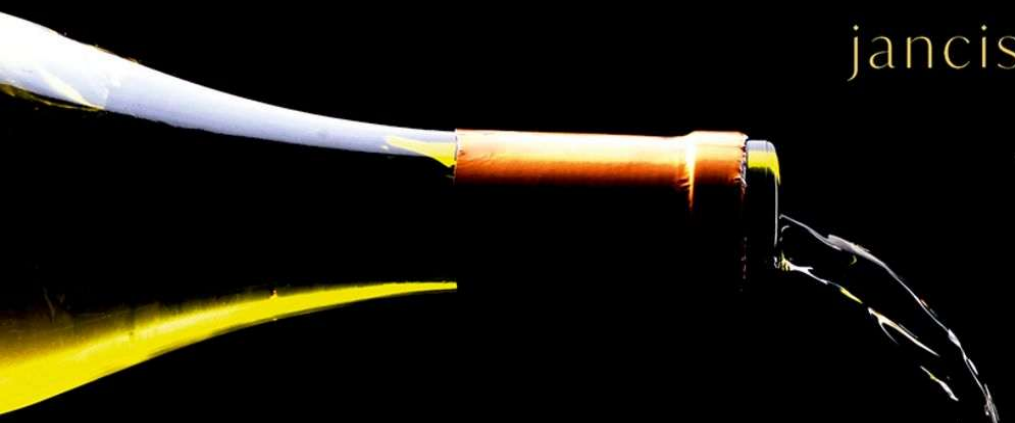
jancis ROBINSON

with TARA Q. THOMAS



THE OXFORD COMPANION *to* WINE

FIFTH EDITION

How to search for terms in *The Oxford Companion to Wine*

To find an entry in this e-book you can:

- Browse the Alphabetical List of Entries and select the entry you would like to view

or

- Use your Search function to be taken to a complete list of references to your search term in the *Dictionary*
  - If your search term has its own entry, it will usually be listed at the top of your results
  - In cases where your search term appears in more than one entry heading, the results will be listed alphabetically

A note on special characters

While most e-readers can display special characters (such as é and â), many cannot search for words containing them, unless the special characters themselves are typed into the search box. If you are unable to type these characters, please browse for your term using the Alphabetical List of Entries.

PREFACE

Editor's preface

A companion is a wonderful thing, and this one is no exception. Its unique combination of depth, breadth, and links between subjects makes it a perfect companion for anyone travelling through the world of wine, for those who are fascinated by it and those who just love it, for pleasure seekers as much as for students.

If you already own a copy, why should you buy this 5th edition of *The Oxford Companion to Wine*? Because the world, and the world of wine, has changed a great deal in the eight years since the 4th edition was published, and every single entry has been reviewed and updated to reflect those changes. The greatest challenge is knowing that even before the ink is dry we will have started a file on possible updates for the 6th edition.

Such changes take us in many directions that are frequently interconnected in the wines we drink. In revised and new entries we have tried to explain advances in scientific and technological understanding that influence the way wine is made and consumed. At the same time, we have recorded the increasingly common and necessary efforts winegrowers around the world are making to care for and regenerate the land in which wine is rooted.

This diversity has taken us to the past and the future, requiring new entries on subjects such as artificial intelligence, biogenic amines, biologicals, blockchain, paper bottles, regenerative viticulture, underwater ageing, and many more.

The greatest change we face in wine as in all else is climate change, so it is not surprising that its repercussions are threaded throughout the book and discussed not just in climate-related entries but also in those that describe the regions most affected, either by extremes such as wildfires, drought, and flooding or because of changes in vineyard location or grape varieties planted. Our regional contributors attest to the creeping spread of vineyards to northerly and southerly regions once thought too cool or otherwise unsuitable

for viticulture, as well as the ascent to elevations where only mad optimists had previously planted vines (see, for example, the new or expanded entries on Estonia, Finland, Gabon, Latvia, Mexico, Norway, Senegal, Uganda, and Vermont). While the vine has a remarkable ability to adapt, some vineyards have (or may) become too hot, too dry, or too prone to disease to keep producing the style of wine we expect from them, hence our coverage of the growing interest in new wine-grape varieties and the changes in regulations that allow them to be planted.

In addition to bringing the book up to date in every nook and cranny of the wine world, we have taken a scalpel to many of the entries, especially the long geographical ones that covered an entire country, to break them down into more manageable and accessible sections that reflect the names found on wine labels. Along with our scrutiny of all the cross-references that take the reader from entry to entry (for more detail or an explanation of a term), this has made the book easier to navigate and, we hope, even harder to put down, as one entry leads to another across regions and topics.

While this edition is only marginally longer overall—the extra 25,000 words taking it to just over one million for the first time—it includes 310 new entries, bringing the total number to 4,489 (including the 335 brief ones that are signposts to other entries). The number of contributors has also expanded, with 109 technical and regional specialists writing for the first time in this edition, bringing the tally of contributors to 267. This has brought an immeasurable increase in depth and accuracy, and we are grateful to every one of them.

During more than two years of long days and many sleepless nights, what motivated me was not just the impending deadline but also the reminder every time I sipped a delicious wine that this is what the book is all about: an invaluable companion to the liquid in your glass.

When in 1999 I queued up at a bookshop in Bristol to have my copy of the second edition signed by Jancis, my constant inspiration,

I had no inkling that just over 20 years later she would pass to me the baton of lead editor for this edition.

I could not have run with it without Jancis's trust in me, built over many years of working and writing together, and her willingness not only to be responsible for reviewing and updating some of the topics but also to guide and advise me when my confidence waned.

Equally, I could not have taken on this weighty responsibility had I not been able to work so closely—albeit physically separated by the Atlantic Ocean—with Tara Q. Thomas, a brilliant assistant editor and great friend who brought not only her editorial skills, global wine knowledge, and diplomacy to this complex task but also her invaluable North American perspective. We may have had to negotiate on many occasions between British and US English to make sure the language of the book is as universally comprehensible as possible, but in every other respect we have seen eye to eye. This has helped to make the book less European and even more truly international—much like wine itself.

The team at OUP, especially Jamie Mortimer, Jo Payne, and Jo Spillane have kept us on the straight and narrow, and we are grateful for their guidance and support.

A few months before I started to climb this wine mountain, I met Deidre Correa, the woman who was to become my wife in September 2022, just a few weeks after I handed in these one million words. Her love, patience, and support have nourished me, both physically and emotionally.

Founding editor's preface

I have known Julia Harding ever since she turned up on my doorstep in 1998 and said she wanted to work for me. She was then a particularly punctilious copy-editor who had caught the wine bug. I was very impressed by her but sent her away, explaining that I was a control freak who was highly unlikely ever to employ anyone.

In 2001 she joined the wine department of Britain's smartest supermarket group, where she was responsible for what they published about wine. It was during this time that she embarked on the fiendishly difficult Master of Wine programme, culminating in exams with a notoriously low pass rate. In the shortest time possible she passed both theoretical and practical (blind tasting) parts of the exam on her first attempt in 2003 and was chosen as the top student of her year after submitting, and receiving a distinction for, her dissertation in 2004.

At that point I realized I should accept her offer of assisting me like a shot, and so, since 19 December 2005, we have worked side by side, with my admiration for her skills deepening by the day. That 'side by side' is meant in a decidedly 21st-century sense. Although we both live in London, we each work at home and find ourselves in the same room only four or five times a year, most notably at the JancisRobinson.com Christmas dinner. Our communication is mainly by email: many, many emails practically every day.

This communication ground to a near halt for much of 2021 and 2022, however, when I persuaded Julia to take over lead editorship of *The Oxford Companion to Wine* from me. I had been, solo, responsible for the first two editions. And in 2001 Julia had demonstrated her mastery of an *Oxford Companion* manuscript by miraculously condensing the second edition into a *Concise* version. So I knew that when, after completing the fourth edition, I felt my memory was no longer up to marshalling over 4,000 entries totalling almost a million words, Julia was the ideal person to take over as

lead editor. She had already proved the most brilliant editor of the viticultural and oenological entries in the third and fourth editions in which she undertook much of the overall editing responsibility anyway.

I was thrilled therefore when she agreed to take on the mammoth task of being in charge of the fifth edition, and I was equally delighted by her choice of assistant editor. Julia and Tara Q. Thomas had already travelled together and bonded over their shared love of Greek wine and high editorial standards. Tara worked for 25 years applying these high standards to the American publication *Wine & Spirits* and agreed to take time off to assist Julia in the two years it takes to put one of these massive reference books together. Tara was responsible for updating all the regional entries (about 40% of the book), while Julia took charge of 50% of the text, including viticulture, oenology, grape varieties, history, packaging, and labelling. I updated the remaining 10% of entries—a very much lighter task that included topics such as people, tasting, and wine and the consumer.

I am hugely grateful to both Julia and Tara for understanding the importance of this book, for maintaining an edifice of great complexity, and, in many instances, giving it a much-needed spring clean. I am confident that this fifth edition is the best yet and am so proud to see the special place it occupies on the shelves of countless wine lovers and wine students the world over. They will not be disappointed this time around.

CONTRIBUTORS

Advisory Viticulture Editor:

Dr Richard E. Smart

Advisory Oenology Editor:

Dr Valeŕie Lavigne

Previous Oenology Editors:

Professor A. Dinsmoor Webb , Dr Patrick J. Williams, and Professor Denis Dubourdieu

Contributors are listed in alphabetical order by their initials. MW stands for master of wine, MS for master sommelier, DipWSET for the wset Diploma, CM for Order of Canada, CBE for Commander of the British Empire, OBE for Order of the British Empire, AM for Member of the Order of Australia, and OAM for Medal of the Order of Australia. Unsigned entries are written by the editors Julia Harding, Jancis Robinson, or Tara Q. Thomas. Where several contributors are named at the end of an entry, the initials of the most recent contributor are given last. Initials of contributors to earlier editions are retained unless the entry has been completely rewritten.

A.A. Alberto Antonini studied in Florence, Bordeaux, and at UC davis. A roving consultant winemaker, he has made wine in California, Argentina, Chile, Spain, Portugal, South Africa, Canada, Romania, Armenia, Israel, Uruguay, Australia, and his native Italy.

A.B. Anthony Borneman is a Research Manager at the awri and an Affiliate of the University of Adelaide. He leads research that is focused on applying genomics to understand the genetic basis of

biological diversity in winemaking, including grapevines, commercial wine yeast and bacteria, and wild ferments.

A.C. Andrew Corrigan MW is based in Brisbane, Australia, and is manager/part owner of Hidden Creek Winery. President of the Queensland Wine Industry Association, wine consultant, educator, writer, judge, and the author of *Table Talk,* a book about the social aspects of wine, he is also a chartered civil engineer.

A.C.S. Dr Amanda Stewart worked in the wine industry in Oregon and New Zealand before taking up her current post as Associate Professor of Enology and Fermentation at virginia tech, where her research and teaching programmes are focused on wine and cider fermentation.

A.D. Abi Duhr studied oenology at geisenheim university and the University of bordeaux. He lives and works in Luxembourg, where he is owner of Ch Pauqué and runs a wine import company.

A.D.W. The late A. Dinsmoor Webb, Oenology Editor of the first edition of this book, retired in 1982 as Professor Emeritus from UC davis and then continued to write and to act as consultant oenologist worldwide.

A.F. Alice Feiring has written six books on wine and culture and has been a leading authority on natural wine for several decades.

A.H. Alex Hunt MW is a London-based wine merchant with a particular interest in the philosophy and language of tasting, on which he has been extensively published.

A.H.L.R. Anthony Rose, wine correspondent for the British newspapers *The Independent* and *i* (1986–2016), author of *Sake and the Wines of Japan* and *Fizz! Champagne and Sparkling Wines of the World*, and a regular contributor on wine auctions and investment for a wide range of publications. He is a founder member of thewinegang.com.

A.H.P. Alexander Purcell is Emeritus Professor of Entomology at the University of California at Berkeley. His research focused on Pierce's disease and other bacterial diseases of plants spread by insect vectors.

A.J.B. Amanda Barnes is author of the *South America Wine Guide.* She has been based in Argentina since 2009, although she travels frequently on assignments for *Decanter*, *Around the World in 80 Harvests*, and other wine and travel publications.

A.J.D. Anne Duggan is Emeritus Professor of Medieval History at King's College, University of London.

A.J.M. Alex Maltman is Emeritus Professor of Earth Sciences at Aberystwyth University. For nearly 40 years, in addition to teaching and research, he has grown vines and made wine as a hobby and travelled the world's vineyards. He has contributed articles on vineyard geology to both popular magazines and scientific journals and is the author of *Vineyards, Rocks, and Soils: The Wine Lover's Guide to Geology*.

A.L. Anthony Lynch is a California-based importer of French and Italian wines at Kermit Lynch Wine Merchant, the company founded by his father, Kermit Lynch. Raised partially in Provence, he takes a special interest in the wines of the Mediterranean.

A.L.W. Andrew Waterhouse is Professor of Enology and Director of the Robert Mondavi Institute at UC DAVIS, where he previously served as Chair of the Department of Viticulture and Enology. He is a widely published wine chemist, studying phenolics, oxidation, and other topics, and is co-author of *Understanding Wine Chemistry*.

A.M. Angela Muir MW joined John Harvey & Sons in Bristol in 1970 and has since been a consultant for importers and retailers in Britain and France and for producers across Europe and South America. A former trustee of the WSET, she has retired to Cyprus.

A.M.R. Arnica Rowan was a professor specializing in sustainable business and is now a private researcher and strategist in the Canadian wine industry.

A.O. Dr Anita Oberholster is a Professor in Cooperative Extension in Enology at the Department of Viticulture and Enology at UC davis. She obtained her first degree in chemistry from stellenbosch university and her PhD in Wine Sciences at the University of adelaide in 2008.

A.P. Dr Andrei Prida, a chemistry graduate of the University of St Petersburg, gained his doctorate from inra Montpellier before post-doctorate studies at UC davis and Miami University. He joined Tonnellerie Seguin Moreau as Head of Research and Development in 2006 and co-ordinates their research in collaboration with the isvv in Bordeaux and other leading institutions.

A.R. Andreś Rosberg is the past president of the Argentine, Pan-American, and International Sommelier Associations. He is a leading wine writer, educator, and judge in his native Argentina.

A.R.P. Andrea Pritzker MW is the founder of Wine inTuition, a wine education and corporate-events business in Sydney, Australia. A certified wset educator, she also works as an independent wine consultant, wine judge, writer, and public speaker.

A.S. Annette Scarfe MW became a Master of Wine in 2012. A wine consultant, she runs tastings and classes for trade and consumers both at home in Singapore and internationally. She also judges at wine competitions across four continents.

A.S.M. Adam Sebag Montefiore worked in the English wine trade before moving to Israel. He has since worked in the Israeli wine industry for 35 years. He is the wine writer for the *Jerusalem Post* and co-author of *The Wine Route of Israel* and *Wines of Israel*.

A.Y. Alder Yarrow is a California-based wine writer, critic, and author of Vinography.com. He is a regular columnist and contributor to

JancisRobinson.com, as well as various other wine publications, and the author of the 2014 book *The Essence of Wine.*

B.B. Dr Benjamin Bois is Associate Professor at the Institute of Vine and Wine (IUVV) in Dijon. His research at the biogeosciences lab focuses on climate/viticulture relationships. He was president of the Viticulture Commission of the OIV from 2015 to 2018.

