration until the end of the 17th century, when BOTTLES and CORKS replaced BARRELS for long-term wine storage. Vintages became particularly important towards the end of the 18th century, when the modern bottle shape evolved, allowing bottles to be stored on their sides. The better red wines of Bordeaux came to be 'laid down' for many years, and it was then that what is now regarded as the traditional Bordeaux style of winemaking for prolonged AGEING in bottle became established.

Broadbent gives details of some of the more famous Bordeaux vintages. The celebrated 1784 clarets, sought out and imported by America's wine-loving President Thomas JEFFERSON, were from one of the many fine vintages spanning the late 18th century and first years of the 19th century, culminating in the reputedly outstanding 'comet' year of 1811. Other runs of predominantly good Bordeaux vintages followed in the 1840s and again in the 1860s and the first half of the 1870s, a period long remembered as the crowning glory of the PRE-PHYLLOXERA era. The limited climatic records available suggest that these were predominantly warm periods.

Vintage years in contemporary Bordeaux and throughout central and western Europe tend still to be those of ample sunshine (especially in spring, and again in late July and August) and average or higher TEMPERATURES leading to a normal or early HARVEST date. Bad vintage years have almost invariably been cool and/or wet, with below-average sunshine.

In hot and reliably sunny viticultural climates, on the other hand, the best years for table wines are usually average or cooler than average. This generalization does not apply to sweet FORTIFIED WINES, which need more or less unlimited warmth and sunshine. Nor does it necessarily apply to all TABLE WINES or to all hot areas. For instance, wet, cloudy, and relatively cool summers in the very warm Hunter Valley of NEW SOUTH WALES are usually inferior for red table wines,

although they may still produce good-quality white table wines. However, the perturbations of CLIMATE CHANGE have made such generalizations less dependable.

The reactions of vines and grapes to seasonal conditions or weather events can also differ widely according to SOIL TYPE within an area. As demonstrated by the extensive studies of Seguin in Bordeaux, vines on well-drained, deep soils may be less affected by variations in RAINFALL, whereas those on shallow and poorly drained soils will alternate between DROUGHT stress and waterlogging under the same rainfall. For this reason, the best vineyards for wine quality, with favourable TERROIR, are the least subject to vintage variation and can maintain consistently high quality.

In addition, VINE VARIETIES can react quite differently to the weather conditions depending on their individual timings of BUDBREAK, FLOWERING, and RIPENESS and the relative sensitivities of their berries to rain, diseases or damaging heat. PINOT NOIR, like most other early-maturing red grape varieties, is very sensitive to heat, which affects wine style and quality. ZINFANDEL, with its tightly packed bunches, is notoriously sensitive to any rain towards harvest time. The least rain and water uptake causes berry splitting and subsequent total BUNCH ROT. This is probably the main reason its extensive use is confined to California and Puglia, where the ripening season is typically free of rain. CHENIN BLANC is similarly susceptible, at least in climates such as those of California and South Africa, where the preceding weather is mostly hot and dry. By contrast, CABERNET SAUVIGNON, with its looser bunches, is relatively tolerant of both heat and rain and is therefore generally less affected by vintage differences, so long as the weather has been warm enough to ripen it.

A final point is that critical weather events, particularly heavy rainfall and HAIL, are not necessarily uniform within a given district and year. Even if they were, vineyard management decisions can lead to quite different results—depending, for instance, on the extent to which SPRAYING has been practised or whether grapes are picked before, during, or after rains at harvest time.

Nor is weather the only possible external influence on the characteristics of a particular vintage year. Market conditions may dictate how or whether certain viticultural practices such as PRUNING and CROP THINNING are carried out so as to influence crop quality or YIELD. Social history may also dictate some characteristics of a vintage year, as in some of the vintages ripened in European vineyards during the Second World War. There have also been very rare instances of CONTAMINANTS from a new pesticide, for example, which have affected particular vintages of certain wines, sometimes on a less than localized scale, as in the use of Orthene in Germany in 1983.

For all these reasons, vintages are seldom uniformly good, medium, or bad, even within a small area (see VINTAGE ASSESSMENT). A generally recognized 'vintage' year can have its failures, often for reasons totally beyond the competence of winegrowers and winemakers. Equally, 'poor' vintages can usually still produce good wines from particular locations and grape varieties, whether because of the characteristics of the TERROIR, thanks to more prescient vineyard management, or both.

See AUCTIONS and INVESTMENT IN WINE. See also LABELLING INFORMATION. R.E.S. & J.R.

Broadbent, M., *Vintage Wine* (2002).

vintner, late Middle English word for wine MERCHANT, which superseded vinter. Mainly because of England's links with BORDEAUX, vintners were some of the most important people in the City of London in the 14th and early 15th centuries (four mayors of London were vintners in Edward II's reign). The Vintners' Company evolved from the 'Mistery of Vintners', a group of London and Gascon merchants who enjoyed a practical monopoly on London's important wine trade with Gascony from at least 1364. It was formally incorporated in 1437 and was recognized by Henry VIII as one of the '12 great' livery companies. It is still based at Vintners' Hall by the Thames in London, in a section of the City known as Vintry ward,

where for centuries wine would be unloaded from ship for sale throughout southern England. Independently of UK licensing restrictions, the Vintners' Company may grant Free Vintner status to members, allowing them to sell wine under certain conditions. Both the WSET and the Institute of MASTERS OF WINE are the result of initiatives of the Vintners' Company.

The word has also come to be used for a wine producer as well as a wine merchant, particularly in North America. KENDALL-JACKSON's Vintner's Reserve Chardonnay is one of the most successful BRANDS in the US.

Simon, A., *History of the Wine Trade in England*, ii (1964).

vin viné is a traditional term for a wine made strong and sweet by the addition of alcohol to grape juice or must at some point before fermentation is complete. A VIN DOUX NATUREL and a VIN DE LIQUEUR are both therefore *vins vinés*. See also MUTAGE.

Viognier became one of the world's most fashionable white grape varieties in the early 1990s, mainly because its most famous wine, CONDRIEU, is distinctive, was associated with the modish RHÔNE, and was then relatively scarce. By the mid 2000s, it was planted all over the Languedoc and had spread to the great majority of the world's wine regions, and in Australia it had become a common blending partner with various red grapes, especially SYRAH, for CO-FERMENTATION, copying traditional practice in CÔTE RÔTIE. CHÂTEAU-GRILLET is the only other all-Viognier French appellation. DNA PROFILING has shown a parent–offspring relationship with MONDEUSE BLANCHE and therefore, not unexpectedly, a close one with SYRAH. It also suggests a close genetic relationship with FREISA from Piemonte, a likely progeny of NEBBIOLO, making Viognier a cousin of Nebbiolo—something of a surprise.

The vines need a relatively warm climate and can withstand drought well but are prone to POWDERY MILDEW. The grapes are a deep yellow, and the resulting wine is high in colour, alcohol, and a very particular perfume redolent of apricots, peaches, and blossom, sometimes with a deeply savoury undertow. Condrieu is one of the few highly priced white wines that should probably be drunk young, while this perfume is at its most heady before the wine's slightly low ACIDITY fades.

The vine was at one time a common crop on the farmland south of Lyons and has been grown on the infertile terraces of the northern Rhône for centuries, but its extremely low productivity, often due to COULURE, saw it decline to an official total of just 14 ha/35 acres in the French agricultural census of 1968—mostly in the three northern Rhône appellations in which it is allowed: Condrieu, Château-Grillet, and, to an even lesser extent, Côte Rôtie, in which it may be included as a stabilizing agent up to 20% but usually closer to 5% of the Syrah-dominated total.

French NURSERIES saw an increase in demand for Viognier CUTTINGS from the mid 1980s, however (when the red wines of the Rhône enjoyed a renaissance of popularity), and by 1988 were selling half a million a year. By 1997 more than 100 ha/250 acres of Viognier qualified for the Condrieu appellation, and by the turn of the century Viognier plantings throughout the LANGUEDOC and ROUSSILLON had reached 1,540 ha (from 139 ha in 1993). By 2019 this total had reached 4,446 ha/10,986 acres. Considerable further plantings in the northern and southern Rhône, many of them outside appellation boundaries, took the total French area of Viognier up to 6,894 ha by 2019—quite a contrast to 50 years earlier. French Viognier is often sold as a relatively inexpensive VARIETAL, although here and elsewhere the variety has shown itself a willing and able blending partner, not just with other Rhône varieties such as ROUSSANNE, MARSANNE, GRENACHE BLANC, and VERMENTINO/ROLLE but also, usefully, with Chardonnay. This latter blend has had some success in Italy, where total plantings had grown to 1,827 ha/739 acres by 2015. Graf Hardegg makes some fine varietal Viognier in Austria, and it has its

champions, such as Gerovassiliou of Greece, in many European wine regions, but it is rarely planted to any great extent.

California has the world's second biggest area of Viognier planted: just over 6,315 ha/2,555 acres in 2020, much of it in the Central Coast. Many examples are notably high in alcohol when ripened under the reliable California sun—and Viognier has to be fully ripe before it reveals its trademark heady aromas. So seductive is it that there has been considerable experimentation with it all over North America, particularly in VIRGINIA, which has adopted it as its signature white wine, and also in Washington, Oregon, Texas, and British Columbia. By 2020 Argentina had 723 ha/1,787 acres and Chile had 761 ha/1,880 acres, both of them having made some convincing examples of this popular variety, which is also planted in Brazil and, with notable success, in Uruguay. Australian producers, led by Yalumba, have welcomed it with particular enthusiasm, using it both as a varietal white wine and as a 5–10% blend with Shiraz. Total plantings stood at 692 ha/1,710 acres in 2022. In New Zealand it is generally slightly less expressive but was planted on 65 ha/161 acres by 2022. South Africa has been catching up fast and had 730 ha/1,804 acres widely spread around the country by 2020. Today the consumer can choose from a range of recognizably perfumed, if slightly light, southern French varietal Viogniers, some of them produced from vines FIELD GRAFTED over to Viognier from less fashionable varieties, some of them perhaps perfumed by other aromas including a dollop of Muscat. The California way with Viognier is a notably alcoholic one, but when it works these monsters can be magnificent.

Viosinho, distinctive white variety producing some fine, TEXTURED, aromatic white wines, especially at higher ELEVATIONS, in the DOURO and Trás-os-Montes. Traditionally a constituent of white PORT, Viosinho is now also used to make unfortified wines and, partly because of its low yields and tendency to oxidize (see OXIDATION), it is generally blended with RABIGATO and GOUVEIO. Total plantings had risen to 1,223 ha/3,022 acres by 2020.

Viré-Clessé, white-wine appellation created in 1998 by separating out two of the top Mâcon-Villages, noted not just for their quality but also for the rich style of their wines. Bizarrely, the appellation initially banned wines with RESIDUAL SUGAR such as those made by Jean Thévenet of Domaine de la Bon Gran, but common sense subsequently prevailed. Although most wines are vinified dry, Viré-Clessé tends to produce heady, full-bodied whites of a sunny disposition. J.T.C.M.

Virgil (Publius Vergilius Maro)(70–19 BCE), Latin poet and good, if unoriginal, source of information on viticulture in ancient ROME. Like HORACE, Virgil benefited from the patronage of the Emperor Augustus, and much of his poetry was written in praise of Roman and Italian virtues. The rural virtues are expounded in the *Georgics*, a didactic poem about agriculture, published in 37 BCE. The second of the four books is devoted mainly to vine-growing. Although it is of little use as a practical manual, it does give a lively and colourful picture of the life and problems of the vine-grower. Like HESIOD, Virgil's purpose was moral, and his main concern is to describe the farmer's virtues of austerity, integrity, and hard work, which made Rome great. Although Virgil is from a literary point of view a more interesting writer than his chief source VARRO, he is not an independent authority, and it is to his predecessors CATO and Varro, and to the later COLUMELLA and PLINY, that we must turn for first-hand information about Roman viticulture.

Virginia , mid-Atlantic state in the eastern United States increasingly known for quality and diversity in its wines. BORDEAUX-style reds, especially made from Cabernet Franc and Petit Verdot, sometimes bolstered with Tannat, can achieve a sophistication

combining American ripeness and European elegance. This often leads to the observation that Virginia is, oenologically as well as physically, about halfway between California and France. Viognier established Virginia's reputation for white wines, but PETIT MANSENG is the current rage, beloved for its effusive tropical fruit flavours combining high acidity and sweetness. Albariño, Sauvignon Blanc, and Italian white varieties also do well, and a few producers make outstanding Chardonnay. Pinot Noir can succeed in select sites at high ELEVATIONS.

Virginia traces its winemaking history to its earliest colonial days and counts Thomas JEFFERSON as its most famous oenophile. Virginia's modern wine history begins in the 1970s, when Italy's Zonin family bought land north of Charlottesville and established Barboursville Vineyards. It took off in the 1990s when Dennis Horton, a restless experimenter with grape varieties, introduced his Viognier and topped some of California's best in a blind tasting. Early expansion in this phase included plantings on farms and vacation properties not ideally suited to grapevines and was hindered by disease-ridden vine stock purchased from west coast NURSERIES. Better vine stock and increased professionalism fuelled a rise in quality in the early 21st century, aided by forward-thinking regulatory and financial support from the state government and oenology and viticulture assistance from VIRGINIA TECH. Virginia's wineries also benefit from the state's booming TOURISM, which features colonial and Civil War history as well as the scenic Skyline Drive in the Blue Ridge Mountains.

By 2021 Virginia boasted nearly 300 wineries. The state's viticultural backbone stretches along the eastern foothills of the Blue Ridge Mountains, from south of Charlottesville northward to Loudoun County in the exurbs of Washington D.C., and includes eight AVAs: Eastern Shore, Northern Neck George Washington Birthplace, Peninsula, Middleburg, Monticello, North Fork of Roanoke, Rocky Knob, and Shenandoah Valley (shared with West Virginia and not to be confused with Shenandoah Valley in California's SIERRA FOOTHILLS).

FUNGAL DISEASES such as DOWNY MILDEW are perpetual enemies in Virginia's humid climate. Late-spring FROSTS can devastate YIELDS, and

Atlantic tropical storms can complicate harvest. So, despite success in growing VITIS VINIFERA varieties, there is increasing interest in French-American HYBRIDS for their disease resistance and lesser need for chemical inputs. Younger winemakers are dabbling in NATURAL WINES and PET-NAT, finding an enthusiastic audience in urban consumers who have embraced a 'drink local' mindset. Most Virginia wines are sold at the winery or over the internet and can be difficult to find through traditional retail distribution. D.M.

Virginia Tech (VT) in Blacksburg, VIRGINIA, is home to thriving research, teaching, and extension programmes in OENOLOGY, VITICULTURE, and FERMENTATION science. Oenology research in the Department of Food Science and Technology, established by B. W. Zoecklein in 1986, aims to improve wine AROMA and flavour through advances in grape chemistry achieved in the vineyard and through the application of targeted fermentation management practices in the cellar. Oenology extension supports the growing Virginia wine industry through collaborative applied research, workshops, and analytical services.

Virginia Tech's viticulture research and extension programmes are conducted through the Alson H. Smith Agricultural Research and Extension Center near Winchester in the northern Shenandoah Valley. Grape research has focused on aspects of cold stress physiology; vine and vineyard management to optimize YIELD; evaluation of wine QUALITY, VINE VARIETIES, and CLONES; and VINE PEST management. Technical information is disseminated through industry meetings, web-based resources, and a Wine Grape Production Guide (SEE WEB LINKS ecommons.cornell.edu/handle/1813/67189). Viticulture, oenology, brewing, and fermentation courses are offered at undergraduate and graduate level. A.C.S.

viroids, particles smaller than VIRUSES which are thought capable of producing virus-like disease effects in the grapevine. Viroids can be

found in nominally virus-free vines following THERMOTHERAPY and are known to cause significant diseases for other crops. They are transmitted by vegetative PROPAGATION as for viruses, but viroid-free grapevines can be produced by TISSUE CULTURE. No viroids have so far been identified with commercially important grapevine diseases. The viroid Yellow Speckle is widespread in Australia but is not known to harm the vines. R.E.S.

virus diseases, group of VINE DISEASES caused by very small and simple organisms, consisting of ribonucleic acid (RNA) wrapped in a protein sheath. Some virus diseases can seriously affect grapevine yield and wine quality, and, since they are mainly spread by PROPAGATION in CUTTINGS, there has been an emphasis on VINE IMPROVEMENT and CLONAL SELECTION to prevent their spread. Virus diseases began to affect European vines probably from about 1890, when GRAFTING on to ROOTSTOCKS was used in France to control PHYLLOXERA. Grafting doubles the risk of virus spread and, unlike many fruiting varieties, rootstocks infrequently show virus symptoms.

Virus diseases are mostly spread by taking cuttings from infected plants, although some are spread by NEMATODES and insects. They are mostly detected by inoculating sensitive plants (see INDEXING) and more recently by serological techniques based on immunological reactions (see ELISA) and RNA analysis. Often viruses do not kill the vine but each year may reduce both growth and yield. For example, rootstocks infected with LEAFROLL VIRUS show no symptoms, but the virus can greatly reduce wine quality as it delays fruit RIPENING. It is probably the most important vine virus disease in many parts of the world. Considerable viticultural effort has been expended in vine improvement and in developing virus-free vines. However, the increased use of NURSERY-propagated cuttings repeatedly taken from virus-free MOTHER VINES, especially rootstocks, has inadvertently led to the spread of TRUNK DISEASES, potentially causing greater harm than the virus diseases they were meant to control.

Common virus diseases are CORKY BARK, FANLEAF DEGENERATION, LEAFROLL VIRUS, RUGOSE WOOD, and NEPOVIRUSES. See also BACTERIAL DISEASES, FUNGAL DISEASES, and PHYTOPLASMA diseases.

New virus diseases continue to be discovered. Grapevine Pinot Gris virus (GPGV), for example, first discovered in Italy in 2012, is now reported worldwide, including in other varieties which may be symptomless. Little is known of effects on growth, yield, and quality, but the virus causes spring-time leaf mottling and deformation on Pinot Gris. R.E.S.

Bettiga, L. J., (ed.), *Grape Pest Management* (3rd edn, 2013).

viscosity, the quality of being viscous, the extent to which a solution resists flow or movement. Honey is more viscous than sugar syrup, for example, which is considerably more viscous than water. Viscosity, which approximates to what wine tasters call BODY, can be sensed by the human palate in the form of resistance as the solution is rinsed around the mouth.

A very sweet wine is more viscous than a dry one, even if they have the same ALCOHOLIC STRENGTH. Alcohol itself is more viscous than water, and higher-strength wines are therefore more viscous than lower-strength wines. An increase of 1% in alcoholic strength increases viscosity relative to water by about 0.04 units, while an increase of 10 g/l in RESIDUAL SUGAR increases viscosity by about 0.03 units. The most viscous wines of all, therefore, are those that are both sweet and strong.

It has been thought that the viscosity and the (quite unrelated) GLYCEROL content of a wine were the main factors in the formation of 'tears' on the inside of a wine glass. While they may be minor factors, the explanation is very different. See TEARS. A.D.W.

Vitaceae, the family in the plant kingdom which includes the genus VITIS containing the grapevine. There are 13–17 genera (taxonomists often disagree) altogether with about 900 species, which are spread through tropical and temperate zones around the world. The plants in the family are characteristically climbers with leaves opposite tendrils. See also BOTANICAL CLASSIFICATION. R.E.S. & J.V.

Vital, low-acid white grape grown in central Portugal, mainly in the Lisboa region, known as MALVASIA Corada in the Douro. Total Portuguese plantings of this vigorous, productive vine were 457 ha/1,129 acres in 2020. It can make fine, minerally wines (see MINERALITY) if planted in cool-enough terrain.

Vitales, the order in the plant kingdom which includes the family Vitaceae, including the genus VITIS, the grapevine. See BOTANICAL CLASSIFICATION.

vitamins, a group of organic compounds that are essential dietary components, deficiencies causing a variety of well-known disorders in humans. The levels of vitamins in grapes increase during RIPENING, but the final values are relatively low compared with those of many other fruits. The most abundant is ASCORBIC ACID (vitamin C), the levels of which vary considerably—15–150 mg/l, which is only 10% of that in oranges (although ascorbic acid is often added during winemaking). Average values for the concentrations of other vitamins are about 1–10 parts per million (ppm) for niacin, pyridoxine, and pantothenic acid; 0.1–1 ppm for thiamine and riboflavin; and 0.001–0.01 ppm for biotin and folic acid. These levels in grapes are too low to be considered as a serious dietary source and are further reduced in wine by the use of SULFUR DIOXIDE and by YEAST growth (although AUTOLYSIS can add others). Wine also contains low concentrations of vitamin B_{12} (cobalamine).

The 'bioflavonoids', or vitamin P, a complex that includes D-catechin and many other FLAVONOIDS, occur in GRAPE JUICE in large amounts, especially in dark-skinned berries, and may play a part in warding off heart disease (see HEALTH). B.G.C. & A.D.W.

viticulteur, French term for a vine-grower.

viticulture, the science and practice of grape culture. Viticulture is practised consciously by VITICULTURISTS, often instinctively by grape-growers or vine-growers. Practices vary enormously around the world; some of these differences are highlighted under NEW WORLD.

Grapes can be grown, over a wide range of LATITUDES, in CLIMATES ranging from very hot (southern California, inland Australia) to very cool (England, Luxembourg, Denmark). Viticulture is practised in very wet climates (parts of England and New Zealand) to very dry ones (Atacama in Chile, Central Valley in California). The TOPOGRAPHY can be very steep, as in the Mosel Valley of Germany or the Douro Valley of Portugal, or very flat plains, as in many regions of Australia and Argentina. VINE DENSITY can vary enormously: from vineyards planted with large numbers of very small vines, as is common in Champagne and Bordeaux (10,000 vines per ha/4,050 per acre), to few, large vines as in the traditional Vinho Verde vineyards of Portugal (600 vines per ha). Some vineyards may be tended entirely by manual LABOUR, while others are MECHANIZED. Vineyards may rely on IRRIGATION for their survival where they are grown in deserts, while in others, such as parts of France, irrigation is severely restricted.

The following entries follow the sequence of vineyard development from initial planning through to picking: VINEYARD SITE SELECTION; choice of ROOTSTOCK, VINE VARIETY, and CLONE; SOIL TESTING and SOIL PREPARATION; choice of VINE DENSITY and TRELLIS SYSTEM; vine PLANTING, VINE TRAINING, and PRUNING; control of VINE PESTS, VINE DISEASES, and WEEDS; and fruit SAMPLING and HARVEST. See also VINEYARD ANNUAL CYCLE.

Effects on wine quality

For still wines, the VITICULTURIST may well have a greater impact on wine quality than the WINEMAKER since so many of the factors affecting quality are determined in the vineyard. The belief that 'wine is made in the vineyard not the cellar' became increasingly widespread during the 1990s and is now probably more widely quoted than ever.

Quite apart from the decisions involved in vineyard site selection, there are obvious ways in which viticulture can influence wine quality—selection of vine variety, rootstock, clone—and some where the effects are more difficult to identify.

Usually premium-quality wines come from vineyards planted to soils with good DRAINAGE and of low SOIL FERTILITY (see also TERROIR). However, inappropriate vineyard management can destroy the potential for wine quality. For example, over-enthusiastic applications of nitrogen FERTILIZERS will result in excess vineyard VIGOUR which may delay RIPENING and encourage FUNGAL DISEASES. The SPRAYING regime adopted by the vine-grower can determine whether the grapes are affected by BUNCH ROT or not.

The choice of vine-TRAINING SYSTEM and associated trellis system can have fundamental effects on wine quality, for example by reducing excessive SHADE. Limits on YIELD are also imposed by appellation laws in some regions. Where vines are pruned lightly to many buds and develop too low a LEAF TO FRUIT RATIO, the fruit will not ripen properly, and wine quality will be reduced.

Vineyards may require judicious IRRIGATION to prevent excessive WATER STRESS (although the practice is banned or restricted in many European regions), but excessive irrigation (like excessive RAINFALL) can cause delayed ripening and a loss of wine quality. Vineyards should be subject to grape sampling programmes so that harvest takes place when the fruit has reached the level of maturity appropriate for the wine style. More broadly, lack of concern for the

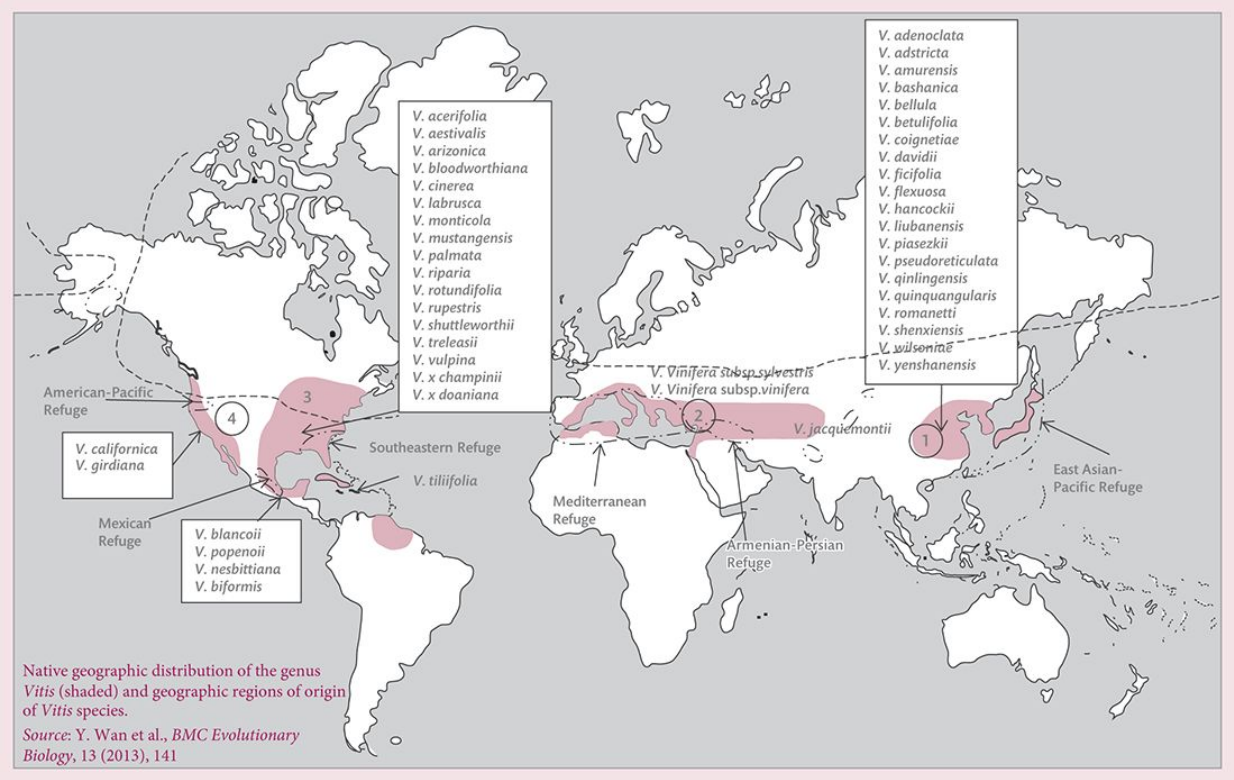
vineyard SOILS and ECOSYSTEM will not make the most of the vineyard site, nor promote its SUSTAINABILITY. R.E.S.

Dry, P. R., and Coombe, B. G. (eds.), *Viticulture*, i: *Resources* (2nd edn, 2004).

Galet, P., *General Viticulture* (2000).

viticulturist, someone who practises VITICULTURE. In many countries the grape-grower is termed simply 'grower' rather than 'viticulturist', the latter being more often used for professionals who typically have some formal tertiary training in viticulture. Grape-growers or vine-growers may also be termed 'winegrowers' if they are also involved in winemaking. R.E.S.

Vitis, the genus of the plant kingdom which includes the VINE (see BOTANICAL CLASSIFICATION). *Vitis* is one of 13–17 genera in the family VITACEAE and contains in turn about 60 species. Centres of *Vitis* diversity are equally divided between the east and south-east of North America and Asia, mainly in the TEMPERATE zones of the northern hemisphere, with a few in the tropics. The most important species for wine production is the single European species (strictly speaking, Eurasian) VITIS VINIFERA, often written *V. vinifera* or simply *vinifera*.



Native geographic distribution of the genus *Vitis* (shaded) and geographic regions of origin of *Vitis* species.
Source: Y. Wan et al., *BMC Evolutionary Biology*, 13 (2013), 141

As shown on the map, there are many different AMERICAN VINE SPECIES. They became the subject of attention by early European settlers as *vinifera* failed to cope with indigenous diseases in the early colonies on the east coast. However, they proved generally unsatisfactory for wine because of their strongly flavoured berries (see FOXY). These indigenous American species have since been crossed with *vinifera* to form new varieties (see AMERICAN HYBRIDS) and among themselves to produce the ROOTSTOCKS used in modern viticulture.

Among Asian species, VITIS AMURENSIS is the world's most northerly vine species and has been used to introduce cold hardiness into VINE BREEDING programmes. Varieties of *amurensis* and *Vitis coignetiae* (see YAMABUDO) are grown in JAPAN.

Note that the systematic botanical classification of species within the *Vitis* genus has been a subject of confusion for more than a century. Hedrick documents this early confusion, especially that concerning *Vitis vulpina*, which has often been wrongly confused with

VITIS RIPARIA, the great taxonomist Linnaeus being the origin of the confusion. GALET clarified the taxonomy in 1967, but there is still some doubt about the taxonomy of Asian species. The French taxonomist Planchon proposed that *Vitis* species be divided into two so-called sections. The first, *Vitis* (originally called *Euvitis*), contains the great majority of species including the 'European' wine grape species *Vitis vinifera*; the second, MUSCADINIA, contains only two species indigenous to North America. These two sections differ in chromosome number and many morphological features. The species of the section *Vitis* have proven to be closely enough related to interbreed easily when this has been attempted, but CROSSES between members of the two sections typically produces sterile hybrids. *Muscadinia* is sometimes considered a separate genus, but recent DNA PHYLOGENIES do not support this distinction.

For *Vitis silvestris*, see WILD VINES. See also VINE, VITIS VINIFERA, AMERICAN VINE SPECIES, VINE VARIETIES, PROLES, CLONE, HYBRIDS, and CROSS. R.E.S. & J.V.

Vitis amurensis often written *V. amurensis* or just *amurensis*, an Asian vine species of the VITIS genus which takes its name from the Amur Valley of northern China. The exceptionally cold climate in which it originates makes it useful to vine breeders seeking to introduce genes for cold hardiness. Professor Helmut BECKER in particular developed HYBRIDS which included both RIESLING and *amurensis* in their complex pedigrees (e.g. SOLARIS). See also CABERNET SEVERNY.

Vitis labrusca, often written *V. labrusca* or just *labrusca*, species of the VITIS genus native to North America. The juice of its grapes and the wine made from them usually have a pronounced flavour described as FOXY.

Vitis riparia, often written *V. riparia* or just *riparia*, species of the VITIS genus native to North America much used in developing suitably resistant ROOTSTOCKS and HYBRIDS.

Vitis rupestris, species of the *Vitis* genus native to North America much used in developing suitably resistant ROOTSTOCKS and HYBRIDS. For more details, see VITIS.

Vitis vinifera, often written *V. vinifera* or *vinifera*, the species of vine from which most of the world's wine is made and to which all the most familiar VINE VARIETIES belong. *Vinifera* is not a classical Latin word but one made up by Linnaeus (see BOTANICAL CLASSIFICATION) to denote 'wine-grape bearing'.