B.C. Professor Barry Cunliffe CBE is Emeritus Professor of European Archaeology at the Institute of Archaeology, University of Oxford.

B.C.S. Professor Barry C. Smith is the Director of the Institute of Philosophy at the School of Advanced Study, University of London, and director of The Centre for the Study of the Senses. He has published articles on the multisensory perception of flavour in *Nature*, *Food Quality and Preference*, *Flavour*, and *The World of Fine Wine*. He is editor of *Questions of Taste: The Philosophy of Wine* (2007) and has held visiting positions at the University of California at Berkeley and the École Normale Supérieure in Paris.

B.D. Barry Dick MW studied Food Science at Queens University, Belfast, and Oenology at the University of Adelaide. He has made wine in Spain, California, Australia, and the Languedoc and at Château Mouton Rothschild and now acts as the Bulk Sourcing Manager for UK retailer Waitrose.

B.G.C. The late Dr Bryan Coombe was an author, lecturer, and researcher who specialized in grapevine physiology at Waite Agricultural Research Institute, Adelaide. The American Society of Enology and Viticulture awarded him Best Viticulture Paper of the Year 1987 and Best Enology Paper of the Year in 1991.

B.M.W. The late Dr Bernard Watney was initially a physician, but his many interests included wine, wine labels, and corkscrews. He co-wrote *Corkscrews for Collectors*, which has since been translated into French and German.

B.Y.-I. Becca Yeamans-Irwin uses her background in wine science and the environment to dissect, review, and provide commentary on current research in fields in or related to oenology and viticulture at AcademicWino.com. She lives in North Carolina.

C.A. Chloe Ashton is COO of Wine Lister and the auctions and secondary-market correspondent for *The World of Fine Wine* magazine.

C.A.S. Con Simos is a winemaker and Group Manager—Industry Development and Support at the AWRI. He leads a group of winemakers, viticulturists, and technical specialists who disseminate research results and provide support to the Australian grape and wine sector.

C.B.S. Carlos Borboa Suaréz is a Mexico-based journalist, sommelier, and director of the wine and spirits competition México Selection by Concours Mondial de Bruxelles.

C.C. Dr Christoph Carlen, Master in Agronomy in Plant Production Sciences and PhD in Plant Physiology at the ETH Zurich, is Head of the AGROSCOPE Plant Production Systems division and member of the Agroscope board.

C.C.F. Christopher Fielden is a retired British wine merchant and collector of wine books.

C.G. Dr Caroline Gilby MW has a special interest in the wines of Central and Eastern Europe. Her first book, *The Wines of Bulgaria, Romania and Moldova*, won the OIV prize in 2020. She contributes to several major wine reference books, magazines, and websites.

C.H.-C. Curly Haslam-Coates is a Tasmania-based wine educator, writer, and sparkling-wine specialist. As an industry ambassador she encourages others to enter meaningful careers in wine, tourism, and hospitality, with a particularly strong focus on inclusive industry representation and access to education and wine networks.

C.O. Claudio Olla DipWSET is a banker by profession but has been deeply immersed in the wine world for two decades, particularly on his native Sardinia. A wine consultant, WSET-accredited educator, and judge, he also contributed to the *World Atlas of Wine* (8th edn, 2019).

C.P. Catherine Petrie MW is a buyer for UK fine-wine merchant Lay & Wheeler. She specializes in Burgundy and the Loire, both regions where she has extensive vineyard and winemaking experience, including two vintages in Sancerre.

C.R.H. Charles R. Hajdamach is one of the UK's top authorities on glass. He lectures internationally and writes extensively on the subject. His books *British Glass 1800–1914* and *20th Century British Glass* remain the standard works on those subjects. In 2000 he was elected a Fellow of the Society of Glass Technology.

C.S.S. Dr Creina Stockley is a clinical pharmacologist actively involved in research into the health effects of wine and wine-derived phenolic compounds, as well as in the preparation of alcohol policy and regulation. Currently Principal of Stockley Health and Regulatory Solutions, she was Health and Regulatory Information Manager at the AWRI from 1991 to 2018. She was also elected President of the OIV Commission IV Safety and Health in 2012, receiving the OIV Merit award in 2019.

C.v.L. Cornelis (Kees) van Leeuwen is Professor of Viticulture at Bordeaux Sciences Agro and the ISVV in Bordeaux. He was the viticulturist at Château Cheval Blanc in St-Émilion for 25 years and has written extensively on various aspects of terroir, soil, and wine quality. He is editor in chief of *OENO One*, the open-access journal of vine and wine sciences.

D.A.D. Dr Donald Dibbern is a retired physician specializing in the diagnosis and treatment of allergic diseases and a Fellow of the American Academy of Allergy Asthma and Immunology.

D.A.H. David A. Harvey is a UK wine importer and sometimes writes about wine, including a history of ethical wine farming. He started as a sommelier before working for Frank Cornelissen on Mt Etna in 2004.

D.B. David Bird MW is a Chartered Chemist and a Member of the Institute of Quality Assurance. He has audited wineries throughout Europe and lectures on winemaking techniques. His publications include *Understanding Wine Technology*, now in its fourth edition.

D.Ca. Dario Cantù, plant biologist and Professor of Systems Biology at UC davis since 2012, specializing in grape genomics and grape–microbe interactions.

D.C.G. David Gleave MW is Chairman of Liberty Wines, a London-based wine importer and distributor. He has been extensively involved with Italian wines since 1983, spending three months of every year in Italy.

D.Co. Danilo Costamagna is from Piemonte, Italy, where his grandfather had a small vineyard, but he has lived since 2002 in Norway, where he runs Norsk Vin winery. He has been the head of the Norwegian Grape Growers Association (Foreningen Norske Druedyrkere) since 2020.

D.D. The late Dr Denis Dubourdieu, Advisory Oenology Co-editor of the fourth edition of this book, was a well-travelled winemaker, owner of six Bordeaux wine estates, and renowned Professor of Oenology and research scientist at the University of bordeaux who had a particularly significant influence on white winemaking throughout France and abroad.

D.De. Dr Daniel Deckers holds a PhD in Catholic theology, is a senior political editor of the *Frankfurter Allgemeine Zeitung,* teaches as associate scientist at geisenheim university, and is devoted to the cultural history of German wine.

D.F. Doug Frost MW MS is a Kansas City author who is one of only three people in the world to be both a Master Sommelier and a Master of Wine. He specializes in wines from America's less famous wine-producing states and owns Echolands Winery, based in Walla Walla, Washington.

D.G. Denis Gastin is a widely published Australian-based wine writer, wine judge, and wine educator who has been has been closely monitoring the evolution of the wine industry in Asia for over 30 years.

D.J. Dr Dan Johnson is Pro Vice-Chancellor, Research, Innovation, and Enterprise, at Macquarie University.

D.L.C. Dr Dimitra Capone, an ARC Research Associate with the University of adelaide, has studied many aspects of wine flavour chemistry, including 20 years of experience at the awri. She was awarded the 2013 Early Career (Life and Environmental Sciences) SA Science Excellence Award.

D.M. Dave McIntyre is a freelance wine journalist and weekly wine columnist for *The Washington Post.* He was co-founder of a movement called 'Drink Local Wine'.

D.P. Daniel Pambianchi is a winemaking lecturer and consultant and the author of *Modern Home Winemaking* and *Techniques in Home Winemaking*. He is an amateur and professional winemaker, having owned and operated a small commercial winery in Niagara Wine Country in Ontario.

D.P.G. Dr Dylan Grigg runs his own viticulture consultancy in premium wine regions across Australia and overseas. His PhD thesis investigating grapevine age leads him into many old vineyards, including his own.

D.S. David Schildknecht trained in philosophy but has since 1978 worked as restaurateur, retailer, importer, and writer. His coverage of diverse regions has appeared in Stephen Tanzer's *International Wine*

Cellar, *Robert Parker Wine Advocate*, and, since 2015, *Vinous*. He is a columnist with *The World of Fine Wine* and Austria's *Vinaria.*

D.V.J. Dirceu Vianna Junior MW is a Brazil-born, London-based wine expert with three decades of experience in the wine industry. He is the founder of Vianna Wine Resources, a wine consulting company, as well as a wine judge, educator, writer, and frequent speaker at global wine events.

E.A.G. Elizabeth Gabay MW has been in the wine trade since 1986. Based in south-eastern France since 2002, she specializes in the wines of southern France and Central Europe and in rosé, on which she published a book in 2018.

E.C. Ed Carr is Group Sparkling Winemaker at Accolade Wines (formerly BRL Hardy), having previously held the same position at Penfolds. In 2018 he received the lifetime achievement award at the Champagne and Sparkling Wine World Championships.

E.C.B. Elaine Chukan Brown is a writer, speaker, and global wine educator specializing in sustainability, diversity, and American wine.

E.J.B. Dr Eveline Bartowsky is R & D Manager and Applied Microbiologist at Lallemand Australia in Adelaide. She is a specialist in malolactic conversion and wine bacteria and fermentation research.

E.L. Ella Lister, investment banker turned wine journalist (*World of Fine Wine*, *Financial Times*, *Decanter*) and entrepreneur, divides her time between London and Paris as she runs the wine department at French newspaper *Le Figaro* while continuing to head up UK-based consulting agency Wine Lister.

E.L.-L. Erica Landin-Löfving is a Swedish-American wine writer and the Chief Sustainability Officer at Vintage Wine Estates in Sonoma, California. She has an MSc in medical biology and has studied ESG (Environmental, Social, and Governance) at Berkeley Law.

E.L.L. Erin Larkin made Western Australia her area of expertise when she worked at the *Halliday Wine Companion.* A writer, judge, and presenter based in Perth, she is now the Australian Reviewer for *Robert Parker Wine Advocate*.

E.M. Dr Edi Maletić is a Professor at the University of Zagreb, where he is head of the Department of Viticulture and Enology. A specialist in grapevine genetics, he was one of the scientists who discovered the Croatian roots of Zinfandel/Tribidrag.

E.M.C.R. Ella Robinson is Communication Manager at the AWRI.

E.M.G. Evan Goldstein MS is a San Francisco–based wine educator and author of the critically acclaimed *Wines of South America: The Essential Guide.*

E.N.H.M. Ed Merrison is a British-born former journalist who has spent the best part of the past 20 years in Australia. A wine judge and Australian Dux of the WSET Diploma based in Victoria's Mornington Peninsula, he makes his living as a wine communicator and educator.

E.P. Eran Pick MW is Israel's first Master of Wine. A graduate of UC DAVIS, he is general manager and winemaker at Tzora Vineyards.

E.P.-R. The late Edmund Penning-Rowsell was one of the world's most respected wine writers and author of *The Wines of Bordeaux* (see his entry).

E.R. Dr Edward Ragg MW is co-founder of Dragon Phoenix Wine Consulting, a former Tsinghua University professor, and reviewer of Chinese wines for the *Robert Parker Wine Advocate.* He is co-coordinator of the Institute of Masters of Wine's Australasian programme and a wine educator, wine writer, and published poet.

E.W. Dr Eric Wilkes is the General Manager of Affinity Labs, the commercial arm of the AWRI, and has over 25 years of experience in technical research and management within the beverage industries.

He specializes in wine chemistry and technical innovation, with a significant interest in environmental concerns.

F.C. Ferran Centelles works for the elBullifoundation and is the Spanish wine critic for JancisRobinson.com. Voted Best Sommelier in Spain in 2006, he has published three giant wine books.

F.W. Fongyee Walker MW is co-founder of Dragon Phoenix Wine Consulting (Beijing) and the first Master of Wine resident in mainland China. She specializes in Mandarin-language wine education and communication, is a frequent contributor to livestreams, podcasts, and media articles, and creates popular television programmes about wine.

G.C. Geoff Cowey is a Senior Oenologist at the AWRI. A wine scientist, winemaker, wine educator, and wine writer, he manages the AWRI helpdesk, a service which provides advice on technical queries, problems, or knowledge gaps encountered by Australian grape-growers and winemakers.

G.C.P. Dr Gary Pavlis is a professor and agricultural agent at Rutgers University in New Jersey. He has served on the board of directors of the American Wine Society and regularly appears in print, on the radio, and on television educating the public on the intricacies of East Coast winegrowing.

G.K. Dr Gisela Kreglinger is an expert on the theology of wine and teaches at the University of Alabama at Birmingham. She leads wine pilgrimages, holds seminars on wine tasting as a spiritual practice, and is the author of *The Spirituality of Wine* and *The Soul of Wine.* She grew up at a winery in Germany.

G.L.C. Dr Glen Creasy, co-author of the CABI book *Grapes*, is a former lecturer and researcher who is now a viticultural consultant for Sabrosia SAS and part owner of Terre des 2 Sources winery in the Languedoc, France.

G.M. Dr Gabriella Mészáros trained as a lawyer and now teaches and writes regularly about wine in Hungary. With her late husband, Dr Gábor Rohály, she published the *Hungarian Wineguide* for 16 years as well as several books on wine and gastronomy. They also founded the first WSET-accredited wine school in Budapest.

G.P. Professor Gary Pickering received his doctorate in Wine Science from LINCOLN UNIVERSITY and is currently Professor of Biological Sciences and Psychology at BROCK UNIVERSITY, as well as Adjunct Professor at CHARLES STURT UNIVERSITY. His research includes wine flavour, taste genetics, and climate-change adaptation.

G.R. The late Dr Gábor Rohály was a physician, a founding member of the Hungarian Wine Academy, and a wine writer who is widely credited with developing Hungary's wine vocabulary.

G.S. Gavin Sacks is Professor of Food Science at CORNELL UNIVERSITY. His research programme is focused on developing and applying analytical tools for characterizing flavour compounds in wines and grapes, and he is co-author of *Understanding Wine Chemistry*.

G.T. Geoff Taylor worked in the technical/analytical area of the UK wine trade for 25 years until his retirement in 2000. He founded the leading UK wine analysis and consultancy laboratories, now part of Campden BRI, the world's largest independent technical/laboratory-based organization for the food and drink industry.

G.V.I. Gido Van Imschoot MS is President of the Flemish Sommelier Association and was European Ambassador of Champagne in 2012. Founder and director of Wine Academy Panta Rhei in Roeselare, he also lectures and has written six books on wine.

G.V.J. Dr Greg Jones runs Abacela Vineyards and Winery in the Umpqua Valley, Oregon. After 25 years as a professor and leading research climatologist specializing in natural ecosystems and agriculture, he now conducts applied research for the grape and wine industry in Oregon. He has written widely on wine economics,

grapevine phenology, climatological assessments of viticulture, and climate change.

H.A.C. Hugh Andrew Caillard MW, former wine auctioneer, now a multimedia wine expert and historian. His books include *Penfolds: The Rewards of Patience*, *Marqués de Riscal: A Travel Through Time*, and *The Australian Ark* (2023), a three-volume work on the history of Australian wine.

H.B. Dr Helen Bettinson, former Fellow of Fitzwilliam College, Cambridge, with a particular interest in historical research.

H.G. The late Howard G. Goldberg wrote for *The New York Times* and was an editor at the paper from 1970 to 2004.