Vinifera is one of about 60 species of the *Vitis* genus, the majority of which originate in North America or Asia. The relationship of *vinifera* to other species of the *Vitis* genus is described under VITIS. The relationship of *Vitis vinifera* to other members of the plant kingdom is discussed under BOTANICAL CLASSIFICATION. *Vinifera* grapes

are used principally for winemaking, TABLE GRAPES, and RAISINS. (See VINE for more details.) There are some 5,000 to 10,000 *vinifera* VINE VARIETIES, grouped into three PROLES.

The species is thought to originate in south-eastern Anatolia or in Transcaucasia (see ORIGINS OF VINICULTURE) and was spread through the Mediterranean and Europe by the Phoenicians and Greeks and later by the Romans. *Vinifera* was spread through the NEW WORLD, initially by Cortés in SOUTH AMERICA and subsequently into western North America. The Dutch took *vinifera* grapevines to the Cape of Good Hope in 1616 (see SOUTH AFRICA), and the English to Australia, then New Zealand, beginning in 1788.

Vinifera is distinguished from other *Vitis* species by a range of general botanical features, including vigorous shoots mostly free of hair, prominent NODES and BUDS, regularly intermittent TENDRILS or BUNCHES, leaves generally orbicular and more or less deeply lobed, PETIOLAR sinus often in a U or lyre shape, and conspicuous dentation (so-called teeth) around the edge of the leaf. *Vinifera* flowers are typically hermaphroditic (both male and female), and there are differences in seeds, too (see GRAPE). Because *vinifera* vines are selected for their fruit characters, the seeds typically represent a small proportion of the berry weight, 10% compared with 80% for *Vitis berlandieri*.

Further details about *vinifera* can be found under the following entries, which describe more fully aspects of the commercial culture of this species, emphasizing its use in winemaking: VINE VARIETIES, VINE GROWTH CYCLE, VINE BREEDING, VINE DISEASES, VINE PESTS, VINE PRODUCTS, VINE TRAINING, and VITICULTURE. R.E.S. & J.V.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Vitovska, high-quality but rare white wine grape from the Karst region of south-west Slovenia and north-east Italy rescued from near-extinction in the 1980s. A CROSS between MALVASIA Bianca Lunga and

GLERA, it produces distinctively fresh and firmly STRUCTURED wines, especially when SKIN-FERMENTED.

Viura is the RIOJA synonym for the MACABEO grape.

Vivarais, Côtes du, AOC on the right bank of the RHÔNE immediately opposite GRIGNAN-LES-ADHÉMAR largely in the Ardèche. The region's 225 ha/556 acres in 2020 are widely dispersed on mainly LIMESTONE soils in a cooler, wetter climate than the rest of the southern Rhône. Red and rosé wine dominates. A small amount of white is made, mainly from Grenache Blanc. M.C.W.

Vizetelly, Henry (1820–94), prolific English wine writer whose detailed accounts of the history of port and champagne are particularly celebrated. Vizetelly came from a family of printers, and so it is particularly appropriate that today his influence is perhaps most marked in the continued, and increasingly imprecise, reproduction of the engravings which distinguished his many and various books about wine. He was introduced to wine in 1869 when he was sent to Paris to report on the French vintage for the *Pall Mall Gazette*, narrowly escaping execution during the Franco-Prussian War the next year. He spent much of the 1870s visiting the vineyards of France and Germany and in 1877 visited Portugal, Madeira, and the Canary Islands. Whereas JULLIEN and REDDING provided global wine surveys for the specialist reader, Vizetelly managed both to delve more deeply into specific wine regions and to produce books which appealed to a wider market. On his eventual return to England, he became a publisher; as Zola's English publisher, he was imprisoned and financially ruined.

voile. See FILM-FORMING YEAST.

Vojvodina, autonomous region within SERBIA.

volatile. All wines are volatile in that they contain volatile FLAVOUR COMPOUNDS and some level of VOLATILE ACIDS, but 'volatile' is used as a pejorative tasting term for a wine in which the level of ACETIC ACID has risen unacceptably high.

volatile acidity (or VA) is a measure of the volatile acids in wine, those that can be distilled. ACETIC ACID is the most prevalent, which is why it is used as the routine measure of VA. Acids such as carbonic, sulfurous, and LACTIC may also be present in trace amounts. It is not the acetic acid itself that causes changes in the aroma of a wine but the ESTER known as ETHYL ACETATE, the reaction product of acetic acid and ETHANOL.

VA in wine is usually considered to be a FAULT but at low levels—below the detection threshold of about 0.7 g/l—the VA may seem to LIFT the aroma. Higher levels result in loss of fruity aromas, less precision, and, at worst, aromas and flavours of VINEGAR and nail-polish remover, but this will depend on the wine style (sweet wines have higher VA levels) as well as the sensitivity of the taster. A few fine red wines are rich enough in BODY, TANNINS, and ALCOHOL to bear quite high concentrations of acetic acid, although they would surely be even better without it. The legal limits for VA in wine in the EU are 1.07 g/l for white and rosé wines and 1.2 g/l for red wines.

There are two sources of VA in wine. YEAST naturally produce small amounts of VA during FERMENTATION (usually up to 0.5 g/l). Its production is influenced by yeast strain, fermentation temperature,

and, for white and rosé wines, juice turbidity. SPONTANEOUS FERMENTATIONS or those that are sluggish will often have elevated levels of VA, which may result in a STUCK FERMENTATION.

The second source of VA is acetic acid bacteria from either the vineyard or the winery. These bacteria are always present, but it is only when they are provided with ideal growing conditions that they form acetic acid. The two main genera in this family are GLUCONOBACTER, which breaks down grape sugars to produce acetic acid, and ACETOBACTER, which will convert ETHANOL to acetic acid in the presence of oxygen. Diseased fruit in the vineyard will have elevated levels of these bacteria. Post fermentation, acetobacter may start growing again if there are low levels of SO_2 or high levels of oxygen. Good cellar hygiene and regular analysis of SO_2 and VA levels will prevent this from happening. K.C. & V.L.

volatile sulfur compounds, or VSCs, group of powerful and conspicuous FLAVOUR COMPOUNDS which play a significant role in wine flavour. Some typically contribute positive fruity flavours; others are considered FAULTS IN WINE. Whether they are seen positively or negatively depends on their concentration, on the style of wine, and on the taste preferences of the wine drinker, although HYDROGEN SULFIDE is always a fault. For more details, see THIOLS, SULFIDES, and REDUCTION. V.F.

volatility, property of having excessive VOLATILE ACIDS.

volcanic describes the processes and products of volcanic eruptions. The products include ejected fragments which settle to produce rocks such as TUFF and lava solidified to give BASALT. Volcanic materials are very varied, but all involve several silicate minerals (see GEOLOGY) and are therefore rich in potential SOIL NUTRIENTS. The rapid

weathering of recently produced volcanic rocks in the tropics, for example, yields some of the most fertile soils on Earth.

So-called volcanic soils were not themselves involved in volcanism but are derived from parent rocks which in most cases erupted tens or hundreds of million years previously. They are typically slightly acid, well-drained, and dark-coloured. The silicate minerals and the nutrients they yield are identical to those in non-volcanic rocks, but some commentators claim that vines grown on volcanic soils have something in common, for example a salty flavour or a specific TEXTURE.

The numerous wine-producing areas with volcanic rocks include SANTORINI and the CANARY ISLANDS; Italy's SOAVE, ETNA, and Monte Vulture in BASILICATA; TOKAJ in Hungary, IDAHO, WASHINGTON, and OREGON in the US; and the Kaiserstuhl-Tuniberg region of BADEN in Germany. See BASALT and TUFF for further examples. A.J.M.

Volnay, attractive small village in the Côte de Beaune district of Burgundy's Côte d'Or producing elegant red wines from Pinot Noir. The wines of Volnay were celebrated under the *ancien régime* for their delicacy: Claude Arnoux describes them as partridge-eye pink in colour and the finest of all the wines of the Côte de Beaune, although they had to be drunk very young. Since then they have alternated in fame with those of neighbouring POMMARD depending on whether FASHION dictated wines of breed or of power.

More than half Volnay's vineyards are of PREMIER CRU status, stretching in a broad swathe from Pommard to MEURSAULT, continuing into the latter village. Because Meursault is renowned for its white wines, its single really fine red-wine vineyard of Les Santenots is sold as Volnay Santenots, which has its own appellation. The best part of this vineyard is Les Santenots-du-Milieu, although it is not as typical of Volnay as Le Cailleret, which it abuts. First-class wines are also made in such vineyards as Champans, Clos des Chênes, Taillepieds, and various MONOPOLES: Clos des Ducs (Marquis d'Angerville), Clos du

Château des Ducs (Domaine Michel Lafarge), and Clos de la Bousse d'Or and Clos Verseuil (Clerget).

VORS and VOS, classifications for age-dated SHERRY.

Vosges OAK comes from the mountains to the immediate west of ALSACE.

Vosne-Romanée, village in the Côte de Nuits district of Burgundy's CÔTE D'OR producing arguably the finest red wines made anywhere from Pinot Noir grapes (see map under BURGUNDY). As well as excellent wines at VILLAGE and PREMIER CRU level, there are six GRAND CRU vineyards, three of which share the name Romanée, the suffix to which Vosne was hyphenated in 1866.

The grands crus are Romanée-Conti, La Romanée, La Tâche, Richebourg, Romanée-St-Vivant, and La Grande Rue. Between them they produce, with Musigny and Chambertin, the greatest wines of the Côte de Nuits. They have more finesse than any other, but to this is allied as much power and stuffing as their nearest rivals.

A vineyard formerly known as Le Cloux was rechristened La Romanée in 1651, presumably on account of Roman remains being discovered nearby. In 1760 the property was bought by the Prince de Conti, subsequently becoming known as Romanée-Conti. Just above this vineyard, whose wines can be the most expensive in the world, is La Romanée. Romanée-Conti has brown, CALCAREOUS soil about 60 cm/23 in deep with 45–49% CLAY and liable to serious SOIL EROSION in the upper, steeper part. La Romanée also has a notably steep slope with less clay and more RENDZINA in the make-up of the soil. The former is the MONOPOLE of the DOMAINE DE LA ROMANÉE-CONTI (DRC), the latter of Comte Liger-Belair. About 300 cases are made each year

from the tiny 0.84 ha/2 acres of La Romanée, double that is produced from the 1.8 ha of Romanée-Conti.

Another monopoly of DRC, and regarded as nearly as fine as the vineyard from which it takes its name, is La Tâche, whose 6 ha (including much of the vineyard of Les Gaudichots, which used to be separate but is considered to be of the same quality) produce a wine which is explosively seductive even when young, whereas Romanée-Conti takes longer to show its astonishing completeness. La Tâche seems to thrive even in lesser years, being judged the only wine worthy of bottling by the Domaine de la Romanée-Conti in 1950 and 1951.

The next most sought-after Vosne-Romanée wine is Richebourg, whose 8 ha are shared between ten growers, notably Domaine de la Romanée-Conti, Domaine LEROY, Grivot, branches of the Gros family, and Domaine Méo-Camuzet. As the name suggests, this is one of the most voluptuous wines of Burgundy and can equal La Tâche in some years.

Romanée-St-Vivant, taking its name from the monastery of St-Vivant founded at Vergy *c.* 900 and subsequent owner of the vineyard, can also make very fine wine, but it is usually lighter and less powerful than its neighbours, being further down the slope and having deeper soil. There are half a dozen owners, of which the largest is Domaine de la Romanée-Conti (5.3 ha out of 9.43). Domaine Leroy and Louis LATOUR's Domaine de Corton Grancey are the next largest owners.

Between La Tâche to the south and La Romanée-Conti to the north lie the 1.4 ha of La Grande Rue, originally classified as PREMIER CRU but promoted, as its location suggests is only right, to grand cru. The vineyard is a monopoly of Domaine Lamarche. Among the best of Vosne-Romanée's premier cru vineyards are Les Malconsorts on the Nuits-St-Georges side, Cros Parantoux made famous by Henry Jayer, above the grands crus, and Les Beauxmonts and Les Suchots abutting Flagey-Échezeaux. Part of Les Beauxmonts is actually in the latter commune, although it is sold as Vosne-Romanée, as is the village wine of Flagey.

While the renown of the Domaine de la Romanée-Conti dominates Vosne-Romanée, it should not overshadow other significant influences: Henri Jayer, for his unparalleled winemaking skills; René Engel, for his patriarchal influence and local historical research and publications; and Lalou Bize-LEROY, who bought and transformed the former Domaine Nöellat. Other particularly fine domaines are those owned by the various members of the Gros family, Domaine Jean Grivot, and Sylvain Cathiard. J.T.C.M.

Vougeot, small village in the Côte de NUITS district of Burgundy producing red wines from the Pinot Noir grape. The name is derived from the diminutive of Vouge, a small stream rising nearby. There are only 2.3 ha/6 acres of vineyards producing VILLAGE WINE and 13 ha designated PREMIER CRU; the village's fame rests squarely with the 50-ha GRAND CRU, Clos de Vougeot.

The fame of Clos de Vougeot is historical since it was the flagship vineyard of the Cistercians (see MONKS AND MONASTERIES), who planted and enclosed what is significantly the largest grand cru vineyard of the Côte de Nuits. Geologically, this is not a homogeneous site: the top, abutting Musigny and Grands Échezeaux, has a light CALCAREOUS and GRAVELLY soil on oolitic LIMESTONE which drains beautifully and gives the wines of greatest distinction; the middle section is on softer limestone with CLAY and some gravel, with moderate drainage on a very gentle slope. The bottom section, almost flat, stretching down to the main D974 road, consists of poorly drained ALLUVIAL clay.

When the wines could be blended by the monks to produce a complete wine from differing constituent parts, Clos de Vougeot doubtless deserved its reputation. Now that the vineyard is

fragmented between 80 or more owners, its grand cru status is less easy to defend, especially as the wines do not shine in their infancy. Classic Clos de Vougeot is likely to be dense and ungiving when young, robust rather than elegant. However, after a decade it opens out into one of the most complete wines of the Côte d'Or with deep, rich flavours reminiscent of truffles and undergrowth.

Of the premier cru vineyards, Le Clos Blanc, the monopoly of Domaine de la Vougeraie in succession to Héritiers Guyot, has produced white wine since first planted by the monks in 1110. The other premier crus are Les Cras, Les Petits Vougeots, and Clos de la Perrière, a MONOPOLE of Domaine Bertagna.

Reliable producers of Clos de Vougeot include Ch de la Tour (the largest owners), Méo-Camuzet, Anne Gros, and Domaine d'Eugénie.

J.T.C.M.

Vouvray, the most important white-wine appellation in the TOURAINE district just east of the city Tours on the right bank of the LOIRE. Vouvray is CHENIN BLANC (although up to 5% MENU PINEAU grapes are theoretically allowed). No other wine made only from this long-lived Loire grape variety, often called Pineau de la Loire, is made in such quantity, from more than 2,200 ha/5,430 acres of vineyard. Vouvray wines vary enormously in quality, thereby offering a true representation of the grape's finicky behavior.

Vouvray itself is a small, pretty town whose wines owe much to the MONKS AND MONASTERIES who refined local viticulture from the Middle Ages. But it was not until the creation of the AOC in 1936 that Vouvray established an identity of its own; before then most of it was shipped out for blending by the energetic DUTCH WINE TRADE, and much of the wine sold as Vouvray came from anywhere in Touraine.

The region's best TERROIR has historically been the flat, stony plateau that overlays the TUFFEAU cliffs overlooking the Loire from Rochecorbon to Vernou-sur-Brenne. Small rivers dissected this plateau, creating perpendicular valleys with sheltered slopes further from the Loire (in Parçay-Meslay, Reugny, Chançay, and Noizay).

Three main topoils cover the LIMESTONE bedrock: a mix of FLINTY-clay or *perruches* (known for wines with great AGEING potential), a CHALKY-clay called *aubuis* (known for wines of concentration), and younger sandy GRAVELS (more suited to sparkling wines). Wine style is also influenced by the weather, as the locals claim that this is where the Atlantic climate meets the CONTINENTAL CLIMATE, inducing much VINTAGE variation. In the least generous years, dry and sparkling wines make up the bulk of production, but top vintages yield styles from bone-dry SEC wines to golden MOELLEUX and LIQUOREUX wines that can age a century or more.

Making top-quality Vouvray Moulleux or Liquoreux wines is as hazardous as making any top-quality sweet white wine which owes its sweetness to NOBLE ROT or extreme RIPENESS because the vine-grower is at the mercy of the weather, which can be changeable in autumn. Thanks to CLIMATE CHANGE, winegrowers increasingly rely on passerillage (see PASSERILLÉ) more than on botrytis to acheive natural sweetness.

Great dry wine (with less than 8 g/l of RESIDUAL SUGAR) is slowly on the rise as a small but increasing number of producers lower yields and hand-harvest their grapes to produce expressive wines. Historically, still Vouvray wines are vinified in neutral vessels such as old oak casks or stainless-steel tanks and bottled by the spring, the wine's naturally high acidity preserved as MALOLACTIC CONVERSION rarely occurs. Yet recently some producers are experimenting with longer ageing for special cuvées. Many demi-sec (medium-dry) wines are also made.

Sparkling wines remain an important style of Vouvray, representing nearly 60% of production in 2021. MOUSSEUX and PÉTILLANT versions are vinified by the TRADITIONAL METHOD and aged on the LEES for at least 12 months. The majority is sold in France as entry-level sparkling wine, with few growers realizing the remarkable potential of the style. Commercial still Vouvray also exists, a medium-sweet, reasonably acidic wine that has little capacity for development. The

thousands of members of the Confrérie de la Chantepleure, a wine fraternity founded in 1937, actively promote Vouvray wines. P.Le.

www.bcvqa.ca

Vranac, very promising indigenous Balkan red grape variety grown in southern CROATIA, Herzegovina (see BOSNIA), Kosovo, Montenegro, NORTH MACEDONIA (where it is known as Vranec), and SERBIA. The wines produced are deeply coloured and can be rich in EXTRACT, responding unusually well to BARREL AGEING. There is an element of refreshing bitterness on the finish of these wines. DNA PROFILING has shown Vranac to be the offspring of Duljenga, an old Montenegrin variety, and Kratošija (see TRIBIDRAG).

VSIG stands for Vin Sans Indication Géographique, the French equivalent of a WINE WITHOUT GEOGRAPHICAL INDICATION and the official EU category for wines sold as VIN DE FRANCE.

VT. See VENDANGES TARDIVES.

Vulkanland Steiermark, wine region of Austria, known prior to 2016 as Südoststeiermark and accorded DAC status in 2018. It covers a vast area and harbours 1,671 ha/4,129 acres of vines, or 3.7% of Austria's vineyard. Top growers stake claims for the distinctiveness of their individual sectors and villages, of which the best-known are Kapfenstein, Straden, Klöch, and Bad Radkersburg. Generally warmer than the rest of STEIERMARK (and warmer as one goes south), this region has a long-standing reputation for both dry and off-dry TRAMINER. Authorized grape varieties for the DAC are WELSCHRIESLING, Morillon (Chardonnay), Riesling, Gelber MUSKATELLER, GRAUBURGUNDER (Pinot Gris), WEISSBURGUNDER (Pinot Blanc), Sauvignon Blanc, and TRAMINER as well as BLENDS from these; but further limitations apply to village-level and SINGLE-VINEYARD WINES. D.S.

Wachau, important wine region in Austria comprising (in 2021) 1,291 ha/3,190 acres of spectacular, typically south-facing vineyards upstream of KREMS on the Danube. 'Wachau' was long used to refer collectively to the vast array of vineyards within a radius of roughly 16 km/10 miles around Krems, then regarded as its capital. But in the aftermath of Austria's 1985 wine scandal, the recently formed growers' association VINEA WACHAU lobbied successfully for a more restricted delimitation. Today the Wachau constitutes just under 3% of Austria's vine surface and, owing to relatively low yields, represents an even smaller proportion of total wine production, but it has since the 1990s arguably become Austria's most prestigious wine region.

The region and its growers' association are best known for the stylistic division of dry, unchaptalized wines (see CHAPTALIZATION) into the weight classes STEINFEDER, FEDERSPIEL, and SMARAGD, each defined by a distinct range of MUST WEIGHT and ALCOHOLIC STRENGTH. These remained unchanged when the three-tiered Wachau DAC, which stipulates hand harvesting, was created in 2020. The Gebietswein (regional wine) category permits all 17 locally significant grape varieties: Grüner Veltliner, Riesling, Chardonnay, Pinot Blanc (Weissburgunder), Pinot Gris, Sauvignon Blanc, Neuburger, Muskateller, Roter Veltliner, and Zweigelt, as well as blends. Wines labelled for commune (village) are restricted to nine varieties, while SINGLE-VINEYARD WINES must be either Grüner Veltliner or Riesling.

Much of the Wachau is dramatically terraced and defined by ancient rocks of VOLCANIC origin—along with their metamorphic and decomposed variants. GRAVEL and ALLUVIUM characterize some level stretches near the Danube, and LOESS—the ancient glacial dust that

dominates many vineyards east of Krems—has settled among rocky slopes in certain places. The role of fast-draining, nutrient-poor soils based on rocks of crystalline structure is far from understood, but local growers as well as many consumers with a penchant for Wachau wine are confident of their ability to distinguish this region's wines according to their vineyards or at least their basic SOIL TYPES. The Wachau's TERRACES accumulate heat and drain moisture so quickly that vine SHUTDOWN is a hazard in years characterized by heat or DROUGHT. This circumstance prompted the installation of IRRIGATION lines, an initiative not without controversy but one that seems to have been instrumental in the more than three decades during which Wachau wines have achieved consistently higher must weights, more harmonious ACIDITY, and greater prestige than at any time since the Middle Ages. A further effect of selective irrigation was to extend the Wachau's already characteristically late harvests into November and sometimes December, though, in the face of climatic warming (see CLIMATE CHANGE) and the gradual increase in alcohol levels, a trend towards earlier harvest is recently in evidence. The Wachau also experiences some of the wine world's most extreme DIURNAL TEMPERATURE RANGES, thanks to a dependable daily pattern by which warm air is sucked upstream along the Danube from the Pannonian-Hungarian Plain, then displaced by cold moving in the opposite direction from the pre-Alps and forests that dominate the west and north of the region.

The Wachau's best-known villages, travelling upstream from east to west, with some of their most famous vineyards, are:

Unterloiben (Kreutles, Steinertal)
Oberloiben (Loibenberg, Schütt)
Dürnstein (Hollerin, Kaiserberg, Kellerberg)
Weissenkirchen (Achleiten, Klaus, Steinriegel, Weitenberg)
Joching (Kollmitz, Pichl Point)
Wösendorf (Hochrain, Kollmütz, Kirchweg)
Spitz (Axpoint, Hochrain, Setzberg, Singerriedel, Tausendeimerberg aka Burgberg)

The Spitzerbach, with its associated village of Viessling and its vineyards Brück and Schön, extends west into high hills from Spitz and away from the Danube, offering favourable conditions in an era of climate change. While the Wachau's right-bank vineyards generally generate little excitement, there are recent pockets of interest, and those of former Roman garrison Mautern—immediately opposite the Danube from Stein, which is part of the official KREMSTAL—are of contemporary as well as historical importance, thanks primarily to the Nikolaihof estate, associated with viticulture since at least the 5th century. Average holdings in the Wachau have largely resisted the national trend towards consolidation, partly due to the continuing success of the Domäne Wachau (formerly Freie Weingärtner Wachau) CO-OPERATIVE, whose nearly 200 members collectively own almost one-third of the Wachau's vineyard area. D.S.

Wädenswil, viticultural research station on Lake Zurich in German-speaking Switzerland established in the late 19th century and now part of AGROSCOPE.

Wagga , abbreviation for the School of Agricultural and Wine Sciences, Wagga Wagga, now part of CHARLES STURT UNIVERSITY.

Wagner, Philip (1904–96), Baltimore newspaper editor, VITICULTURIST, WINEMAKER, and author of books on vines and wine. Beginning as a HOME WINEMAKER during PROHIBITION, Wagner published *American Wines and How to Make Them* (1933). Interested in improving the basis of eastern American winemaking, Wagner began to import and test FRENCH HYBRID vines in 1939 and to distribute them from the NURSERY and vineyard he founded, Boordy Vineyard, in Maryland. His *A Wine-Grower's Guide* (1945) was the first work to publicize French hybrids in the US; in the same year he produced, at Boordy, the first French hybrid wine on record in the US. Wagner's success with his wines, his activity in supplying French hybrids from

his nursery, and the persuasiveness of his writing in favour of a better selection of VINE VARIETIES entitle him to be regarded as the man who changed the course of winemaking in the eastern US. T.P.

Wagram is a 2,439-ha/6,027-acre wine region of Austria (5.4% of its vineyards) on the largely LOESS and broadly terraced left bank of the Danube between KREMSTAL and VIENNA. Until 2007 it was part of a region known as 'Donauland', including today's TRAISENTAL as well as the right-bank vineyards of KLOSTERNEUBURG. After years of heated discussion, a Wagram DAC was announced in February 2022 that includes Klosterneuburg and its right-bank neighbourhood and recognizes 27 villages (three times as many as in the similarly sized and better-known Kremstal). The only significant limitations are that village-designated wines are restricted to seven of the region's 13 widely planted grape varieties and SINGLE-VINEYARD WINES to Grüner Veltliner, Roter Veltliner, and Riesling.

GRÜNER VELTLINER dominates plantings, at 54% of all vines in 2021. ROTER VELTLINER (no relation of Grüner Veltliner), while representing little more than 4% of Wagram vine hectarage, yields piquant, distinctive wines. Like RIESLING (with its 5.4% regional share), Roter Veltliner tolerates the dry conditions associated with those Wagram vineyards that are underlain by GRAVEL. Most other grapes familiar from parts of NIEDERÖSTERREICH west of Vienna are at home in the Wagram (ZWEIGELT being second most planted by far at 12.5%), which also boasts some impressive recently revived remnants of GEMISCHTER SATZ. D.S.

Wairarapa, GEOGRAPHICAL INDICATION (GI) at the southern end of New Zealand's North Island about one hour's drive from the nation's capital, Wellington. The dry, cool climate is ideal for PINOT NOIR, which occupies half the region's 1,039-ha/2,567-acre vineyard area and is naturally low yielding due to habitually cool weather at FLOWERING. The region comprises several subregions, of which Martinborough

(GI) is the most southerly and largest, with 42 wineries, including the famed Ata Rangi and Dry River. Vineyards rest on free-draining alluvial GRAVELS and CLAY terraces. Gladstone (GI) is centrally located while Masterton lies to the north, with ten producers between them. Most wineries are small, family-run affairs with CELLAR DOORS that benefit from weekend traffic from city dwellers. Nearly one-third of the total vineyard area is Sauvignon Blanc, while Chardonnay and Pinot Gris cover less than 100 ha/247 acres each. S.P.-T.

Waitaki, GEOGRAPHICAL INDICATION in North Otago, is the coolest viticultural region in New Zealand, with 59 ha/146 acres of vines planted on LIMESTONE soils. The climate and soils show particular promise for PINOT NOIR, though excellent Pinot Gris, Riesling, and Chardonnay are also produced. S.P.-T.

waiter, wine. See SOMMELIER.

Wales had 35 vineyards covering 58 ha/143 acres in 2021. CLIMATE CHANGE has benefited well-sheltered sites, and better YIELDS coupled with more interest in local wines has made viticulture more financially viable than it was in the past. Wine quality is still behind that of neighbouring ENGLAND, although a 2018 Blauer FRÜHBURGUNDER from a Welsh vineyard won a gold medal in a major UK wine COMPETITION (Decanter World Wine Awards).

Wales has the same CONTROLLED APPELLATION system as England, allowing producers to make Welsh Quality Wine and Welsh Regional Wine in both still and sparkling. S.S.

Walker Bay, southerly, relatively cool MARITIME wine district in South Africa. Its most important wards are Hemel-en-Aarde Valley, Upper Hemel-en-Aarde Valley, and Hemel-en-Aarde Ridge. Walker Bay's vineyards produce many of South Africa's most promising wines made from Chardonnay and Pinot Noir.

Wälschriesling. See WELSCHRIESLING.

war, effects on wine. Wine is a way of life literally rooted in the soil. It is also capital- and LABOUR-intensive and reliant on a complex distribution network, which make it highly vulnerable during times of war.

The most visible effect of war is the destruction of vineyards. Just as it was customary for warring ancient Greeks to cut down or burn the vines of their enemies, so the BARBARIAN invaders of Roman Europe signalled victory in the same way.

Planting on newly captured territory likewise symbolized success. When the Christians drove the Moors from medieval SPAIN, they planted vines behind them, as did the Crusaders who briefly held parts of the Holy Land. It is difficult to imagine a clearer expression of a battle won and determination to stay than the planting of such a long-term crop as vines.

Certain regions have suffered ruin disproportionately because of their strategic geographical position. The location of the CHAMPAGNE region at the crossroads of northern Europe has ensured the destruction of its vineyards dozens of times, most famously when they were bisected by the trenches of the First World War.

The short-term effects of war have sometimes had permanent consequences. The Thirty Years War (1618–48), which ravaged 17th-century Europe, was so destructive that many northern German vineyard areas were never replanted (see GERMAN HISTORY). Recovery was hampered by the sheer scale of the devastation, by lack of a labour force due to depopulation, and by destruction of capital equipment.

Plundering of existing wine stocks is another common feature of European war, with Champagne, once again, an obvious example. When Russian soldiers occupied the region in 1814 they were not slow to help themselves. In this case the Champagne houses did at least have the subsequent consolation that the Russians became their wines' most loyal peacetime consumers until 1917. In general,

however, terrible hardship resulted from forced requisitioning and outright plunder. Civil conflicts, such as the French Wars of Religion in the 16th century, were at least as destructive.

The sale and distribution of wine is a complex operation which is inevitably dislocated by war. TRANSPORT becomes hazardous. During the HUNDRED YEARS WAR (1337–1453), ships carrying wine between Bordeaux and England were attacked so often that convoys were arranged for safety.

Wars also frequently led to a ban on trade with the enemy. When Britain and France were at war in the early 18th century, French wine imports into Britain were prohibited. Smuggling was one answer to the problem; switching to wine produced by the ally Portugal was another. Thus war altered trading and consumption patterns, and PORT became the staple wine of Georgian England.

Wars do not bring uniform misfortune. The demand for wine to provision troops in some cases provided a stimulus to wine regions not directly involved in the fighting. The Roman army needed huge supplies to send it into battle. Records show that, when Edward I embarked on his Scottish campaign in 1300, he first bought in vast quantities of wine from Bordeaux.

It is also probable that the influx of American forces into Second World War Europe and its aftermath was an important factor in building the wine market in the UNITED STATES.

Historically the effects of war on wine, as on so many other commercial activities, have been mixed, and in some cases one grower's suffering made another's fortune.

warm-climate viticulture is characterized by growing seasons long and warm enough for regular ripening of mid-season grape varieties (such as CABERNET FRANC, MERLOT, SYRAH (or Shiraz), and SANGIOVESE) and late-mid-season varieties (such as CABERNET SAUVIGNON and NEBBIOLO) to make mainly medium- to full-bodied red TABLE WINES. CLIMATE CLASSIFICATION indices indicate that warm-climate viticulture is typically practised in Winkler Regions III and IV, Huglin Index warm-temperate and warm classes, and within 17–19 °C/62.6–66.2 ºF on the growing-season average-temperature index.

Typical regions are BORDEAUX and the northern RHÔNE Valley in France; the RIOJA Alta in Spain; much of northern ITALY and TUSCANY; the intermediate and warmer coastal valleys of California, such as NAPA and SONOMA; the north and east coasts of the North Island of NEW ZEALAND; Margaret River and the south coast of WESTERN AUSTRALIA; the Barossa Valley and Coonawarra in SOUTH AUSTRALIA; and much of central and northern VICTORIA.