H.G.B. The late Bill Baker was a wine merchant and wine judge whose distinctive Reid Wines list was famously decorated with unusual vinous quotations and his wit.

H.H. Huon Hooke is one of Australia's most respected wine writers. Based in Sydney, he makes his living entirely from writing, judging, and educating about wine. A journalist first and wine professional second, he has tertiary qualifications in both fields and has been writing on wine since 1983.

H.H.A. Hamish Aird, classicist and former Sub-Warden of Radley College, Oxfordshire, in England.

H.He. Dr Hildegarde Heymann is an author and Distinguished Professor of Sensory Science in the Department of Viticulture and Enology at UC davis. She has worked in all areas of sensory science and has evaluated numerous food and non-food products. Her main areas of expertise are descriptive analysis methodology and multivariate data analyses.

H.J. Hugh Johnson OBE is the world's most successful wine author and was introduced to specialist wine writing by the late André Simon (see entries on both).

H.L. Harriet Lembeck, certified wine and spirits educator based in New York, is a writer and a founder of the Society of Wine Educators.

H.M.W. Dr Hanneke Wilson is the author of *Wine and Words in Classical Antiquity and the Middle Ages*. She is the wine steward of two Oxford colleges, Exeter and Lincoln, and does a little work for wine merchant Haynes Hanson & Clark. She is also the coach of the Oxford University Blind-Tasting Society.

H.-P.H. Hans-Peter Hoehnen qualified at geisenheim university and worked in Australia, New Zealand, and his native Germany until 1997, when he moved to Thailand for three years. He is now a consultant in tropical viticulture and winemaking throughout South East Asia.

H.S. Professor Hans Schultz is President of geisenheim university. He was formerly the Director of the Geisenheim Research Institute and Professor of Viticulture. He has also worked and studied at charles sturt university, at ENSA/inra Montpellier, and at UC davis. Professor Schultz grew up on a wine estate in the Mosel Valley.

I.G.d.C.-A. Dr Iñaki Garcia de Cortazar-Atauri is a Research Engineer at inrae Agroclim. He graduated as an agronomist from the Universidad Publica de Navarra and completed his PhD at INRA. His current research focuses on the interaction between phenology and climate change. He co-ordinates TEMPO, the French National Network of Phenology Observatories, and is a member of the STICS Project team.

I.S. Ilkka Sirén is a wine writer, educator, and occasional wine judge based in Helsinki, Finland. He is a regular contributor to many Finnish wine, food, and lifestyle magazines such as *Viinilehti*, *Maku*, and *Anna.* Internationally, he has written for *Saveur*, *VICE*, and *Wine Enthusiast*, among others.

I.S.-B. Dr Irina Santiago-Brown is a global leader in sustainability in viticulture. Her PhD in grape-growing sustainability was the first in the world, and she developed the Sustainable Australia Winegrowing

(SAW) programme. She and her husband Dudley Brown own Inkwell Wines in McLaren Vale, South Australia.

J.A. Dr Jean Aitchison is Emeritus Rupert Murdoch Professor of Language and Communication at the University of Oxford. She gave the Reith Lectures in 1996.

J.A.B. The late Dr Jeremy Black was Director of the British School of Archaeology in Iraq and later a Fellow of Wolfson College, Oxford, and university lecturer in Akkadian. He wrote several studies on Sumerian and Babylonian literature and ancient philology.

J.A.G. Dr Jamie Goode has a PhD in plant biology and for many years worked as a scientific editor. He publishes wineanorak.com and is wine writer for Britain's *Sunday Express*. His books include *Wine Science*, *I Taste Red*, and *Flawless*.

J.A.R. Jamal Awri Rayyis is a NYC-based writer, editor, and educator focused on the intersection of gastronomy, culture, and politics. A pioneer in covering Middle Eastern wine, he is at work on a book on the politics of wine in the Middle East.

J.-B.A. Jean-Baptiste Ancelot, the founder of Wine Explorers, has visited more than 85 countries, documenting their wine industries in his blog as well as in his book *Wine Explorers, le 1er tour du monde du vin* (2019).

J.B.-E. Jenne Baldwin-Eaton, a winemaker in Colorado for 27 years, developed the first Associates of Applied Science Viticulture and Enology programme at Western Colorado Community College, a division of Colorado Mesa University.

J.D. Dr Janet Dorozynski DipWSET has been working in and with the Canadian wine industry for over 20 years. An educator, writer, and wine judge, she writes for publications worldwide and has contributed Canadian content to WSET's Global certification courses.

J.E.H. Julia Harding MW, editor of *The Oxford Companion to Wine*, studied modern languages at Cambridge before becoming a

freelance book editor. She qualified as a Master of Wine in 2004, winning the Robert Mondavi award for best theory papers and the Tim Derouet Memorial Prize for excellence in all parts of the exam and dissertation. She is Senior Editor at JancisRobinson.com, where she has been a member of the team since 2005. She is cartographic editor of *The World Atlas of Wine* (8th edn, 2019) and co-author of *Wine Grapes* (2012).

J.F.B. Jon Bonné. the former wine editor of the *San Francisco Chronicle,* is author of *The New California Wine*, *The New French Wine*, and *The New Wine Rules.* He has also won three Roederer Awards for wine writing.

J.G. Dr John Gladstones, am, author of *Viticulture and Environment* (1992) and *Terroir and Climate Change* (2011), is former Senior Lecturer in the University of Western Australia Department of Agriculture.

J.H. James Halliday, oam, Australia's most prolific and most respected wine writer, an ex-lawyer who also found time to establish Coldstream Hills winery in the Yarra Valley.

J.H.B. Jullianne Ballou, Associate Director of Strategic Initiatives at UC davis Institute of the Environment, was previously the Warren Winiarski Fellow at the UC Davis Library, where she managed its Wine Writers Collection as well as food and wine collections.

J.H.H. Dr Judith Harvey became a medical practitioner after a distinguished career as a research scientist.

J.J.P. Jeremy Paterson, until retirement Senior Lecturer in Ancient History at the University of Newcastle-upon-Tyne, is a specialist in Roman economic and social history with a particular interest in the Roman wine trade, on which he has published.

J.K. Jeremy Kerswell studied Animal Science at Reading University and worked at several land-based colleges before being appointed

Principal of Plumpton College, East Sussex, England, in 2015. He is also part of the Management Advisory Group for WineGB.

J.L. James Lawther MW is a Bordeaux-based wine writer for JancisRobinson.com whose works include *The Heart of Bordeaux* and *The Finest Wines of Bordeaux* as well as contributions to *On Bordeaux* and *Hugh Johnson's Pocket Wine Book*.

J.M.B. The late Michael Broadbent MW was founder of Christie's Wine Department and an author (see BROADBENT).

J.M.R. Dr Jane Renfrew (Lady Renfrew of Kaimsthorn) is a prehistorian and palaeoethnobotanist and is an Emeritus Fellow of Lucy Cavendish College, University of Cambridge, and a retired Affiliated Lecturer in the Department of Archaeology, University of Cambridge.

J.P. John Platter became a South African wine farmer and wine writer after a career as a foreign correspondent for United Press International. He and his wife Erica founded *Platter's South African Wine Guide,* which became the country's best-selling wine book, a position it has retained since they sold it in 1998. He is also author of *Africa Uncorked* and *My Kind of Wine*.

J.P.H.B. Dr John Barker is widely experienced in the field of wine regulation as a lawyer, consultant, and researcher. He was elected Director General of the OIV in 2023—the first person from the southern hemisphere to take this role. He is a former General Counsel for New Zealand Winegrowers, President of the OIV Law and Economy Commission, and Industry Chair of the WORLD WINE TRADE GROUP.

J.R. Jancis Robinson OBE MW, founding editor of *The Oxford Companion to Wine*, is one of the world's leading authorities on wine. The first person outside the wine trade to have passed the notoriously tough Master of Wine exams, she now writes weekly for the *Financial Times* and daily for JancisRobinson.com, which has members all over the world. Voted the first-ever International Wine

Communicator of the Year in 1996, she has won multiple awards and written many books. Most recently she wrote *The 24-Hour Wine Expert* (2017), co-wrote *The World Atlas of Wine* (8th edn, 2019) and *Wine Grapes* (2012), and hosted the BBC Maestro online wine course *An Understanding of Wine*.

J.R.U.-T. Dr José Ramón Úrbez-Torres is a plant pathologist currently working as a Research Scientist for Agriculture and Agri-Food Canada in the Summerland Research and Development Centre in British Columbia. He is also an Adjunct Professor at the University of British Columbia Okanagan and Research Affiliate in the Cool Climate Oenology and Viticulture Institute at Brock University. His primary research focus is the etiology, biology, epidemiology, and control of fungal diseases of grapevines and fruit trees, with a special emphasis on grapevine trunk diseases.

J.T. James Tidwell MS is a writer and consultant in Texas. He founded TexSom, the biggest wine-trade education conference in the world, and produces one of the largest wine competitions in the United States. He sits on the Classic Wine Library editorial board and collects rare wine books.

J.T.C.M. Jasper Morris MW is author of the comprehensive book *Inside Burgundy* and runs the website of the same name. Previously he was a noted importer of Burgundy wines, firstly through his company Morris & Verdin Ltd and then with Berry Bros & Rudd.

J.V. Dr José Vouillamoz, Swiss grape geneticist, trained at UC Davis, specializing in the study of the origin and parentage of grape varieties through DNA profiling. Co-author with Jancis Robinson and Julia Harding of *Wine Grapes* (2012), he has also authored and co-authored scientific papers and other grape books. He is a member of the Académie Internationale du Vin and the Académie du Vin de Bordeaux.

K.A. Kym Anderson is the George Gollin Professor Emeritus of Economics and foundation Executive Director of the Wine Economics Research Centre at the University of Adelaide and an Honorary

Professor of Economics at the Australian National University's Crawford School of Public Policy. His unrivalled global statistical compendia of winegrape plantings, national wine markets, and related e-books are freely available at

https://economics.adelaide.edu.au/wine-economics.

K.A.W. Kelli A. White is a sommelier, writer, and educator. Her book *Napa Valley, Then & Now* won both an IACP and a Graphis design award, and her articles have earned her two Roederer Awards. She has contributed to many books, including the *World Atlas of Wine* and *On California*.

K.C. Kirsten Creasy has been a winemaker, educator, researcher, and international consultant for over 30 years. She has recently relocated from New Zealand to the Languedoc, where she is part-owner of Terre des 2 Sources winery.

K.H. Kieran Hirlam is the Project Team Manager for Affinity Labs, the commercial arm of the AWRI. He has worked on specific trials including life cycle analysis and waste transformation opportunities for a broad range of wineries, as well as comparing the impact and influence of alternative packaging.

K.K. Klara Kollárová, DipWSET and Weinakademiker, is a Czech sommelier, wine journalist, and judge.

K.L. Konstantinos Lazarakis MW was the first Greek Master of Wine and is the president of WSPC wine school in Athens, the Buying Director of Aiolos, a fine-wine importer and distributor, and the co-owner of Wine Wonders, a creative design company. He is the author of *The Wines of Greece* (2018).

K.L.B. Dr Karen Block joined the Department of Viticulture and Enology at UC DAVIS in 2011, where she is now the Director of Industry Relations. She received a BS in Chemical Engineering from the University of Michigan and a PhD in Molecular Biology and Pharmacology from the University of Pennsylvania.

K.M. Kristjan Markii, sommelier and wine writer, is president of the Estonian Sommelier Association and lecturer at the Estonian Sommelier School.

K.O. Ken Ohashi MW is a leading Japanese wine and sake consultant and an international judge of wines and sake, running his own Red Bridge Consultancy in Tokyo. He is a Master of Sake.

K.R.P. Dr Kevin R. Pogue is a Professor of Geosciences at Whitman College in Walla Walla, Washington State. Dr Pogue's research focuses on variations in growing conditions related to vineyard topography, climate, and soil chemistry. He has authored the petitions for six AVAs in the Pacific Northwest.

L.B. Larry Brooks studied plant pathology at the University of California at UC DAVIS and has been a winemaker or winemaking consultant in California ever since.

L. & E.S. Lush Susaj lectures in ampelography at the University of Tirana, where he is a professor. He has published widely in both Albania and abroad, as has Dr Elisabeta Susaj, who is a lecturer on genetics and plant breeding at the Agricultural University of Tirana.

L.F.B. Dr Linda Bisson, a microbiologist trained in genetics who specialized in yeast biology. She is a Professor Emeritus of Enology and until her retirement worked as a geneticist in the Agricultural Experiment Station at UC DAVIS.

L.H.-S. Dr Leofranc Holford-Strevens is a classical scholar, author of *Aulus Gellius: An Antonine Scholar and His Achievement*, and editor of the Oxford Classical Text of Gellius. Until his retirement in 2011, he worked for Oxford University Press.

L.M. Linda Murphy is co-author, with Jancis Robinson MW, of *American Wine: The Ultimate Companion to the Wines and Wineries of the United States*, contributor to publications such as *Decanter*, *Sonoma* magazine, and Santa Rosa *Press Democrat* newspaper, and former wine editor of the *San Francisco Chronicle*.

L.T.M. Lucie Morton is an independent viticulturist in the US. She writes, lectures, and consults on ampelography, rootstocks, and vineyard development and is a founding member of the International Council on Grapevine Diseases. She translated *A Practical Ampelography* from Pierre Galet's original and wrote *Winegrowing in Eastern America*.

M.A.S. Dr Mark Sefton was formerly a Principal Research Chemist at the AWRI, where he led the Institute's research programme on the chemistry of volatile grape and wine aroma and flavour compounds, and is now an Adjunct Associate Professor of the University of Adelaide.

M.A.W. Dr Andrew Walker held the Louis P. Martini Endowed Chair at UC Davis from 2000 to 2015, when he became the Louise Rossi Endowed Chair in Viticulture. His lab pursues grape breeding and resistance to pests and diseases. He has released five rootstocks with strong nematode resistance and five Pierce's disease-resistant wine-grape cultivars. His teaching includes grapevine identification, vineyard establishment, and pruning.

M.B. Dr Marlize Bekker is a Senior Research Scientist at the AWRI. Her PhD at Stellenbosch University focused on the identification of natural products used in mammalian semiochemical communication. Her main research interests are the formation and fate of undesirable sulfur compounds in wine.

M.C. Professor Dr Monika Christmann is head of the oenology department at Geisenheim University with research and teaching responsibilities. She currently serves as Vice President of the OIV.

M.C.K. Mel Knox is based in California, where he sold wine, taught wine appreciation classes at the University of California, and sold French barrels. He has also been involved in wine production and was awarded the Mérite Agricole by the French government in 2010.

M.C.W. Matt Walls is an award-winning wine writer, author, and broadcaster who contributes to various international publications. He

is a contributing editor for *Decanter* and panel chair for the Rhône at the Decanter World Wine Awards. His latest book is *Wines of the Rhône* (2021).

M.D.K. Matthew Dennis Kettmann covers California's Central Coast and southern reaches for *Wine Enthusiast* and is author of *Vines & Vision: The Winemakers of Santa Barbara County*. He is also senior editor for the *Santa Barbara Independent*, where he started his journalism career in 1999.