Warm viticultural climates, if sunny enough, will ripen early and mid-season grape varieties to high sugar levels and make the best sweet, FORTIFIED WINES. They will also ripen late-maturing grape varieties such as MOURVÈDRE (Mataro), CARIGNAN, GRENACHE, TREBBIANO, and CLAIRETTE for making table wines. Examples are the south of France, the DOURO Valley of Portugal and the island of MADEIRA, the Adelaide district and McLaren Vale in South Australia, the MURRAY DARLING regions of South Australia and Victoria, and the Hunter Valley and Mudgee in NEW SOUTH WALES in Australia.

Typical hot-climate viticultural regions are those producing TABLE GRAPES and RAISINS in GREECE and TÜRKIYE and in the SAN JOAQUIN VALLEY of California. Growing-season average mean temperatures are mostly 21–22 °C/69.8–71.6 ºF or higher. Subtropical and TROPICAL VITICULTURE for table grapes and wine, using mainly non-VITIS VINIFERA grape varieties, also falls into this temperature category. G.V.J.

Warre, important PORT shipper. See SYMINGTONS.

Washington , state in the Pacific Northwest that ranks second in wine-grape production in the US, with 24,281 ha/60,000 acres of wine grapes in 2021 and an average annual wine production of 181,843,600 l/40 million gal (about 5% of the national total). Over 99% of Washington's wine grapes are produced in the eastern part of the state, from irrigated vineyards in the arid to semi-arid lowlands of the Columbia Basin. Washington boasts 20 AVAs and over 1,000 wineries, with 90% producing fewer than 5,000 cases annually.

History

Italian and German immigrants planted Washington's first documented wine-grape vineyards in the Walla Walla and Yakima valleys during the latter half of the 19th century. By the 1870s Walla Walla was home to grapevine NURSERIES and was annually producing thousands of gallons of wine. Devastating WINTER FREEZE events in eastern Washington in the 1880s led many growers to doubt the long-term viability of their vineyards, stalling the early growth of the wine industry. Wine production was revitalized in the early 1900s by W. H. Bridgman, who successfully established vineyards with multiple VITIS VINIFERA varieties on Snipes Mountain in the Yakima Valley. Following the end of PROHIBITION in 1933 and until the early 1960s, the Washington wine industry was dominated by sweet FORTIFIED WINES produced from blends of *vinifera* and HYBRID grapes. Pioneering viticultural research in the Yakima Valley by Dr Walter Clore confirmed the viability of multiple European cultivars, and under his guidance wine-grape plantings continually expanded: during the 1970s, plantings of European varieties expanded from 162 ha/400 acres to 1,207 ha/3,000 acres, and Washington wines produced by Chateau Ste Michelle and Associated Vintners began to be marketed throughout the US. By the end of the 1970s there were 16 wineries in Washington producing 1 million gallons of wine. Critical acclaim for Washington Riesling in the 1970s and for Cabernet Sauvignon- and Merlot-based wines in the 1980s spurred the expansion of Washington's vineyards and wineries, such that by 1990 over 7 million gallons of wine were produced by 92 wineries. The Yakima Valley became Washington's first federally sanctioned AVA in 1983, followed the next year by the Columbia Valley and Walla Walla Valley AVAs. The number of wineries and vineyard hectarage have continued to increase at a rapid rate into the 21st century.

Geography

Washington's most dramatic landscape feature is the Cascades, a range of mountains oriented north–south and punctuated by VOLCANIC peaks, some recently or potentially active, that include Mt Rainier, which rises over 4,267 m/14,000 ft. West of the Cascades, wine-grape vineyards have been planted on the coastal lowlands surrounding Puget Sound (Puget Sound AVA) and further south in the lowlands between the Cascades and Willapa Hills. Most of Washington's vineyards lie east of the Cascades in the Columbia Basin, a large low-ELEVATION plain traversed by the Columbia River, the fourth-largest river in the US. The viticultural areas east of the Cascades are predominantly situated at elevations below 610 m/2,000 ft, within the 11.25-million-acre Columbia Valley AVA, which includes 15 sub-AVAs whose boundaries are based on local variations in GEOLOGY, SOIL TYPE, and geomorphology. The vineyards in many sub-AVAs, including the Horse Heaven Hills, Red Mountain, Candy Mountain, Snipes Mountain, Rattlesnake Hills, Royal Slope, and Wahluke Slope AVAs, are situated on the south-facing slopes of ridgelines that traverse the Columbia Basin.

Washington's winegrowing regions are situated at latitudes 46–48° N, which corresponds to the area of France between Bordeaux and Burgundy. At these latitudes, throughout most of the growing season the sun is above the horizon for longer each day than in the wine regions of California.

Geology and soils

East of the Cascades, vineyards within the Columbia Basin are underlain almost everywhere by BASALT bedrock. In most vineyards, the bedrock is beyond the reach of vine roots as it is locally covered by the deposits of ancient rivers and lakes and, at most elevations below 366 m/1,200 ft, by SILT, SAND, and GRAVEL deposited by ice-age floods. The Missoula floods, which are the most recent of the flood events and have the most impact, were derived from the repeated failure of glacial ice dams in northern IDAHO between 13,000 and 16,000 years ago. The surficial sediments of the Columbia Basin, which comprise most vineyard soils, consist predominantly of wind-deposited silt and sand derived from the deposits of the Missoula floods. Since the flood sediments were largely sourced from the glacial erosion of GRANITIC rocks outside the Columbia Basin, the soils are chemically distinct from the underlying basalt bedrock.

The Lake Chelan and Rocky Reach AVAs on the western side of the Columbia Basin have granitic bedrock overlain by sediments deposited by glaciers, meltwater streams, and outburst floods. Further south along the Columbia Basin's western edge, the Naches Heights, Rattlesnake Hills, and Columbia Gorge AVAs contain regions underlain by bedrock derived from lavas and ash erupted from Cascade volcanoes.

The vineyard soils of eastern Washington are mostly deep and well-drained with very little CLAY and ORGANIC MATTER. Owing to the arid climate of eastern Washington, they often contain horizons of calcium carbonate (caliche; see GEOLOGY) with elevated PH values. A unique feature of many Columbia Basin vineyards are granite boulders (erratics) that were floated into place within icebergs that were entrained in the Missoula floods.

Since the vineyard soils in Washington west of the Cascades were mostly transported and deposited by streams and glaciers, they vary substantially in texture and overlie a large variety of bedrock types. Their thickness generally precludes interactions between vine roots

and the underlying bedrock. They are generally much richer in clay and organic matter than the soils of the Columbia Basin.

Climate

The major influences on Washington's climate are the Pacific Ocean and the Cascades. West of the Cascades, the climate is heavily influenced by the cool (13 °C/55 °F) waters of the Pacific Ocean, which moderate temperatures. The climate of the Columbia Basin, east of the Cascades, is much more CONTINENTAL. Precipitation throughout Washington is highly seasonal, derived from Pacific storm systems that are most common October–April.

The Cascades deprive the Columbia Basin of eastern Washington of most of the moisture from Pacific storm systems. The moist Pacific air masses expend the bulk of their moisture in the Cascades, then the air is warmed by compression as it descends the eastern slopes of the Cascades, further reducing humidity and inhibiting cloud formation. These processes combine to create a dramatic rain shadow, so that much of eastern Washington's grape-growing areas receive less than 254 mm/10 in of annual precipitation. Sunny skies are the norm in eastern Washington from June to September, and during this time it is common for parts of the Columbia Basin to receive no measurable rainfall for 60–80 days. The AVAs on the mountainous fringes of the Columbia Basin, such as the Columbia Gorge and Walla Walla Valley, receive substantially more precipitation than AVAs nearer the basin's centre, such as Red Mountain and Yakima Valley.

The relatively cloud-free skies and dry air of the Columbia Basin allows temperatures to drop rapidly after sunset and warm quickly at daybreak. These conditions commonly produce wide DIURNAL TEMPERATURE RANGES, especially in the late summer and fall. The FROST-free period in the Columbia Basin generally occurs between mid April and mid October, yielding a growing season of 180–200 days. Growing degree days (see CLIMATE CLASSIFICATION) typically range from 2800 in cooler sites to 3600 in the warmest locations. Throughout the year, colder air often becomes ponded in the valleys that lie between the ridgelines of the Columbia Basin. This creates inversions where the coldest daily low temperatures are experienced

at the lowest elevations on the valley floors. Every seven years on average, eastern Washington vineyards experience potentially damaging WINTER FREEZE events associated with Arctic air masses that push westward over the Rocky Mountains and into the Columbia Basin. During these events, temperatures often drop below −18 °C/0 °F.

In western Washington, summer is typically very dry, but a persistent layer of cool Pacific air often promotes the formation of fog and low clouds except in late summer. Western Washington's Olympic Mountains and the western slopes of the Cascades record the highest annual precipitation (2,540 mm/100 in or more) in the continental US. The lowland areas that host western Washington's vineyards receive more moderate annual precipitation (35–45 in). Due to the climate-moderating effects of the nearby Pacific Ocean and the topographic barrier of the Cascades, Western Washington generally has a longer frost-free growing season and less susceptibility to hard winter freeze events compared with the Columbia Basin. However, western Washington vineyards accumulate far fewer growing degree days (1500–2000) and receive far less solar radiation relative to their Columbia Basin counterparts due to the strong marine influence.

Viticulture

IRRIGATION is a necessity for most of Washington's vineyards. Water is sourced primarily from the Columbia and Yakima Rivers and from aquifers within the basalt bedrock. Vines can only be DRY-FARMED west of the Cascades, in the western part of the Columbia Gorge AVA, and in the eastern part of the Walla Walla Valley AVA. Most vineyards in the Columbia Basin are planted above valley floors on south-facing slopes, in a thermal belt that lies at elevations of 244–457 m/800–1,500 ft. Many vineyards have installed WIND MACHINES to mitigate damage from late-spring and early-fall freeze events. To protect vines from damage from winter incursions of Arctic air, viticulturists commonly bury canes or the lower parts of vine trunks after harvest. (See WINTER PROTECTION.)

The most common vine-TRAINING SYSTEM is vertical shoot positioning (VSP; see VERTICAL TRELLIS) in rows oriented north–south, but growers are beginning to implement other training methods as new areas less suited to traditional trellising are planted. The silt-based soils of Columbia Basin vineyards require COVER CROPS as they are highly susceptible to SOIL EROSION. Many growers regularly apply COMPOST between the rows to build ORGANIC CONTENT and promote biological activity in the desert soils.

Most of Washington's vines are own-rooted since it was long thought that the Columbia Basin's cold winters and clay-poor soil would thwart the infiltration of PHYLLOXERA. Unfortunately, phylloxera has recently been discovered to be spreading, albeit very slowly, in Columbia Basin vineyards. Many viticulturists have thus begun a programme of replanting on ROOTSTOCK. The arid, sunny, and often windy climate of the Columbia Basin discourages the growth of fungi, so the incidence of fungal diseases such as POWDERY MILDEW is low compared with most viticultural regions.

Varieties and styles

Washington's diverse topography and climate and the availability of irrigation water enables the cultivation of many grape varieties. At least 80 wine-grape varieties are currently planted. Of the 200,000 tons annually harvested, 60% are red varieties and 40% are white. Of the red varieties, the most commonly planted are Cabernet Sauvignon (50%), followed by Merlot (20%) and Syrah (17%). The most common white varieties are Chardonnay (40%), Riesling (35%), Pinot Gris (10%), and Sauvignon Blanc (10%). Washington's Chateau Ste Michelle Winery is the world's largest single producer of Riesling, with a half-million cases distributed annually. In the vineyards within the Puget Sound area, COOL-CLIMATE white grapes such as Müller-Thurgau, Madeleine Angevine, and Siegerrebe dominate. Pinot Noir is also cultivated in some of the warmer regions west of the Cascades, and plantings of this grape will likely expand there as the climate warms. (See CLIMATE CHANGE.)

Washington's ripening season is cooler than that of California, which helps to preserve ACIDITY and maintain the balance between phenolic ripeness and sugar content (see RIPENING). Critics often describe Washington wines as possessing TYPICALITY and bright fruit flavours and as bridging OLD WORLD and NEW WORLD styles. K.R.P.

www.washingtonwine.org

water is the most important constituent of wine (see WINE COMPOSITION) and access to reliable supplies of good-quality water, particularly for IRRIGATION, is a pressing problem for an increasing number of wine producers, particularly in inland Australia and much of California—not least because of CLIMATE CHANGE, DROUGHT, and problems associated with SALINITY.

SOIL WATER, the product of RAINFALL and/or irrigation, is a prerequisite for vine growth and survival. PHOTOSYNTHESIS, without which grapes would never ripen, depends on water being available (which is why RIPENING stops if WATER STRESS is too severe). Water in the form of well-timed rain can also be useful in dusting off grapes immediately prior to HARVEST.

Water is also vital in the winery: HYGIENE's best friend is the hosepipe, and many systems of TEMPERATURE CONTROL depend on copious supplies of water. In warmer regions, the operation known euphemistically as HUMIDIFICATION is sometimes undertaken for ALCOHOL REDUCTION.

And then there is water as a drink. For centuries wine was always diluted with water; indeed, drinking undiluted wine was the mark of a barbarian in ancient GREECE and ancient ROME. Wine was a safer drink than most available water until the 17th century in major cities and much later than that elsewhere. In the late 1960s, this book's founding editor was offered unlimited wine as part of her board when working in a smart Italian hotel but had to pay for bottled water, the only reliable drinking water.

Modern wine drinkers rarely choose to dilute their wine (other than to make the occasional SPRITZER), but for HEALTH reasons they are well advised to drink at least as much water alongside every glass of wine. Despite its incontrovertible appeal, wine is a poor quencher of thirst.

water addition. See HUMIDIFICATION.

waterberry, an alternative name, current in California, for BUNCHSTEM NECROSIS, the physiological disorder of grape berry stems, drying and shrivelling grapes as they approach RIPENESS.

water deficit. See WATER STRESS.

water shoot, a shoot that arises from the wood of the vine, not from buds left at PRUNING. In fact they mostly arise from BASAL BUDS embedded in the wood and are generally not FRUITFUL. Suckers are a type of water shoot which arise at the base of the TRUNK at or below soil level. B.G.C.

water stress is the physiological state of plants, including vines, suffering from a shortage of water. Water stress during the later stages of the viticultural growing season is common, since a considerable proportion of the world's vines are grown in MEDITERRANEAN CLIMATES, where rain falls principally in the winter months and irrigation is restricted or not used. By the time of ripening, after mid summer, the amount of SOIL WATER may well be limiting. It is commonly held that mild water stress, often referred to as water deficit, is desirable for optimum wine quality, especially for red wines, but there is little agreement about exactly how much. There is, however, almost universal agreement that water deficit should be sufficient before VERAISON to stop SHOOT TIPS actively growing. Otherwise the shoot tips attract assimilates, the products of PHOTOSYNTHESIS, away from the ripening fruit, to the detriment of wine quality.

Water deficit is essential for growing good-quality dark-skinned grapes. It not only reduces shoot growth but also limits berry size and increases the PHENOLICS in the skins. However, these beneficial effects require a CANOPY free from SHADE and, generally, low YIELDS. A combination of high yields and water stress leads to poor ripening due to insufficient photosynthesis. This explains why great wines may be produced in very dry climatic conditions in southern France or Spain, for example, but only when yields are kept to 30 hl/ha or less. Peyrot des Gachons et al. have shown that water stress is not generally favourable for the quality of white wines, causing them to be less aromatic.

IRRIGATION can be used to overcome water stress. Although the practice is outlawed or severely restricted in some European

countries, CLIMATE CHANGE is provoking reconsideration of this approach. Water stress results in restriction of growth and loss of yield. Unirrigated or DRY-FARMED vineyards in hot climates may yield only 2–5 tonnes/ha, for instance. PARTIAL ROOTZONE DRYING is an irrigation method which aims to stimulate the vines' perception of water stress while minimizing any drop in yield. Another irrigation strategy designed to induce water stress is REGULATED DEFICIT IRRIGATION. However, this technique is more likely to reduce yield and can induce excessive water stress in hot weather if not applied judiciously. Both techniques are successfully used in California and Australia to control water stress in vines at critical times to achieve better fruit and wine quality.

Water stress depends on two components: the available water content in the rootzone of the vine (see SOIL WATER); and the evaporative demand of the atmosphere, which shows signs of increasing as a result of climate change. The latter depends on factors affecting the rate of EVAPORATION, which is high on sunny, hot, windy days with low humidity. On days with extremely high evaporation, even well-watered vines can show temporary wilting. On the other hand, vines growing in dry soils but in overcast, cool, and humid climates do not show as much water stress. The combination of climate, soil, and vine architecture (consisting of VINE DENSITY, TRELLIS and TRAINING SYSTEMS, and PRUNING) which results in maximum vine stress is high evaporation, low soil water content, and large exposed leaf area (per unit of soil surface); minimum stress results from low evaporation, wet soils, and small leaf area.

Water stress is measured by vine physiologists as water potential in the plant but is more easily understood in terms of the effect on the vine. One of the first signs of impending water stress is the drooping, or wilting, of TENDRILS near the shoot tip, followed by wilting of the young, then the mature, leaves. With severe stress, the leaves exhibit yellowing, then NECROSIS, and may eventually fall off. Berries start to shrivel. As water stress develops in the vine, the plant responds by endeavouring to reduce water loss. In NEW WORLD

countries in particular, where irrigation is more common, water stress is sometimes indicated by measurements of SOIL WATER content or suction, with irrigation decisions based on this information.

The direct measurement of water stress as experienced by the vine has been made possible by the commercial availability in the last decade of the 20th century of equipment such as PRESSURE BOMBS, which measure leaf or stem water potential. *In situ* tensiometers to measure water potential in the vine trunk have also been developed. Although time-consuming, such measurements can indicate day-to-day fluctuations in vine water status and are widely used in California and in other irrigated wine regions. They can be used to monitor irrigation, although such data are not always easy to interpret because the readings are affected by ambient weather conditions (temperature, sunshine, and humidity), which vary according to the time of day (discussed by Smart).

A very promising technique to measure the water deficit experienced by vines is to analyse carbon isotope discrimination by measuring the ratio of ^{13}C to ^{12}C in the sugar content of fully ripe grapes. In the process of photosynthesis, plants incorporate preferentially ^{12}C and thus 'discriminate' against ^{13}C, but in water-stress conditions isotope discrimination is less effective so that the $^{13}C/^{12}C$ ratio is lower. This ratio can therefore be used as a measurement of average water uptake conditions from veraison through to ripeness, as described in van Leeuwen et al. (2009). The measurement can be outsourced to specialized laboratories and requires no other field work than grape SAMPLING. Possible applications are the assessment of vine water status in TERROIR studies and validation of irrigation strategies at the end of the season.

A well-watered vine opens the pores called STOMATA on the underside of the leaf in response to the first light of dawn, and they remain open all day, allowing the free exchange of water vapour (the air humidity) and CARBON DIOXIDE between the leaf interior and the atmosphere. Water stress causes the vine leaf partially to close

stomata during the day, and the hormone ABSCISIC ACID regulates this response. Initially this may be in the middle of the day, but subsequently, as the stress worsens, they are shut for most of the day. While this action is sufficient to reduce further water loss, photosynthesis is reduced because of the lack of carbon dioxide. Further, because the cooling benefit of transpiration is lost, leaves exposed to direct sunlight show a temperature increase of around 5 ºC/40 ºF or more. Using modern thermal imaging techniques, these elevated temperatures can be detected by PROXIMAL or REMOTE SENSING, as described by Matese et al. Recent studies have shown that stomata may stay open during the night, so that night-time water losses may occur (referred to as 'night-time transpiration') but with no benefit for photosynthesis since this occurs only in daylight conditions.

Water stress also affects a range of other vine functions. It can substitute for winter cold in promoting DORMANCY in TROPICAL VITICULTURE. During the growing season, DROUGHT causes shoot growth to slow and then stop as the leaf tip loses activity. Leaves are smaller and paler in colour, and the growth of LATERAL SHOOTS is also inhibited. Severe stress early in the season can reduce FRUIT SET, and later stress reduces BERRY SIZE.

The effect of water stress on wine quality is not straightforward. There is no doubt that severe water stress interrupts grape RIPENING and reduces wine quality (especially when yields are high). It is not clear whether water stress leads to higher SUGARS and better wine in dry viticultural areas such as the LANGUEDOC and ROUSSILLON in southern France. In humid MARITIME CLIMATES, such as that of BORDEAUX, however, there has been ample demonstration that mild water stress during ripening is favourable to wine quality. For example, the Bordeaux growing seasons of 1989, 1990, 1995, 1998, 2000, 2005, 2009, and 2010, all superior VINTAGES, were all relatively dry. Van Leuwen et al. (2009) show that all the driest vintages produced good quality while all the wettest vintages were relatively poor.

Waugh, Harry (1904–2001), English wine merchant famous for his longevity, courtesy, and open mind. He did not enter the wine trade until he was 30, joining as a clerk in a long-established City of London business associated with the fashionable West End company of Block, Grey & Block, where he went to work and first displayed his ability in selecting and selling fine wines. At that time, few British wine merchants visited the sources of their wines, and most relied on agents or their principals, who paid regular visits to Britain. In this way, Waugh met such well-known Bordeaux merchants as Christian Cruse, Jean Calvet, and Ronald BARTON.

During the Second World War, Waugh served in the Welsh Guards; at the beginning of 1946 he joined the London office of Harveys of Bristol. With wine in very short supply after six years of war, there was great demand for red bordeaux, the favoured table wine among regular wine drinkers. On holiday in Bordeaux, he was introduced by Édouard Cruse to the wines of POMEROL, then almost unknown in Britain. In 1950 he acquired and imported in cask the distinguished 1949 vintage of the then obscure PETRUS; by coincidence, so did that other Bristol wine merchant Ronald Avery. He also visited other

French wine regions, including Beaujolais, then imported as a somewhat anonymous quaffing blend, but he introduced Harveys' customers to individual CRU Beaujolais.

After the devastating FROSTS of February 1956, Waugh, by then a director of Harveys, went with a colleague to Bordeaux and, through broker Jean-Paul Gardère, bought large quantities of the fine 1955 vintage, thereby bypassing the BORDEAUX TRADE, for which he was long remembered. He was a regular visitor for his firm to Oxford and Cambridge colleges, and in 1953 he instituted an annual Oxbridge undergraduate wine-tasting competition, sponsored until 1990 by Harveys (and subsequently by POL ROGER).

In 1962 the families who owned Ch LATOUR decided to sell and offered this famous Bordeaux FIRST GROWTH to Harveys. Although Waugh and his chairman were in favour, the majority of the board was against, so that Pearson, publishers of the *Financial Times*, acquired a 51% stake, while Harveys were allotted only 25%. Waugh became one of two Harvey representatives on the board, on which he remained through two changes of ownership. He introduced as joint managers Jean-Paul Gardère and his friend Henri Martin, proprietor of Ch Gloria (see ST-JULIEN). In 1966 when Harveys was bought by Showerings, producers of Babycham, a popular perry, Waugh, then 62, retired. (Seven years later his first children, twins, were born, both of whom went on to work in the UK wine trade.)

Then began Waugh's close association with wine amateurs in the United States. For many years he made regular lecture tours and achieved a reputation in the US unequalled by any other British wine professional. Several volumes of *Harry Waugh's Wine Diary* were published as a record of his punishing itineraries. He did much to publicize Ch Latour and Bordeaux in general. He also introduced California wines to British (and east-coast American) wine connoisseurs in the early 1970s when they were little known. For his services to French wines, he received the French Mérite Agricole in 1984, and in 1988 he was made a Chevalier de l'Ordre du Mérite National. In 1989 he was made an honorary member of the Institute of MASTERS OF WINE. He will always be remembered for his reply to

someone who asked whether he had ever mistaken claret for burgundy: 'not since lunch'. E.P.-R.

Waugh, H., *Harry Waugh's Wine Diaries*, vols. i–ix (vols. i–v were individually entitled) (1966–81).

weather, probably the single most exasperatingly unpredictable variable in the viticultural equation, as in most other farming activities. For details of overall weather patterns, see CLIMATE, MACROCLIMATE, and CLIMATE CLASSIFICATION. For accounts of specific climatological phenomena with implications for wine production, see DEW, DROUGHT, FLOODING, FROST, HAIL, RAINFALL, SUNLIGHT, TEMPERATURE, and WIND. The weather in a specific growing season is the most important influence on the characteristics of a particular VINTAGE YEAR.

weed control, a range of viticultural practices to avoid WEEDS competing with vines—particularly young vines—for water and NUTRIENTS. The practices vary from region to region and with VINE AGE, with the common options being TILLAGE (ploughing) or HERBICIDES.

Mechanical control of weeds involves cultivating down the row alley using discs or tines. Tilling directly under the row is more difficult, as the weeding device needs to avoid the TRUNKS. A number of appropriate cultivators have been developed, with the swing-back action achieved manually in early models but now controlled automatically by touch-sensing the trunk. Even so, such tilling disturbs the ground under the vine row where the majority of roots are, and many machines can cause some vine damage. Hand hoeing of weeds is still found in some vineyards, although often this is restricted to the control of particularly difficult weeds in young vineyards. The alternative is to use herbicides, and spraying an undervine strip is common.

Mowing between the rows is common in summer rainfall areas or where there is plentiful IRRIGATION, otherwise the weeds growing there cause excessive WATER STRESS and sometimes NITROGEN

deficiency, leading to incomplete fermentations. Other methods of weed control include using MULCH or cereal straw, for example, placed as a mat under the rows. This has the added advantage of increasing ORGANIC MATTER, EARTHWORM populations, and water infiltration. During the vines' early years, weeds may also be controlled by planting through a strip of plastic. R.E.S.

University of California Agriculture & Natural Resources, 'Integrated weed management', www.ipm.ucdavis.edu/PMG/r302700111.html.

weeder, implement used in vineyards for removing WEEDS, typically from the vine row. These machines, usually mounted on a tractor, have fallen from favour owing to the damage to some vines and the introduction of certain diseases because of vine injury, although modern machines cause less damage. In many parts of the world, undervine weeders has been replaced by HERBICIDES or the use of undervine MULCH. R.E.S.

weeds. A weed is defined as a plant out of place. Although vine-growers have traditionally regarded a weedy vineyard as a sign of poor management, attitudes changed in the late 20th century, and the sight of a 'weedy' vineyard is now commonplace. Weeds, now sometimes referred to more kindly as volunteer COVER CROPS, are considered environmentally desirable as part of the vineyard ECOSYSTEM. Alternatively, some vineyards are frequently tilled to keep them free of weeds, to the detriment of SOIL STRUCTURE. HERBICIDES are also used, perhaps in combination with less frequent TILLAGE.

There is no doubt that weed growth can inhibit the growth of vines, especially when they are young. When the vine root system is small and shallow, weeds compete for water and nutrients, especially NITROGEN, but with older vines the competition can be less as the vine root system is larger and deeper. Some plant species seem to have a

further effect in inhibiting others, a phenomenon known as allelopathy. In very weedy vineyards, the weeds may also compete with the vines for light.

Weeds can cause inconvenience and discomfort to vineyard workers and can also harbour VINE PESTS and VINE DISEASES, although they can also usefully shelter predators of insect vine pests. Weeds play an important part in the spread of the disease FLAVESCENCE DORÉE. In some vineyards, other plants may be deliberately encouraged to grow between the rows as a COVER CROP.

Weeds which occur in vineyards obviously vary from region to region and are representative of the local flora. Those present depend on prior land use, soil preparation, seed reserves in the soil, and the extent to which seeds arrive in the vineyard, by wind or on implements, for example. Weeds which are difficult to control and can be found in many vineyards worldwide include field bindweed (*Convolvulus arvensis*), Johnson grass (*Holcus halepensis*), and Bermuda or couch grass (*Cynadon dactylon*). R.E.S.

Bettiga, L. J. (ed.), *Grape Pest Management* (3rd edn, 2013).

weighing of grapes is an important operation at any centre where grapes are received from a number of different growers who are paid by weight. This applies to most wine CO-OPERATIVES and many individual wineries, even if the more progressive take other factors such as grape quality and health into account before determining PRICE. Weighing is normally done with large platform scales on which the lorry is weighed full and empty.

It is also important to weigh grapes before PRESSING in order to measure the volume of juice extracted in relation to the fruit weight. See, for example, CHAMPAGNE for the regulations concerning pressing and yield.

Wein (pronounced 'vine') means 'wine' in GERMAN and is therefore how a WINE WITHOUT GEOGRAPHICAL INDICATION would be described in

Germany and Austria. It is also the first syllable of a host of important German wine names such as Weinbau ('vine-growing'), Weinbrand ('basic brandy'), and Weingut ('wine estate') as distinct from a Weinkellerei, which buys in grapes, must, or wine but probably owns vineyards only if it describes itself as the all-purpose Weingut-Weinkellerei. A Weinprobe is a wine tasting; Weinsäure is TARTARIC ACID, some of which may eventually be precipitated as crystal TARTRATES, or Weinsteine. A wine made by blending ingredients from more than one EU country is a Wein aus der europäischen Gemeinschaft.

Weinviertel, a vast arc of viticulture in AUSTRIA north of the Danube, extending along the border of CZECHIA, then east and south along the River March and Austria's frontier with SLOVAKIA, its western edge abutting the KAMPTAL and WAGRAM, and its southern fringes abutting the urban vineyards of VIENNA. With 14,001 ha/34,597 acres of vines (2021), the Weinviertel is Austria's largest official wine region, generating roughly one-third of Austrian wine. Volume has gone hand in hand with modest prices and relative lack of cachet, but it has also made the Weinviertel an indispensable feature of Austria's passionate wine-drinking culture, and an increasing number of quality-conscious growers are carving a niche for themselves and this region among their country's many wine sophisticates.

By 2021 half of the Weinviertel's vineyard area was planted with GRÜNER VELTLINER, but that dominance came about only after the middle of the last century. In a region this large and diverse geologically, climatically, and culturally, it is not surprising that growers have scored striking successes with many grape varieties, notably MUSKATELLER, Pinot Blanc (Weissburgunder), Riesling, and TRAMINER. Among the more important wine communities of the Weinviertel are Maissau, Retz, and Röschitz; Falkenstein, Poysdorf, and Wolkersdorf in the north-east (prominent for SEKT base wine but capable of far greater distinction); along with west-centrally located Ebenthal and Hohenruppertsberg. An important cluster of tiny villages

abuts Vienna, especially in the Bisamberg sector adjacent to Vienna's 21st District, of which the best known is Stetten, being home to the Weinviertel's most prominent pioneer of ambitious quality, Roman Pfaffl.

Weinviertel DAC was the first Austrian DAC appellation and applies only to wines made from Grüner Veltliner. A DAC Reserve category stipulates marginally higher minimum alcohol and a later release date. Other than slight differences in the adjectives used to characterize their styles, criteria for Weinviertel DAC are not materially different from those governing Grüner Veltliner in the KAMPTAL, KREMSTAL, or TRAISENTAL DACs. Since its inception in 2002, many growers have chosen to submit only one or two of their Grüner Veltliner bottlings for DAC approval, and several prominent producers now submit none. Any QUALITÄTSWEIN grown in the Weinviertel that does not meet DAC requirements or that is not submitted for approval gets labelled for its state of origin, NIEDERÖSTERREICH.

D.S.

Weissburgunder, or Weisser Burgunder, is the synonym for PINOT BLANC used in German-speaking wine regions. The Germans have a much greater area planted, up to 5,922 ha/14,634 acres by 2020, than the French (although less in total than they have of the Pinot Gris they call GRAUBURGUNDER). It is now Germany's fourth most planted white wine variety, with vinous personalities ranging from the full, rich, oaked examples of Baden and the Pfalz to relatively delicate, mineral-inflected variations along the Nahe and Mosel, and with quality aspirations ranging from a workaday norm to occasional brilliance. It is popular with growers seeking food-friendly wines that are softer than Riesling and can reflect local TERROIR.