M.E. Marcel Essling is a Senior Viticulturist with the AWRI and chairs the Agrochemical Reference Group for the Australian wine industry. He belongs to the Wine Industry Technical Advisory Committee and the Market Access Group. In these roles he advises the Australian wine sector on regulatory and technical aspects of agrochemical use in grape production.

M.F. Michael Fridjhon is South Africa's leading wine writer, Visiting Professor of Wine Business at the University of Cape Town's Graduate School of Business, Wine Wizard, and liquor industry specialist.

M.H. Dr Markus Herderich is a food chemist and Group Manager—Research at the AWRI and leads a research group of more than 30 professional scientists. His research interests include oenology, aroma chemistry, analytical chemistry, and metabolomics. He is also an Affiliate Associate Professor at the University of Adelaide and an expert at the OIV.

M.J.D. Maiah Johnson Dunn is a wine writer based in the Finger Lakes region of New York State.

M.J.E. Margaret Emery was the librarian at Roseworthy Agricultural College from 1975 until 1995 and holds a Graduate Diploma in Wine.

M.J.G. Maria Jose Granier has been in Bolivia's wine and singani industry for over a decade. The former president of the Asociación

Nacional de Industriales Vitivinícolas (ANIV) and a co-founder of Wines of Bolivia, she currently manages a winery in the Cinti Valley.

M.J.T. Matt Thomson is a winemaker and consultant based in Marlborough, New Zealand. He has an MSc in Biochemistry and has worked 30 vintages in Marlborough and 30 consecutive harvests in Europe. He has consulted in Italy, France, Spain, Hungary, Romania, and Chile.

M.K. Max Kantelia is an electronics engineer turned investor and entrepreneur currently specializing in blockchain, NFT, and metaverse ventures for the music industry and luxury brands.

M.L.-G. Miles Lambert-Gocs researches the wine history and traditions of Eastern Europe, from Slovakia south through Greece.

M.P.K. Dr Mark Krstic is a viticulturist and Managing Director at the AWRI. He is also an Adjunct Professor at Macquarie University and Honorary Senior Fellow at the University of Melbourne.

M.P.L. Martin Lam, food and wine consultant, was the owner, chef, and celebrated wine buyer of Ransome's Dock restaurant in London.

M.R.K. Michael Karam is a British-born Lebanese author of several books on Lebanese wine. He also edited *Tears of Bacchus: A History of Wine in the Arab World*; contributed to *The World Atlas of Wine*, *Hugh Johnson's Pocket Wine Book*, and *The Sotheby's Wine Encyclopedia*; and collaborated on the documentary *Wine and War*.

M.S. Matthew Stubbs MW has 34 years of experience in the wine trade. An advocate for the wines of the Languedoc and Roussillon, he established Vinécole wine school near Carcassonne and lived in the region for 12 years.

M.Ta. Michael Tabone is a wine consultant and the former wine correspondent for the *Sunday Times of Malta*. In 2001 he established Malta's first wine school.

M.Tr. Madeline Triffon MS was the sixth American and the second woman in the world to achieve the Master Sommelier credential in 1987. An American wine specialist and sommelier, she has since mentored many service professionals and is a Chairman Emeritus of the American Chapter of the Court of Master Sommeliers.

M.v.H. Dr Maarten van Helden is a Senior Research Entomologist at the South Australian Research and Development Institute (SARDI). He graduated from Wageningen agricultural university in 1995 and worked as an Associate Professor in plant protection and agro-ecology at Bordeaux Sciences Agro from 1997 to 2016, conducting research on landscape ecology, ecosystem services, and pest management in viticulture.

M.W. Monty Waldin is a wine writer based in the UK. He has written several respected books on both organic and biodynamic wine and gardening. His television series *Chateau Monty* (2008) was the first to document biodynamic wine production from pruning to bottling.

M.W.E.S. Michael Schuster is a wine writer who for many years ran his own wine school in London and has translated the work of Professor Émile Peynaud. He is the author of *Essential Winetasting*.

N.B. Nick Bulleid MW is a freelance winemaking consultant in Australia and New Zealand and was for 13 years a visiting professor at charles sturt university. He is also a wine writer, wine judge, and wine producer in New South Wales. In 2020 he was appointed a Fellow of the Australian Society of Oenology.

N.F. The late Nicholas Faith was a financial journalist whose numerous specialities included champagne, cognac, and railways.

N.G. Nayan Gowda is a wine consultant and itinerant winemaker who has made wine from more than 50 different varieties in eight countries, including Kazakhstan, where he has overseen production at the country's only organic winery.

N.G.W. Nigel Wilson FBA is Emeritus Fellow and Tutor in Classics at Lincoln College, Oxford. His main work as a classical scholar is as an expert in Greek palaeography and the history of the classical tradition.

N.J.B. The late Nicolas Belfrage MW was the author of four books and countless articles on Italian wine, the region in which he specialized as merchant, importer and agent, and writer.

N.S. Nigel Sowman was awarded a BSc in Viticulture and Oenology by lincoln university in 2000. He returned to Marlborough, New Zealand, to join the newly formed Dog Point vineyard team and has since led the conversion of 270 ha/667 acres of vineyards to organic certification.

O.P.-T. Olga Pinevich-Todoriuk is the editor-in-chief of *Drinks+*, the leading Ukrainian wine magazine. She also instigated the Wine Travel Awards, launched in 2021.

O.W. Owen White is Professor of History at the University of Delaware in the US. He is the author of *The Blood of the Colony: Wine and the Rise and Fall of French Algeria* (2021).

P.A.H. Professor Paul A. Henschke is Emeritus Fellow, formerly Principal Research Microbiologist, at the awri in Adelaide and is Affiliate Professor at the University of Adelaide. He has more than 40 years' experience in yeast research.

P.A.N. Dr Philip Norrie is a medical practitioner and wine producer in New South Wales, Australia, with a particular interest in wine history. He is the inventor of the world's first full-strength resveratrol-enhanced wine.

P.B. Dr Paul Boss leads the csiro High Value Crops Group, which includes most of its grape and wine research. He has been conducting research on grapes and wine since 1994 on topics that include flower and fruit development, secondary metabolism, and the genetics of consumer traits.

P.C. Patrick Comiskey is a Senior Correspondent and chief domestic critic for *Wine & Spirits*. For more than a decade he also covered the wine scene for the *Los Angeles Times*. His book *American Rhône: How Maverick Winemakers Changed the Way Americans Drink* was published in October 2016.

P.E.M. Patrick E. McGovern is the Scientific Director of the Biomolecular Archaeology Project for Cuisine, Fermented Beverages, and Health at the University of Pennsylvania Museum in Philadelphia, where he is also an Adjunct Professor of Anthropology. He has published three books on ancient wine, including *Ancient Wine*: *The Search for the Origins of Viniculture* and *Uncorking the Past: The Quest for Wine, Beer, and Other Alcoholic Beverages*, together with numerous articles.

P.J.Con. Dr Patrick Conner received his BS in Horticulture from Purdue University and his PhD in Plant Breeding from cornell university. He is a Professor in the Horticulture Department at the University of Georgia, where he studies the genetics and breeding of pecan trees and Muscadine grapes.

P.J.Cos. Dr Peter Costello is a Research Scientist in the Biosciences group at the awri. His research has focused on wine lactic acid bacteria, malolactic conversion (MLF), and bacterial spoilage of wine. Recently he has investigated stress tolerances among *Oenococcus oeni* and approaches to improve MLF efficiency.

P.J.W. Dr Patrick Williams, Oenology Editor of the second edition of this book, was until his retirement the Deputy Director of, and a researcher for 24 years at, the awri.

P.K. Dr Philip Kennedy is Professor of Middle Eastern and Islamic Studies and Comparative Literature at New York University and the General Editor of *The Library of Arabic Literature* series published by NYU Press.

P.K.C.S. Patricia Stefanowicz MW is a wine consultant and educator as well as a qualified architect and structural engineer. She is based in

the UK and divides her working life between wine and construction project management.

P.L. Peter Liem is an American wine writer, author of the James Beard Award-winning book *Champagne,* and author of ChampagneGuide.net. He is the co-founder of La Fête du Champagne, one of the world's largest champagne events, and also serves as the regional chair for Champagne at the Decanter World Wine Awards.

P.Le. Pascaline Lepeltier MS is a Loire-raised, New York–based sommelier, wine educator, and contributor to *La Revue du Vin de France* writing about the Loire and low-intervention wines. She was awarded the titles of Best French Sommelier and Un des Meilleurs Ouvriers de France in 2018.

P.L.L. Peder Lehmann Larsen is a Danish WSET-educated wine writer, educator, and judge specializing in Danish, Hungarian, and Greek wine.

P.R.D. Dr Peter Dry AM is Adjunct Associate Professor, School of Agriculture, Food and Wine, University of Adelaide and former consultant to the AWRI.

P.R.-G. The late Pascal Ribéreau-Gayon was head of the Faculty of Oenology at the University of Bordeaux and one of the most renowned French authorities on making and tasting wine. His father, Jean Ribéreau-Gayon, was also Director of Bordeaux's Institute of Oenology and a descendant of Professor Ulysse Gayon, who worked with Louis Pasteur.

P.S. Paul Strang is a musician-cum-lawyer who became a wine writer after buying a house in France in 1961. Twice winner of the Prix Gourmand for books on the wines of France's South West and Languedoc, he was made a Chevalier de l'Ordre du Mérite Agricole for services to French wines in 2020.

P.S.M.C. Dr Peter Cousins is a grape breeder at E & J gallo, Modesto, California. He has bred and introduced several grape varieties to cultivation, including rootstocks, genetics research varieties, and improved clones. He has collected and studied grape germplasm in nature across North America.

P.T. Patricio Tapia is a journalist based in Santiago with a diploma in oenology and tasting from the University of Bordeaux. Since 1999 he has published *Descorchados,* a guide to South American wines. Tapia also writes regularly for *Wine & Spirits*, *Adega*, and *Decanter*.

P.T.H.U. Tim Unwin is Emeritus Professor of Geography and Chairholder of the UNESCO Chair in ICT4D at Royal Holloway, University of London. He is author of *Wine and the Vine* and was one of the founding editors of the *Journal of Wine Research*.

R.B. Dr Roger Brock is a Senior Lecturer in Classics at the University of Leeds and specialist in Greek history and historiography.

R.D. Dr Bob Dambergs is a Senior Lecturer in Wine Science at charles sturt university. He has been a pioneer in the development of rapid analytical methods such as infrared and UV-visible spectroscopy that are now routinely used within the global wine industry.

R.d.G. Ronald de Groot is founder and editor-in-chief of Dutch wine magazine *Perswijn*, which has been published for over 30 years.

R.D.G. Régis D. Gougeon is Professor of Chemistry and Oenology at IUVV Jules Guyot in dijon, deputy director of research on the physico-chemistry of food and wine, and chairman of the scientific board of the Bourgogne Vigne et Vin cluster, a public-interest group promoting the co-ordination of research, teaching, and transfer across Bourgogne-Franche-Comté.

R.E.G. Rosemary George MW, wine writer, was one of the first women to become a Master of Wine. Her 14 books include three on *Chablis* and, most recently, *The Wines of Roussillon.*

R.E.S. Dr Richard Smart has been Viticulture Editor of every edition of this book and a substantial contributor to it. He is an Australian viticultural scientist, author, and consultant and lecturer in over 40 countries, known particularly for his studies and applications of canopy management, his research on trunk diseases, and his long-standing concern regarding the impact of climate change on the wine sector. He is well known for his OIV-award-winning book *Sunlight into Wine*.

R.E.W. Robert White is Emeritus Professor of Soil Science at the University of Melbourne, Australia. He consults to the wine industry and provides technical advice on soil matters to the AWRI. His book *Principles and Practice of Soil Science* is a standard textbook for soil science. He has also written *Soils for Fine Wines*, *Understanding Vineyard Soils*, and *Healthy Soils for Healthy Vines* (with Mark Krstic) and co-edited the four volumes of Earthscan's *Soil Science*.

R.F. Ryoko Fujimoto DipWSET works for a wine and Japanese sake consultancy in Japan. She is also a wine and sake educator, a judge in various international wine competitions, and a contributor to the 8th edition of the *World Atlas of Wine*.

R.F.G. Robert Gorjak was raised in a wine-growing family close to Jeruzalem, Slovenia. He has written five guides to Slovenian wines and is the author of *Slovenia, a Winemaking Country*. With his wife he established Belvin, Slovenia's first wine school.

R.G. Richard Gawel was until 2022 a Research Scientist with the AWRI. He established ways of describing red wines' mouthfeel and specialized in the chemistry of polysaccharides and phenolics and their effect on white-wine texture.

R.G.V.B. Dr Rob Bramley is a Senior Principal Research Scientist with CSIRO in Adelaide. Since 1998 he has been at the forefront of research aimed at understanding vineyard variability, the associated development of precision viticulture, and its application to improved understanding of terroir.

R.H. Rosi Hanson is a journalist and author of a book on the recipes and traditions of the French wine harvest.

R.J.M. Richard Mayson, an authority on port, madeira, and Portuguese wines. After working for The Wine Society in the UK, he wrote *Portugal's Wines and Winemakers*, *Port and the Douro* and *Madeira: The Islands and their Wines.* He is Series Editor for the Infinite Classic Wine Library.

R.J.T. Rachel Triggs worked as a winemaker and wine lawyer prior to joining Wine Australia in 2013. She is a delegate to the OIV and the WORLD WIDE TRADE GROUP and is on the boards of the public policy group FIVS and the International Wine Law Association.

R.K.C.T. Dr Reinhard Töpfer has been head of JULIUS-KÜHN-INSTITUT's Institute for Grapevine Breeding Geilweilerhof since 1995 and Honorary Professor at Justus Liebig University, Giessen, since 2014. His expertise is in plant breeding, molecular genetics, and grapevine phenotyping.

R.K.S. Reva K. Singh, a veteran of the Indian magazine industry, is the founder of *Sommelier India Wine Magazine*, India's first print and online publication on wine. In 2009 she founded and was co-chair of the Sommelier India Wine Competition (SIWC).

R.N.H.B. The late Robin Butler was an antiques dealer with a particular interest in wine. He co-wrote *The Book of Wine Antiques* in 1986 and in 2009 wrote *Great British Wine Accessories 1550–1900*.

R.T. Raimonds Tomsons DipWSET was recognized as Best Sommelier of Europe 2017 and Best Sommelier of the World 2023 by the Association de la Sommellerie Internationale. Based in Latvia, he is co-founder of Wine-teach.com, a board member of the Latvian Sommelier Association, and judge at the Decanter World Wine Awards.

R.T. du C. Rémi Teissier du Cros is a forest and wood engineer currently working at Tonnellerie Taransaud, France. Having started his career at the French National Forest Inventory, he now shares his time between research on oak wood and barrels and running the engineering office at the cooperage.

R.Z. Rick Zouad spent many years working as a sommelier in top restaurants in New York City before heading back to his native Morocco, where he is a restaurant and beverage consultant.

S.A. Sarah Ahmed publishes thewinedetective.co.uk and is a recognized authority on the wines of Portugal. A contributor to *The World Atlas of Wine* and columnist for *Revista de Vinhos* and *Decanter,* Ahmed has chaired the judging of Portuguese wines at the Decanter World Wine Awards since 2011.