Weissburgunder is the fifth most planted white wine grape in Austria, accounting for nearly 1,884 ha/4,655 acres and 4.2% of the total vineyard area. As a dry white VARIETAL, Weissburgunder is associated with scents of almond and apple, inherent textural creaminess, and an ability to age. It has also received attention in Austria for rich, BOTRYTIZED wines, either solo or in a blend.

weisser, meaning 'white', is a common prefix in German for pale-skinned grape varieties (e.g. Weissburgunder or Weisser Burgunder is PINOT BLANC in German-speaking wine lands).

Weisser Riesling, common synonym for the great White RIESLING grape variety of Germany.

Weissherbst is by German law a rosé wine at least 95% of which is made by direct pressing of a single red wine grape variety named on the label (SPÄTBURGUNDER and PORTUGIESER are especially common). In practice, the 5% red wine permitted to achieve a desired colour is rarely added since consumers expect Weissherbst to be very pale. The term is also used in German-speaking SWITZERLAND for very much the same style of wine. See also SCHILLERWEIN.

Wellington , warm inland wine district in SOUTH AFRICA just north of PAARL, which produces full-bodied wines, mainly reds.

Welschriesling, or Wälschriesling, important white grape variety which, as Germans are keen to point out, is completely unrelated to the great RIESLING grape of Germany. Indeed it rankles with many Germans that the noble word is even allowed as a suffix in the name of this inferior variety, preferring the word 'Rizling', as used in synonyms such as Welsch Rizling or Welschrizling. Welsch simply means 'foreign' in Germanic languages, which provides few clues but suggests that the variety may well have originated in a non-German-speaking country. *Wine Grapes* lists five reasons why its country of origin is most likely to be CROATIA, where it is by far the single most planted vine variety, and why its official name should be Graševina, its historical Croatian name. It is also widely planted in much of the rest of central and eastern Europe.

Welschriesling may be the variety's most common name in AUSTRIA, but it is known in Hungary as OLASZ RIZLING (under which

more details of its importance in Hungary are to be found), in Slovenia and Serbia it is LAŠKI RIZLING (as well as the historical name Grašac in Serbia), and in CZECHIA and SLOVAKIA it is the very similar Rizling Vlašský. The Italians call it RIESLING ITALICO (as opposed to Riesling Renano, which is the Riesling of Germany), and variants of this are used all over Eastern Europe. In ROMANIA, Riesling Italico is the third most planted white variety but is known locally simply as 'Riesling'. Welschriesling is also planted in CHINA.

It does best in dry climates and warmer soils and has a tendency to produce excessively acid wines in cool climates. Like German Riesling, it is a relatively late-ripening vine whose grapes keep their ACIDITY well and produce light-bodied, relatively aromatic wines. Welschriesling can easily be persuaded to yield even more productively than Riesling, however, and indeed this and its useful acidity probably explain why it is so widely planted throughout eastern Europe and, partly, why so much of the wine it produces is undistinguished (although poor-quality viticulture and winemaking equipment may also have played a part).

As a wine, Welschriesling reaches its apogee in AUSTRIA, where, despite long-standing decline, it remains the country's second most planted white grape after Grüner Veltliner. While the bulk of Austrian Welschriesling goes into lightweight wines intended for casual and immediate consumption or into Austrian SEKT, it figures both solo and blended (especially with Chardonnay) in impressively rich yet lively late-harvest BOTRYTIZED wines made on the shores of the Neusiedlersee in Burgenland, where one-third of Austria's 2,942 ha/7,270 acres of the variety is planted. TROCKENBEERENAUSLESE bottlings can boast impressive longevity, albeit not that of a corresponding German Riesling. Increasingly, prominent winegrowers, especially in SÜDSTEIERMARK and SÜDBURGENLAND, are crafting serious dry Welschriesling from OLD VINES, the wines often benefiting from long LEES CONTACT. All of these more ambitious efforts capitalize on the grape's stubborn acid retention—which, like its DROUGHT-tolerance, could become increasingly valuable in the face of CLIMATE

CHANGE—without being handicapped by its inherently unassuming aromatics.

Croatia's 4,525 ha/11,181 acres of Graševina are planted all over the country, but the finest wines are produced in Slavonia in the east. It is second only to Grüner Veltliner in Czechia with 1,182 ha planted, and in Slovakia it is the second most planted variety after Müller-Thurgau, with 1,685 ha in 2021.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Wente. See HERITAGE CLONES.

Western Australia, or WA, is Australia's biggest state, home to the country's second-oldest wine region (after the Hunter Valley, in NEW SOUTH WALES). The Swan River Colony was founded by British settlers in 1829, on the traditional lands of the Whajuk Noongar people. As a part of the Land Acquisition system established by the Colonial Office, the land was divided into lots, which were given to settlers under condition of improving the land. Houghton was originally known as Swan Location 11 and was named 'Houghton' in November 1836, after the most senior ranking officer in its original ownership syndicate (Houghton, Yule and Lowis). It later rose to prominence as a premium grape-growing company under the leadership of Dr John Ferguson (1859). Viticulture—for wine, TABLE GRAPES, and RAISINS—was developed in the Swan due to the suitable soils and, perhaps more pertinently, its proximity to the growing Perth colony. The Swan Valley (as it is now called) was at the centre of WA's viticulture for the next century (specializing in FORTIFIED WINE, VERDELHO, CHENIN BLANC, and SHIRAZ). The 1960s and 1970s were dynamic times in WA's viticultural history, when Margaret River and the Great Southern emerged as commercially significant and premium regions. Tony Smith at Denbarker and John Roche at Frankland can be credited with the beginnings of the commercial eras

in the Great Southern. The catalyst for Margaret River's development was a vigorously researched report in 1966 from renowned agronomist Dr John Gladstones that highlighted the potential of Margaret River as a viticultural region. State Viticulturist Bill Jamieson and Dorham Mann at the Department of Agriculture supported the research and assisted with regional certification, vine CUTTINGS, viticulture advice, and winemaker training. Without their work, it is unlikely that the tenacious Dr Tom Cullity would have planted the vines at what is now Vasse Felix in 1967 which marked the beginning of Margaret River's modern commercial era.

Geography and climate

WA comprises nine wine regions, stretching from just north of Perth down to the south-west tip of Australia and continuing east for some 400 km/249 miles to the eastern boundary around Boxwood Hill. From north to south, these are the zones and GEOGRAPHICAL INDICATIONS (GIs):

Greater Perth Zone , including the Swan District GI, 25 km/16 miles north-east from Perth, on the traditional land of the Whajuk Noongar people, has a warm MEDITERRANEAN CLIMATE. Olive Farm released the region's first commercial wine in the early 1830s. Fortified wines have long been a specialty, although a new generation of winemakers are revitalizing the wine landscape with dry versions of Chenin Blanc, the region's dominant variety, as well as Shiraz and Grenache. The GPZ represents 8.76% of total WA crush in 2021, from 890 ha/2,200 acres of vines.

Perth Hills is a small GI (less than 1% of total crush in 2021) that runs 32 km/20 miles east from Perth to Bickley Valley. Whajuk Noongar *boodja* (land). The specialty is warm-climate Shiraz, and VIOGNIER can be exceptional.

Peel , in Pinjarup country, 59 km/37 miles south of Perth, had little more than 50 ha/124 acres of vines—mostly Chardonnay, Cabernet, and Shiraz—and a handful of wineries in 2021.

Geographe has a varied climate as one moves inland from the Indian Ocean coast. Pinjarup and Kaniyang *boodja.* Picturesque rolling hills on the Darling Scarp support a range of crops and dairy cows; in the vineyards Shiraz leads, followed by Chardonnay, Sauvignon Blanc, and SÉMILLON. The region is developing a reputation for TEMPRANILLO, MALBEC, and ZINFANDEL, with pockets of brilliant GRENACHE. The GI was responsible for 6.16% of total crush in 2021.

Margaret River is WA's most premium GI, responsible for 47% of the state's total crush in 2021. Wardandi *boodja*. The region sits 270 km/162 miles south of Perth, a cape framed by two oceans on three sides. The significantly MARITIME CLIMATE contributes to some of Australia's finest Chardonnay and Cabernet Sauvignon. The Gingin clone (see HERITAGE CLONES) dominates plantings and produces powerful, voluminous, long-lived, high-acid iterations. The South Australian Cabernet CLONES SA125 and SA126 account for most

plantings in WA, however the Houghton clone now leads in Margaret River, favoured for its superior flavour, STRUCTURE, and ability to express the regional DNA of Margaret River—the best examples stand out for their red-berry, liquorice, and iodine COMPLEXITY and ferrous MINERALITY. Sauvignon Blanc and Sémillon—often blended together—are also star performers here, making up almost 12,000 tonnes in 2021 between them. Margaret River has no legally defined subregions, but many winegrowers recognize distinct growing areas such as Karridale (southern area, cooler, wetter), Yallingup (in the north, warmer), Wilyabrup (halfway between Margaret River town and the northern cape, noted for Cabernet Sauvignon), and the Wallcliffe/Boodjidup area (just south of the township, cooler although not as cool as Karridale).

Blackwood Valley , a landlocked region well inland from Margaret River (on Bibbulmun *boodja*) first planted to grapes in 1978. The diversity of varieties grown within the GI speaks as much to its ability to foster a wide range of vines as it does to the lack of certainty of the region's strengths. Broad-acre farming dominates the landscape, with Sauvignon Blanc, Sémillon, Shiraz, and Cabernet Sauvignon the main varieties.

Pemberton/Manjimup , colloquially referred to as Southern Forests, are two cool, inland GIs, both Bibbulmun *boodja*. Manjimup is directly south of Blackwood; Pemberton is further south. Although the data for these regions are bundled as one, much of the total can be attributed to Pemberton. Sauvignon Blanc leads by a factor of two here followed by Chardonnay and Pinot Noir (speaking to the region's dominance in WA as a resource for SPARKLING WINE). The areas, particularly Pemberton, are blanketed by towering Karri trees, which form the basis of the region's history as timber towns. Pemberton/Manjimup accounted for 5.8% of total crush in 2021.

Great Southern , Australia's largest GI by land size, stretching 200 km/124 miles east to west and 100 km north to south, accounting for 28.4% of total crush in 2021. Minang and Kaniyang *boodja*. Its five

subregions each have distinct strengths. Frankland River—generally cool, with wide DIURNAL TEMPERATURE RANGE in summer—excels at structured, long-lived Cabernet Sauvignon and Shiraz, and austere Riesling. Further inland, Mount Barker offers fleshier, powerful Riesling as well as Cabernet Sauvignon and Shiraz. Porongurup, a cool, elevated extrusion of rock, is best known for floral, long-lived Riesling and Pinot Noir. Denmark, under the maritime influence of the Southern Ocean, counts Chardonnay, Pinot Noir, Shiraz, and Sauvignon Blanc as lead varieties. Further west, Albany wraps around the coast's numerous coves and bays. Although Riesling is fifth in crush volume in 2021, it is one of the Great Southern's most consistent varieties. E.L.L.

www.winewa.asn.au

Western Cape, the most important of the five geographical units making up South Africa's production areas defined by the country's WINE OF ORIGIN scheme and accounting for well over 90% of the nation's vineyards and wineries. (Even the extensive COASTAL REGION is a region within it.) On wine labels it generally indicates a multiregional BLEND.

western grapeleaf skeletonizer, a vine pest and native insect of Mexico and the states of Arizona, New Mexico, and Texas, first found in California in 1941 in San Diego County and sighted in the Napa Valley in 2022. The young larvae feed on the soft leaf tissue, leaving a skeleton framework. Left unchecked this insect will completely defoliate a vine, seriously affecting RIPENING, and may then feed on the berries. Chemical control is possible, but timing is critical. The granulosis virus, if introduced to the vineyard, reduces populations effectively, as do insect parasites.

University of California Agriculture & Natural Resources, 'Western grapeleaf skeletonizer'.

.

Western Victoria Zone comprises Grampians, Henty, and Pyrenees regions in the Australian state of VICTORIA.

Weststeiermark, the least known of the three subdivisions of STEIERMARK (Styria) in Austria and a DAC since 2018. Its significant total expanse harbours a mere 550 ha/1,350 acres of vines, dominated by the local speciality, SCHILCHER, made from Blauer Wildbacher grapes and most often as rosé. Weststeiermark DAC, however, allows for eight additional grape varieties as well as BLENDS and encompasses bottlings at regional, communal, and SINGLE-VINEYARD levels. D.S.

whip graft, the form used in GRAFTING which simply involves an angled slice across the SCION stem and a similarly angled cut of the stock, with the two cuts then matched and the graft tied tightly with grafting tape. Whip-and-tongue is the same except that another cut is made to raise 'tongues' of stem tissue that dovetail with each other and improve the strength of the graft. B.G.C.

Whispering Angel, the world's best-selling BRAND of rosé that ignited the pink-wine revolution from its base in PROVENCE. In 2006 Sacha, son of Alexis LICHINE, sold his father's château in Margaux and moved to Ch d'Esclans in the hills above Fréjus. The next year he launched the notably pale Whispering Angel, which grew to become the height of FASHION and Americans' favourite imported French wine. LVMH acquired a majority stake in the brand and Ch d'Esclans in 2019. A total of 9 million bottles of Whispering Angel were sold in 2021.

white has a special meaning when applied both to grapes and wine. Any light-skinned grape may be called a white grape, even though the grape skin is not white but anything from pale green through gold to pink. In a similar fashion, white wines are not white but vary in colour from almost colourless to deep gold. See COLOUR.

White Riesling, common synonym for the great white RIESLING grape variety of Germany.

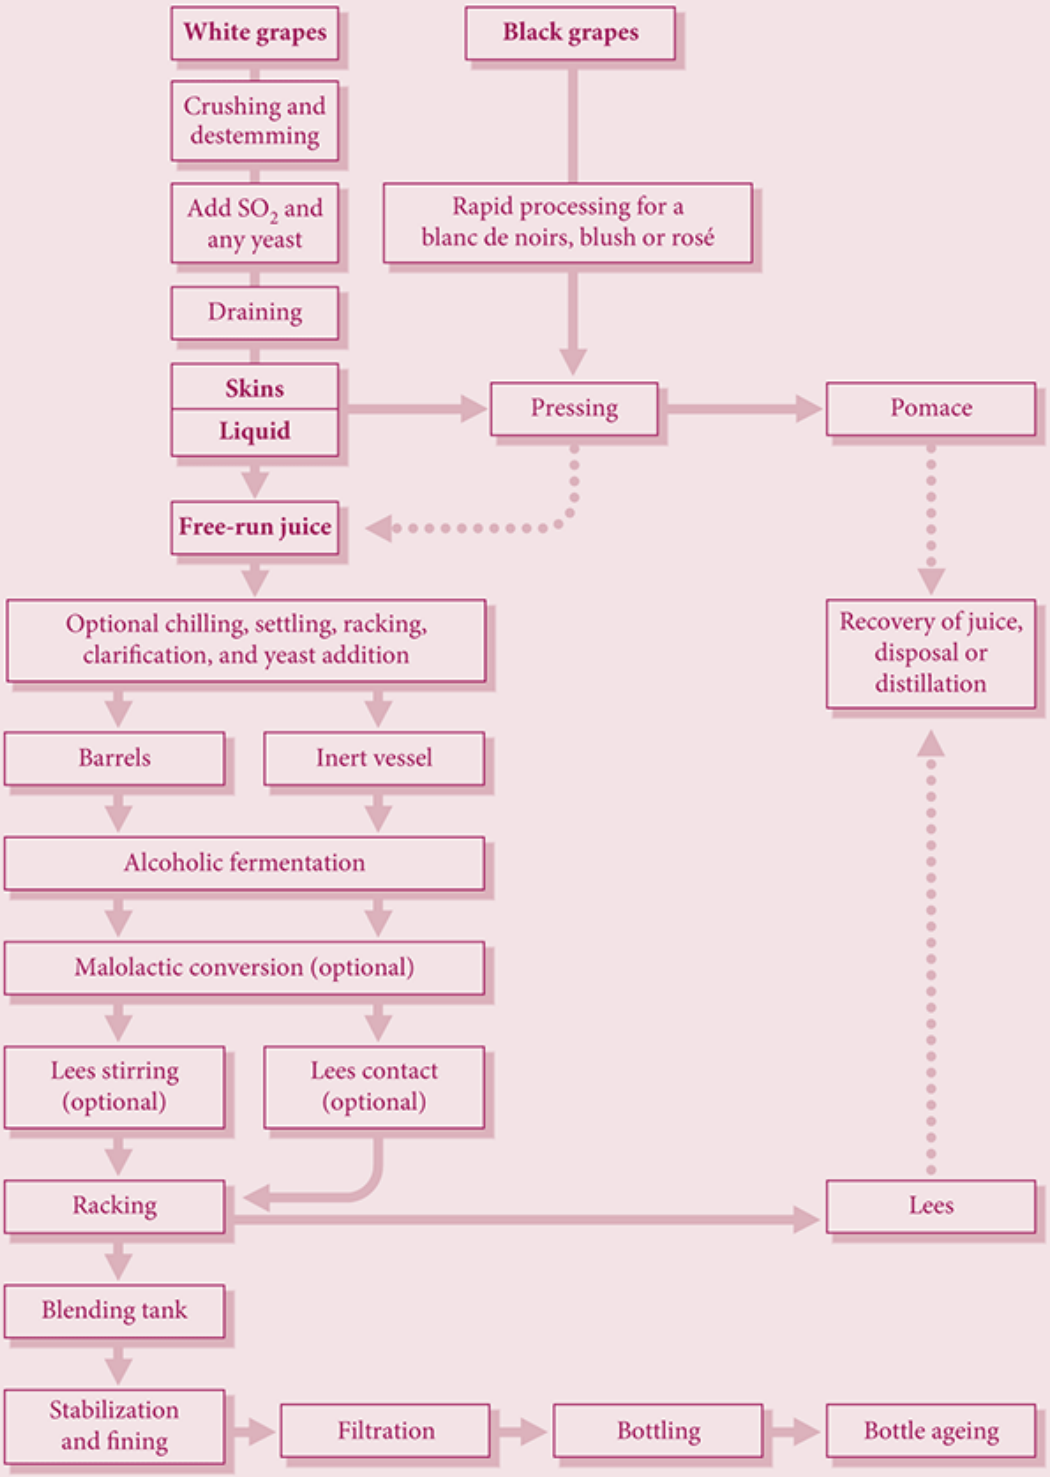
white rot, FUNGAL DISEASE affecting vines that occurs in those parts of Europe most prone to HAIL, also known as hail disease. Crop losses can be as high as 80%. The fruit is attacked after a hailstorm and, because the berry skin is lifted from the flesh, the berries appear white, hence the name. High summer rainfall, high humidity, and high temperatures also favour the disease. The fungus responsible is *Coniella diplodiella*, which is controlled by a range of chemical sprays.

R.E.S.

white winemaking, the production of wines with almost imperceptible to golden COLOUR. If the juice is separated from the grape skins gently and soon enough (as in the production of CHAMPAGNE), white wines can be made from black-skinned grapes, but the great majority of white wines are made from grapes with yellow or green skins. White wines can be made from grapes of all hues, so long as there is no SKIN CONTACT or MACERATION with dark-skinned grapes. The only exception to this is the red-fleshed TEINTURIERS. White wines are distinguished from their red counterparts by their absence of ANTHOCYANINS and PIGMENTED TANNINS. As with any WINEMAKING operation, the production of white wines generally entails CRUSHING and DESTEMMING the grape clusters on arrival at the winery, although occasionally white grapes may be crushed beforehand at a field pressing station (and see also WHOLE-BUNCH PRESSING and STABULATION). After crushing and destemming, the sweet MUST requires draining and PRESSING to separate the liquid from the solids.

The timing of the separation of juice from solids constitutes the major difference between red and white winemaking: before FERMENTATION for whites and afterwards for reds.

White winemaking



Prolonged contact between juice and grape skins (see SKIN CONTACT and MACERATION) encourages the transfer of soluble materials, including PHENOLICS, FLAVOUR COMPOUNDS, and FLAVOUR PRECURSORS, from the skins to the juice. The extracted phenolics, which are essential to a red wine, providing both colour and TANNIN, are generally undesirable in a white wine, for they promote OXIDATION and can lead to ASTRINGENCY. The skin phenolics also lead to the development of amber to brown colours deemed inappropriate for most white wines (but see ORANGE WINES and other SKIN-FERMENTED whites). The challenge for the white winemaker is therefore to find the balance, through suitable juice-handling techniques, between appropriate transfer of the flavour compounds and minimal phenolic extraction. Because of their light colour and delicate flavours, white wines show the unappetizing effects of oxidation much faster than red wines, and so white winemaking is in general a more delicate operation than RED WINEMAKING. Small amounts of ACETALDEHYDE are produced by the reaction of oxygen with alcohol, and this compound can easily spoil the AROMA of a fresh, fruity young wine. There are two possible solutions to this inconvenience. Exposure to oxygen may be minimized during extraction, winemaking, ÉLEVAGE, and right up to and including BOTTLING (see PROTECTIVE WINEMAKING, for example). Alternatively, a policy of unprotected handling is adopted whereby the juice is deliberately, and sometimes in the case of everyday wines violently, aerated so that its susceptible phenolics oxidize, these brown compounds being removed during CLARIFICATION. This technique is sometimes referred to as hyperoxidation (see OXIDATION). The disadvantage of this pre-fermentation oxidation is that it removes some of the compounds that would have contributed to AROMA.

White wines are usually fermented at cooler temperatures than reds, now much easier to control than in the past thanks to REFRIGERATION. However, BARREL FERMENTATION followed by BARREL AGEING is a common phenomenon for more ambitious white wines, particularly for wines made from the CHARDONNAY grape. Among these

barrel-fermented white wines, LEES STIRRING is also popular (though less so than in the past), as is MALOLACTIC CONVERSION. P.J.W.

white wines, made with much less SKIN CONTACT, are much lower in PHENOLICS than red wines (see WHITE WINEMAKING). This does not necessarily mean, however, that they are inherently less interesting or shorter lived (see AGEING). They vary enormously in colour from virtually colourless to deep gold or ORANGE— even, in extreme age, deep tawny (not unlike the colour of some very old red wines). They are made in virtually all wine regions, although in hot regions ACIDIFICATION and some form of REFRIGERATION are usually needed to produce white wines suitable for modern tastes. White wines are typically much more versatile when it comes to FOOD-AND-WINE MATCHING.

French for 'white' is *blanc*, Italian is *bianco*, Spanish is *blanco*, Portuguese is *branco*, and German is *weiss*, while in most eastern European languages the word for 'white' is some variant of *byeli*.

White Zinfandel was California's great commercial success story of the 1980s. Although Bob Trinchero of Sutter Home was not the first to vinify California's heritage ZINFANDEL grapes as a white, and therefore BLUSH, wine, he launched 'White' Zinfandel down the commercial slipway in 1972, and it gained traction after he bottled the 1975 vintage with a little RESIDUAL SUGAR left in the wine. The semi-sweet pale pink sent Trinchero's own sales rocketing from 25,000 cases in 1981 to 1.5 million cases six years later, and other producers followed. The wine evolved as a way of making California's vast hectarage of Zinfandel acceptable to the predominantly white-wine-drinking American public, and its popularity saved many OLD VINE Zin vineyards from being GRUBBED UP. While the style began to fall out of favour in the 2000s as US consumers increasingly gravitated to drier rosés, it has seen a renaissance in the 2010s as

respected producers such as Turley and Broc Cellars interpret it as a bone-dry rosé.

whole-bunch fermentation, ultra-traditional method of red-wine FERMENTATION in which grape berries are not subjected to DESTEMMING. This was the default position before the introduction of the DESTEMMER-CRUSHER. Aside from the influence of the STEMS themselves, the process generally involves an element of CARBONIC MACERATION at the start of the ferment. The possible disadvantages are that, unless the stems are very ripe (i.e. well LIGNIFIED) and the MUST is handled very gently, the stems may impart harsh TANNINS and GREEN flavours to the wine. The technique also involves a greater total capacity of FERMENTATION VESSELS, which are often open-topped to allow PUNCHING DOWN of the CAP. The practical advantages are that the stems can ease the drainage of the juice through the cap, aerate the ferment so that it is slightly cooler, and encourage healthy oxygenation by increasing the cap's interface with the atmosphere during MACERATION. Stems may also absorb a very small amount of alcohol, which may be a benefit in warmer vintages with higher-alcohol wines. On the other hand, the level of POTASSIUM in the juice is increased slightly, resulting in lower ACIDITY in the wine.

Whole-bunch fermentation is most common in BURGUNDY and now more generally with Pinot Noir. An increasing number of winemakers in both hemispheres are experimenting with the inclusion of stems, varying the percentage of whole bunches according to the vintage conditions, the overall character of the fruit, the ripeness of the stems, and the desired wine style. There are many variations: some winemakers layer whole bunches with destemmed fruit, while some prefer to put the whole bunches at the bottom of the tank. A few crush the whole bunches to avoid the flavours of carbonic maceration. Proponents suggest that whole-bunch fermentation imparts organoleptic benefits such as firmer TANNINS and increased aroma, freshness, elegance, COMPLEXITY, and apparent sweetness.

Opponents—most famously the late Henri Jayer of Burgundy—point to the potential loss of colour (absorbed by the stems), tougher tannins, and increased herbal or green characters in the wine.

A more labour-intensive and therefore expensive technique that is said to result in all the benefits of whole-bunch fermentation, such as freshness and fruit purity, and none of the possible disadvantages involves cutting the individual berries off the STEM and retaining the PEDICEL, thereby keeping the berries intact at the start of fermentation. It might be more accurately described as whole-berry fermentation.

Wimalasiri, P. M., et al., 'Whole bunch fermentation and the use of grape stems: effect on phenolic and volatile aroma composition of *Vitis vinifera* cv. Pinot Noir wine', *Australian Journal of Grape and Wine Research* (2021).

whole-bunch pressing, WHITE WINEMAKING technique whereby the grapes are not subjected to DESTEMMING and bunches of ripe grapes are pressed whole, with the stems used as conduits for what can often be particularly viscous juice. This works best for very ripe grapes and would not be suitable if a period of SKIN CONTACT precedes PRESSING since excess TANNINS could be leached into the must from the STEMS. This technique is almost universal in the production of top-quality SPARKLING WINES and most other white wines from dark-skinned grapes and in the direct pressing of BOTRYTIS-affected clusters of super-ripe grapes as in SAUTERNES. It is also increasingly popular with some quality-conscious producers of white wines in some wine regions since the juice that results tends to be low in PHENOLICS and PROTEINS.

whole-cluster fermentation. See WHOLE-BUNCH FERMENTATION.

whole-grape fermentation. Alternative name for CARBONIC MACERATION.

Wien is how the natives of Vienna refer to the Austrian capital and also identifies the official 580-ha/1,433-acre winegrowing region it comprises. Vienna serves as an axis between Danubian growing regions, nowadays dominated by GRÜNER VELTLINER but also starring RIESLING (11.5% of Viennese vine surface), and those regions more strongly influenced by the warmth of the Pannonian-Hungarian Plain and significantly planted with diverse red wine grapes (16% of Vienna's total), notably in two important viticultural neighbourhoods on the city's southern fringe, Oberlaa and Mauer. Although traditional FIELD BLENDS shrank in the early 21st century to less than 15% of the city's vineyard area, they represent a distinctive contribution to its winegrowing and drinking culture and in 2013 were made the basis for Wiener Gemischter Satz DAC, whose regulations (see below) make it theoretically possible to produce a volume of DAC wine much larger than what could be rendered solely from Vienna's surface of field blends, which are mostly dominated by or consist exclusively of white wine grapes, with older vineyards generally incorporating significant shares of Grüner Veltliner as well as Chardonnay, Pinot Blanc (WEISSBURGUNDER), Pinot Gris, and NEUBURGER. Riesling, ROTGIPFLER, SILVANER, TRAMINER, WELSCHRIESLING, ZIERFANDLER, and unidentified vines are also common.

The Kahlenberg and Nussberg vineyards, along with sites in the nearby suburbs of Grinzing, Sievering, and Neustift—all in Vienna's 19th District—offer a stunning panorama of the city thanks to the ELEVATION. The sunny exposure, attendant breezes, and soils typically rich in fossils and LIMESTONE also commend them as high-quality sites. MUSTS seldom dip below 12.5% POTENTIAL ALCOHOL. On the Danube's left bank, important vineyards extend north and west from the suburbs of Stammersdorf and Strebersdorf to the edges of the Bisamberg and the WEINVIERTEL, some of whose growers also have holdings in Wien. Each wine district has managed to keep the look of

a wine village, even within the borders of a large city. Their often-bucolic wine taverns are a refuge for thirsty urbanites and an emblematic part of Austria's HEURIGER culture of grower-dispensed new wine. No account, however brief, of modern Viennese wine history would be complete without mention of the role played by Fritz Wieninger as a model winegrower and international ambassador for his vine-rich native city.

Wiener Gemischter Satz DAC is the official Austrian appellation of origin designed to showcase Vienna's mixed-vine plantings. As officially defined, these wines must include at least three white grape varieties, though these may be planted in dedicated blocks as opposed to truly intermingled, provided those blocks are contiguous. No single variety may constitute more than half of a wine's volume, and if it consists of just three varieties then none may constitute less than 10% of the total volume. Wines from grapes grown in Vienna but vinified and bottled in another region—and there are many producers just outside the city limits in the neighbouring WEINVIERTEL or THERMENREGION as well as in KLOSTERNEUBURG—may apply for a dispensation to allow their Viennese wines that meet all other DAC requirements to be bottled as Wiener Gemischter Satz DAC. Wines of this DAC that are bottled without vineyard designation may not (with the usual half-percentage labelling tolerance) exceed 12.5% alcohol, whereas those labelled as SINGLE-VINEYARD WINES must reach a minimum 12.5%, which nowadays happens as a matter of course. It seems possible that the creation of this DAC will encourage Viennese growers to plant more vineyards with GEMISCHTER SATZ. Since Wien is the name of an Austrian state as well as of an official wine region, Viennese wines that do not qualify for the Wiener Gemischter Satz DAC may be labelled Wien (see other DAC regulations). D.S.

WIETA, or Wine and Agricultural Ethical Trade Association, is an organization dedicated to improving social and employment conditions in the wine industry of SOUTH AFRICA. Members include grape-growers, wine producers, trades unions, retailers, agents,

importers, and exporters of South African wine. Its code of conduct includes a prohibition on child and enforced LABOUR and obliges members to provide a safe and healthy working environment with freedom of association, the right to collective bargaining, a living wage, reasonable working hours, regular employment, security of tenure, and protection against unfair discrimination. Members are subject to regular audits and, when compliant, are accredited by WIETA. WIETA compliance is incorporated in a single seal issued by the Wine & Spirit Board and covering not merely compliance in terms of the WINE OF ORIGIN scheme but also environmental SUSTAINABILITY (see INTEGRATED PRODUCTION OF WINE) and ethical responsibility. M.F.