S.A.S. Dr Simon Schmidt is a Research Manager at the AWRI. His research interests include understanding the relationship between nutrient availability and yeast fermentation performance, yeast and bacterial stress tolerance, and the role of oxygen in shaping fermentation outcomes.

S.C. Suzie Chung is a Korea-based wine journalist for wine21.com, a wine lecturer and judge, and a WSET Level 2 textbook technical editor.

S.C.-J. Samantha Cole-Johnson DipWSET is based in Oregon, where she writes for JancisRobinson.com and teaches WSET courses.

S.D.W. The late Dr Steve Wratten was Professor of Ecology at LINCOLN UNIVERSITY in New Zealand as well as being on the staff of the Bio-Protection Research Centre. He was a world leader in biological control of pests.

S.E.A. Susy Atkins is a television presenter and wine writer who is based in Britain but travels widely.

S.F. Professor Sigfredo Fuentes leads the Digital Agriculture, Food and Wine Sciences at the University of Melbourne. His scientific interests include climate change, remote sensing, and the development of

new computational tools using artificial intelligence (AI) applications for psychiatry, plant physiology, food, animal, and wine sciences.

S.J.C. Dr Steve Charters MW is Professor of Wine Marketing, School of Wine and Spirits Business, Burgundy Business School, with research interests in the consumer's engagement with wine and the social and cultural context of its production and consumption.

S.J.G. Sam Glaetzer, member of a well-known South Australian winemaking family, has a degree in civil and environmental engineering and a graduate diploma in oenology. He started his career at treasury wine estates before joining constellation brands, where he is currently SVP of Global Operations and International Commercial Sales for Wine & Spirits.

S.K.H. Sarah Heller MW graduated from Yale University with an art degree before embarking on a wine career in Hong Kong. A writer, educator, and visual artist, she received the 2013 wset Vintner's Cup and was 2022 IWSC Wine Communicator of the Year.

S.N. Dr Simon Nordestgaard is a Senior Engineer at the awri. His research interests include winery solid–liquid separation techniques and process optimization. He has studied the evolution of many winery technologies and practices from their historical origins through to the current state of the art.

S.P.D.L. Simon Loftus is a retired renowned English wine merchant and award-winning author.

S.P.-T. Sophie Parker-Thomson MW is a wine-industry consultant and wine producer based in Marlborough, New Zealand. Aside from a brief interlude training as a lawyer, she has spent her life immersed in wine appreciation, education, production, and communication.

S.S. Stephen Skelton MW has grown vines and made wine since 1974. After training in Germany, he returned to Kent, where he made wine until 2000. Since then he has been a vineyard consultant and has

written several books on both viticulture and English and Welsh wine.

S.T. Dr Stephen D. Tyerman, a Fellow of the Australian Academy of Science, is Emeritus Professor of Viticulture at the University of Adelaide, School of Agriculture, Food and Wine, Senior Editor for *Plant Cell and Environment*, and Associate Editor for the *Australian Journal of Grape and Wine Research*. He is a Clarivate Highly Cited Researcher.

T.C. Dr Tyler Colman is a wine writer and wine educator. The author of two wine books, *A Year of Wine* and *Wine Politics*, he also blogs at DrVino.com.

T.D.C. Tamlyn Currin DipWSET is a wine writer who was born and brought up in Zimbabwe but now lives in the UK and writes for JancisRobinson.com, where she is Sustainability Editor.

T.E.M. Dr Tim Martinson has been active in grape extension and research at cornell university since completing his PhD in entomology in 1991. Since 2007 he has been statewide Senior Extension Associate at Cornell AgriTech, where he led development of a sustainable practices workbook and directed the USDA-funded Northern Grapes Project. In 2020 he was cited as one of 40 wine industry leaders by *Wine Business Monthly*.

T.H. Thomas Heaton is a New Zealand food writer and journalist who spent two years in Nepal covering agriculture and the food and beverage industry.

T.H.L. Professor Terry Lee OAM was Director of the awri in Adelaide before working for E. & J. gallo in California. He is editor of *The Australian Journal of Grape and Wine Research*.

T.J. The late Dr Tony Jordan OAM started his career as research scientist and lecturer in oenology. He established the Chandon Australia Yarra Valley winery and vineyard for Moët Hennessy, later becoming CEO of the Moët Hennessy Wine Estates Group of

Australian and New Zealand wineries, before running his own wine consultancy.

T.K.W. Dr Tony Wolf is Professor of Viticulture and has served as viticulturist with virginia tech since 1986. His education includes an MS from Pennsylvania State University and a PhD from cornell university, both in viticulture research. He was editor and principal author of the 2008 *Wine Grape Production Guide for Eastern North America*.

T.M.S. Tyson Stelzer, wine writer, scientist, and TV host, is the author of 15 books, including *Taming the Screw: A Manual for Winemaking with Screw Caps* and his annual *Champagne Guide.* He is Chief Editor of the *Halliday Wine Companion*.

T.P. Professor Thomas Pinney is a retired Professor of English at Pomona College in Claremont, California, and author of the two-volume *History of Wine in America*.

T.Q.T. Tara Q. Thomas, assistant editor of *The Oxford Companion to Wine*, is the former Executive Editor of *Wine & Spirits* in New York. She has worked in the wine industry for 25 years as a writer, editor, wine judge, and educator and is now Managing Editor of JancisRobinson.com.

T.R.C. Tom Carson is the youngest chairman of Australia's National Wine Show and chief winemaker and general manager of Yabby Lake Vineyard, Mornington Peninsula, Victoria.

T.S. The late Dr Tom Scott was a wine merchant and Honorary Professor in the Institute of Reformation Studies at the University of St Andrews. He specialized in the economic and social history of Germany, 1300–1600.

T.T. Todd Trzaskos is a lifelong resident of the north-eastern United States, with three decades in Vermont, where he advocates and organizes for local producers and is an avid home winemaker. He is

also the author of *Wines of Vermont: A History of Pioneer Fermentation.*

U.C. Umay Çeviker is a Turkish architect and WSET-educated wine enthusiast with a passion for Türkiye's deep-rooted wine culture. In 2015 he won the Geoffrey Roberts Award for his work with rural vineyards and ancient varieties in Türkiye, and he was a contributor to the eighth edition of *The World Atlas of Wine*.

V.C. Dr Véronique Cheynier, Director of Research at INRAE, has been managing INRA Montpellier's internationally acclaimed research on grape and wine polyphenols for over 30 years. From 2012 to 2016 she was President of Groupe Polyphénols, the international society dedicated to the promotion of research on plant polyphenols.

V. de la S. Victor de la Serna is a Madrid-based journalist and wine writer, columnist, and former deputy editor for *El Mundo* as well as a wine producer.

V.F. Vicente Ferreira is Professor of Analytical Chemistry at the University of Zaragoza and head of the Laboratory for Aroma Analysis and Enology (LAAE). He is a specialist in the chemical analysis of aroma molecules and in the interpretation of sensory perception, specifically in wine.

V.J. Dr Vladimir Jiranek is Professor of Oenology and Head of the Department of Wine Science at the University of Adelaide. Through his 30 years' experience he has published extensively on the characterization of wine yeast and bacteria. His work centres on understanding microbial ecology and controlling the impact of microbes on wine quality.

V.K.R. Valentina Kasper Rosputinska is a business innovation executive, WSET Level 3 holder, and co-organizer of Humbuk, natural wine educational pop-ups in Slovakia.

V.L. Dr Valérie Lavigne, Advisory Oenology Editor of this book, has a PhD in Oenology from the University of Bordeaux. She is a Research

Associate on secondment from cooper Seguin Moreau to the ISVV in Bordeaux. Her research focuses on premature ageing of white and red wines and the aromas of Chardonnay wines. She started as an oenology and viticulture consultant alongside the late Professor Denis Dubourdieu (see above) and now works with Christophe Olivier and Professor Alex Marchal in all of France's main wine regions as well as in Italy, Portugal, Spain, South Africa, Greece, Egypt, Morocco, and Lebanon.

V.P. Dr Vladimír Pukis has a master's degree in linguistics and is the former communications director of Fanagoria winery in Russia. A historian, translator, and ethnologist, he has written several books (in Ukrainian, English, and Russian), including *Wine Lexicon* and *The New Old World: Sketches on the History of Kuban Winemaking*, and contributes to numerous media outlets.

W.B. William Bolter is a Bordeaux-based wine merchant, author, and winemaker who worked for Alexis LICHINE from 1958 to 1964.

W.G.G. Dr W. Gill Giese Jr is the Viticulture Extension Specialist/Assistant Professor, Department of Plant and Environmental Sciences, New Mexico State University. He has also made wine since 1995, working in several states.

W.J.B. Bill Blatch worked in the Bordeaux wine trade from 1974 until 2012. He is now Senior Consultant in Bordeaux for Christie's and Founder and Senior Partner in Bordeaux Gold, Sauternes specialists.

W.L. Wink Lorch, wine educator, writer, and editor, specializes in the wines of the Jura, Savoie, and French Alps. She has written two award-winning books: *Jura Wine* and *Wines of the French Alps.*

W.M.B. Wojciech Bon´kowski MW is the founder of *Ferment*, Poland's only printed wine magazine. He writes for Timatkin.com and *Meininger's Wine Business International*, judges at Decanter World Wine Awards and 50 Great Greek Wines, and has served as President of the Polish Wine Trade Association since 2016.

W.P. Dr Wendy Parr is a New Zealand wine sensory scientist with a PhD in Psychology (Cognition & Psychophysics) and a PhD in Wine Science (Sensory).

W.S. Walter Speller is the Italian correspondent for JancisRobinson.com and a wine writer specializing in Italy. He has contributed to the eighth edition of the *World Atlas of Wine* and to *Decanter* magazine. He divides his time between Padova and his base in London.

W.S.S. Wolfgang Schaefer graduated from geisenheim university before establishing and running a 40-ha viticultural research station in Tanzania in the 1970s. He has since travelled to 78 countries and is a senior consultant on all things related to (sub)tropical viticulture.

W.W. Wayne Wilcox was a Professor of Plant Pathology for 34 years at cornell university in New York State, where he led their grape pathology programme until retiring. He was the senior editor and a major contributing author to the comprehensive *Compendium of Grape Diseases, Pests, and Disorders*, 2nd edition.

X.V. Xeniya Volosnikova is a wine specialist from Kazakhstan now living in Europe while pursuing a dream of becoming her country's first Master of Wine.

Y.S. Young Shi is a Warwick Business School graduate and MW student who divides her time between Shanghai, London, and the world's wine regions. She is a bilingual wine writer, consultant, educator, and wine judge.

ACKNOWLEDGEMENTS

As for the four previous editions, this *Companion* owes most to a host of people around the world who have been extraordinarily generous with their time and knowledge, perhaps because wine is a subject which naturally inspires generosity and enthusiasm.

Dr Richard Smart, Australian viticulturist extraordinaire, went to exceptional lengths as long-standing advisory editor for viticulture to ensure that all the entries related to this multifaceted subject were brought fully up to date. With equal dedication and attention to detail, Bordeaux-based international consultant Dr Valérie Lavigne has assumed the complementary role of advisory editor for oenology, taking on the full weight of this task that she shared in the last edition with her former colleague and mentor the late Professor Denis Dubourdieu.

Nevertheless, when it came to final detailed updates to specific entries, it is remarkable how many specialists came to our aid, not only from the AWRI in Adelaide but also from the University of California at DAVIS and from many other academic and research institutions around the world, including Professor Vicente Ferreira of Zaragoza University and Professor Andrew Sacks of Cornell University, who brought their formidable understanding of, respectively, flavour and sulfur to this edition for the first time. Dr Andrei Prida and Rémi Teissier du Cros ensured even greater precision than before on all things oak- and barrel-related.

Our co-author of *Wine Grapes* Dr José Vouillamoz, as well as considerably revising the entry on his native Switzerland, has updated many of the grape-variety entries based on his unique database of DNA profiles, so that while this volume cannot be as

exhaustive as *Wine Grapes*, it is even more up to date in identifying relationships among vine varieties.

Professors Alex Maltman and Robert White made sure the key topics of geology and soil are better defined and described than ever before, and Dr Greg Jones not only substantially revised the entry on climate change but also gave all the main climate-related entries a thorough overhaul. Dr John Barker, recently elected Director General of the OIV, took great pains once again in this edition to clarify and update with lawyerly precision all things regulatory in the EU and beyond.

Patrick McGovern of the University of Pennsylvania Museum has significantly updated his contribution on the origins of what he calls viniculture, and all our other historical entries have been reviewed by their authors to ensure that necessary updates have been made.

We owe an enormous debt to all our regional specialists, many of whom were far more helpful than they need have been, especially those such as Walter Speller, Ferran Centelles, and Sarah Ahmed who reviewed and updated a huge number of entries on Italy, Spain, and Portugal respectively. New to this edition, Carlos Borboa Suárez gave the entry on Mexico a much-needed overhaul, shining a light on a country deserving of much more attention in the wine world. Dirceu Vianna Junior MW did the same for Brazil and in record time. Olga Pinevich-Todoriuk managed to file her entry on Ukraine just before war broke out and updated it later, during the war, nine days after having a baby. And a strong team of US writers, significantly expanded for this edition, made sure the US was better represented than ever before: Alder Yarrow, Elaine Chukan Brown, Kelli White, Matt Kettman, Kevin Pogue, Samantha Cole-Johnson, Maiah Johnson Dunn, Todd Trzakos, Gill Giese, Jenne Baldwin-Eaton, Becca Yeamans-Irwin, Doug Frost MW, Patrick Comiskey, James Tidwell, and Gary Pavlis.

The late Angeliki Tsioli diligently unearthed and distilled the much-amended European wine regulations to produce our unique list of appellations and their permitted grape varieties in Appendix 1. She also gathered from her former employer the OIV their formidable

statistics for Appendix 2. Her sudden and premature death in 2022 was a terrible shock, and yet her work on this edition is a testament to her sharp mind, generous heart, patience, and multilingual skills.

There were also many individuals whose initials do not appear at the bottom of any entry but without whose advice or contacts our work would have been very much more difficult. We apologize to anyone whose name we have failed to record—all too easy, alas, when dealing with literally thousands of people during the preparation of this work. Those who made notable contributions to this fifth edition in particular, other than those recorded in the list of contributors, include:

Yves Abautret

NOTE TO THE READER

Entries are arranged in letter-by-letter alphabetical order up to the first punctuation in the headword, except that names beginning with Mc are ordered as if they were spelt Mac, and St and Ste (French) are arranged as if they were spelt Saint and Sainte. When Château and Châteaux are part of a proper name they appear in full as headwords, but they are abbreviated to Ch and Chx elsewhere. Entries appear under the name of the château and not under C. Place names that start with a definite article are listed under the article (e.g. La Mancha is found under L).

We have attempted to limit cross-references to other entries likely to amplify or increase understanding of the entry being read. They are not given in all instances where the name of an entry appears in the text.

All wine-producing countries have an entry. The most significant ones also have individual entries for regions within them. Some countries or regions have individual entries for specific appellations, depending on what is on the label and which wines are widely available or especially famous. We have tried to give all the most significant appellations their own entry, as we have the individual people, wine producers, and properties which have played or are playing an important part in the history of wine.