Wildbacher. See BLAUER WILDBACHER.

wild ferment. See SPONTANEOUS FERMENTATION.

wildfires have become an increasingly severe consequence of CLIMATE CHANGE affecting several wine regions around the world, especially CALIFORNIA and AUSTRALIA, where SMOKE TAINT has had a significant impact on production. A.Y.

wild vines, plants of the genus VITIS growing in their natural state without any cultivation by people. Such vines are lianas and are often found climbing trees (see ARBOREAL VITICULTURE) but may also grow as shrubs. They are widespread in the Americas, especially in the east and south-east, in Asia, and up until the late 1800s in Europe. Indigenous wild grapevines can sometimes be confused with feral or naturalized vines derived from plants once cultivated. Examples of feral vines are the wild vines of the Pays BASQUE and the AMERICAN VINE SPECIES *Vitis riparia* and *Vitis rupestris* along the Rhône and Garonne rivers after importation as ROOTSTOCKS. Wild vines are typically spread by BIRDS eating the berries and passing the seeds.

Where wild vines of different species grow together, it is common for natural HYBRIDS to develop, as for example in the east of America (see AMERICAN HYBRIDS). Such hybrids can also develop from natural pollen interchange with cultivated grapes.

Perhaps the most famous of all wild vines are those described in the legend about the discovery of VÍNLAND. The early settlers and explorers in the Americas and the Caribbean found profuse growth of wild vines in the woods. Such vines had tolerance to the harsh winter climate, to indigenous pests such as PHYLLOXERA, to FUNGAL DISEASES such as DOWNY MILDEW and POWDERY MILDEW, and to PIERCE'S DISEASE, and so they could grow without check, while the VITIS VINIFERA vines imported from Europe perished in cultivation.

Wild vines of the wine-producing *vinifera* species were once widespread in Europe and western Asia, although they have disappeared from large areas of Europe since the introduction of the American pests and diseases noted above and because humans have taken over so many of their natural habitats. Sometimes such wild vines are called *Vitis vinifera* subsp. *silvestris*, while cultivated vines are called *Vitis vinifera* subsp. *vinifera* (sometimes *sativa*). The main difference between the two forms lies in the sexes of the flowers: the subspecies *silvestris* is dioecious, with flowers that are either male-only or female-only on the same plant, while the subspecies *vinifera* is hermaphroditic, with flowers containing functional male and female parts. This feature of subspecies *vinifera* results in better FRUIT SET and has been the basis of selection from the wild by humans.

Wild vines are important to modern viticulture as they are the source of many resistance genes that can used in breeding NEW VARIETIES. The genetic diversity of wild *Vitis* varieties has not yet been extensively explored, and the possibilities for improving modern varieties' resistance to pathogens and environmental stresses such as DROUGHT are endless. See also GENETIC MODIFICATION. R.E.S. & J.V.

wild yeast. See YEAST.

Willamette Valley, named for the Willamette River running through it, is OREGON's most famous wine region and oldest AVA, established in 1983. Starting just north of Portland, sandwiched between the Cascade Range to the east and Coastal Range to the west, the region spans 241 km/150 miles north to south and 97 km/60 miles at its widest point. However, the planted area is less than 0.1% and is further divided among 11 sub-AVAs. Most specify an ELEVATION of at least 61 m/200 ft to distinguish themselves from the more fertile valley floor. PINOT NOIR dominates plantings in all Willamette AVAs, with PINOT GRIS and CHARDONNAY in attendance.

Tualatin Hills, the northernmost sub-AVA, was officially established in 2020 though it has one of the oldest histories. The site of David Hill Vineyard and Winery was planted in 1965 by Charles Coury, the second person to root VITIS VINIFERA in the Willamette Valley. The soils here are predominantly Laurelwood, a mix of weathered BASALT and LOESS.

Yamhill-Carlton District, named for two towns, lies in the rain shadow of the Coast Range, on the hillsides of a south-facing bowl. The free-draining coarse-grained marine sedimentary soil series known as Willakenzie stops vegetative growth earlier in the season and encourages more complete RIPENING. The AVA's first commercial vineyard was established in 1974 by the Campbells of Elk Cove Vineyards. Ken Wright, another early advocate for this area, authored the proposal for its AVA status.

Chehalem Mountains was established in 2006 with a proposal authored by David Adelsheim, Paul Hart (Rex Hill Vineyard), and Richard Ponzi. It contains the AVAs of Ribbon Ridge and Laurelwood District. The planted areas feature all three of the Willamette Valley's predominant soil types: VOLCANIC, marine sedimentary, and loess.

Laurelwood District, located within the Chehalem Mountains AVA, was established in 2020 and named for the Laurelwood community, though the name also references the Laurelwood soils, which differ from those of the Tualatin Hills AVA only in their greater homogeneity.

Ribbon Ridge was named in 1865 for its twisting spine but did not receive recognition as an AVA until 2005. It is geographically isolated from the surrounding Chehalem Mountains AVA by creek valleys on all sides. The area is east-facing and features marine sedimentary soils that are younger and finer-textured than those of the Yamhill-Carlton AVA.

Dundee Hills, often referred to as 'the Red Hills of Dundee', is unique for its ruddy-coloured volcanic clay soils known as Jory. This AVA was home to the first *vinifera* plantings in the Willamette Valley, planted by David Lett of The Eyrie Vineyards in 1965. Pioneers Erath and Sokol-Blosser also contributed to the region's fame.

McMinnville, named for the city, was granted its AVA in 2005 based on the Nestucca formation, a bedrock foundation consisting of marine SANDSTONE, mudstone, and basalt, with shallow topsoils.

Eola-Amity Hills stands out for shallow basalt soils that have a lower water-holding capacity than the similarly volcanic Jory soils of the Dundee Hills. Respected for Pinot Noir, the region also has more land devoted to Chardonnay than any other AVA (just over 8%).

Van Duzer Corridor is distinguished from its neighbouring AVAs by having the lowest number of growing degree days (see CLIMATE CLASSIFICATION), highest WINDS, and lowest elevation. The soils are quick-draining sedimentary and volcanic, with shallow ALLUVIAL overlay. The high winds dry the vine CANOPIES, leading to thicker grape skins and lower FUNGAL DISEASE pressure, which some growers

use as an advantage to implement ORGANIC farming or BIODYNAMIC VITICULTURE.

Mount Pisgah, Polk County, Oregon, established in 2022, encompasses a small mountain to the west of the city of Salem. Elevation ranges up to 255 m/835 ft, and producers here cite lower average temperatures, lower average wind speeds, and silty clay-LOAM topsoils as their points of differentiation. Only three producers are located within this AVA: Illahe, Open Claim, and Amalie Robert.

Lower Long Tom, established 2021, is the southernmost sub-AVA, consisting of a series of north-to-south hills bisected by streams that feed the Long Tom River, which runs on the AVA's eastern boundary. Soils are predominantly Bellpine with some Bellpine/Jory complex (see OREGON, Geography and climate). While Pinot Noir dominates, the region's generally warmer temperatures support a range of varieties, particularly Chardonnay, Riesling, Pinot Gris, and Sauvignon Blanc. S.C.-J.

wind, or strong air movement, is a problem on many coastal and otherwise exposed viticultural sites. Major valleys can also be windy, acting as funnels and having their own distinctive systems of wind force and directions. The mistral of the southern Rhône is one of the more notorious examples of this, as is the Salinas Valley in MONTEREY. The detrimental effects of wind on vines are described under WIND STRESS; installing WINDBREAKS can provide a solution.

Hot, dry winds in summer are a particular hazard of viticultural regions bordering deserts. The sirocco of North Africa afflicts the vineyards of southern Europe, occasionally reaching France, for example. The hot, very dry, strong zonda winds of ARGENTINA can cause major problems for vineyards.

The effects of wind are by no means all detrimental, however. The normally regular afternoon sea breezes of coastal regions with otherwise summer-dry climates, such as those of Portugal, California, and much of southern Australia, have a useful moderating effect on viticultural climate and are thought to contribute significantly to the

quality of their wines (see CLIMATE AND WINE QUALITY). In all environments, some air movement is needed to prevent excessive build-up of HUMIDITY within the vineyard and to encourage drying of wet foliage and bunches, thereby reducing the risk of FUNGAL DISEASES. Night winds (or WIND MACHINES) largely prevent radiation FROSTS, while during sunlight hours the moderate movement of leaves encourages a more uniform spread of intermittent sunlight exposure among them, thus promoting a more efficient use of SUNLIGHT. Some degree of windiness is also often an unavoidable concomitant of the TOPOGRAPHIES that are viticulturally the best in other respects, for example in Waipara in NEW ZEALAND.

In summary, winds cannot be entirely avoided; nor are they wholly undesirable. The selection of sheltered sites, where possible, is important in windy regions. Beyond that, the answers to wind problems lie mainly in suitable vineyard strategies of TRELLISING and where necessary in the use of windbreaks. J.G.

windbreak, a barrier of vegetation or other materials to break the force of WINDS and avoid WIND STRESS. The benefits of windbreaks go beyond reducing physical vine damage. A combination of reduced wind force and (in dry atmospheres) the maintenance of higher HUMIDITIES among the vines reduces closure of the leaf pores (STOMATA) and therefore enhances potential PHOTOSYNTHESIS. Quite substantial YIELD increases are commonly recorded in the lee of effective windbreaks, amply exceeding any losses that might be incurred through any reduced area of vineyard or SHADING by the windbreaks.

The best natural windbreaks are fast-growing trees or tall shrubs whose roots do not extend too far laterally. Tall winter COVER CROPS such as cereal rye, planted between the vine rows, can also afford useful protection to young vineyards in early spring. VINE GUARDS can also protect young vines from wind. J.G. & R.E.S.

Veste, M., et al., 'Windbreaks as part of climate-smart landscapes reduce evapotranspiration in vineyards, Western Cape Province, South Africa', *Plant, Soil and Environment*, 66 (2020), 119–27.

wind machine, a strong fan for stirring up and mixing cold, dense air settled on the land surface with warmer air from above, thereby preventing FROSTS on still spring nights when there is no WIND to do the job. Such machines, introducing an aeronautical look to vineyards, have been used on valley floors that are prone to radiation frosts, such as in the NAPA Valley of California. HELICOPTERS can be used to the same effect. J.G.

wind stress can reduce vine YIELD and RIPENING in some exposed vineyards. Severe gusts of wind can have dramatic effects on vineyards, breaking SHOOTS and removing leaves. However, even lower-velocity wind can also cause vine problems which are apparent only to the trained eye. Wind cools plants by removing the warming effects of the sun's rays, as well as other more substantial effects on physiology. For some plants, including vines, wind can have a major effect on growth. Shoot length, leaf area, and fruit growth can all be substantially reduced. The problem is particularly acute for young vines, as in older vineyards the CANOPY can usually offer some degree of self-protection. FLOWERING, FRUIT SET, and VERAISON may be delayed.

Some vines respond negatively to movement of shoots and leaves, probably a response involving plant HORMONES. A major effect of wind is that of closing STOMATA. Freeman and colleagues of the University of California showed that wind speeds of 3 m/10 ft per second in the Salinas Valley caused stomata to close partially, which has the effect of reducing both PHOTOSYNTHESIS and TRANSPIRATION. Vines ripening in windy places will show reduced ripening and higher PH. R.E.S.

Freeman, B. M., et al., 'Influence of windbreaks and climatic region on diurnal fluctuation of leaf water potential, stomatal

conductance, and leaf temperature of grapevines', *American Journal of Enology and Viticulture*, 33 (1982), 233–6.

wine, alcoholic drink made by fermenting the juice of fruits or berries (see FRUIT WINES). By extension, this most general definition can also include products of the FERMENTATION of sugar solutions flavoured with flowers or herbs, but it normally excludes those of hydrolysed barley starches involved in brewing and the products of the fermentation of sugar-containing liquids destined for DISTILLATION. There are also certain drinks, such as mead, cider, and perry, which depend on sugar fermentations for their alcohol content but for historical reasons merit their own names.

The narrower definition, relevant to this book and accepted throughout Europe, is that wine is 'the alcoholic beverage obtained from the fermentation of the juice of freshly gathered grapes, the fermentation taking place in the district of origin according to local tradition and practice'. This is to distinguish 'proper' wine from alcoholic drinks made from imported grape concentrate, which are known in Europe as MADE-WINE. These include BRITISH WINE and a significant proportion of the liquid produced by HOME WINEMAKING. New World definitions of wine are very similar except that the last phrase is omitted and wine may be made from a mixture of grapes grown many hundreds of miles apart.

Etymology

The modern English *wine* comes from Old English *wīn*, pronounced like modern 'wean'; that indeed was how Chaucer pronounced his *wyn*, but Shakespeare's pronunciation was closer to our own. The Old English form was in turn descended from the Latin *vīnum*, or as the Romans wrote it *vinvm*, by way of a loan-word represented in all Germanic languages (e.g. German *Wein*, Icelandic *vín*). A similar loan into Celtic has yielded Welsh *gwin* and Irish *fíon*. The explanation is that the Germans and CELTS, whose native beverage was beer, learnt to drink wine from the Romans; with it came the Latin word, borrowed while Latin *v* was still pronounced [w]. From Germanic territory drink and name passed in turn to the Slavs (e.g. Russian *vinó*) and Balts (Lithuanian *vỹnas*, Latvian *vīns*).

Within Latin itself, from *vīnum* comes the noun *vīnea* 'vineyard'; this word, reinterpreted of a single vine (classically *vītis*, whence 'viticulture'), yielded French *vigne*, which was naturally brought over to England by the Normans. However, once the native English began to learn their masters' language, they adjusted it to suit their own speech habits. Since English then as now lacked the palatal sound of French *gn*, it was simplified to *n*, so that *vigne* became *vine*. This was adopted into English and subjected to the normal sound-changes of the late medieval and early modern period: the final *-e* ceased to be pronounced and the long *i* became a diphthong. The French word was also substituted in the term for the place where vines were grown, originally *wīngeard*, now 'vineyard', with the vowel shortened as often in compounds (e.g. 'shepherd' vs 'sheep').

Whereas *vitis* can be related to an Indo-European verb-root meaning to 'wind' or 'twine', as in English *withy*, the ultimate origins of *vinum* and *vinea* are less clear. Similar words are found in many Mediterranean languages, even those belonging to different language-families, but few interrelations can be established. For instance, although Latin *ī* often comes from *ei*, since the change did not take place till the late 2nd century BCE it cannot have occurred in *vinum*, for which forms with *vin-* are found in the kindred languages

of ancient Italy. This rules out a direct link with the term current in ancient GREECE, according to dialect *woinos* (*ϝοῖνος*) or *οἶνος* (*οἶυος*), as in OENOLOGY, akin to the **woiniyo-* (*denotes a reconstructed form) underlying Armenian *gini* and sometimes associated with Sanskrit *veṇi* or *veṇī* 'braid'. The form *wiyana* and *wayana* are quoted from the ancient ANATOLIAN languages Hittite and Luvian: outside Indo-European, a Semitic noun **wayn*, 'grape, vine, wine', which yields Hebrew *yayin* and Ethiopic *wäyn* besides an Arabic *wayn* 'black grape' found in an ancient lexicon, has sometimes been considered the source of the Greek word and sometimes a derivative. Even Georgian *yvino* has been proposed: no theory is convincing, except after a few glasses. L.H.-S.

Editorial note:
See WINE COMPOSITION, WINEMAKING, WINE TYPES, and the other entries which immediately follow. The word 'wine' appears in only these titles. Otherwise, for instance, for wine press see PRESS, for wine and religion see RELIGION AND WINE, for wine trade see TRADE, and so on. For details of specific wines, see under their names or their provenance.

Wine & Spirit Education Trust. See WSET.

wine composition differs quite considerably from GRAPE COMPOSITION, partly because parts of the grape are discarded during WINEMAKING and partly because the processes involved effect a complicated series of transformations. Alcoholic FERMENTATION, for example, transforms sugars into alcohol, while MALOLACTIC CONVERSION reduces the level of malic acid in favour of lactic acid. The precise composition of a wine varies with WINE TYPE, HARVEST conditions and timing, VINTAGE characteristics, and the age of the wine (see AGEING for details of how wine composition may change with age). Nevertheless, the table gives some guidance as to the likely range of

concentrations of the essential constituents of the approximately 1,000 so far identified.

Wine composition

Component	Proportions per l	Comments
Dissolved gases		
CARBON DIOXIDE	0–50 cc	
SULFUR DIOXIDE		
Total	80–200 mg	More in some sweet wines
Free	10–50 mg	More in some unstable wines
Volatile substances		
WATER	700–900 g	
ETHANOL (alcohol)	8.5–15% by vol	More in fortified, less in low-alcohol wines
HIGHER ALCOHOLS	0.15–0.5 g	
ACETALDEHYDE	0.005–0.5 g	Higher amounts in sherry and similar wines
ESTERS	0.1–0.3 g	
ACETIC ACID	0.35–0.6 g	
Fixed substances		
RESIDUAL SUGAR	0.8–180 g	According to type of wine; more in sweet and botrytized wines
GLYCEROL	5–12 g	
PHENOLICS	0.2–0.5 g; 1.5–4.0 g	Lower range for white wines, higher range for reds
Organic acids		
TARTARIC ACID	3–10 g	Depending on grape origin
MALIC ACID	0–4 g	According to climate and extent of malolactic conversion
LACTIC ACID	0–1 g	
SUCCINIC ACID	0.2–1.5 g	
CITRIC ACID	0–1 g	Found in wines where additions have been made
Mineral salts		
Sulfates	0.1–0.4 g	Expressed as potassium salts
Chlorides	0.25–0.85 g	
Phosphates	0.08–0.5 g	
Mineral elements		
POTASSIUM	0.7–1.5 g	
CALCIUM	0.06–0.9 g	
IRON	0.002–0.006 g	

Based on Navarre, C., and Langlade, F., *L'Oenologie* (7th edn, 2010)

Navarre, C., and Langlade, F., *L'Oenologie* (7th edn, 2010).

wine grape, a term used to describe grapes used for winemaking, as opposed to TABLE GRAPES for eating and RAISINS for use by the dried-fruit industry. For discussion about the plant which bears wine grapes, see VINE; for more detail of the fruit itself, see GRAPE.

Wine Group, The, Based in Livermore, California, The Wine Group (TWG) is the second largest wine producer by volume in the US, behind E. & J. GALLO. Privately owned and relatively secretive about its financial affairs, it boasts among its brands the Sonoma biodynamic pioneer Benziger, the Lodi Zinfandel-led 7 Deadly portfolio, and Concannon, established in 1883 in Livermore by Irish immigrant James Concannon and the first to bottle Petite Sirah as a stand-alone VARIETAL in the US. TWG's considerable market clout, however, comes from the BOXED wine juggernauts Franzia and Almaden; the moderately priced Cupcake bottled line; and the slightly more expensive Chloe Wine Collection.

winegrowing, collective term for VITICULTURE and WINEMAKING.

wine lake, term coined for Europe's wine SURPLUS. With the introduction of compulsory DISTILLATION in 1982, it was rapidly transformed into an ALCOHOL lake. See EU for the various reforms that have been introduced to try to balance supply and demand.

winemaker, one who makes WINE. In its broadest sense, the term includes those who engage in HOME WINEMAKING as a hobby, although in a professional sense a winemaker is someone employed (sometimes by themselves) to produce wine. An increasing proportion of such people recognize that wine production includes every aspect of vineyard management, and there are wine producers all over the world whose production is so small that they personally conduct, or at least oversee, every stage from planting to marketing.

A wine production unit of any size, however, will employ both a VITICULTURIST, or vineyard manager, and a winemaker, whose active responsibilities begin with receiving grapes from the vineyard and continue with their SAMPLING, CRUSHING, PRESSING, FERMENTATION, ÉLEVAGE, BOTTLING, and storage—all those operations outlined in WINEMAKING. Larger wine producers may even employ a team of winemakers, each with different responsibilities.

Curiously, there is no obvious synonym for the word 'winemaker' in any of the major European languages, perhaps because historically wine was thought to make itself. The most common candidates have very different literal translations into English: *maître de chai* in Bordeaux; *Kellermeister* in Germany; *enologo* in Italy; *œnologue* in some French wineries. While most (though not all) modern winemakers have studied OENOLOGY and will certainly consider themselves oenologists, the term OENOLOGIST is in Europe more usually applied to an outside CONSULTANT than to a full-time employee. The most temporary winemakers of all are the breed known colloquially as FLYING WINEMAKERS or, if lower down the pecking order, CELLAR RATS.

During the early 1980s, some winemakers enjoyed a brief period of near-cult status, most notably in the NEW WORLD, until VITICULTURISTS re-established their status to become the wine gurus of the 1990s and early 2000s. Today there are ever-closer links between those responsible for vineyard and cellar, and in an increasing number of cases they are the same person.

Most successful winemakers understand that making fine wine depends not only on a respectful understanding of the complicated biochemistry involved but also, perhaps more importantly, on an appreciation of the greatest potential within each lot of grapes and then the skill and patience to reveal that potential in the finished wine.

winemaking, the practical art of producing WINE. In its most general sense it encompasses all operations in both vineyard and

cellar, but for the purposes of this entry winemaking excludes vine-growing, or VITICULTURE.

Winemaking, while a sophisticated practical art for several millennia, became an applied SCIENCE only towards the end of the 19th century after Louis PASTEUR's discovery of the existence and activities of BACTERIA and YEAST. Since then, knowledge of the detailed chemical and biochemical reactions involved in their metabolic processes has steadily increased, as has the sophistication of the CONTAINERS and equipment used in the professional cellar.

Winemaking in brief is a series of simple operations, the first of which is CRUSHING or smashing the fruit to liberate the SUGAR in the juice for FERMENTATION, which is the second step and occurs naturally when YEAST cells come into contact with sugar solutions. The new wine must then be subjected to numerous treatments to ensure CLARIFICATION and STABILIZATION and various other cellar operations which are collectively called ÉLEVAGE before the final step, BOTTLING.

Details in this sequence of operations vary considerably with WINE TYPE and its origin. General (as opposed to local) differences of technique dictated by different sorts of wine are outlined in WHITE WINEMAKING, RED WINEMAKING, ROSÉ WINEMAKING, SWEET WINEMAKING, and SPARKLING WINEMAKING and under the names of various FORTIFIED WINES.

Halliday, J., and Johnson, H., *The Art and Science of Wine* (1992).

Rankine, B., *Making Good Wine: A Manual of Winemaking Practice for Australia and New Zealand* (rev. edn, 2004).

Wine of Origin, area-of-origin designation scheme described in detail in SOUTH AFRICA. Established in 1973, it is the oldest and arguably the most extensive and rigorous in the NEW WORLD.

wine press. See PRESS for details of the equipment used during PRESSING. For the interface between wine and the press, see WINE WRITERS.

winery, modern, essentially NEW WORLD term for the premises on which wine is made. Its first recorded use was in the United States in 1882. It may refer to either the entire enterprise or to the specific building(s) used for WINEMAKING. The nearest French equivalent is CAVE (but see also CHAI and CUVE). WINERY DESIGN is a specialist art most dramatically practised in RIOJA, BORDEAUX, and northern CALIFORNIA, where, neatly, the FASHION is for caves: winemaking facilities burrowed into hillsides, the cost of maintaining suitable temperatures and humidity in such subterranean tunnels being minimal. However, there are spectacular examples all over the wine world today, with increasing emphasis on SUSTAINABILITY.

winery design is a specialist branch of building design. Although WINEMAKING can take place almost anywhere, modern wineries are much more than mere processing facilities. Nowadays wineries should be efficient in energy and resource consumption, suit the individual styles of wine and winemaking, and, of equal importance, support the BRAND image, often through architectural appearance, public display of winemaking processes, specialized hospitality and CELLAR DOOR facilities, and other amenities designed to engage the TOURIST and customer.

To ensure functionality and efficient workflow, a winery layout is based on a thorough understanding of the logistics of the specific winemaking practices and processes from grape receipt through production, bottling, storage, and shipping. Other issues include winery offices, laboratory, tasting bench, equipment sizes and types, and finish materials. The impacts of site conditions, environmental concerns, health and safety matters, and maintenance are also considered. Finally architectural requirements in terms of style and

functionality of the winery and associated facilities, including cellar-door sales, amenities, access, and infrastructure, are incorporated.

Building a winery to make an architectural statement is not new—the 19th-century CHÂTEAUX of Bordeaux, like the imposing Ch MARGAUX or the whimsical Ch Cos d'Estournel in ST-ESTÈPHE, or Andrea Palladio's 16th-century Villa di Maser in the VENETO make that clear. There are also 21st-century icons created by the world's greatest architects. Ysios by Santiago Calatrava and Marques de Riscal by Frank Gehry are two examples, both in RIOJA; Clos Pegase of NAPA Valley by Michael Graves, Craggy Range in NEW ZEALAND by John Blair, and Graham Beck Coastal Cellar in SOUTH AFRICA by Johan Wessels are three examples outside of Europe.

Other wineries find beauty in their simplicity and clarity. Many top producers aim for quick, cool, and gentle processing, which means GRAVITY flow instead of PUMPS wherever possible, as at Ridge in the SANTA CRUZ MOUNTAINS. If the site permits, as many as seven different levels may be achieved, where grapes are received at the highest level and shipping takes place from the lowest, as at Calera in MONTEREY. If the winery can be part-buried into a hillside, it aids natural TEMPERATURE and HUMIDITY control. Otherwise, creating cellars deeply dug from ancient LIMESTONE deposits is a possibility, as in Champagne or on the South Downs in England. Perhaps the most ambitious winery project thus far has been realized in the Loisium Wine Centre in Langenlois, Austria, by Stephen Holl with clients Karl and Brigitte Steininger. The entire medieval wine-village with its subterranean cellars has been transformed to include hotel, spa, and restaurant set amid the vineyards.

A well-planned winery development can conserve resources, manage WINERY WASTE and noise pollution, and be easy to maintain. A winery can offer high potential environmental SUSTAINABILITY, utilizing techniques such as renewable construction materials, solar panels for energy, and recycling winery waste water for IRRIGATION. winery waste comprises the liquid, solid, and gaseous waste that results from the process of turning fruit into wine. Globally the wine industry has been working to establish SUSTAINABLE systems to deal with these waste streams so as to maintain the beautiful rural environments in which wine is typically made. In many wine regions, there are now stringent local and sometimes national guidelines, policies, and legislation covering this area.

Water is a by-product of the HYGIENE or sanitation required to make wine, for example washing tanks, fermenters, and barrels. Roughly two volumes (litres/gallons) of water is used in the production of one volume of wine, though the exact amount depends on winemaking processes, winery equipment, and winery practices. Over a year, about 70% of the total volume of waste water generated is during the VINTAGE period, so sustainable waste-water systems need to be designed to handle these loads at this time.

Liquid winery waste tends to have a high oxygen requirement or BOD (organic acids, sugars, alcohol, etc.), low levels of nitrogen and phosphorus relative to carbon, and high solids content; it is generally acidic (low PH) due to organic acids, moderately saline (from sodium-based cleaning chemicals); and there may be imbalances in sodium, calcium, and magnesium.

This kind of waste water stored for a period of time releases malodours and degrades any land/vegetation that it continually comes into contact with. There are winery waste-water treatment systems all over the world that are now able to turn this liquid waste stream into a reusable resource via solids removal, pH adjustment, anaerobic digestion and/or aeration, clarification, and final polishing.

Treated water is often then reused to irrigate golf courses, vineyards, or winery gardens or be used back in the winery. These treatment systems can further capture and reuse the biogas generated (primarily methane) as a fuel for electricity and heat generation in combined heat and power systems.

What are collectively known as cleaner production procedures can help minimize water use in the winemaking process and thereby reduce treatment costs and reliance on potable water. These procedures include waste-stream segregation, for example keeping stormwater out of the waste system and diverting heavily polluted waste water (from CRUSHING or FERMENTATION areas, for example) away from less polluted; improved operating practices, for example screening solids from the waste system, using high-pressure hoses, and sweeping floors rather than hosing them down with water; personnel practices, including management initiatives, employee training, and incentives; and procedural measures, including documentation, material handling and storage, material tracking, and inventory control.

Winery solid wastes include STEMS, MARC, LEES (tartrates, grape solids, and dead yeast cells), spent DIATOMACEOUS EARTH used in FILTRATION, and sludge, which is a by-product of waste-water treatment.

Stems and marc are produced only during the vintage period. Approximately two units of marc are generated for every ten units of grapes processed. Marc can be distilled to recover alcohol, cream of tartar for TARTARIC ACID production, colour extract, and tannin extract. Marc can also be co-composted for under-vine application or used as a stock feed. Lees can be collected and sent to the still for alcohol recovery. Stems can be used to improve the organic levels of soils if they are thinly spread and worked into the soil. Many garden COMPOSTS use grape stems and sludge as an ingredient.

Spent diatomaceous earth can be processed by third parties to produce tartaric acid. Spent earth also has agronomic benefits and can be worked into most soil types to improve the SOIL STRUCTURE.

However, many filtration processes now use cross-flow membrane technology instead of diatomaceous earth, thereby reducing waste.

More recently, some wineries are turning their attention to gaseous waste. Chx Smith Haut Laffite and Montrose in Bordeaux and Domaine Dujac in Burgundy, for example, have implemented a system to capture the CARBON DIOXIDE produced during fermentation and recycle it to produce sodium bicarbonate. Heat capture and reuse onsite can further aid in minimizing energy demands and improving sustainable operations.

When the correct resources, management initiatives, and support are allocated to ensuring winery waste is treated in an environmentally sustainable manner, wineries will continue to exist in harmony with their surroundings. S.J.G. & K.H.

Wine Society, The, seminal British member-owned wine club-cum-merchant. The International Exhibition Co-operative Wine Society (IECWS), generally known as The Wine Society, was founded in 1874 by an architect, an eye surgeon, and a prominent Customs and Excise official following a food and wine exhibition in London's Royal Albert Hall that year. The objects and rules included a membership holding of one share only, no dividends to be paid on these until extinction on the member's death, and the introduction of

unfamiliar wines as well as those in general use—all to be bought 'for ready money only' at the lowest possible price. The Society remained small for many years, attaining its 5,000th member only in 1922, but grew substantially between the two World Wars. The number of active shares exceeded 180,000 by 2022.

The Society is governed by a Committee of Members. Edmund PENNING-ROWSELL was the Society's longest-serving chairman, from 1964 until 1987.

The Society's cellars were under the London Palladium theatre and London Bridge railway station (where the London AUCTIONEERS subsequently stored their wine) until the Society moved out of London to purpose-built and regularly extended premises in Stevenage in 1965. The Wine Society is one of the two biggest independent retail wine merchants in Britain (the other being its mail-order direct rival LAITHWAITE's) with a turnover exceeding £130 million in 2021. The policy of cash-with-order is retained. The Society is distinguished by its fair prices, perceptive buying, the efficiency of its bureaucracy, and the quality of wine STORAGE offered to members.

wine tasters. The animate sort are humans, often of widely varying abilities, experiences, SENSITIVITIES, preferences, and prejudices, engaged in the pursuit of wine TASTING. The inanimate sort are shallow, usually silver, saucers for tasting young wines, known in French and often in English as TASTEVINS.

wine types may be classified in several ways, the most usual being by alcohol level. Those whose ALCOHOLIC STRENGTH is entirely due to FERMENTATION, and usually in the range of 9 to 15%, are what we tend to call simply 'wine' or sometimes 'table wine' (although TABLE WINE used to have a specific meaning within the EU). Such wines may be further classified by COLOUR into RED WINES, WHITE WINES, ROSÉ WINES, and, more recently, ORANGE WINES. Or they may be classified according to their concentration of dissolved carbon dioxide

as SPARKLING WINES, still wines, and a host of terms in between such as PERLANT and FRIZZANTE. Wines may also be classified according to SWEETNESS.

Wines with higher concentrations of alcohol, between 15 and just over 20%, are called FORTIFIED WINES in this book since (with the exception of some DRIED-GRAPE WINES) they owe some of their alcoholic strength to the process of FORTIFICATION (i.e. the addition of spirit). PORT and SHERRY are the best known of these wines, officially called *vins de liqueur* in EU terminology. This higher-strength category also includes sweet alcoholic drinks made by adding grape spirit to grape juice or partly fermented grape juice at various points, for details of which see VIN DOUX NATUREL, VIN DE LIQUEUR, and MISTELA.