Measurements are given in metric accompanied by the United States equivalent.

The format of this fifth edition is very similar to the fourth, including a complete list of entries by region and topic (see pp. xxix–lii) to provide a specific guide to the scope of this book, and to suggest another way of navigating your way through it. A revealing

list of new entries is included on ; all new entries are of course included in the thematic listings too.

The appendices include a completely updated list of all significant wine appellations (very rarely found in printed form) together with details of those grape varieties currently specified by them, including many recent changes (an even rarer listing), as well as tables of total vineyard area by country, total wine production, and per capita wine consumption. All have been thoroughly updated to include the most recent OIV statistics available.

Abbreviations

Ch, Chx	Château, Châteaux
ft	feet
gal	US gallon
g/l	grams per litre
ha	hectare
hl	hectolitre
in	inches
l	litre

A

ABC, acronym for the weary sentiment 'Anything But Chardonnay (or Cabernet)' which encouraged interest in grapes other than the (two most famous) INTERNATIONAL VARIETIES on the part of both producers and consumers. Rhône varieties were the earliest beneficiaries in the 1980s, but by the 2010s INDIGENOUS VARIETIES and ALTERNATIVE VARIETIES, the more obscure the better, were all the rage.

Abel. See HERITAGE CLONES.

Abona, small Spanish DOP covering the semi-desert south of Tenerife in the CANARY ISLANDS. Inland, at Vilaflor, it boasts Europe's highest vineyard, reaching 1,700 m/5,577 ft ELEVATION. Soils are SANDY and CALCAREOUS at its lower levels, with CLAY and well-drained VOLCANIC soils in the higher sites. It produces an increasing number of interesting wines from local grapes such as MALVASIA, LISTÁN, and Baboso Negro (ALFROCHEIRO). V. de la S. & F.C.

Abouriou, early-ripening minor south-western dark-berried vine variety that was still grown on 322 ha/796 acres of France in 2019. It is allowed into Côtes du MARMANDAIS, where Elian Da Ros makes a varietal version. Its wine is relatively high in tannin and low in acidity. DNA PROFILING has suggested a parent–offspring relationship with Magdeleine Noire des Charentes, the obscure mother of Merlot and COT. Known in California as Early Burgundy. J.V.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties Including Their Origins and Flavours* (2012).

Abruzzo, mountainous region in central Italy with a significant coastline on the Adriatic Sea to the south of MARCHE and an important producer of wine (see map under ITALY). Abruzzo is fourth among Italy's regions in terms of production, with a total output of 3.4 million hl/87 million gal in 2020. Despite the presence of one of Italy's better red grape varieties, MONTEPULCIANO d'Abruzzo, a climate ranging from MEDITERRANEAN to CONTINENTAL, and largely hilly vineyard sites in the shadow of the 3,000m/9,843 ft-high Gran Sasso Massif—aspects that help mitigate CLIMATE CHANGE—most of the region's production remains undistinguished.

Abruzzo's best-known varieties, the red Montepulciano and the white TREBBIANO d'Abruzzese, have been underachievers, mainly because of ignorance of site specifics and because YIELDS of more than 100hl/ha are legal. This is not helped by the facts that until recently the entire region was covered by a single DOC, Abruzzo, and required only 80% of each principal variety (amended to 85% in 2010).

But the region has made convincing attempts at improving quality, helped by falling BULK WINE prices and the VINE-PULL SCHEME of the EU which has seen total vineyard area decline from 36,000 ha/89,000 acres to 32,500 ha in 2020, with just under half of that dedicated to DOC production.

Montepulciano d'Abruzzo was once prized as a blending wine in Italy's north, Germany, and France, but there are an increasing number of more serious examples from single producers, rather than from the omnipresent CO-OPERATIVES. It is generally produced in two styles: young and robustly fruity or structured and ageworthy. The latter are typically aged in large oak casks rather than BARRIQUES as was once fashionable. Most of Abruzzo's whites labelled Trebbiano are made of the bland Trebbiano Toscano rather than Trebbiano d'Abruzzese, which some serious producers prove can turn out complex wines.

The Abruzzo DOC has been divided into five subzones (Alto Tirino, Casauria, Teate, Terre dei Peligni, and Terre dei Vestini), while the

tiny DOC Controguerra allows for varietal Chardonnay, Cabernet Sauvigon, and Merlot as well as local varieties. Subject to stricter production rules, several subzones require a VINE DENSITY of at least 4,000 vines/ha compared with DOC Abruzzo's 2,500, the latter due to the TENDONE training method. Two tiny and potentially exciting DOCs, Villamagna and Ortona, share the same tighter rules, but for wines made with a minimum of 95% Montepulciano. The large DOC Cerasuolo d'Abruzzo, requiring a minimum of 85% Montepulciano, can be a source for well-priced *rosato*, with the potential to achieve more, and the tiny Terre Tollesi or Tullum, elevated to DOCG in 2019, excels in white wine made from PECORINO. The region's other DOCG, Montepulciano d'Abruzzo Colline Teramane, has still to prove its worth. In March 2022 new regulations saw the folding of Abruzzo's eight IGTS into a single one called Terre d'Abruzzo; additionally, 'Superiore', stipulating lower yields and higher minimum alcohol, and 'Riserva', stipulating two years of ageing, may appear on labels of Abruzzo DOC and DOCG wines. W.S.

www.vinidabruzzo.it

abscisic acid, or ABA, HORMONE that occurs naturally in vines and other plants which regulates growth and physiology. It has been shown to be involved in the control of gene expression, thereby influencing certain characteristics of the vine such as the biosynthesis of ANTHOCYANINS. Its synthesis is encouraged by physiological stresses including short days and WATER STRESS. In the vine, abscisic acid is involved in LEAF FALL, shoot and root growth, bud dormancy, opening of STOMATA, and regulation of grape ripening. The irrigation technique PARTIAL ROOTZONE DRYING works by manipulating ABA levels.

P.R.D. & R.E.S.

Böttcher, C., and Davies, C., 'Hormonal control of grape berry development and ripening', in H. Gerós et al. (eds.), *The Biochemistry of the Grape Berry* (2012).

Keller, M., 'Botany and anatomy', in *The Science of Grapevines* (3rd edn, 2020).

Abu Nuwas (d. 814 CE), half Arab/half Persian, was court poet and close friend of the Abbasid Caliph al-Amīn (reigned 809–813 CE). He was one of the greatest ARAB POETS of classical Arabic/Islamic culture and, despite his eloquence in all the poetic genres, is remembered principally in the Arabic tradition for his wine poems (the *Khamriyyāt*). P.K.

Kennedy, P., *Abu Nuwas: A Genius of Poetry* (2005).

Rowell, A., *Vintage Humour: The Islamic Wine Poetry of Abu Nuwas* (2018).

abv, abbreviation for alcohol by volume. See ALCOHOLIC STRENGTH.

Abymes, CRU just south of CHAMBÉRY whose name may be added to the eastern French appellation SAVOIE. The vineyards border those of APREMONT and the wines are similar: typically light, dry, stony whites made from the local JACQUÈRE grape. W.L.

academe, originally a Greek word for a site of scholastic endeavour, and today a term embracing all that is achieved there. It impinges considerably on the world of wine.

Winemaking was already a sophisticated practical art by the beginning of the 19th century, and Europe's first formal viticultural training school was established in SACHSEN in what is now eastern Germany in 1811–12. In the second half of the century, however, the seminal work of Louis PASTEUR heralded its transition to an applied science worthy of academic study. Vine-growing and winemaking were soon recognized as academic disciplines, and in 1880, coincidentally, both the University of California (now established at

DAVIS) and the Institut d'Oenologie at the University of BORDEAUX began teaching and researching VITICULTURE and OENOLOGY. The devastation caused in the mid to late 19th century by FUNGAL DISEASES and the PHYLLOXERA pest may help to explain the coincidence.

During the 20th and early 21st centuries, academic institutions throughout the world have worked in tandem with their local wine industries both to teach the scientific principles of vine-growing and winemaking (increasingly regarded as the single discipline of winegrowing) and to research refinements and solutions. Other academic institutions of importance to wine include ADELAIDE, AGROSCOPE, AWRI, BROCK UNIVERSITY, CHARLES STURT UNIVERSITY, CONEGLIANO, CORNELL UNIVERSITY, DIJON, GEISENHEIM, ISVV, JULIUS-KÜHN-INSTITUT, KLOSTERNEUBURG, LINCOLN UNIVERSITY, MAGARACH, MONTPELLIER, PLUMPTON, SAN MICHELE ALL'ADIGE, STELLENBOSCH, and VIRGINIA TECH. Some of these are government funded, although grants for specific research projects are increasingly sought from industry.

In traditional wine regions, winegrowing was taught by apprenticeship, and apprentices were taught to respect tradition above SCIENCE. Formal academic training has long been the norm in the NEW WORLD, on the other hand. By the late 20th century, however, it was customary for even seventh-generation European wine producers to have received some sort of formal academic training, certainly in their own region and very possibly abroad. This not only reflected a fundamental change of attitude towards the science of wine production on the part of European producers but also played a crucial role in the widespread improvement in wine quality during the 1980s and 1990s. Academe, with its annual crop of graduates, could be said to have spawned FLYING WINEMAKERS. Wine courses today need not be focused on production or tasting, however, with such tertiary qualifications as the wine MBAs available in Bordeaux, Davis, and Sonoma.

Acadie. See L'ACADIE BLANC.

access systems, wine. See PRESERVATION SYSTEMS.

Accolade Wines, global wine group based in Australia, an obvious rival to TREASURY WINE ESTATES. Brands with the longest history are Hardys and Houghton. Other Australian brands include St Hallett, Petaluma, Grant Burge, Banrock Station, House of Arras, and Jam Shed while Echo Falls is a mass-market brand sourced in California. Accolade's Berri Estates in South Australia is the largest grape processor in the southern hemisphere, crushing about 220,000 tonnes of grapes annually. The Park in Bristol, UK—owned by Accolade—is Europe's largest wine packaging and distribution centre in Europe, receiving about 180 million litres of wine a year in BULK, much of it for other companies. Accolade delivers approximately 276 million litres of wine to 130 countries every year.

acetaldehyde, the most common member of the group of chemical compounds known as ALDEHYDES, a natural constituent of nearly all plant material, including grapes. Acetaldehyde is the next to last substance involved in the FERMENTATION pathway (and is therefore a minor constituent of all fermented products). Post-fermentation traces of acetaldehyde remain in all wines.

In pure liquid form, acetaldehyde has a particularly penetrating and unpleasant aroma. Above a certain level it can make the wine smell 'flat', vapid, and OXIDIZED. At slightly higher concentrations, it contributes to the distinctive and characteristic smell of FINO sherry and other FLOR wines. Acetaldehyde binds with SULFUR DIOXIDE. It also adds to ANTHOCYANIN pigments, CATECHINS, and PROANTHOCYANIDINS (condensed TANNINS), and it is thus involved in the formation of PIGMENTED TANNINS and other derived tannins and pigments in wines. When free acetaldehyde is present in an oxidized white wine, it may react with α-ketobutyric acid to form SOTOLON, which is a marker for the premature ageing of white wine aromas (see PREMATURE OXIDATION).

Because it is the first compound formed when OXYGEN reacts with the ETHANOL in wine, winemakers are careful to minimize delicate white wines' exposure to air. (This is not so critical with heavier red wines, possibly because acetaldehyde reacts with tannins and anthocyanins.) Special care must be taken while BOTTLING white wines as this is when the introduction of oxygen can most easily damage the delicate aromas. When a bottle of white wine is only partially emptied, the freshness of its aroma is rapidly lost and replaced by a vapid oxidized smell that is due to, among other reactions, the conversion of ethanol to acetaldehyde. The formation of perceptible acetaldehyde, accompanied by a browning of colour, is a typical sign of OXIDATION. V.C. & V.L.

acetic acid, a simple two-carbon fatty acid which is the main flavour constituent responsible for the aroma and sour taste of VINEGAR. In wine it is the main component of what is called VOLATILE ACIDITY (VA).

Acetic acid is produced by a range of microbial activity including primary FERMENTATION, MALOLACTIC CONVERSION, and other fermentations carried out by spoilage organisms (LACTIC ACID BACTERIA, acetic acid bacteria, and spoilage yeasts including BRETTANOMYCES). If wine is exposed to OXYGEN after fermentation, ACETOBACTER can produce high levels of acetic acid from ETHANOL.

The sensory threshold for acetic acid is about 0.7 g/l. The EU legal limit is 1.07 g/l for dry white and rosé and 1.2 g/l for dry reds. Levels above 1.1–1.2 g/l become unpleasant (sharp, vinegary) and are regarded as a wine FAULT. However, in botrytis-affected white wines, higher levels may be produced because yeast activity is disrupted by the high sugar concentration in the must. In this case, up to 1.47 g/l of acetic acid is permitted. T.J. & V.L.

acetic acid bacteria, a family of genera which includes ACETOBACTER and GLUCONOBACTER.

acetobacter, genus within the family of acetic acid bacteria (AAB) capable of spoiling wine by converting it ultimately into VINEGAR. They are found on all grapes but especially rot-affected grapes. Acetobacter can survive only in OXYGEN and are also one of the very few groups of bacteria which can live in the high-acid (low PH) environment of wine (although see also LACTIC ACID BACTERIA).

Ideal conditions for the growth of acetobacter are temperatures between 30 and 40 °C (86–104 °F), relatively high pH values of between 3.5 and 4, low alcohol concentrations, absence of SULFUR DIOXIDE, and generous supplies of oxygen. For these reasons, safe winemaking favours low storage temperatures, good levels of ACIDITY and alcohol, use of appropriate levels of sulfur dioxide as a disinfectant, and, to minimize oxygen contact, barrels, vats, and tanks kept full at all times, that is with minimum ULLAGE. If this last cannot be avoided, the stored wine is blanketed with CARBON DIOXIDE, NITROGEN, or an INERT GAS mixture. P.J.W.

acid, when used as an adjectival tasting term rather than a chemical noun (see ACIDS), is usually pejorative, a bit like 'tart' or 'sour', and means that the wine has too much ACIDITY.

acid adjustment, euphemism for DEACIDIFICATION or, more usually, ACIDIFICATION.

acidification is the winemaking process of increasing the ACIDITY in a grape must or wine. This is a common practice in warm wine regions (as common as ENRICHMENT, or CHAPTALIZATION, in cool wine regions) and is often the only course open to a winemaker wanting to make a balanced wine from grapes which have been allowed a growing season long enough to develop flavour by reaching full PHYSIOLOGICAL RIPENESS. This is because in warm conditions a large amount of the grape's natural MALIC ACID is degraded during the

ripening process. A good level of ACIDS (and therefore low PH) not only increases the apparent freshness and fruitiness of many wines but also protects the wine against attack from BACTERIA and spoilage yeasts such as BRETTANOMYCES, enhances the effectiveness of SULFUR DIOXIDE, and can improve COLOUR (as explained under ACIDITY) as well as increasing a wine's potential to age in bottle.