Wines which have been deliberately manipulated so that their alcohol levels are particularly low, say below 5.5%, are sometimes called LOW-ALCOHOL wines. However, some regular wines such as MOSCATO D'ASTI and lighter SAAR wines may have a NATURAL ALCOHOL of between 5 and 9%. See also DE-ALCOHOLIZED WINE.

Wine types may also be loosely, and somewhat subjectively, classified according to when they are drunk, for example APERITIF wines (or 'appetizer wines'), 'food wines' or 'dinner wines', and SWEET WINES or DESSERT WINES. See also VINO DA MEDITAZIONE.

Although geographical classifications are of wines not wine types, once-popular GENERIC wines represent an attempt at a geographical classification of wine types.

wine without geographical indication is the EU term adopted since 2008 to designate those wines, previously categorized as TABLE WINES, that have neither a PDO (Protected Designation of Origin) nor a PGI (Protected Geographical Indication). Such wines must be labelled with the word 'wine', in the appropriate language(s), and the country of origin must also appear somewhere on the label. Examples include Vin de France in France, Vino in Italy and Spain, Vinho in Portugal, and Deutscher Wein in Germany. They are also

permitted to specify on the label VINTAGE year and/or grape variety (varieties), though some countries have not implemented this in their local wine law.

wine writers, imprecise term to include all those who communicate via today's burgeoning media (see SOCIAL MEDIA) on the subject of wine. Some of them style themselves wine CRITICS (notably the consumerist Robert PARKER), while such literary stylists as Hugh JOHNSON and Gerald Asher are or were undoubtedly wine writers. One sort of commentator hardly ever writes at all but occupies regular slots on radio or television, often reaching a much wider audience than most authors could hope to.

Such was the increase in wine-writing opportunities in the late 20th century that by the early 1980s, for probably the first and only time ever, it was possible, with luck and hard work, to make a living as a wine writer with no other source of income. But it would be unreasonable to expect an activity as pleasurable as wine writing to be lavishly rewarded financially, and many wine writers also rely either on a private income or on income from dangerously closely related activities such as trading in wine or undertaking specific commissions for wine companies. Wine-writer ethics became a hot topic after several well-publicized cases of unseemly activity. As detailed in the LITERATURE OF WINE, Britain had a long tradition of wine merchants who wrote, who sometimes became wine writers who used to trade. Kermit Lynch is an American example of this phenomenon, Michael Fridjhon a South African one, while John Platter and James Halliday are examples of wine producers turned wine writers in South Africa and Australia respectively.

Wine writers in continental Europe such as France's Michel Bettane, Spain's Jose Peñín, and Italy's phalanx of specialists tend to concentrate on the wines of their own countries.

Britain may have the greatest concentration of full-time wine writers in the world, perhaps partly because it is a centre of wine book publishing—and possibly because the British wine market is so

diverse that British consumers need more advice than most. It certainly has the highest proportion of women among the country's wine writers; in the United States and most European countries wine writing has been dominated by men, although this is at last changing.

Changes in wine writing have wrought changes in wine writers. Given the 1990s preponderance of buyer's guides, TASTING NOTES, and SCORING in place of writing, there was a time when it would have been quite possible to be a highly successful wine writer without ever visiting a vineyard or cellar. A sound palate and a good database (see INFORMATION TECHNOLOGY) would in theory be quite sufficient, if a poor substitute for the excitement of exploring the world of wine.

See also WINE WRITING.

wine writing, a parasitical activity undertaken by WINE WRITERS, enabled by vine-growing and winemaking but more usually associated with wine TASTING, and even with wine drinking, than with either of the former. For an analysis of wine books through the ages, see LITERATURE OF WINE; for a discussion of words used to describe wine, see LANGUAGE OF WINE.

The proliferation of information and comment available free online and on SOCIAL MEDIA, together with the paucity of advertising of wine, led in the early years of the century to a sharp decline in regular columns, newsletters, and books devoted to wine.

Virtually all countries of any interest to wine exporters have at least one specialist wine consumer magazine (and major wine-producing and wine-trading countries tend to have specialist trade publications too), but they have increasingly looked to expand into other, more profitable activities such as events and COMPETITIONS. The world's best-selling wine magazine is the glossy, New York–based *Wine Spectator*. Its American consumer rival is *Wine Enthusiast*, but there are several lively wine-trade publications. Britain fields *Decanter* (of which there is also a Chinese edition) and *The World of Fine Wine.* Europe's three major wine-producing countries offer much less

consumer wine coverage than might be imagined. Few print publications are without an online version and associated app(s).

In the world of books, food outweighs wine very substantially; indeed many bookstores locate such wine titles as they do stock in an obscure corner of their cookery section. New wine titles continue to appear, perhaps sometimes the result of publishers' famous fondness for the fruits of the vine, but only a handful of authors can generate the sort of sales the increasingly agglomerated book trade now seeks worldwide, and self-publishing is increasingly common.

Buyer's guides, typically annual, proliferate, and for a while more and more of the words written about wine resembled shopping lists with SCORES rather than literature. But specialist wine books, some of them stunningly good, have been striking back.

Winiarski, Warren (1928–) , Napa Valley winegrower whose debut vintage, 1973, of Stag's Leap Cabernet Sauvignon took first place in the orginal 1976 JUDGMENT OF PARIS. The prospect of a life making wine in the Napa Valley lured him with his young family from a lectureship in Chicago in 1964. After apprenticing briefly with Lee Stewart at Souverain and then with Robert MONDAVI, he put down the roots of Stag's Leap Wine Cellars, with partners, in 1972. A more cerebral winemaker than many of his neighbours, Winiarski played an important part in creating and retaining Napa Valley's official status as an agricultural preserve. In 2007 he sold Stag's Leap Wine Cellars to Chateau Ste Michelle of WASHINGTON State with ANTINORI holding a minority advisory stake. In 2018 he made a major donation to the Shields Library at the University of California at DAVIS to enable it to establish the world's most comprehensive collection of wine writers' archives. This was followed in 2021 with a further donation enabling an update, in view of CLIMATE CHANGE, of the famous WINKLER climate classification of California.

Winkler, Albert Julius (1894–1989), scientist at the University of California at DAVIS whose name (and that of Maynard AMERINE) is

commonly associated with a method of CLIMATE CLASSIFICATION involving heat summation whereby California was divided into five viticultural regions, Regions I (the coolest) to V (the warmest). He edited *General Viticulture*, published in 1962 and revised in 1974, which was long considered the most comprehensive book on VITICULTURE in the English language.

winter freeze, a climatic stress which can be lethal to parts or all of the vine. In areas of high LATITUDE and high ELEVATION, the risk of very cold winter weather is substantial, particularly in CONTINENTAL CLIMATES away from the moderating effects of oceans (although even in MARITIME CLIMATES winter freeze can kill thousands of vines in exceptionally cold winters such as that of 1956 in ST-ÉMILION and POMEROL). Such continental climates typically show colder temperatures but also greater TEMPERATURE VARIABILITY.

Cold-hardy varieties, such as the American vine CONCORD, can be grown in the midwestern United States in sites with annual minimum temperatures of −29 °C/−20 °F occurring once in three years. European VITIS VINIFERA varieties sensitive to cold require relatively warmer sites, however, where annual minimum temperatures of −20 °C/−4 °F are recorded no more than once in a decade. CROWN GALL disease commonly develops on vines injured by winter freeze, killing tissue and causing trunk splitting.

An essential first step towards avoiding winter freeze injury is wise VINEYARD SITE SELECTION. Sites which export cold air, such as those offering AIR DRAINAGE on free-standing hills, can avoid winter injury by being up to 5 °C/9 °F warmer than sites which import cold air, such as those on valley floors. Vineyard sites within a few kilometres of large bodies of water (such as the MÉDOC, which suffered far less from the great winter freeze of 1956 than the inland vineyards of St-Émilion and Pomerol, for example) are also preferred because of the moderating effects on temperature (and see LAKE EFFECT in North America).

Selecting varieties with noted winter hardiness is also important. Varieties such as CABERNET FRANC and RIESLING are more winter-hardy than Pinot Noir, Chasselas, and Cabernet Sauvignon. In turn, *vinifera* varieties are less hardy than some interspecific HYBRIDS such as SEYVAL or TRAMINETTE, which in turn are less winter-hardy than such American varieties as DELAWARE and CONCORD. VINE BREEDERS have used VITIS AMURENSIS as a parent to produce winter-hardy varieties such as CABERNET SEVERNY and VITIS RIPARIA to breed complex winter-hardy hybrids such as MARQUETTE. Choice of ROOTSTOCKS which avoid stress is also critical for vine survival.

The vine's reserves of CARBOHYDRATES act like a biological antifreeze. The aim of vine management to avoid winter stress is to achieve maximum carbohydrate reserves at the end of the growing season. This entails choice of suitable TRAINING SYSTEM, appropriately severe PRUNING level, and SHOOT THINNING and CROP THINNING so as to restrict YIELD, which, when excessive, can act to reduce levels of vine carbohydrates.

An alternative strategy to avoid winter kill is to bury the vines in autumn (see WINTER PROTECTION). TRUNK RENEWAL is an established practice in upstate New York to recover vines affected by freeze injury. R.E.S.

winter protection, cumbersome viticultural techniques aimed at protecting vines in cold, CONTINENTAL CLIMATES against the effects of WINTER FREEZE. Most commonly, vines are buried in autumn to benefit from the fact that winter temperatures below the soil surface are never more than a few degrees Celsius below freezing point, whereas the air temperature can be more than 20 °C/36 °F colder. Burying vines is, however, LABOUR-intensive and expensive. This was traditionally practised in central Europe and North America but is uncommon now because of the cost. Only in the vineyards of RUSSIA, parts of UKRAINE, some of the central Asian republics, and CHINA is it still considered an acceptable price to pay for viticulture, although

some severe winters in upper NEW YORK State in the early 21st century have engendered some reconsideration. The procedure has been modified so that just those few CANES to be used for fruiting the following year are buried. Vines are also trained to have several TRUNKS, so-called 'spare-parts viticulture', so that those killed in winter can easily be replaced. Growers in ONTARIO, Canada, have widely adopted wind machines to combat winter freeze, and more recently GEOTEXTILES. It is possible that TRUNK DISEASE may contribute to winter-freeze injury, and their symptoms may be confused.

Willwerth, J., et al., 'Best management practices for reducing winter injury in grapevines' (2014). www.brocku.ca/webfm/Best_Practices_Manual__Winter_Injury_Sept_14_(5).pdf.

Winzer, which is the German equivalent of the French VIGNERON, is a common prefix in Germany for a CO-OPERATIVE wine cellar, as in Winzergenossenschaft, Winzerverein, and Winzervereinigung.

wire, used to form vine TRELLIS SYSTEMS, along with POSTS. Wine consumers might never credit something as mundane as wire in vineyards with their enjoyment, yet it is difficult to conceive of how wine could be so widely produced without it. The widespread use of wire revolutionized trellising of vines, making it possible to train vines to forms which maximize their production and MECHANIZATION. High-tensile wire can support very heavy loads without breaking. Normally, thicker wire is used to support the weight of grapes in a trellis, and thinner wires to support foliage. See TRELLIS SYSTEMS and TRAINING SYSTEMS.

R.E.S.

WO. See WINE OF ORIGIN.

wood has been the most popular material for wine CONTAINERS both for TRANSPORT and STORAGE for centuries, and even today trees are almost as important to some wines as vines. Merchants in ancient ARMENIA shipped wine down the Tigris in palm-wood casks seven centuries BCE, according to HERODOTUS. Wooden BARRELS eventually succeeded AMPHORAE as containers for both transport and storage in the 3rd century CE.

It was not until the mid 20th century, however, that wood was irrevocably replaced by the bottle and tanker for transport and widely replaced by inert materials such as CONCRETE and STAINLESS STEEL for storage and FERMENTATION.

For fine wines, wood is still valued as the prime material for maturing (see BARREL AGEING and CASK AGEING) and for fermenting certain types of white wine, for some handmade red wines (see BARREL FERMENTATION), and for some larger fermentation vats.

The chemistry of wine's maturation in wood is still not fully understood, but experience shows that wood (unlike sealed tanks made of inert materials) exposes the wine to a certain amount of OXYGEN and actively aids CLARIFICATION and STABILIZATION of the wine matured in it—quite apart from the wide range of flavours and characteristics which may be added and transformed as a result of exposure to that particular wood, either directly as OAK FLAVOUR or indirectly as WOOD INFLUENCE.

See also WOOD TYPES.

Wood also plays a part in viticulture, not just because the vine's own wood is important (see CANE and TRUNK) but also because wood is a common material for POSTS and STAKES in the vineyard.

For more detail of wood structure, see CAMBIUM and XYLEM.

Guimberteau, G. (ed.), *Le Bois et la qualité des vins et eaux-de-vie* (1992).

wood alcohol. Alternative name for harmful METHANOL.

wood influence. If a wine is fermented or matured in a wooden container, many different aspects of that container may shape its character and flavour, quite apart from those compounds that may be directly extracted from the oak wood and absorbed into the wine as wood flavour (see OAK FLAVOUR). The most obvious advantage of holding a wine in wood (see BARREL AGEING and CASK AGEING) rather than in an inert material is that wood encourages natural CLARIFICATION and STABILIZATION. The precise influence of a wooden container on any wine held in it is a function of the way that wine was made as well as of the following aspects.

Wood type

Historically, barrels and tanks have been made from many different WOOD TYPES although OAK is now the most common. The type of wood, even the type of oak, can have a powerful effect on flavour and STRUCTURE. There can be large differences between oak species. For example, the compounds extracted from white oak or from European oaks such as sessile and pedunculate oak are very different.

Origin of the wood

In addition to the species—and a barrel may be made from more than one—the origin of the oak can also have an effect on the wine in the barrel. This is influenced by genetic lineage, forest management, growth conditions, and climate.

For example, white oak from Missouri will not have exactly the same aromatic profile as white oak from other US states. Sessile oak from the Loire Valley will be different in terms of aromatic aldehydes and eugenol compared with sessile oak from the Carpathians. However, scientific studies tend to show a high degree of variability between trees in one forest or between forests, so the way coopers buy and select their wood is critical.

Manufacturing techniques

Several aspects of BARREL MAKING can have a marked impact on wine flavour, for example whether the STAVES are sawn or split (see OAK) or how the staves are graded (by GRAIN or by chemical composition). If the grain is not respected, the watertightness and aromatic profile of the wood may be affected.

The method of drying the wood, from seasoning in the open air to kiln drying, can also affect the character of the wine, as does the local climate, the ways the staves are stacked, and whether they are sprinkled with water.

Lastly, the degree to which the staves are heated while being bent and the level of barrel TOAST also have an obvious and profound effect on flavour (see BARREL MAKING).

Size of container

The larger the container, the smaller the ratio of surface area to volume and the greater the contact between the wine and the oak, so the barrel must be chosen in relation to the richness and style of the wine. Barrels holding less than 190 l/50 gal can overwhelm wine with OAK FLAVOURS. Containers holding more than 570 l/150 gal will provide little wood oak flavour, particularly after their first use. (See BARREL TYPES for detail of barrel sizes most commonly used.)

The use of large wooden VATS or tanks as FERMENTATION VESSELS fell out of favour after the advent of STAINLESS STEEL and other inert materials because the latter are much easier to clean than wood and because TEMPERATURE is harder to control in large-volume wooden containers, but there is currently a resurgence of interest in them (and in CONCRETE). Fermenting in a wooden vat is particularly suitable for high-quality wines with a firm tannic structure. It allows better integration of the wood and offers many of the advantages of barrel ageing.

Many of Italy's and some of the southern Rhône's, Germany's, and Alsace's most revered wines are the product of cask ageing in large, old wooden casks. Proponents of such wooden vats note that some of the greatest wines in the world are made in them and suggest that ageing in large wooden tanks provides gentle oxygenation of the wine and, hence, a desirable form of pre-bottling maturation.

Age of container

Barrels may be valued simply because they are containers made from a material that clarifies and stabilizes wine naturally, offers wine some mild but useful oxygenation, and can actually add OAK FLAVOUR to wine. The newer the barrel, the more wood flavour it is capable of imparting, and in most wine regions new barrels command a premium, with one-year-old barrels selling for approximately 70%, two-year-old barrels selling for less than 50%, and five-year-old barrels selling for just 10% of the cost of a new barrel.

However, some winemakers deliberately minimize oak flavour by using only a small proportion of new barrels or by 'breaking in' new barrels on lesser wines. Within a given type and style of wine, the richest wines will absorb the most oak with positive effects. A wine needs to have sufficient structure and aroma to balance those brought by the oak, and wines matured in 100% new oak are becoming much less common.

Older barrels are important for wines where the winemaker seeks slow oxygenation of the wine but no perceptible oak flavour, such as in making PORT, SHERRY, and, in many cases, RIOJA. Some champagne producers ferment or age their base wines in older oak.

When new oak was the height of FASHION at the end of the 20th century, some winemakers boasted of using '200% new oak', meaning that wines were first put into one new barrel and then into another. Very few wines can withstand such an onslaught.

Time

Time remains the winemaker's greatest tool. A wine's character is also influenced by how long it remains in wood, which can vary from about two months for relatively light white wines to two or even three years for certain red wines. More traditionally minded producers in Spain, Italy, and Portugal may keep wines in old wooden cooperage for even longer. The most practical approach is to age the wine in barrels for 12 months, because the barrels are never empty (see BARREL MAINTENANCE) and you don't need two sets of barrels, but the decision typically depends on the winemaker's preference and the capacity of the wine to support the oak. Wines with exceptional tannin structure can undergo the longest ageing; lighter wines will be quickly OXIDIZED and overwhelmed by the flavours and TANNINS from the oak. In general, the length of time a wine spends in barrel has reduced as grapes are picked riper and tannins are less ASTRINGENT.

Vintage

The character of individual VINTAGE YEARS also affects the influence of any wood on a wine's flavour. Wines, especially red wines, vary so much from vintage to vintage that it is impossible to specify the perfect barrel for a given wine. For this reason, some winemakers order a range of different WOOD TYPES with variation in TOAST in anticipation of each harvest.

Wine-making techniques

Just as important as the direct flavour effects from the wood are the indirect or secondary flavour effects that are more the result of the environment of the wooden tank or barrel. For more details, see CASK AGEING and BARREL AGEING respectively. White wines fermented in barrel may change enormously in character. For more details, see BARREL FERMENTATION.

Storage conditions

Exact temperatures and humidity levels, even draughts, can affect the character of a wine held in a wooden container. For more details, see BARREL STORAGE. M.C.K. & R.T. du C.

Prida, A., and Puech, J.-L., 'Influence of geographical origin and botanical species on the content of extractives in American, French, and East European oak woods', *Journal of Agricultural and Food Chemistry*, 54/21 (2006), 8115–26.

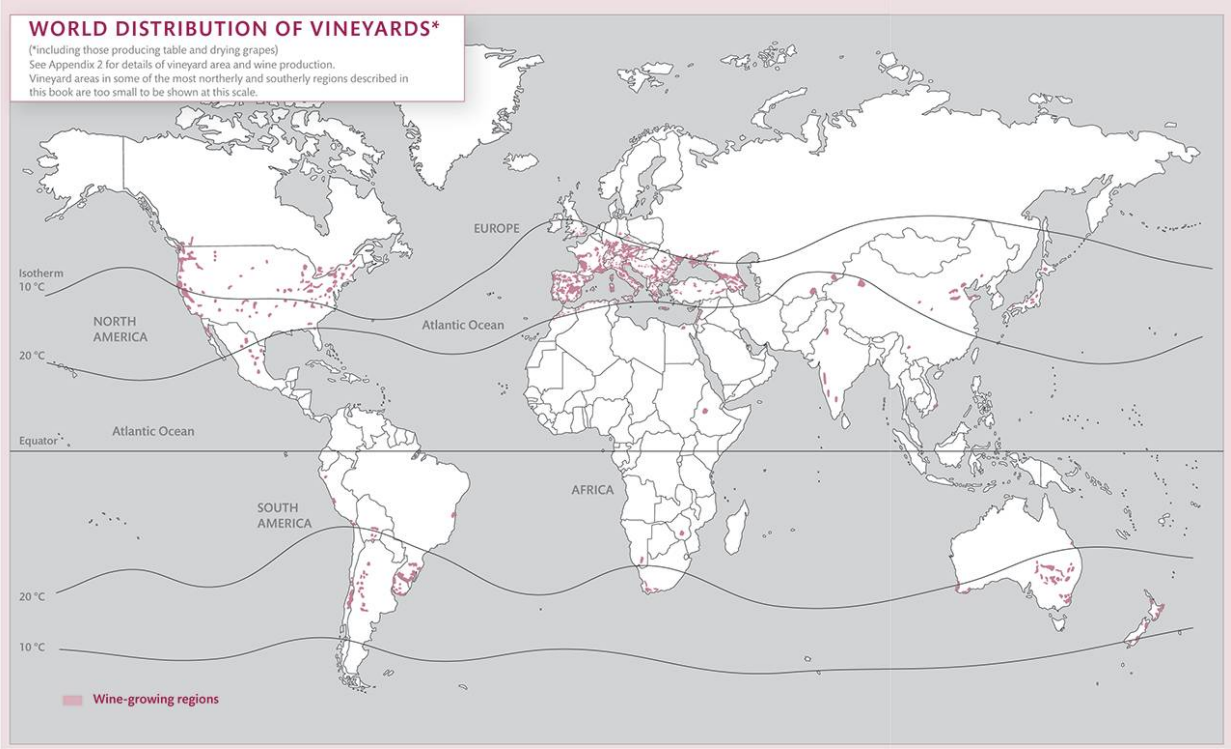
wood types. Over the years, many different kinds of wood have been used to make small BARRELS and larger VATS and CASKS. Acacia, cypress, chestnut, ash, redwood, pine, eucalyptus, and poplar are just a few of the woods that have been used.

Chestnut has long been popular for large oval casks in the Rhône, Beaujolais, and parts of Italy and Portugal, but as this wood offers strong TANNINS and is also relatively porous, chestnut barrels and tanks are often coated with paraffin or silicone to neutralize the wood. Wines made in unlined new chestnut barrels can be so tannic as to be undrinkable.

In other countries, pine and eucalyptus have been used for casks, but these woods produce wines with flavours that strike many consumers as odd unless the wood is very well seasoned (see BARREL MAKING) or coated on the inside. Acacia is used successfully, notably in Austria and Istria (see CROATIA), although some coopers say it is very porous. In Chile, the local evergreen beech, or *rauli*, wood was once common. Redwood was used for large upright tanks in America for many years, although very few have been built since the early 1970s. Redwood is rarely made into barrels because the wood is difficult to bend and the flavours are aggressive. Since the advent of neutral STAINLESS STEEL and enamel-lined tanks, wooden COOPERAGE must offer something extra to the wine to be worth the premium.

By far the most popular wood type in use in winemaking today is OAK, which has none of the disadvantages outlined above and whose particular aspects of WOOD INFLUENCE and OAK FLAVOUR have come to be appreciated by both winemakers and wine drinkers. M.C.K.

Worcester, warm inland wine district within the Breede River Valley region in South Africa. This extensive fertile district beyond the Du Toitskloof Mountains and within the Breede River Valley region produces about 12% of the national wine crop. Generally warm and reliant on IRRIGATION, the region used to be heavily dependent on Colombard and Chenin Blanc, but Chardonnay, Sauvignon Blanc, Viognier, and Shiraz have all become relatively important too.



world production of wine is concentrated in two bands of generally TEMPERATE to MEDITERRANEAN CLIMATE in each hemisphere, as shown on the map on page 842. TROPICAL VITICULTURE is becoming increasingly common but so far on a small scale relative to the established wine-producing countries. The limits of viticulture are also

shifting polewards, particularly in the northern hemisphere, as a result of CLIMATE CHANGE. (See LATVIA, for example.)

Total production of wine is affected by each year's weather (particularly by FROST, poor FRUIT SET, or HAIL, especially but not exclusively within Europe) and by the effects of VINE-PULL SCHEMES, offset by those of new plantings. The underlying trend is downwards, largely because of determined efforts by the EU to reduce its wine SURPLUS.

See also PRODUCTION, CONSUMPTION, and, for precise figures, SURPLUS of wine as well as Appendices 2A, 2B, and 2C.

World Wine Trade Group (WWTG) is a group of government and industry representatives from the following non-EU wine countries: Argentina, Australia, Canada, Chile, Georgia, New Zealand, South Africa, the United States, and Uruguay. It was founded in 1998 as a counterweight to the hegemony of the EU and its wine regulatory model in international affairs. It aims to facilitate international trade in wine through information sharing, discussion of regulatory issues, and joint actions to address trade barriers. While little known, it is highly influential. Members have signed two treaty-level agreements on mutual recognition of winemaking practices and requirements for labelling (see LABELLING INFORMATION), and the principles of these agreements have been included in other international free-trade agreements involving Pacific Rim countries. The WWTG is active in working with other Asia-Pacific economies on wine issues and has also established important guidance on matters such as SUSTAINABILITY, regulatory principles, and certification.

J.P.H.B.

www.wwtg-gmcv.org

Wrattonbully, now substantial wine region just north of Coonawarra in SOUTH AUSTRALIA with a strongly LIMESTONE-based soil.

Cabernet Sauvignon is the most planted grape variety.

WSET. The Wine & Spirit Education Trust is the world's leading provider of wine, spirits, and sake EDUCATION. Based in London, it offers classroom and online courses and qualifications for both industry professionals and consumers at four different levels, culminating in the WSET Diploma, which is the usual prerequisite for studying to become a MASTER OF WINE. These qualifications are offered through a network of over 800 course providers across more than 70 countries in more than 15 languages. Since its inception as an educational charity in 1969, WSET has awarded over 1 million people a WSET qualification.

Württemberg, wine region in southern Germany (in the State of Baden-Württemberg) with 11,394 ha/28,155 acres of vineyard in 2019 which loosely follow the River Neckar and its tributaries (see map under GERMANY) and whose soils are dominated by MARL and fossil-rich LIMESTONE. Much of the region lies between Stuttgart (including several suburbs) and Heilbronn with vineyards to the north segueing into those of BADEN's Kraichgau. In these sectors, steep, DROUGHT-sensitive, and demanding terraced slopes look down on the Neckar. The climate varies from south to north but is at its most CONTINENTAL along the Kocher, Jagst, and Tauber, three tributaries at the north-eastern edge of the region. Nearly 19% of Württemberg's vineyards are planted in RIESLING, while other white wine varieties are in decline and collectively amount to little more than 10% of the vineyard surface. Just over two-thirds of the region is planted to dark-skinned grapes, notably TROLLINGER with 18%, LEMBERGER with 16%, Schwarzriesling/Müllerrebe (PINOT MEUNIER) with 12%, and SPÄTBURGUNDER (Pinot Noir) with 12%.

Württemberg's Swabian populace is known for its thirst and the local wines for being drunk before leaving the region, but an increasing number of producers have begun garnering attention

abroad. While Swabians are also notorious for thrift, their wines sell for prices well above German averages. Some 70% of Württemberg's production represents smallholders who sell to 32 CO-OPERATIVES which process their fruit at a single huge central cellar (see ZENTRALKELLEREI). The viticultural institute at Weinsberg (affiliated with a state winery) perpetuates a 150-year reputation for research and teaching. D.S.

würzelecht, German for UNGRAFTED.

Würzer is a Gewürztraminer × Müller-Thurgau CROSS made at the German viticultural station of Alzey in 1932 and only planted in any significant quantity in the 1980s, peaking in 1995 at 121 ha/300 acres, mainly in Rheinhessen. Planted on only 50 ha/124 acres in 2020, it is overpoweringly heady and yields well, but a little goes a very long way indeed.

X

Xarello, or Xarel-lo, fine white grape variety planted on an increasing total of 10,445 ha/25,810 acres of CATALUÑA in 2020, producing powerful, ageworthy still and sparkling wines. Under the name Pansa Blanca, it is particularly important in ALELLA. It is most commonly found in PENEDÈS, however, where, with Parellada and Macabeo, it makes up most CAVA blends. It needs careful pruning, and the wine it produces can be very strongly flavoured. It is the rather vegetal smell of Xarello that often distinguishes so many Cavas from other TRADITIONAL METHOD sparkling wines. Xarello was recently authorized in France.

Xenophon , writer in ancient GREECE in the late 5th century BCE famous for his *Anabasis*. In the *Economics*, a dialogue between a farmer, Ischomachos, and the famous philosopher Socrates, the planting and care of vines is discussed: vines should be planted in well-dug earth, at an angle, and the earth should be trodden down around the vine. H.H.A.

Xérès, French name for both JEREZ and SHERRY.

Xinomavro, black grape variety grown on 2,185 ha/5,399 acres (in 2021) all over northern GREECE as far south as the foothills of Mount Olympus, where Rapsani is produced, but most famous as the grape of NAOUSSA. Its name means 'acid black', and the wines can indeed seem harsh in youth, but they age well, losing their colour relatively quickly and becoming much more perfumed and complex.

One of the few Greek vine varieties which may not reach full ripeness in some years, it is blended with a small proportion of the local NEGOSKA to produce Goumenissa and is also used as a base for sparkling wine on the exceptionally cool, high vineyards of AMYNDEO. The wines tend to be well-structured by both TANNINS and ACIDITY and have an attractive bite. It has also been planted in Gansu in CHINA at a JOINT VENTURE project by Mihalis Boutaris of Kir-Yianni in Naoussa.

xylem, the principal water-conducting tissue in vascular plants. In woody stem tissues, the secondary xylem forms the wood. The CAMBIUM differentiates xylem tissue on its inside. A single ring of xylem is produced each year with the first-formed vessels (in spring) being larger than those of late wood. This is how the annual rings which help to assess the age of a plant are formed. In the grapevine, the vessels are large and porous so that its wood is very water conductive, a feature of vines generally. In autumn, however, vessels may become blocked by structures which plug the tubes, called tyloses, formed by the 'ballooning' of adjacent cell material into the vessel through pits in the walls; some vessels remain functional for up to seven years, but most become blocked by tyloses in their second or third year. The secondary xylem of QUERCUS forms the wood from which oak barrels are made. (See also PHLOEM.)

B.G.C.

Xynisteri, the most common white grape variety grown on Cyprus, more than 2,085 ha/5,152 acres in 2020, more than one-quarter of the island's vineyard. It is preferred to the dark-skinned MAVRO for the rich fortified wine COMMANDARIA, the island's most distinctive wine, and also makes dry whites of varying quality.

Y

Yamabudo, meaning 'mountain vine' in Japanese and also known as crimson glory vine, is the common name for the Asian vine species *Vitis coignetiae,* which grows wild in Japan. The vine has small berries and high acidity and is showing promise for a range of red wines, from fresh and lively to rich.

Yamhill-Carlton District, wine region and AVA in the WILLAMETTE VALLEY of Oregon.

YAN. See NITROGEN.

Yarra Valley, historic, cool-climate Australian wine region just north-east of Melbourne, VICTORIA. Its 120-plus producers (2021) make internationally recognized Chardonnay, Pinot Noir and Cabernet blends, and, increasingly, Shiraz. In some quarters, CLIMATE CHANGE and the presence of PHYLLOXERA have prompted replanting, GRAFTING, exploitation of cooler exposures, and the emergence of later-ripening varieties such as GRENACHE. Iconic heritage producers such as Mount Mary, Yarra Yering, and Yeringberg rub shoulders with dynamic experimentalists in a creative melting pot that is a popular and growing centre for wine TOURISM. E.N.H.M.

Ycoden-Daute-Isora, complicated name from the Guanche pre-Hispanic times for the most ancient geographically DELIMITED wine region in the CANARY ISLANDS. It is centred on the town of Icod de los Vinos, where wine has been made since the Spanish conquest in the

15th century. It now produces some of the best dry whites in the islands, from LISTÁN Blanco (PALOMINO FINO) and, increasingly, from the more distinctive VIJARIEGO and MARMAJUELO. In the 1990s, coastal vineyards were consistently uprooted and vines were planted inland at much higher ELEVATIONS on the verdant VOLCANIC slopes. By 2021 there were 1,600 ha/3,954 acres under vine. V. de la S. & F.C.

yeast, microscopic, single-celled fungi, having round to oval cells which reproduce by forming buds, are vital to the alcoholic FERMENTATION process, which, starved of oxygen, transforms grape juice to wine. SUGARS are used as an energy source by yeast, with ETHANOL and CARBON DIOXIDE as major by-products of the reactions.

The word 'yeast' (which may be singular or plural unless it encompasses yeasts from more than one species) is an old one whose meaning has changed significantly with the flowering of microbiological science. It originally derived from an ancient word meaning 'to boil', 'to seethe' or 'to be troubled'. In 16th-century English, it referred to the froth on the top of a brewing tank and to the semi-solid material that could be collected both from that froth and from the bottom of the tank. From the mid 17th century, the meaning of the word 'yeast' changed to that of a single-celled plant, a *thallophyte* and one of the lowest members of the plant kingdom along with algae, lichens, and fungi.

In common with other fungi, yeasts are differentiated from plant cells by absence of chloroplasts, which contain the plant cell's chlorophyll. The modern fermentative yeasts have evolved from an ancestral yeast by a process of genome duplication, rearrangements, and deletions estimated to have occurred over the past 100 million years, most likely in response to the high availability of sugar as flowering plants evolved. The genetic, and hence phenotypic, diversity of the pre-eminent fermentation yeast, *Saccharomyces cerevisiae*, is now immense.

Nomenclature

The nomenclature of various yeasts is far from straightforward and is in the process of being revised. Taxonomists—scientists who classify and name plants and animals—have traditionally had difficulty with the various microorganisms, both because early microscopes revealed little detail and because the appearance of an organism depended on the conditions of its growth, isolation, and preparation for observation. The result has been that names have changed over time as laboratory equipment improved and as new techniques were perfected. In particular, the development of methods to study the genetic information contained in chromosomal DNA has provided more reliable ways to characterize and classify yeasts. Indeed, a *Saccharomyces cerevisiae* yeast was the first higher organism to have its whole genome sequenced, by 1996. Genome analysis has revealed that some yeasts which were thought to be closely related were in fact only distantly related, and vice versa. Furthermore, some characteristics of yeasts that were used to differentiate species, such as the pattern of sugars that can be fermented, were found to represent natural variation within that species and consequently did not represent different species. For this reason, many yeast names in common usage several decades ago are no longer accepted.

Saccharomyces cerevisiae is the name now most frequently used for the yeast involved in making wine and beer and in leavening bread. *Saccharomyces*, the genus name, means 'sugar fungus', and *cerevisiae* derives from the same root as 'cereals'. Older literature frequently called this yeast *Saccharomyces ellipsoideus* because the cells associated with fruit juices appeared more elliptical than the often-circular bakers' yeast. Within this yeast species are several hundred different strains or selections, each with real or fancied minor differences. Some strain differences relate to fermentation vigour, lack of off-flavour formation, ESTER production, and enhancement of a wine's VARIETAL character, such as fruity notes in Sauvignon Blanc. Many strains are being DNA-sequenced to reveal the genetic basis of their important winemaking characteristics, which

will ultimately facilitate the breeding of strains with enhanced fermentation characteristics (see GENETIC MODIFICATION). Another species within the same genus, *Saccharomyces uvarum*, is often used in the distilling and brewing industries. It can grow at lower temperatures than *S. cerevisiae* and is often the dominant yeast fermenting musts located in cool-climate viticultural regions of countries including New Zealand, France, and Italy. It and other closely related species, *Saccharomyces kudriazvevii* and *Saccharomyces paradoxus*, as well as their hybrids made by breeding with *Saccharomyces cerevisiae*, are showing potential for increasing the diversity of wine aromas and flavours. Several of the non-*Saccharomyces* yeast species which are commonly associated with grapes and fermentation (see below), such as *Candida zemplinina* (previously called *stellata*), *Lachancea* (previously *Kluyveromyces*) *thermotolerans*, *Metschnikowia pulcherrima*, and *Torulaspora delbrueckii*, are now being used in combination with *Saccharomyces cerevisiae* to introduce new and diverse flavour profiles in wine.

Editorial note: In this article and throughout the book we use the term ambient yeasts to refer to yeasts of any genus that are present in the vineyard or winery (i.e. the opposite of inoculated yeasts); some writers refer to non-inoculated yeasts as 'native' or 'indigenous' yeasts. We use wild yeasts to refer to non-*Saccharomyces* yeasts, although 'wild yeasts' is used by many writers to refer to non-inoculated yeasts of any genus.

Cultured versus ambient yeasts

Ecology studies have shown that intact grape berries harbour a number of other yeast and yeast-like genera in significant populations. Spread around wineries and vineyards by insects, particularly fruit flies (DROSOPHILA), and possibly air currents, the most common genera are *Aureobasidium*, *Klöckera/Hanseniaspora*, and *Candida*, with *Pichia*, *Lachancea* (formerly *Kluyveromyces*), *Metschnikowia*, *Zygosaccharomyces*, and *Torulaspora* usually representing a low proportion. *Saccharomyces* species are rarely isolated from grape berries unless they are damaged by, for example, disease, birds, insects, or hail. More sensitive to SULFUR DIOXIDE and generally intolerant of an ALCOHOLIC STRENGTH above 5%, these wild yeasts are generally active during the early stages of non-inoculated or spontaneous fermentations, especially those occurring when insufficient or no sulfur dioxide is added to the MUST or GRAPE JUICE. Fortunately, there are usually enough *Saccharomyces cerevisiae* cells present on the surfaces of harvesting, transportation, and winery processing equipment that enter the must or grape juice, so that these latter yeasts continue the fermentation above the unstable alcoholic strength of 5%, depleting the supply of sugar and producing a stable wine. Inoculation with *Saccharomyces* yeast does not totally suppress wild yeasts which are naturally present in musts and juices during the early stages of fermentation. Therefore, wine is commonly the result of a mixed microflora, although the impact of wild yeasts on the wine is usually very much restricted by the inoculated yeast.

Ambient yeast, generally a mixture of yeast genera and species, have in the past been much more commonly used than cultured yeast in the traditional wine regions of Europe. (See also PIED DE CUVE.) The concept of 'château' or resident/indigenous populations of ambient yeast which promote the particular character of an estate wine is controversial among wine scientists. (See also MICROBIAL TERROIR.)

The advantage of a well-adapted population of ambient yeast is that they are generally composed of more than one strain and, because of their different abilities and aptitudes, they may be capable of producing a wine with a more balanced, wider range of flavours and characteristics. In an attempt to verify such a view, current research is working systematically with mixed-culture fermentations in combination with chemical analysis of FLAVOUR COMPOUNDS (referred to as 'metabolic footprinting') and sensory evaluation of wines to compare inoculated with uninoculated ferments. Given the more unpredictable nature of ambient-yeast fermentations, it is likely that even more sophisticated blended yeast cultures, which better simulate the apparent characteristics of spontaneous ferments, will be developed in the future.

Increasing numbers of OLD WORLD producers and the majority of NEW WORLD winemakers use cultured yeast (sometimes called pure culture, selected yeast or inoculated yeast). The advantage of cultured yeast is that it has been specifically selected and extensively characterized, so that its behaviour across a defined range of grape-juice parameters is robust and predictable. Among the many genera of yeasts, there are astounding variations in terms of alcohol production and tolerance, aroma and flavour, rate of fermentation, temperature tolerance, flocculation characteristics, sulfur-dioxide tolerance, REDUCING potential, and micronutrient requirements. Most wild yeasts cannot tolerate alcohol concentrations above 5%. However, a tolerance of up to 13 or 15% is required for yeasts used in the production of dry wine. Accordingly, strains of *S. cerevisiae* have historically been preferred as cultured strains, although non-*Saccharomyces* yeasts are increasingly being developed as co-inoculants (either simultaneously or sequentially) with commercial *S. cerevisiae* strains.

Strains have been selected and exploited by OENOLOGISTS and winemakers for characteristics such as fermentation vigour, high-alcohol and sulfur-dioxide tolerance, tolerance to temperature extremes, ability to referment wine to make sparkling wine, freedom from ACETIC ACID (VOLATILE ACIDITY) and sulfidic off-flavours, film or

FLOR formation needed for SHERRY production, enhancement of wine varietal character, fruity-ester profile and intensity, increased MOUTHFEEL, lower alcohol production, low-foaming, sedimentation (flocculant) property, yeasticidal properties, improved red wine colour, better tolerance to nutrient deficiencies, lower potential to form sulfur dioxide, and compatibility with LACTIC ACID BACTERIA. Yeast with a high alcohol production and tolerance may be chosen for FORTIFIED WINES or dry red wine made from overripe grapes with very high sugar content in some New World wine regions. Yeast which flocculate particularly well, such as that called Épernay, may be used for SPARKLING WINEMAKING; FILM-FORMING YEAST are used to make sherry; while a yeast with good tolerance of sulfur dioxide may be useful in certain examples of SWEET WINEMAKING. Strains with well-defined flavour characteristics are becoming popular and can offer better colour and tannin structure, improved fruity/ESTERY notes or greater enhancement of varietal flavour; strains which emphasize, for example, the tropical/passion-fruit aroma in Sauvignon Blanc are now widely available.

Because the selection and characterization of new yeast isolates is a laborious and time-consuming process, a variety of conventional breeding techniques are increasingly being used. These include selecting natural variants from a population or using a mutagen such as ULTRAVIOLET RADIATION to increase genetic variability; culturing yeast under specific stressful conditions (often referred to as adaptive or directed evolution); and hybridization or rare-mating, which exploits the sexual cycle in yeast. See also GENETIC MODIFICATION.

Cultured yeast production

Yeast are cultured in large sterile tanks with vigorous aeration under conditions which encourage biomass but discourage alcohol formation. They are then filtered, washed, dried, and packed in sterile containers, often under vacuum, for transfer to the winery (or brewery or bakery). Well over one hundred different strains are now produced worldwide as active dried wine yeast preparations. Active dried yeast is quickly and simply reactivated with warm water or diluted grape juice at 40 °C/104 °F for 15 minutes. Some wineries culture their favoured yeast in grape juice with or without vigorous aeration and add about 2–4% by volume to the juice or must to initiate fermentation. Following use in winemaking, the yeast and grape debris are freed of as much wine as possible and usually discarded. A minor proportion may be processed to recover alcohol, TARTRATES, and occasionally grapeseed oil. P.A.H. & A.B.

How yeast works

Yeast, like most living organisms, need a good supply of carbon and NITROGEN; a source of SULFUR, PHOSPHORUS, and OXYGEN; and various MINERALS and micronutrients (e.g. trace elements, and several VITAMINS) for growth and reproduction. The usual carbon sources are the six-carbon sugars, GLUCOSE and FRUCTOSE. Wine yeast can also use SUCROSE, which may be added to the juice of underripe grapes (CHAPTALIZATION) and is used in SPARKLING WINEMAKING to induce the second fermentation. Grape AMINO ACIDS and ammonium compounds most often supply the nitrogen; most fruit juices, including grape juice, provide the other components necessary for growth. Nutrient supplements, based on nitrogen or vitamins, may be added to encourage yeast activity at the beginning of fermentation. This is especially important in the case of underripe grapes, ROT, grapes from low SOIL POTENTIAL vineyards, or grape- and must-processing conditions that deliberately or unwittingly lead to nutrient depletion, such as harvesting and transport under hot conditions that permit extensive microbial growth, or excessive CLARIFICATION. Grape solids provide a source of LIPIDS, which, in the absence of oxygen, are used to build stronger cell membranes that confer better tolerance to fermentation stresses, such as extremes of alcohol and temperature. Oxygen is an especially important nutrient, which is supplied in large quantity during production of the yeast starter culture. Small amounts of oxygen may also be supplied during the early or middle stage of fermentation to improve yeast survival and fermentation activity later in fermentation, especially in anaerobic, high-sugar, highly clarified grape juice at low temperatures (see STUCK FERMENTATION).

All cells require energy to exist, grow, and reproduce. Yeast can release a small amount of the energy stored in glucose and fructose of grape juice by a series of complex biochemical reactions known as glycolysis. This nearly universal biological process is so complex and involves so many steps that it has taken scientists years of research

to understand it. Through a series of ENZYME reactions, the yeast cell splits the six-carbon sugar molecule into two molecules of the three-carbon compound PYRUVATE. The final two steps, known collectively as fermentation, convert the pyruvate to ETHYL ALCOHOL and carbon dioxide. In this fermentative decomposition of pyruvate, the first step is removal of the terminal carbon dioxide from pyruvate, leaving the two-carbon fragment ACETALDEHYDE. Acetaldehyde is then reduced to ethyl alcohol. A small amount of acetaldehyde is also converted to ACETIC ACID, which is required for cell processes (e.g. biosynthesis of lipids, needed to make cell membranes); some acetic acid escapes from the cell and contributes to wine volatile acidity.

When all of the sugar is fermented to alcohol and carbon dioxide, and a small amount of oxygen is present, yeast can reconvert some of the ethyl alcohol back to acetaldehyde. Further oxidative decomposition occurs, by a complex series of reactions, to carbon dioxide and water. This process, which takes place in the mitochondria within the cell and which releases most of the energy originally stored in sugar, is known as RESPIRATION. The exposure of wine to oxygen is, however, rigorously prevented except in some circumstances, such as in the making of FLOR wines such as FINO sherry. Normally wine is protected from air during fermentation by the blanket of carbon dioxide produced.

During fermentation of grape juice, yeast produce small amounts of other compounds as by-products of glycolysis and the metabolism of amino acids and other nutrients. Some of these compounds are volatile and contribute fermentation-derived characteristics to the AROMA of wine. The most important compounds are esters, aldehydes, and ketones, fatty acids, higher alcohols, and volatile sulfur compounds (HYDROGEN SULFIDE and MERCAPTANS). Recent research has shown that some of these volatile compounds play a much greater role in the distinctive aroma profile of certain grape varieties than previously believed. Furthermore, advances in the understanding of how yeast control the formation of these aroma compounds is leading to the development of new yeast strains which can alter the

emphasis of various aroma notes in wine. GLYCEROL, acetic acid, and SUCCINIC ACID, which contribute to the taste of wine, are the most important non-volatile compounds produced by yeast.

In addition to yeast-derived compounds, there are also complex metabolic/enzymatic interactions that exist between yeast and various grape-derived compounds, many of which contribute to the characteristic aroma and flavour of specific grape varieties. For example, a certain class of enzymes termed glycosidases are released by yeasts and are capable of hydrolysing various FLAVOUR PRECURSORS, notably sugar conjugates of MONOTERPENES, norisoprenoids, aliphatics, PHENOLS, and benzene derivatives. Monoterpenes are important to the aroma of wines made from floral grape varieties such as MUSCAT, RIESLING, and TRAMINER, while β-damascenone, which is responsible for stewed-apple, rose, and honey aromas in young wine, is an example of an important norisoprenoid. See FLAVOUR COMPOUNDS.

Cysteine- or GLUTATHIONE-linked compounds represent another important class of grape-derived flavour precursors that generate polyfunctional volatile THIOLS with fruity aromas when hydrolysed by enzymes present in some strains of yeast. These compounds, which contribute box tree, passion-fruit, grapefruit, guava, and gooseberry aromas, are important in Sauvignon Blanc wines and have also been identified in wines made from Colombard, Riesling, Sémillon, Merlot, and Cabernet Sauvignon.

Some yeasts also have the ability to degrade phenolic acids to volatile vinyl phenols (e.g. 4-vinylphenol and 4-vinylgaiacol), which contribute to phenolic off-flavour. BRETTANOMYCES yeasts are able to convert these unstable vinylphenols to the stable ethylphenols (e.g. 4-ethylphenol and 4-ethylgaiacol), responsible for phenolic, medicinal, and barnyard aromas in wine. Yeast also produce carbonyl compounds, which, under some circumstances, can enhance red-wine colour. For example, acetaldehyde and pyruvic acid can react with anthocyanins to form more stable pigmented pyranoanthocyanins that can contribute to the stable colour of aged red wines. On the other hand, most aldehydes are ultimately

converted to the corresponding alcohol (just as acetaldehyde becomes ethyl alcohol), such that the oak-derived aldehyde vanillin is reduced to vanillic alcohol, thereby lowering flavour intensity.

After the yeast have converted all of the sugar, they slowly die, flocculate, and fall to the bottom of the vessel, forming a sediment known as gross LEES. In bottle-fermented sparkling wines, the interaction between this sediment and the wine in the bottle is an important element in sparkling winemaking (see AUTOLYSIS). The traditional STIRRING of wine on yeast lees in barrel and in tank is now becoming widely practised as a means to improve palate weight and texture. P.A.H. & A.B.

Yecla , DOP in Murcia in south-east Spain, sandwiched between JUMILLA, ALICANTE, and ALMANSA (see map under SPAIN) and dominated by La Purísima, a large CO-OPERATIVE. The red MONASTRELL represents the majority of the 6,420 ha/15,864 acres of grapes grown in the region.

yellow mosaic, vine disease. See FANLEAF DEGENERATION.

yellows. See GRAPEVINE YELLOWS.

Yellow Tail, Australian wine BRAND whose growth in the US, from a standing start in 2001, set records in the history of branding and gave birth to the infamous 'critters' (small animals on labels) wine category. The CASELLA FAMILY had just 16 ha/40 acres of vines in RIVERINA and supplied BULK WINE until John Casella with an aggressive, export-orientated manager planned an assault on the embryonic US market for Australian wines in the late 1990s. A first attempt failed, but new branding involving a yellow kangaroo image and the irritating but eye-catching logo [yellow tail] (*sic*), together with particularly fruity, not to say sweet, wines and a bold profit-sharing scheme with their US importer W. J. Deutsch & Sons, paid off. Annual US sales rose from 200,000 cases in the launch year to 7.5 million in 2004, by which time Yellow Tail was the top imported wine brand in the US. But the brand is often blamed for ruining, or at least cheapening, the image of Australian wine there.

yema bud, alternative name for CHIP BUDDING.

yield, how much a vineyard produces, is an important statistic in wine production and has been a subject of intense interest from at least the time of classical ROME, not least because of alleged effects on wine quality.

Factors affecting yield

Vineyard yield depends on many factors, which will be briefly described here. For a more complete discussion, see the individual factors listed.

Yield may be measured as either a weight of grapes or a volume of wine (see below) and is usually considered per unit area of vineyard, since this is what matters in agricultural terms. Those who believe that increasing VINE DENSITY is associated with improved wine quality argue that yield per vine is a more important consideration. Disciples of CANOPY MANAGEMENT, on the other hand, argue that the amount of sunlit leaf area per unit of land is more important than yield per vine or per hectare.

Yield per vine depends on the number of bunches per vine and the average bunch weight. The number of bunches per vine depends on the winter PRUNING policy, the BUDBREAK, and the number of bunches per shoot, or FRUITFULNESS. Bunch weight depends on the number of FLOWERS per bunch and the success of FRUIT SET in forming berries, then on the weight of individual berries.

Yield per vine also depends on VINE AGE (very old vines often produce very little), on the way the vines have been managed, and on the WEATHER over at least the last two years, together with other factors such as VINE PESTS and VINE DISEASES.

After VIGOUR and pruning, the weather is one of the most important factors affecting vineyard yield. Cold winters may promote budbreak, but FROSTS in spring can kill young shoots and bunches. Warm, sunny weather promotes FLOWERING and POLLINATION, but cold, wet, and windy weather can cause poor fruit set. Some varieties are more prone than others to poor set. DROUGHT conditions commonly reduce berry size—to less than half that of vines well supplied with water in extreme cases. Rain will generally increase yield as it causes berries to swell, but too much rain near harvest causes BOTRYTIS BUNCH ROT and potentially a considerable loss in yield.

Perhaps surprisingly, the weather the preceding season can also have an effect on yield. It has been shown that warm, sunny weather during flowering encourages bunch INITIATION in the buds that are forming to produce shoots and bunches for the next growing season. So this weather pattern can prepare the vine for a high potential yield the following year.

How yield is measured

Conventional units of yield are the weight of fresh grapes per unit land area, such as tonnes/ha or tons/acre. (One ton/acre is about 2.5 tonnes/ha.) This is the standard measurement in most NEW WORLD wine regions.

Although many Italians and Swiss measure yield in weight of grapes, in most other European countries production is measured in volumes of wine per unit area, normally expressed as hectolitres per hectare, or hl/ha. In many cases, this measurement is an extremely important one, often limited to a maximum (depending on the VINTAGE) specified by local regulation (see AOC, DOC, etc. and the note below).

The two measurements interrelate, although the volume of wine produced by a given weight of grapes can vary considerably according to vine variety, individual vintage conditions, winery equipment, winemaking policy, and, most importantly, wine type. To make 100 litres of red wine, which is fermented in the presence of grape skins that can be pressed rather harder than white grape skins, about 130 kg (0.13 tonnes) of grapes are needed. To make 100 litres of white wine, about 150 kg are needed (more like 160 kg for top-quality SPARKLING WINEMAKING). Assuming an average of 140 kg of grapes per 100 litres of wine, 1 tonne/ha is about 7 hl/ha, while 1 ton/acre is about 17.5 hl/ha (typically slightly less for whites, slightly more for reds).

Despite its importance in measuring yield, there is no uniform approach in determining the area of a vineyard. Excluding the essential and normally cultivated areas along the ends (called headlands) and at the sides, which are indubitably part of the productive unit, effectively reduces the size of many vineyards by 10% or so, and the figure may be higher for small vineyards.

Yields and wine quality

A necessary connection between low yields and high-quality wine has been assumed at least since Roman times when *Bacchus amat colles* encapsulated the prevailing belief that low-yielding HILLSIDE VINEYARDS produced the best wine. Wine law in many European countries is predicated on the same belief, and the much-imitated AOC laws of France specify maximum permitted yields for each appellation (even if an additional allowance is often permitted; see below).

There is little doubt that heavily cropped vines with a low LEAF TO FRUIT RATIO ripen more slowly, so that in cooler climates the fruit may not reach full RIPENESS and wine quality suffers. It is less widely understood that undercropping can also adversely affect wine quality. A high leaf to fruit ratio will certainly ripen grapes, but the resultant shaded CANOPY MICROCLIMATE will produce grapes high in POTASSIUM and PH and low in PHENOLICS and flavour.

It should also be noted that, within a given wine region (Bordeaux is a notable example), there is no correlation between size of the crop and quality of the wine. Some of the finest red bordeaux VINTAGE YEARS of the 1980s, for example, were also those in which yields were relatively high; while the lowest crop levels of the decade were recorded in lesser vintages such as 1984 and 1980.

There are countless commercial examples of high vineyard yields associated with low quality, however. Very high yields are common to vineyards of high VIGOUR, which in turn is typically due to planting on very fertile soil, well supplied with water and nutrients, but the negative effects are more likely to be the result of excessive shoot and leaf growth and canopy SHADE. High-yielding vineyards are also often in hot climates, where the climate reduces the potential for wine quality anyway.

Very low yields may be the deliberate result of careful pruning, SHOOT THINNING, or even CROP THINNING, but they may also be associated with excessive vine stress. This can be due, for example, to weeds, pests, or disease or to very shallow soils and WATER STRESS

(as in many traditionally dry-grown vineyards of Mediterranean Europe), and a vine that is too severely stressed will not function properly and will not produce premium wine.

The yield which a vineyard can ripen properly will depend on the VINE VARIETY, the region, vine management practices (particularly pruning and vine-TRAINING SYSTEMS), and climate as well as weather. For example, a yield of 8 tonnes/ha, or 56 hl/ha, might be considered excessive in a very cool climate, but a yield four times this figure might be easily ripened to a similar or higher sugar level in a warmer climate. Some varieties seem more prone than others to crop-level effects on wine quality, and in general red wine varieties are more affected than white. PINOT NOIR is an outstanding example, as the inverse relationship between yield and quality in red burgundy demonstrates. Both Pinot Noir and MERLOT show less colour in the skins and wine, whereas yield effects are much less evident in deeply pigmented varieties such as Syrah.

Some specific examples

Vineyard yields vary enormously around the world and (in some regions with less dependable climates) from year to year. Among the highest reported yields are about 100 tonnes/ha for TABLE GRAPES grown on complex trellises in Israel (if their juice were made into wine, this would convert into about 1,750 hl/ha!). The Argentine vine-breeder Angel Gargiulo was in the 1970s and 1980s encouraged to breed new wine grape varieties specifically designed for the Argentine environment which can yield up to 500 hl/ha (but were commercially planted only to a very limited extent). Commercial, well-managed vineyards in irrigated DESERT regions in California, Australia, and Argentina can routinely produce 15 tons/acre, almost 38 tonnes/ha (260 hl/ha). At the other end of the spectrum, pests, disease, drought, or bunch rot can all reduce yields to less than 1 tonne/ha, or 7 hl/ha. See Ch d'YQUEM as well as Domaine LEROY and CHAPOUTIER for some examples of particularly low yields, encouraged for the sake of wine quality.

Some attempt at calculating national average yields may be made using OIV statistics, although these are more reliable for some countries than for others, and they include vineyards dedicated to TABLE GRAPES or RAISINS as well as to wine grapes, which makes comparisons difficult. According to figures for 2020, South Africa has the highest national average yield, at 85 hl/ha. See EU for a discussion of yields in Europe.

Certain wine types (most red wines, for example) are apparently more sensitive to yield, perhaps because wines from higher-yielding vineyards are often lighter in colour, but this is more likely the result of a vine vigour producing a shaded canopy, which is known to depress PHENOLIC synthesis. Vineyards dedicated to sparkling wines, or base wines for brandy, are in general allowed to yield rather more than those dedicated to still wine production. In Champagne, for example, permitted yields of 12 tonnes/ha (5 tons/acre) or over 80 hl/ha are common.

From a financial point of view, high yields are attractive to vine-growers, who have traditionally been paid on the simple basis of weight (although quality factors such as MUST WEIGHT are also taken into account; see PRICE of grapes). Vine-growers whose aim is to produce good-quality wine may, however, deliberately restrict yields by such measures as pruning, crop thinning, and shoot thinning, although the evidence for a direct yield–quality equation is lacking. One of the most important economic issues facing modern viticulture is whether high-vigour and high-yielding vineyards can produce high-quality wine using vineyard management techniques such as CANOPY MANAGEMENT.

The fact that yields are officially limited by regulation in the two most important wine-producing countries of France and Italy has undoubtedly encouraged worldwide respect for low yields—and perhaps some inertia in those countries for researching ways of increasing both quality and quantity. Alternatively, such restrictions could be seen as a device to avoid production surplus. It should be noted, however, that the official maxima cited in wine regulations were almost routinely increased in France by a device called the *plafond limite de classement*, or PLC, which allowed a certain increase (often 20%) on the base yield according to the conditions of the year. Average yields for the top appellations of the MÉDOC in 1989, 1990, and 1996, for example, were between 55 and 60 hl/ha when the theoretical maximum yield is 45 hl/ha.

Although the PLC has been abolished and the wording has changed, the practice has not. Leeway still exists thanks to the so-called *rendement butoir*, which is higher than the basic maximum. Derogations are also made when yields are severely reduced by severe weather such as HAIL. Another mechanism, the so-called *volume complémentaire individual* (VCI), helps producers balance their stocks when a vintage is expected to face challenges in terms of either quantity or quality, but it applies to wine and not to grapes.

yield monitors, sensors fitted to mechanical grape harvesters which assess and record the amount of fruit being harvested in real time. When used in conjunction with a differential GLOBAL NAVIGATION SATELLITE system, they allow maps of yield to be produced. Such maps are a tool in the implementation of PRECISION VITICULTURE and ZONAL VITICULTURE. R.G.V.B.

Yquem, Château d', the greatest wine of SAUTERNES and, according to the famous 1855 CLASSIFICATION, of the entire BORDEAUX region. It is sweet, golden, and apparently almost immortal.

It had been in the Lur Saluces family since 1785 when Françoise-Joséphine, descendant of original owners the de Sauvage family, married Louis-Amédée de Lur Saluces, in whose family it remained until 1999 when it was sold, after a bitter family struggle, to LVMH. The Lur Saluces generations initiated the system of progressively harvesting only botrytized grapes, a system that quickly spread to neighbouring estates and caught the eye of the Parisian salons, of Thomas JEFFERSON, of the Russian tsars, and finally of all major markets. In the 20th century, the estate was dominated by the Marquis Bertrand de Lur Saluces and, from 1968, by his nephew Comte Alexandre de Lur Saluces, both of whom were totally dedicated to the continued supremacy of Yquem.

The château, dating from the 15th century (the vineyard is considerably older), stands on the crest of an imposing hill overlooking all of the Sauternes FIRST GROWTHS. The vineyard on all sides extends to 100 ha/247 acres in production, of which 80% of vines are Sémillon, the rest Sauvignon Blanc. Production is intentionally restricted to around 96,000 bottles, a fraction of the typical output of a top red-wine property in the MÉDOC. The secret of

Yquem's renown is its strict and ever-changing selection from its varied soils, aspects, and MESOCLIMATES according to vintage. The estate's owners have always been determined to run risks and sacrifice quantity for painstakingly upheld quality. Each year, all necessary passes through the vineyard are meticulously performed so that only the best BOTRYTIS-affected grapes are picked. The YIELD is generally just 8–9 hl/ha (the Sauternes appellation permits up to 25). The first pressing is undertaken gently in a horizontal bladder PRESS and accounts for a good 75% of the final volume; the rest is from subsequent pressings in a traditional vertical press made from modern stainless steel. The selected juice is run off into new barrels for BARREL FERMENTATION and then maturation, previously for three years but in the LVMH era closer to 30 months, with the different lots kept separate until they are progressively blended into the final wine.

Since 1959, a dry white wine, Y, or Ygrec, has been intermittently produced. Initially it was a unique wine that smelled strongly of Sauternes but tasted dry or medium-dry. From 2004 it has become a much fresher dry white Bordeaux, with a higher proportion of Sauvignon Blanc in the blend, the acidity balanced by a point of sweetness. W.J.B.

Olney, R., *Yquem* (1985, 1986).

Yonne, a river and a *département* in north-west BURGUNDY as well as an IGP often used for wines falling outside the regulations for AOCs such as CHABLIS, ST-BRIS, and IRANCY. The region is also an important source of OAK for wine barrels. See CHABLIS for more information.

Yugoslavia , eastern European union of peoples that existed for barely 60 years before breaking up amid bloodshed, privation, and extreme ethnic tension at the beginning of the post-communist era in the early 1990s.

Viticulture in this region dates back at least to Roman times and almost certainly earlier, to the Illyrians in the 4th–5th centuries BCE. In the socialist era, production of volume at low prices was the

priority in large state-controlled CO-OPERATIVES. At its peak in the 1970s, the former Yugoslavia was one of the world's top ten wine producers, making around 6 million hl/158 million gal a year, and was famous for wines such as Lutomer Laški Rizling, once the UK's best-selling white wine. Marshal Tito's regime was less hardline than those running other Eastern Bloc countries, and some degree of private land ownership, and even private wine production, was permitted. Some family producers were able to start bottling their wine as early as the 1970s. The first private producer, industry hero Stanko Čurin, and (Tito's favourite) Movia of SLOVENIA kept producing throughout this era. This meant that some connection between land and vine growing was retained and provided a strong foundation for the emergence of today's private wine producers. Yugoslavia has since been split into (roughly from north to south) SLOVENIA, CROATIA, SERBIA, KOSOVO, MONTENEGRO, BOSNIA AND HERZEGOVINA, and NORTH MACEDONIA.