Acidification is usually sanctioned by local wine regulations within carefully delineated limits in order to prevent stretching of wine by adding sugar and water along with the permitted acid. In TEMPERATE zones such as Bordeaux and Burgundy, acidification is allowed, but with the understandable proviso that no wine may be both acidified and enriched.

The timing of the acid addition varies, but adding acid usually lowers pH so that an addition before or during FERMENTATION results in better microbiological control of subsequent processes and favours the formation of desirable aromas. Fine-tuning of acid levels may take place at the final BLENDING stage, but acid added at this stage can be too obvious.

Regulations vary from country to country, but the most common permitted additives for acidification are, in descending order, TARTARIC ACID, MALIC ACID, LACTIC ACID, and CITRIC ACID. Tartaric is the acid of choice for adding to grape juice before fermentation for several reasons: it is the natural acid of ripe grapes, it is the most effective option, and, unlike both citric and malic acid, which can be attacked by LACTIC ACID BACTERIA, tartaric acid is rarely degraded. Tartaric acid has the disadvantages, however, that it is the most expensive of the four and that significant amounts of the acid may be precipitated as TARTRATES and lost from the wine. If grapes are harvested with high levels of malic acid, tartaric acid may be added so that the wine retains sufficient acidity after MALOLACTIC CONVERSION. Malic acid is used infrequently because of its microbiological instability and its cost. Citric acid, while also being susceptible to microbiological attack, has the merit of being the least expensive and is used widely for inexpensive wines. However, this practice is not permitted in wines

made or sold in the EU. It is often chosen for late acid additions because, unlike tartaric acid, it does not affect cold STABILIZATION. Where regulations permit (in the United States, for example), a blend of acids is often used.

EU regulations permit the addition of calcium phosphate (gypsum) to low-acid must destined for fortified wines. In SHERRY country, for example, it is sometimes added in conjunction with tartaric acid.

One of the problems with acidification is that it is difficult to calculate how much acid to add to reach a desired final pH, in part because each wine or must has its own BUFFERING CAPACITY.

See also DEACIDIFICATION. J.A.G. & V.L.

acidity is a general term for the fresh, tart, or sour taste produced by the natural organic ACIDS present in a liquid and one of the primary tastes sensed by tastebuds on the tongue (see TASTING). Wines, together with most other refreshing or appetizing drinks, owe their attractive qualities to a proper balance between this acidic character and the sweet and bitter sensations of other components.

The acidity of the original grape juice has an important influence on wine quality because of its direct influence on COLOUR (see below), its effect on the growth of YEASTS and BACTERIA (harmful and beneficial), and its inherent effects on flavour qualities. It also plays a part in wine AGEING.

Grape juice acidity is highest just at the beginning of RIPENING, at which stage grapes have half as much concentration of acidity as lemons (see also VERJUS).

Acidity is one of the most important components in both grape juice and wine, and it is also easily quantifiable. What is measured, although in different ways in different countries, is usually the TOTAL ACIDITY, which is the sum of the FIXED ACIDS and the VOLATILE ACIDS. To a scientist, acidity is the extent to which a solution is acid, caused by protons (hydrogen ions or H+), which may be present in either free or bound forms. Another way of measuring acidity is to measure the

concentration of hydrogen ions (H+) free in solution, using the logarithmic PH scale. Generally the higher the total acidity of a wine, the lower is its pH.

Acidity helps to preserve the colour of red wines because the pH affects the ionization of ANTHOCYANINS, which in turn affects their colour. The lower the pH, the redder (less blue) the colour is and the greater the colour stability. As pH values rise (in less-acid wines), pigments become increasingly blue and the colour becomes less stable with pigments eventually assuming muddy grey forms. Red wines from warmer regions and made without ACIDIFICATION can have colours that are less red (and often with a brownish tinge) than those from colder regions which produce wines with higher acidity.

Excessive acidity—resulting either from excessive concentrations of natural plant acids in less-than-ripe grapes or, more rarely, from over-enthusiastic acidification in the winery—makes wines sharp, tart, and sometimes unpleasant to drink. Too little acidity, on the other hand—the consequence of picking too late, or such heat during ripening that the natural plant acids are largely decomposed—results in wines that are flat, uninteresting, and described typically by wine tasters as 'flabby'. B.G.C. & P.J.W.

acids, members of a group of chemical compounds which are responsible for the sharp or sour taste of all drinks and foods, including wine. The most important acids contained in grapes are TARTARIC ACID and, usually in slightly lower concentrations, MALIC ACID. Malic acid occurs in many different plants and fruits, but vines are among the very few plants with large concentrations of tartaric acid in their fruit. The principal acid component in most plants is CITRIC ACID, but VITIS VINIFERA vines are also unusual among plants in accumulating only very small amounts of citric acid.

Some other acids involved in the growth of vines accumulate in the berry in very small amounts, and some of these persist into the wine. Other acids found in wines, while possibly present in traces in grapes, are formed mainly during FERMENTATION. Among those present

in the largest concentrations are LACTIC ACID, SUCCINIC ACID, ACETIC ACID, and CARBONIC ACID.

Various acids are also occasionally added during winemaking. (See ASCORBIC ACID, SORBIC ACID, and sulfurous acid, which is SULFUR DIOXIDE.)

Acids are important in wine not just because, in moderation, they make it taste refreshing, but also because they prevent the growth of harmful BACTERIA and spoilage yeasts such as BRETTANOMYCES and can keep the wine microbiologically stable. In addition, with higher acidity and therefore likely lower PH, SULFUR DIOXIDE is a more effective antimicrobial substance. Most bacteria, and all of those of greatest danger to people, are incapable of living in distinctly acid solutions such as wines. Two groups of bacteria are major exceptions to this rule, however, the ACETOBACTER and the various LACTIC ACID BACTERIA.

A wine's concentration of acids is called its ACIDITY, which can be measured in various ways. Acidity is closely, if inversely, related to pH. P.J.W. & M.J.T.

acidulation, winemaking process more commonly known as ACIDIFICATION.

Acolon, GERMAN CROSS of LEMBERGER and DORNFELDER authorized in 2002 and planted mainly in Württemberg and the Pfalz. Plantings totalled 1,432 ha/3,539 acres in 2020.

Aconcagua, wine region of CHILE north of Santiago encompassing the valleys of Aconcagua, CASABLANCA, and SAN ANTONIO.

acrotony. See APICAL DOMINANCE.

additives, as controversial in wine as in any other foodstuff, have long been hidden from wine drinkers since wine was exempt from

INGREDIENT LABELLING regulations, although producers had to state on the label if their wines contained SULFITES. Since 2022, all additives used in the production of wines made or sold in the EU have had to be declared on the label or via a QR code. Widely used and perfectly legal additives include YEAST to carry out FERMENTATION, lactic acid bacteria for MALOLACTIC CONVERSION, sugar to increase ALCOHOLIC STRENGTH (see CHAPTALIZATION), acid for ACIDIFICATION, OENOLOGICAL TANNINS for TEXTURE and COLOUR stability, SWEET RESERVE for sweetness, alcohol for FORTIFICATION, ASCORBIC ACID as an ANTIOXIDANT, DIAMMONIUM PHOSPHATE as a yeast nutrient, ENZYMES to improve juice extraction, and SORBIC ACID as a preservative. Specific limits on additions (those on which EU member states have reached agreement) are set out in the OIV's International Code of Oenological Practices. Instances of the use of illegal additives such as FLAVOURINGS and OAK essence may be more common than we think, and prosecutions for ADULTERATION are seemingly rare. Additives should not be confused with PROCESSING AIDS.

adega, Portuguese word for cellar or winery.

Adelaide, usual abbreviation in the wine world for the University of Adelaide, in South Australia, with which ROSEWORTHY Agricultural College was merged in 1991 into what is now known as the Department of Wine Science, Australia's principal and influential

centre of wine education and research (see ACADEME and AUSTRALIAN INFLUENCE).

Most of the teaching in OENOLOGY, VITICULTURE, and wine business studies takes place in the South Australian capital city of Adelaide at the Waite and North Terrace campuses. At the Waite Campus, students undertake their winemaking in the multi-million-dollar Hickinbotham Roseworthy Wine Science Laboratory owned by the University of Adelaide. They also have access to collaborating partners in the Wine Innovation Cluster located on the Waite Campus that includes the Commonwealth Scientific and Industrial Research Organization (CSIRO) Plant Industry, the AWRI, and the South Australian Research and Development Institute (SARDI), all of them having established a considerable international reputation for research in viticulture and oenology. S.T. & V.J.

www.thewaite.org/waite-partners/wine-innovation-cluster

Adelaide Hills, fashionable, relatively high (450–550 m/1,480–1,800 ft), cool wine region in SOUTH AUSTRALIA, part of the MOUNT LOFTY RANGES ZONE with CLARE VALLEY. Lenswood and Piccadilly Valley are officially recognized subregions. The region excels in Chardonnay, Pinot Noir, and Sauvignon Blanc, although SHIRAZ also stands out, both in a fuller style from the lower-elevation west-facing slopes in the north of the region and in a northern Rhône mode (sometimes married with VIOGNIER) from cooler parts. ALTERNATIVE VARIETIES are increasingly grown, the main successes being TEMPRANILLO, NEBBIOLO, PINOT GRIS, and FIANO.

Adelaide Plains, a flat, dry, warm-to-hot region immediately north of Adelaide with one notable winery, Primo Estate (which sources much of its fruit from outside the region). Shiraz makes up

just over half of total volume harvested, most of it destined for lower-priced bottlings.

Adelaide Zone, Australian super zone encompassing the MOUNT LOFTY RANGES ZONE, FLEURIEU ZONE, and BAROSSA ZONE, stretching from CLARE VALLEY in the north to the foot of the Fleurieu Peninsula, plus the gaps in between; hence Penfolds Magill Estate is a notable resident. Infrequently used as a GEOGRAPHICAL INDICATION on wine labels.

adulteration and fraud have dogged the wine trade throughout its history. The variability and value of wine have traditionally made it a target for unscrupulous operators, as catalogued in the LITERATURE OF WINE. The long human chain stretching from grower to consumer affords many opportunities for illegal practices. It is important to remember, however, that at various times the law has viewed the same practices differently, sometimes condoning, sometimes condemning them. What we know as adulteration, our ancestors may have classed as a legitimate part of the winemaking process. See also MANIPULATION.

The simplest and most obvious form of adulterating wine is to add water (see HUMIDIFICATION). This is not necessarily fraudulent. In ancient GREECE, for example, no civilized man would dream of drinking undiluted wine, and even today wine made from extremely ripe grapes may achieve better BALANCE if slightly diluted. The practice becomes illegal when done surreptitiously to cheat the consumer or defraud the tax collector.

Another means of stretching wine is to 'cut', or blend, it with spirits or other (usually poorer-quality) wines. BORDEAUX merchants in the 18th century cut fine CLARETS with rough, stronger wine imported from Spain, the Rhône, or the Midi to increase profits, but also because it was genuinely believed that the resulting fuller-bodied concoction was more to the English taste. JULLIEN describes this

common practice as *travail à l'anglaise*. Similarly, merchants in 18th-century OPORTO began to adulterate port with brandy. The systematization of this process by the Portuguese government eventually led to an accepted method of 'adulteration', entirely lawful, to produce PORT as we know it today.

Other ways of altering the nature of a wine were perfectly legal. In the past, wines turned sour after a year or two and techniques used to cure or disguise 'sick' wines were commonplace. Classical and medieval recipes suggested adding various substances ranging from milk (perhaps a precursor of FINING with CASEIN) and mustard to ashes, nettles, and LEAD. Although home doctoring was routine, when these techniques were employed by merchants or taverners deliberately to mislead the customer the practice was as illegal as it was ubiquitous. In the 1st century CE, PLINY the Elder bemoaned the fact that 'not even our nobility ever enjoys wines that are genuine'.

It is assumed today that, unless explicitly stated otherwise, wine is the product of naturally fermented grape juice. However, the practice of fabricating wine, as opposed to simply doctoring it, has a long and chequered history, often most prolific and ingenious at times when true grape wine has been difficult to obtain. In 1709 Joseph Addison wrote in the *Tatler* of the 'fraternity of chymical operators … who squeeze Bourdeaux out of a sloe and draw Champagne from an apple', apparently a profession of long standing. Even today in CHINA's relatively uncontrolled wine market, it is not uncommon to encounter chemical concoctions sold as wine.

Wines were also fabricated from raisins. In the 1880s and 1890s during the scourge of PHYLLOXERA, a thriving industry manufacturing wine from imported raisins sprang up on the Mediterranean coast. During American PROHIBITION in the 1920s, various methods were contrived to circumvent the law by producing wines at home from raisins, dried grape 'bricks', and tinned GRAPE CONCENTRATE (using techniques common to HOME WINEMAKING today).

One of the most common forms of fraud does not involve any doctoring or fabricating of the wine but merely the renaming of it.

Once a region made a name for its wines, others tried to steal it. In Roman times, ordinary wines were passed off as valuable FALERNIAN. From the 19th century, vine-growers have fought for the legal apparatus to protect their names (see AOC), and today producers of some of the most expensive wines go to great lengths to design labels which cannot be counterfeited (see INVESTMENT).

The adulteration or fraudulent sale of wine can be dangerous. The consumer may even be put medically at risk, by the use of lead in ancient times and by METHANOL contamination in the 20th century.

Consumers, growers, and merchants are not alone in trying to prevent adulteration and fraud. Local authorities and (from the last century) governments have fought it. Regulations and legislation have been passed for many reasons: to protect the consumer; to preserve the good name of the local wine; or to facilitate TAXATION.

In medieval London it was illegal for taverners to keep French or Spanish wines in the same cellar as those from Germany to prevent mixing or substitution. A winegrower found selling corrupt wine was forced to drink it, then banned from the trade. German punishments of the time were more severe, ranging from beatings and branding to hanging.

The legal apparatus existing to combat fraud and adulteration today is the culmination of many battles waged by both consumers and trade. In 1820 Frederick Accum published his *Treatise* stating that wine was the commodity most at risk. Thirteen years later Cyrus Redding reported no improvement, and it was not until 1860 that the first British Food and Drug Act was passed.

As for wine-producing countries, the economic distress caused by phylloxera was the main stimulus to legislation. The French government produced a legal definition of wine in 1889, the Germans framed the first GERMAN WINE LAW in 1892 (superseded by the more thorough 1909 version), and the Italians in 1904. The French Appellation Contrôlée system, defining wines by geography rather than simply composition, did not become nationally viable until the 1930s.

Although once rife, adulteration and fraud have been considerably rarer in the wine trade since the adoption of CONTROLLED APPELLATION systems and methods by which to enforce them such as France's Service de la Répression des Fraudes. There have been examples of CONTAMINANTS in wine, both deliberate and accidental, but passing off has become increasingly difficult and, just possibly, less rewarding as wine consumers become ever more sophisticated and more concerned with inherent wine quality than the hierarchy of famous names. Consumers may, with justification, feel that the wine trade has attracted more than its fair share of charlatans because fraud in any field in which expertise is difficult to acquire and viewed with suspicion (such as wine and fine art) attracts more media attention than most other types of commercial fraud.

For details of modern fine wines encountered in fake form, see COUNTERFEIT WINE. H.B. & J.R.