C.G.

Z

Zalagyöngye, Muscat-like TABLE GRAPE cross of a variety bred in EGER and Pearl of Csaba that is planted on 605 ha/1,495 acres in Hungary, where some undistinguished wine is also made from it, mainly in Kunság. It is also grown in Italy, Croatia, Romania, and Israel for table grapes and is usually called by a local translation of the expression 'Queen of the Vineyards'.

Zalema, Spanish white grape variety still making light, neutral whites from 3,952 ha/9,766 acres of Andalucía in 2020, particularly in the southern CONDADO DE HUELVA zone, where its MUSTS and wine can oxidize easily. It is being replaced by higher-quality varieties such as PALOMINO.

Žametovka, Slovenian dark-skinned grape variety most famous for a single plant (see SLOVENIA). Wine made from this variety from the Dolenjska wine region in Posavje in the south of the country is typically an ingredient in the pale, tart, local Čvicek wine.

Zefír, early-ripening 1951 Hungarian CROSS, said to be LEÁNYKA × HÁRSLEVELŰ, producing soft, spicy white wine.

Zelen, old, south-west SLOVENIAN vine variety making crisp, aromatic dry whites in Vipavska Dolina.

Zenit, 1951 Hungarian CROSS of EZERJÓ and BOUVIER which ripens usefully early on 697 ha/1,722 acres (as of 2020) to produce crisp,

fruity, but not particularly aromatic white wines.

Zentralkellerei, a vast central co-operative wine cellar peculiar to GERMANY. See CO-OPERATIVES.

zero-zero, term for wine to which no ADDITIVES, especially SULFITES, have been added and nothing subtracted by, for example, FINING or FILTRATION. See also NATURAL WINE.

Zéta, Hungarian vine CROSS of FURMINT and BOUVIER, formerly known as Orémus, which, with Furmint, Hárslevelű, and Sárga Muskotály, is permitted in TOKAJ, where there were 116 ha/287 acres in 2020. The Bouvier character can dominate unless it is very ripe.

Zibibbo, Sicilian name for the MUSCAT OF ALEXANDRIA white grape variety, sometimes made into wine, notably Moscato and Passito di PANTELLERIA, although more usually sold as TABLE GRAPES. It is very much less common in Italy than Moscato Bianco (MUSCAT BLANC À PETITS GRAINS). In 2020 there were 2,686 ha/6,637 acres planted on Sicily. The rich, sweet, orange-gold Moscato di Pantelleria is geographically closer to Tunisia than to Sicily, which administers it. In fact this is the only wine with even a modicum of international renown that is made remotely near the city after which the variety is named.

Zierfandler, the finer of the two white wine grape varieties traditionally associated with Gumpoldskirchen, the dramatically full-bodied, long-lived spicy white wine of the THERMENREGION district of Austria. (The other is ROTGIPFLER.) Plantings had fallen to just 62 ha/153 acres by 2020. It ripens late, as its synonym Spätrot suggests, but keeps its acidity better than Rotgipfler. Unblended, Zierfandler has sufficient nerve to make LATE HARVEST wines with the

ability to evolve over years in bottle, but many Zierfandler grapes are blended, and sometimes vinified, with Rotgipfler. The variety, as Cirfandli, is also known in Hungary. DNA parentage analysis suggests it may be a natural cross of ROTER VELTLINER and a relative of SAVAGNIN (Traminer).

Žilavka, the most famous grape variety in Herzegovina (see BOSNIA AND HERZEGOVINA). This characterful variety makes distinctive whites that manage to combine high alcohol with high acidity and a certain nuttiness of flavour. The Žilavka made around the inland town of Mostar is particularly prized. It is not, however, necessarily made exclusively from Žilavka grapes. Žilavka is also found in North Macedonia and to a limited extent in Serbia.

Zimbabwe , southern AFRICAN country with a chequered history of very small-scale wine production since the 1960s. Production peaked at over 6 million l/1.3 million gal in the mid 1990s; however, land redistribution policies and economic instability reduced vineyard area from over 650 ha/1,606 acres to under 40 ha by 2019.

Historically, wine was made by two CO-OPERATIVES, Cairns Holdings (owner of Mukuyu wine estate) and African Distillers, with around 16 growers supplying them with grapes. By 2019 there were only three active vineyards left, and both co-operatives were importing wine from SOUTH AFRICA in tankers, diluting, sweetening, and bottling it under their own brands. Apart from Bushman Rock, Zimbabwe's only surviving boutique wine producer with just 10 ha/25 acres, most of the domestic harvest was destined for DISTILLATION or turned into wine-based products.

Recent changes in land-tenure policies and economic factors have renewed interest and investment in wine production. Mukuyu, which lost all its vineyards, started a replanting programme with 19 ha/47 acres in 2021.

Existing vineyards are in the eastern part of the country, south-east of the capital, Harare, in the provinces of East Mashonaland and Manicaland. The TEMPERATE climate averages eight hours of daily sunshine, and mean annual temperatures are just under 19 °C/66 °F. Summer rain falls from November to April, but DROUGHT is a constant threat. Uneven budding and ROT are annual hazards in the long, hot, humid summers, and the grapes can be affected by dilution and HAIL. The better vineyard areas lie at an ELEVATION of about 1,500 m/4,920 ft. Wines are frequently adjusted by ACIDIFICATION and ENRICHMENT (Zimbabwe has no official wine regulations). Chenin Blanc, Colombard, Sauvignon Blanc, Chardonnay, Semillon, Viognier, and Hanepoot (MUSCAT OF ALEXANDRIA) vines produce dry and off-dry whites; Shiraz, Merlot, Cabernet Sauvignon, Cabernet Franc, and Alicante Bouschet produce reds.

T.D.C.

zinc, essential element for healthy vine growth. A deficiency of zinc affects the plant's ability to synthesize the hormones AUXINS, deficiency in which results in a failure of the SHOOTS to grow normally. The principal symptoms are CHLOROSIS between the veins of young and old leaves, their small size, and a widened leaf sinus where the PETIOLE attaches. FRUIT SET can also be poor. Zinc deficiency commonly occurs in vineyards on SANDY soils and on some high-PH soils; it is treated by daubing pruning wounds with pastes containing zinc or by applying a zinc spray to the leaves in summer.

R.E.S. & R.E.W.

Zinfandel is the best-known California name of the black grape variety known in its native CROATIA as both TRIBIDRAG and CRLJENAK KAŠTELANSKI and in Puglia as PRIMITIVO. California grows far more of the variety than anywhere else: nearly 16,017 ha/39,578 acres in 2020.

For much of the 20th century, the viticultural 'pioneer' Agoston HARASZTHY was credited with introducing this important variety to California from his native Hungary, but a more worthy Zinfandel hero is the California historian Charles L. Sullivan, who unearthed the truth, or at least part of it, about Zinfandel's route to California. It was he who pointed out that there was no mention of Zinfandel in Haraszthy's copious promotional literature in the early 1860s and that the variety was well known on the American east coast long before Haraszthy arrived in California in 1849.

The vine was imported, possibly unnamed, to the US from the Austrian imperial nursery in Vienna by George Gibbs of Long Island, probably in 1829. He took it to Boston, and by the early 1830s it had acquired such names as 'Zenfendel' and 'Zinfindal' among New England growers, many of whom added it to the range of VITIS VINIFERA vines they grew under glass as a TABLE GRAPE.

Many of those who participated in the California GOLD RUSH of 1849 turned to agriculture, often dependent on shipments of plant material from the east coast. 'Zinfindal' was included in a particularly important consignment which arrived in 1852, and by 1859 the variety was grown in both Napa and Sonoma. In 1862 the secretary of the Sonoma Horticultural Society gave some wine made from these grapes to a French winemaker working in California who reported that it tasted like 'a good French claret'.

Because Zinfandel has no French connection, it had escaped the detailed scrutiny of the world's AMPELOGRAPHIC centre in MONTPELLIER, and its European origins rested on local hypothesis until the application of DNA PROFILING to vines in the early 1990s. Only then was it irrefutably demonstrated that, as had been suspected, Zinfandel and the variety known as PRIMITIVO in Puglia are one and the same. Subsequent DNA profiling at DAVIS established that the Croatian variety PLAVAC MALI is in fact a cross between Zinfandel and Dobričić, an obscure and ancient Croatian variety found on the island of Šolta near Split. This suggested a probable Dalmatian origin for Zinfandel too, and Croatian researchers Pejic and Maletic

collaborating with Carole Meredith at Davis searched the coastal vineyards for Zinfandel until in 2001 they discovered an ancient and almost extinct variety in the region of Kaštela near Split called Crljenak Kaštelanski (literally 'red grape of Kaštela') that was established as Zinfandel by DNA profiling. Analysis of this variety's DNA showed an exact match with that of a 90-year-old herbarium specimen of an ancient Croatian vine known locally as Tribidrag. Montenegrin growers strongly contest this Croatian origin.

Zinfandel took firm hold on the California wine business in the 1880s, when its ability to produce in quantity was prized above all else. Many was the miner or other beneficiary of California's gold rush whose customary drink was Zinfandel. By the turn of the century, Zinfandel was regarded as California's own CLARET and occupied some of the choicest North Coast vineyard. During PROHIBITION it was the choice of many a HOME WINEMAKER, but since then its viticultural popularity has become its undoing.

In 20th-century California, Zinfandel occupied much the same place as SHIRAZ (Syrah) did in Australia and for many decades suffered the same lack of respect simply because it was the most common black grape variety, often planted in unsuitably hot sites and expected to yield more than was good for it. Zinfandel may not be quite such a potentially high-quality grape variety as Syrah, but it is certainly capable of producing fine wine, especially from older, HEAD-TRAINED vines, as Ridge Vineyards and others have proved. And the fact that so many of California's oldest vines are Zinfandel means that the best wines that bear its name (which are sometimes FIELD BLENDS) are exceptionally complex (see VINE AGE) and ageworthy.

Zinfandel's viticultural disadvantages are uneven ripening and thin-skinned berries in compact clusters. Bunches sometimes have harsh, green berries on the same cluster as those that have reached full maturity, and once grapes reach full ripeness (in direct contrast to its great California rival Cabernet Sauvignon, for example) they will soon turn to raisins if not picked quite rapidly. Zinfandel

performs best in warm but not hot conditions and prefers well-drained soils that naturally reduce VIGOUR and excess moisture.

Although Zinfandel has been required over the years to transform itself into virtually every style and colour of wine that exists, it is best suited to dry, sturdy, vigorous reds. Dry Creek Valley in Sonoma, the Sierra Foothills, and Lodi has demonstrated a particular aptitude for this underestimated variety. See CALIFORNIA for more details of Zinfandel the wine, both red and white.

In the late 1980s, thanks to the enormous popularity of WHITE ZINFANDEL, Zinfandel plantings, which had been declining, increased by up to 1,215 ha/3,000 acres a year, mostly in the Central Valley, so that they totalled 34,000 acres/13,760 ha in 1992, just ahead of California's total acreage of Cabernet Sauvignon at the time. The resurgence of Zinfandel continued in the late 1990s as red Zinfandel began to enjoy mildly cult-like status (with many examples commanding prices over $30), driving total plantings to 50,000 acres/20,000 ha in 2003, only slightly less than Merlot and two-thirds as much as California's most important black variety Cabernet Sauvignon. By 2020 Zinfandel was California's third most planted black variety, just ahead of Merlot but some way behind Pinot Noir.

Zinfandel is also grown to a much more limited extent in warmer sites in other western states in the US as well as in Mexico. Because of its prominence in California, Zinfandel is grown in many of the world's wine regions, albeit to a very limited extent—quite apart from Puglia, where it is known as Primitivo, and NORTH MACEDONIA and MONTENEGRO on the other side of the Adriatic, where it is known as Kratošija. There is some 'Zinfandel' in the Languedoc, South Africa, and Australia, where there were 86 ha/213 acres in 2015, and Cape Mentelle in Western Australia has been particularly successful with it.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

zonal viticulture, form of PRECISION VITICULTURE in which vineyards are divided into zones of characteristic performance in terms of YIELD and/or grape composition. These are then managed as separate units with respect to SELECTIVE HARVESTING and/or particular inputs. Typically, zones are identified on the basis of visual inspection, imagery acquired by REMOTE SENSING or PROXIMAL SENSING, yield maps, and/or maps of other vineyard attributes, simple classification of such data or the use of statistically based clustering algorithms.

This approach has been adopted in several locations in Australia, Chile, Spain, and the US. R.G.V.B.

Zweigelt, or Blauer Zweigelt, is Austria's most popular dark-berried grape variety, covering 6,130 ha/15,148 acres by 2022. It is a BLAUFRÄNKISCH × ST-LAURENT cross, bred by Dr Fritz Zweigelt at the KLOSTERNEUBURG research station in 1922, which combines the brightness of the first with the fruitiness of the second if it is not overcropped or picked too late. It is popular with growers because it ripens earlier than Blaufränkisch and is vigorous, productive, not picky about site, and expressive even when unoaked and bottled early. Grown throughout all Austrian wine regions, its wines range from exuberantly fruity reds and rosés to highly extracted, oak-influenced versions, particularly in BURGENLAND's DAC. So successful has it been in Austria that the variety is also popular over the border in Czechia and Slovakia as well as in western Hungary. It has also been planted in Canada, across the US, and, surprisingly widely, on Hokkaido in JAPAN. Recognizing the influential Dr Zweigelt's collaboration with Austria's 1938–45 Nazi government, there is growing pressure to revert to a synonym devised in the 1980s for his most successful crossing: Rotburger.

zymase, group of ENZYMES which encourage the conversion of GLUCOSE and FRUCTOSE into ETHYL ALCOHOL during fermentation.

zymurgy, the study or practice of FERMENTATION. It is a word more useful in Scrabble than in everyday life.

APPENDIX 1

CONTROLLED APPELLATIONS AND THEIR PERMITTED GRAPE VARIETIES

It is still impossible to tell from the labels of many geographically named wines which grape varieties were used to make them. The following is a unique guide to the varieties officially allowed into the world's CONTROLLED APPELLATIONS (therefore by no means all known wine names), grouped by country or, where appropriate, by region. Within the groups the appellations are listed alphabetically using local names.

For each appellation, varieties are listed alphabetically, not in order of importance. Italics denote minor grape varieties. Regulations sometimes use local synonyms or spellings for grape varieties and occasionally give alternative names in brackets. We have followed that usage rather than trying to impose consistency.

R, W, P, and S denote red, white, pink, and sparkling wines respectively. Where both white and rosé sparkling wines may be produced using a different mix of varieties, these are abbreviated WS and PS. In some instances, appellation regulations allow the inclusion of a stated percentage of other (unnamed) red or white varieties, which generally refers to those that are locally authorized for PDO wines within that appellation or region, indicated below by *OR*, *OW*, and *OR&W*.

VARIETAL appellations and appellations that permit a very wide range of varieties are not included in this list because they are so numerous

and because the region of origin and the grape variety are, in most cases, clearly stated on the label.

AUSTRIA

Carnuntum (R) Blaufränkisch, Zweigelt, *OR* (W) Chardonnay, Grüner Veltliner, Weissburgunder, *OW*

Leithaberg (W) Chardonnay, Grüner Veltliner, Neuburger, Weissburgunder

Neusiedlersee (W) any local white varieties

Rosalia (P) any local red varieties

Ruster Ausbruch (W) any local white varieties

Südsteiermark (W) Gelber Muskateller, Grauburgunder, Morillon, Riesling, Sauvignon Blanc, Traminer, Weissburgunder, Welschriesling

Vulkanland Steiermark (W) Gelber Muskateller, Grauburgunder, Morillon, Riesling, Sauvignon Blanc, Traminer, Weissburgunder, Welschriesling

Wachau (R) Pinot Noir, St Laurent, Zweigelt (W) Chardonnay, Frühroter Veltliner, Gemischter Satz, Grauburgunder, Grüner Veltliner, Müller-Thurgau, Muskat Ottonel, Muskateller, Neuburger, Riesling, Roter Veltliner, Sauvignon Blanc, Traminer, Weissburgunder

Wagram (R) Blauburgunder, St Laurent, Zweigelt (W) Chardonnay, Frühroter Veltliner, Gelber Muskateller, Grauburgunder, Grüner Veltliner, Riesling, Roter Veltliner, Sauvignon Blanc, Traminer, Weissburgunder

Weststeiermark (W) Gelber Muskateller, Grauburgunder, Morillon, Riesling, Sauvignon Blanc, Traminer, Weissburgunder, Welschriesling (P) Blauer Wildbacher

Wiener Gemischter Satz (W) at least three white varieties out of a possible 40

CROATIA

Dingač (R) Plavac Mali
Ponikve (R, P) Plavac Mali Crni (W) Posip Bijeli, Rukatac

CYPRUS

Commandaria (R, W) Mavro, Xynisteri

FRANCE

In 2021 the INAO introduced a category for experimental varieties (see VIFA). These are included below for the appellations that have taken up this option so far (see Bordeaux, for example).

Alsace and North-East

Crémant d'Alsace (S) Auxerrois, Chardonnay, Pinot Blanc, Pinot Gris, Pinot Noir, Riesling

Vin d'Alsace Edelzwicker (W) Auxerrois, Chasselas, Gewürztraminer, Muscat Blanc à Petits Grains, Muscat Ottonel, Pinot Blanc, Pinot Gris, Pinot Noir, Riesling, Savagnin Rose, Sylvaner

Côtes de Toul (R) Pinot Noir (W) Aubin, Auxerrois (P) Gamay, Pinot Noir, *Aubin*, *Auxerrois*, *Pinot Meunier*

Moselle (R) Pinot Noir (W) Auxerrois, Müller-Thurgau, Pinot Gris, *Gewurztraminer*, *Pinot Blanc*, *Riesling* (P) Pinot Noir, *Gamay*

Bordeaux

Blaye (R) Cabernet Franc, Cabernet Sauvignon, Merlot, *Carmenère*, *Cot*, *Petit Verdot*

Bordeaux, Bordeaux Supérieur (R) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot, plus, experimentally, *Arinarnoa*, *Castets*, *Marselan*, *Touriga Nacional* (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon, *Colombard*, *Merlot Blanc*, *Ugni Blanc*, plus, experimentally, *Alvarinho*, *Liliorila* (*Alvarinho* only for Bordeaux)

Bordeaux Clairet (P) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot, plus, experimentally, *Arinarnoa*, *Castets*, *Marselan*, *Touriga Nacional*

Bordeaux Rosé (P) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot, *Sauvignon Blanc*, *Sauvignon Gris*, *Sémillon*, plus, experimentally, *Arinarnoa*, *Castets*, *Marselan*, *Touriga Nacional*, *Alvarinho*, *Liliorila*

Bordeaux Haut-Benauge (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon

Bourg, Côtes de Bourg, Bourgeais (R) Cabernet Franc, Cabernet Sauvignon, Cot, Merlot (W) Colombard, Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon

Côtes de Blaye (W) Colombard, Ugni Blanc, *Muscadelle*, *Sauvignon Blanc*, *Sauvignon Gris*, *Sémillon*

Côtes de Bordeaux (R) Cabernet Franc, Cabernet Sauvignon, Cot, Merlot, *Carmenère*, *Petit Verdot* (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon, *Colombard*, *Ugni Blanc*

Crémant de Bordeaux (WS) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Muscadelle, Petit Verdot, Sauvignon Blanc, Sauvignon Gris, Sémillon, *Colombard*, *Merlot Blanc*, *Ugni Blanc* (PS) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot, Sauvignon Blanc, Sauvignon Gris, Sémillon

Entre-Deux-Mers, Entre-Deux-Mers Haut-Benauge (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon,

Colombard, *Mauzac*, *Merlot Blanc*, *Ugni Blanc* (R) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot

Fronsac, Canon Fronsac (R) Cabernet Franc, Cabernet Sauvignon, Merlot, *Carmenère*, *Cot*, *Petit Verdot*

Graves, Graves Supérieures (R) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon

Graves de Vayres (R) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon, *Merlot Blanc*

Haut-Médoc, Listrac-Médoc, Margaux, Médoc, Moulis, Pauillac, St-Estèphe, St-Julien (R) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot

Lalande-de-Pomerol, Lussac-St-Émilion, Montagne-St-Émilion, Puisseguin-St-Émilion, St-Georges-St-Émilion (R) Cabernet Franc, Cabernet Sauvignon, Cot, Merlot, *Carmenère*, *Petit Verdot*

Pessac-Léognan (R) Cabernet Franc, Cabernet Sauvignon, Carmenère, Cot, Merlot, Petit Verdot (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon

Pomerol (R) Cabernet Franc, Cabernet Sauvignon, Cot, Merlot, Petit Verdot

St-Émilion (R) Cabernet Franc, Cabernet Sauvignon, Carmenère, Malbec, Merlot, *Petit Verdot*

Sauternes, Barsac, Ste-Croix-du-Mont, Loupiac, Cadillac, Cérons, Premières Côtes de Bordeaux, Côtes de Bordeaux St-Macaire (W) Muscadelle, Sauvignon Blanc, Sauvignon Gris, Sémillon

Burgundy

Regional appellations

Bourgogne, Bourgogne La Chapelle Notre-Dame, Bourgogne Le Chapitre, Bourgogne Chitry, Bourgogne Côtes d'Auxerre, Bourgogne Côte Chalonnaise, Bourgogne Côte St-Jacques, Bourgogne Coulanges-la-Vineuse, Bourgogne Hautes-Côtes de Beaune, Bourgogne Hautes-Côtes de Nuits, Bourgogne Montrecul or **Montre-Cul** or **En Montre-Cul** (R) Pinot Noir, *César* (Yonne only), *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay, Pinot Blanc, *Pinot Gris* (P) Pinot Gris, Pinot Noir, *César* (Yonne only), *Chardonnay*, *Pinot Blanc*

Bourgogne Aligoté, Bouzeron (W) Aligoté

Bourgogne Clairet (P) Pinot Gris, Pinot Noir, *Chardonnay*, *Pinot Blanc*, *César* (Yonne only)

Bourgogne Côte d'Or (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris*, *César* (Yonne only) (W) Chardonnay, Pinot Blanc, *Pinot Gris*

Bourgogne Côtes du Couchois (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris*

Bourgogne Epineuil (R) Pinot Noir, *César*, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (P) Pinot Gris, Pinot Noir, *Chardonnay*, *Pinot Blanc*

Bourgogne Mousseux (S) César (Yonne only), Gamay, Pinot Noir, *Aligoté*, *Chardonnay*, *Gamay de Bouze*, *Gamay de Chaudenay*, *Melon*, *Pinot Blanc*, *Pinot Gris*

Bourgogne Passe-tout-grains (R, P) Gamay, Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris*

Bourgogne Tonnerre (W) Chardonnay, Pinot Blanc, *Pinot Gris*

Coteaux Bourguignons (R) Gamay, Pinot Noir, César (Yonne only), *Aligoté*, *Chardonnay*, *Gamay de Bouze*, *Gamay de Chaudenay*, *Melon*, *Pinot Blanc*, *Pinot Gris* (W) Aligoté, Chardonnay, Melon, Pinot Blanc, Pinot Gris (P) Gamay, Pinot Gris, Pinot Noir, César (Yonne only), *Aligoté*, *Chardonnay*, *Melon*, *Pinot Blanc*

Crémant de Bourgogne (S) Aligoté, Chardonnay, Gamay, Melon, Pinot Blanc, Pinot Gris, Pinot Noir, Sacy

Beaujolais

Beaujolais, Beaujolais-Villages (R, P) Gamay, *Aligoté*, *Chardonnay*, *Gamay de Bouze*, *Gamay de Chaudenay*, *Melon*, *Pinot Gris*, *Pinot Noir* (W) Chardonnay

Beaujolais Supérieur (R) Gamay, *Aligoté*, *Chardonnay*, *Gamay de Bouze*, *Gamay de Chaudenay*, *Melon*, *Pinot Gris*, *Pinot Noir*

Brouilly, Chénas, Chiroubles, Côte de Brouilly Fleurie, Juliénas, Morgon, Moulin-à-Vent, Régnié, St-Amour (R) Gamay, *Aligoté*, *Chardonnay*, *Melon*

Chablis region

Irancy (R) Pinot Noir, *César*, *Pinot Gris*
Petit Chablis, Chablis, Chablis Premier Cru, Chablis Grand Cru
(W) Chardonnay
St-Bris (W) Sauvignon Blanc, Sauvignon Gris
Vézelay (W) Chardonnay

Côte Chalonnaise

Note: The communes indicated with an asterisk contain PREMIER CRU vineyards.

Givry* (R) Pinot Noir, *Chardonnay*, *Pinot Gris* (W) Chardonnay, *Pinot Blanc*, *Pinot Gris*

Mercurey*, Rully* (R) Pinot Noir, *Chardonnay*, *Pinot Gris* (W) Chardonnay, *Pinot Gris*

Montagny* (W) Chardonnay

Côte d'Or

Note: The communes indicated with an asterisk contain PREMIER CRU vineyards.

Aloxe-Corton* (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay, *Pinot Blanc*

Auxey-Duresses*, Chassagne-Montrachet*, Chorey-lès-Beaune, Côte de Nuits-Villages, Fixin*, Meursault*, Monthelie, Morey-St-Denis*, Nuits-St-Georges*, Puligny-Montrachet*, St-Aubin*, St-Romain, Santenay*, Savigny-lès-Beaune*, Vougeot* (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay, Pinot Blanc (plus *Aligoté* for the premier cru Monts Luisants in Morey-St-Denis)

Blagny*, Côte de Beaune-Villages (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris*

Chambolle-Musigny*, Gevrey-Chambertin*, Pommard*, Volnay*, Vosne-Romanée* (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris*

Côte de Beaune, Beaune*, Ladoix*, Pernand-Vergelesses* (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay, Pinot Blanc, *Pinot Gris*

Maranges* (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay

Marsannay (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay, Pinot Blanc, *Pinot Gris* (P) Pinot Gris, Pinot Noir, *Chardonnay*, *Pinot Blanc*

Côte d'Or—Grands Crus

Bonnes-Mares, Chambertin, Chambertin-Clos de Bèze, Chapelle-Chambertin, Charmes-Chambertin, Griotte-Chambertin, Latricières-Chambertin, Mazis-Chambertin, Mazoyères-Chambertin, Ruchottes-Chambertin, Clos des Lambrays, Clos de la Roche, Clos St-Denis, Clos de Tart, Clos de Vougeot, Échezeaux, La Grande Rue, Grands Échezeaux, Richebourg, Romanée-Conti, Romanée-St-Vivant, La Romanée, La Tâche (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris*

Charlemagne, Corton-Charlemagne (W) Chardonnay, *Pinot Blanc*

Corton (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay, *Pinot Blanc*

Montrachet, Bâtard-Montrachet, Bienvenues-Bâtard-Montrachet, Chevalier-Montrachet, Criots-Bâtard-Montrachet (W) Chardonnay

Musigny (R) Pinot Noir, *Chardonnay*, *Pinot Blanc*, *Pinot Gris* (W) Chardonnay

Mâconnais

Note: The communes indicated with an asterisk contain PREMIER CRU vineyards.

Mâcon-Villages (W) Chardonnay

Mâcon (R, P) Gamay, Pinot Noir (W) Chardonnay

Mâcon followed by a commune name (R, P) Gamay (W) Chardonnay

Pouilly-Fuissé*, Pouilly-Vinzelles, Pouilly-Loché, St-Véran, Viré-Clessé (W) Chardonnay

Champagne

Champagne (S) Arbane, Chardonnay, Meunier, Petit Meslier, Pinot Blanc, Pinot Gris, Pinot Noir

Coteaux Champenois (R, P, W) Arbane, Chardonnay, Meunier, Petit Meslier, Pinot Blanc, Pinot Gris, Pinot Noir

Rosé de Riceys (P) Pinot Noir

Villányi Franc (R) Cabernet Franc

ITALY

Most Italian DOCs and DOCGs allow a percentage (anywhere between 5% and 50% is common) of other varieties authorized for DOC wines within the region, either red (OR) or white (OW), sometimes both (OR&W). In some instances aromatic varieties are excluded. Only those varieties specifically named in the regulations, as compulsory or optional, are listed below. The *disciplinare* for each appellation can be found on the Italian Ministry of Agriculture's website (

www.politicheagricole.it/flex/cm/pages/ServeBLOB.php/L/IT/IDPagina/4625), but the information is not updated as often as on the Lavinium website (

www.lavinium.it/doc-e-docg).

Abruzzo

SPAIN

Note: The Spanish regulations, or *pliegos de condiciones*, for each DOP specify which red and white varieties are allowed, usually distinguishing between 'recommended' and 'authorized' (the latter shown here in italics). Many DOPs also produce rosado, sparkling, and other styles of wines. For details of varieties allowed in these wines, see the individual *pliegos*, most of which are on the government website: SEE WEB LINKS www.mapa.gob.es/es/alimentacion/temas/calidad-diferenciada/dop-igp. Single-estate DOPs, known as VINOS DO PAGO (e.g. Dominio de Valdepusa or Pago Guijoso), are not listed below.

Abona (R) Castellana Negra, Listán Negro (Almuñeco), Malvasía Rosada, Negramoll, Tintilla, *Bastardo Negro* (*Baboso Negro*), *Cabernet Sauvignon*, *Listán Prieto*, *Merlot*, *Moscatel Negro*, *Pinot Noir*, *Ruby Cabernet*, *Syrah*, *Tempranillo*, *Vijariego Negro* (W) Albillo Criollo, Bermejuela (Marmajuelo), Doradilla, Forastera Blanca, Gual, Malvasía Aromática, Malvasía Volcánica, Moscatel de Alejandría, Sabro, Verdello, Vijariego Blanco (Diego), *Bastardo Blanco* (*Baboso Blanco*), *Listán Blanco de Canarias*, *Pedro Ximénez*, *Torrontés*

Alella (R) Garnacha Tinta, Syrah, *Cabernet Sauvignon*, *Garnacha Peluda*, *Mazuela*, *Merlot*, *Monastrell*, *Sumoll Tinto*, *Tempranillo* (W) Xarello, *Chardonnay*, *Chenin Blanc*, *Garnacha Blanca*, *Macabeo*, *Malvasía Aromatica*, *Moscatel de Grano Menudo*, *Parellada*, *Picapoll Blanco*, *Sauvignon Blanc*

APPENDIX 2B

WINE PRODUCTION BY COUNTRY

These 2010 and 2020 OIV figures include vineyards dedicated to TABLE GRAPES and RAISINS. OIV figures are given in hectolitres so the equivalent figures in gallons have been rounded.

	2010 (000 hl)	2010 (000 gal)	2020 (000 hl)	2020 (000 gal)
Italy	48,525	1,281,885	49,066	1,296,186
France	44,381	1,172,413	46,673	1,232,970
Spain	35,353	933,920	40,949	1,081,758

APPENDIX 2C

PER CAPITA CONSUMPTION BY COUNTRY

These 2010 and 2020 figures are based on official OIV statistics, which use the UN's World Population Prospects database of those aged 15+. OIV figures are given in litres, so the equivalent figures in gallons are rounded.

	2010 (litres)	2010 (gal)	2020 (litres)	2020 (gal)
Portugal	52.4	13.9	49.1	13.0
Luxembourg	64.8	17.1	48.1	12.7
Italy	46.1	12.2	46.7	12.3
France	57.1	15.1	43.6	11.5
Slovenia	43.4	11.5	43.0	11.4
Georgia	27.7	7.3	36.6	9.7