Aegean Islands, islands in the Aegean Sea between modern GREECE and TÜRKIYE, populated by Greeks for millennia. In ancient times, some of the best wines came from these islands, with CHIAN wine, from the island of Chios, ranked highly in both ancient Greece

and ancient ROME. Wines from Lesbos, Thasos, and Cos also featured strongly. Chian wine was still highly valued in the Middle Ages and traded in quantity by the GENOANS, for example. Today the islands, led by SANTORINI, are home to several important wines and appellations. In addition, several grape varieties such as ASSYRTIKO, MANDILARIA, and LIMNIO are considered quintessentially Aegean. The regional PGI Aegean Sea can be applied to dry and medium-dry wines from any Aegean island (or combination thereof) except for Evvia and Crete, while PGI Cyclades applies only to southern Aegean Islands. K.L.

aeration, the deliberate and controlled exposure of a substance to air, and particularly to its reactive component OXYGEN.

The aeration of wine during WINEMAKING must be carefully controlled, since excessive exposure to oxygen can result in OXIDATION, the possible formation of excess ACETIC ACID, and the loss of aroma compounds. At the beginning of FERMENTATION some aeration is necessary since YEAST needs oxygen for growth. The cellar operation of TOPPING UP can expose the wine to an amount of oxygen that contributes to the BARREL AGEING process. The amount of aeration involved in the cellar techniques of RACKING wine from one container (usually a BARREL) to another, RACK AND RETURN, and PUMPING OVER can also be positively beneficial to a wine's development. Specifically, aeration can often cure wines suffering from REDUCTION and can usually remove malodorous and volatile HYDROGEN SULFIDE and MERCAPTANS.

Often for the same reasons, some aeration before SERVING by pouring the contents of a bottle from a great height or from one container into another can also benefit some wines after AGEING, as can simply swirling the wine in the glass. See also DECANTING and BREATHING.

aerial imagery. See REMOTE SENSING.

Afghanistan , Middle Eastern country in which 96,312 ha/237,992 acres of vines were officially cultivated for TABLE GRAPES and RAISINS in 2020, according to OIV figures. At one time wine may have been made here and shipped along the old Silk Road to India; today, any wine made is kept quite quiet as alcohol is prohibited for its citizens.

age in a wine is not necessarily a virtue. See AGEING. See also VINE AGE.

ageing of wine, an important aspect of wine CONNOISSEURSHIP, and one which distinguishes wine from almost every other drink (see BACTERIA). See also BARREL AGEING, CASK AGEING, and ÉLEVAGE.

History

When a fine wine is allowed to age, spectacular changes can occur which increase both its complexity and its monetary value. Ageing is dependent on several factors: the wine must be intrinsically capable of it; it must be correctly stored (in a cool place and out of contact with air; see STORING WINE); and some form of capital INVESTMENT is usually necessary.

Although the BIBLE suggests that Luke understood that old wine was finer than new wine, the Romans (see ancient ROME and, specifically, HORACE) were the first connoisseurs systematically to appreciate fine wines which had been allowed to age, although there is some evidence of wine ageing in ancient GREECE. Certain wines (DRIED-GRAPE WINES, for example) were suitable for ageing because of their high sugar content and were stored in sealed earthenware jars or AMPHORAE. The best, FALERNIAN and SURRENTINE wines, required 15–20 years before they were considered at their best and were sometimes kept for decades.

The Greek physician GALEN (b. 130 CE) noted that an 'aged' wine need not necessarily be old but might simply have the characteristics of age. In other words it was possible, indeed very common, to age wines prematurely by means of heating or smoking them (see ancient ROME). At one time the smoky taste of 'aged' wines became a vogue in itself, though Galen warned that they were not as wholesome as naturally old wines.

After the collapse of the Roman Empire, the appreciation of aged wines disappeared for a millennium. The thin, low-alcohol wines of northern Europe were good for only a few months, after which they turned sour and were sold cheaply. The only wines that could be enjoyed a little longer were the sweeter and more alcoholic wines of the Mediterranean such as MALMSEY and SACK.

By the 16th century, exceptions to this rule could be found in the huge casks of top-quality wine made from RIESLING kept beneath German palaces (see GERMAN HISTORY). These wines were preserved

through a combination of sweetness and ACIDITY, the coldness of the cellar, and the cellarmaster's habit of constantly TOPPING UP the cask to avoid OXIDATION.

The real breakthrough came with the introduction in the 17th century of CORKS and glass BOTTLES. The ageing of wine in bottle was pioneered in England by connoisseurs of fine CLARET and PORT. English wine drinkers rediscovered pleasures largely unknown since Roman times.

Other methods of preserving wine were developed or rediscovered: the addition of spirits to a partially fermented wine to produce fortified wines (see FORTIFICATION); the systematic topping up of a SOLERA system to produce wines like SHERRY; and the heating of MADEIRA.

Demand for mature wines transformed the wine trade. Aside from a few wealthy owners, most vine-growers could not afford to keep stocks of past vintages. Only MERCHANTS could do that, and their economic power and hold over the producers increased during the 18th and 19th centuries. This was most demonstrably the case in BORDEAUX, BEAUNE, and OPORTO, where merchants amassed huge stocks, vast fortunes, and powerful reputations. H.B.

Johnson, H., *The Story of Wine: From Noah to Now* (2020).

Younger, W., *Gods, Men and Wine* (1966).

Which wines to age

The ageing of wine is an important element in getting the most from it, but, contrary to popular opinion, only a small subgroup of wines benefit from extended bottle ageing. The great bulk of wine sold today, red as well as white and pink, is designed to be drunk within a year, or at most two, of BOTTLING.

Wines which generally do not improve with time spent in bottle, and which are usually best consumed as soon as possible after bottling, include the following—although this is only the most approximate generalization: wines packaged in any containers other than bottles—BOXES, for example; most basic WINE WITHOUT GEOGRAPHICAL INDICATION in the EU, JUG WINE in the US, and their everyday, commercial equivalents elsewhere; almost all BRANDED wines, with the possible exception of some red bordeaux; most pink wine; all wines released within less than six months of the vintage such as those labelled NOUVEAU.

Fine wines are usually vinified expressly so that they will benefit from ageing in bottle. In the past, this tended to make them unattractive when consumed young, but with more consistent PHYSIOLOGICAL RIPENESS and the evolution in winemaking techniques, including more gentle EXTRACTION, such wines can also be enjoyed in their youth. In some cases the high levels of sugar, acid, and FLAVOUR COMPOUNDS, as in great Rieslings which may not contain much alcohol, can also benefit greatly from bottle ageing. Specific techniques such as MICRO-OXYGENATION may also make wines more approachable without the need for long bottle ageing.

Even among finer wines, different wines mature at different rates, according to individual VINTAGE characteristics, their exact provenance, and how they were made. Such factors as BARREL FERMENTATION for whites and BARREL AGEING for wines of any colour play a part in the likely life cycle of the wine. In general, the lower a wine's PH, the longer it is capable of evolving. Among reds, generally

speaking the higher the level of flavour compounds and phenolics, particularly TANNINS, the longer it is capable of being aged. Wines made from Cabernet Sauvignon and Nebbiolo grapes, for example, and many of those made from Syrah/Shiraz, should be aged longer than those based on Merlot—and certainly much longer than the average wine made from Gamay or Grenache. Among white wines, partly because of their higher acidity and FLAVOUR PRECURSORS, the finest Riesling and Loire Chenin Blanc evolve more slowly than wines based on Chardonnay.

In general terms, better-quality wines from the following regions or made from the following grape varieties should benefit from some bottle age, with a *very* approximate number of years in bottle in brackets (of course, it all depends on vintage, winemaker, storage conditions, and many other factors):

WHITES

Almost all wine retailing at under £10/$20: 1–2
Chablis: 3–15
Côte d'Or white burgundy: 3–10
Other wines based on Chardonnay: 2–6
Wines based on Riesling: 3–20
Wines based on Sauvignon Blanc: 1–5
Wines based on Viognier: 1–3
Wines based on Chenin Blanc: 3–15
Skin-fermented whites: 5–10
Botrytized sweet wines: 5–35

REDS

Almost all wine retailing at under £10/$20: 1–3 (although some particularly good red Côtes du Rhône and old-vine Spaniards can provide exceptions)
Bordeaux, Madiran: 5–25
Burgundy: 4–20
northern Rhône: 4–15 (Hermitage longer)
southern Rhône: 3–10
Languedoc, Roussillon: 3–8
Barolo, Barbaresco: 6–25
Brunello di Montalcino: 5–13
Chianti: 4–10
Rioja: 5–20
Ribera del Duero: 3–15
Douro table wines: 4–12
Vintage port: 12–50
Other wines based on Cabernet Sauvignon: 7–17
Other wines based on Pinot Noir: 4–10
Other wines based on Syrah/Shiraz: 4–12
Other wines based on Grenache: 3–8

ICEWINE and all but the finest EISWEIN matures quite rapidly. Most fortified wines and their like, such as VINS DOUX NATURELS and VINS DE LIQUEUR, are bottled when their producers think they are ready to drink. Exceptions to this are the extremely rare bottle-aged SHERRIES, vintage PORT (which is expressly designed for decades of bottle ageing), single-quinta ports, and crusted port.

Producers of most SPARKLING WINES usually claim that their wines are ready to drink on release, but this may not be true when demand exceeds supply. Even if yeast AUTOLYSIS ceases when the wine is disgorged, better-quality young sparkling wines with their high levels of acidity can often improve considerably with an additional year or so in bottle.

Factors affecting ageing

STORING WINE in particular conditions can affect the rate at which wine ages; the lower the TEMPERATURE, the slower the maturation. Conversely, ageing can be hastened by stripping a young wine of its solids (by very heavy FILTRATION or FINING, for example) and by storing wine in warmer conditions. Thus, a wine stored in a centrally heated Manhattan apartment will mature very much faster than one stored in an unheated warehouse in Scandinavia. In general, the more slowly a wine matures, the greater the complexity of the flavour compounds that go to make up its BOUQUET (see below).

It is also popularly believed that, in general, the smaller the BOTTLE SIZE the faster its contents mature, presumably because of the greater proportion of OXYGEN in the bottle, as a consequence both of the bottling process and of any possible oxygen ingress via the cork seal during ageing. This is one of the reasons LARGE FORMATS carry a premium.

One of the most significant factors affecting ageing is the type of CLOSURE and the amount of oxygen the wine is exposed to. For more details, see OXYGEN TRANSMISSION RATES and TOTAL PACKAGE OXYGEN.

How wine ages

The descriptions below concern only those wines designed specifically to be aged.

Red wines To the untutored taster, older red wines seem to be softer and gentler than harsh, inky young ones. Those who notice such things will also observe a change in colour, typically from deep purple to light brick red. There should also be more SEDIMENT in an old wine than a young one. All these phenomena are related, and are related in particular to the behaviour of phenolics, the compounds of the grape, particularly the skins, including the blue/red ANTHOCYANINS, which together with the astringent but colourless flavonoids form the PIGMENTED TANNINS (tannin-anthocyanin adducts) that are responsible for a red wine's COLOUR and TEXTURE.

Most phenolics are leached out of the grape skins and seeds during RED WINEMAKING. They react with each other, especially under the influence of the small amounts of oxygen dissolved in the wine during such processes as RACKING, TOPPING UP, and, later, bottling, to generate various derivatives including pigmented tannins. There is some evidence that these reactions start during the primary FERMENTATION process, and by about 18 months later the anthocyanins have mostly been converted to derived pigments responsible for the colour of older red wines. A fine red wine ready for bottling, therefore, may contain colourless tannins, a low concentration of anthocyanins, as well as derived pigments including pigmented tannins, and more complex COLLOIDS such as tannin-POLYSACCHARIDES, and tannin-PROTEINS. Reactions and aggregation continue in bottle. When the resulting polymers and particles reach a certain size, they precipitate as dark reddish-brown sediment, leaving wine that is progressively less astringent, some of the red/blue pigments and tannins having been precipitated. Thus, to a certain extent, holding a bottle of wine up to the light to determine how much sediment it has precipitated can give some indication of its maturity (although the amount of sediment deposited is a function not just of time but of storage conditions and the initial composition of the wine, phenolic and protein content for example, and any FINING carried out prior to bottling).

At the same time as these visible changes occur, the impact of the wine on the nose and palate also evolves. A wide range of FLAVOUR PRECURSORS that were attached to glucose detach themselves (through a natural, and time-dependent, process of HYDROLYSIS) and contribute their individual flavour characteristics to the older wine.

Other flavour compounds responsible for the initial primary AROMAS of the grape and those of fermentation (sometimes called secondary aroma, or secondary bouquet) are also interacting, with each other and with other phenolics, so that gradually the smell of the wine is said to be transformed, by a pathway as yet not understood, into a bouquet of tertiary aromas, a very much more subtle array and arrangement of flavours which can be sensed by the nose (see TASTING).

ESTERS are formed from combinations of the increasingly complex array of wine ACIDS with ALCOHOLS. Continued esterification in bottle produces another range of possible aromas, all the more unpredictable since the esters are formed at very different rates.

The rate at which all these things happen is influenced by a host of factors: storage conditions (particularly temperature), the state of the cork or other stopper, the ULLAGE when the wine was bottled, its pH level, and SULFUR DIOXIDE concentration, all of which can inhibit or slow the all-important influence of oxygen.

OENOLOGISTS understand this much about the maturation of ageworthy red wine but are unable to predict with any degree of certainty when such a wine is likely to reach that complex stage called full MATURITY, when it has dispensed with its uncomfortably harsh tannins and acquired maximum complexity of flavour without starting to decay. Part of the joy of wine has long been said to be monitoring the progress of a case of wine, bottle by bottle, but this is strictly a rich person’s sport.

White wines If our understanding of red-wine maturation is incomplete, even less is known about the ageing process in white wines. Nevertheless, research has shown the importance of certain grape GLYCOSIDES (and the hydrolysis of these constituents) during white-wine ageing to the development of varietal aroma in the wine. White wines begin life in bottle with a much lower tally of phenolics, although those phenolics strongly influence colour and apparent astringency. White wines become browner with age, presumably because of the slow OXIDATION of their phenolic content.

Ageing potential is indirectly proportional to a white wine's concentration of phenolics. For example, fine Rieslings, which are relatively low in phenolics, can in general age much longer than comparable Chardonnays, which contain more phenolics. However, the concentration of phenolics is also determined by the extent to which they are extracted during PRESSING.

Experienced tasters, however, often note that wines affected by NOBLE ROT have a much greater ability to last than their non-botrytized counterparts. Experience also seems to suggest that white wines which undergo barrel fermentation are capable of lasting longer than those fermented in inert containers and then transferred to barrel for BARREL AGEING. Nevertheless, some unwooded white wines also have a great ageing ability, particularly if they have been aged on their LEES.

Most white wines which can mature over several decades rather than years are notably high in acidity. Few of them undergo MALOLACTIC CONVERSION, with the notable exception of some top white burgundies. Many of the venerable sweet wines which demonstrate exceptional ageing ability today may well have been bottled with higher levels of sulfur dioxide than are acceptable to the modern consumer. See also ATYPICAL AGEING.

Stages of ageing

Maturing fine wines go through a number of perceptibly different stages. Very young wines are usually delicious, full of fruit and vivacity, but slightly simple. At some (unpredictable) time after bottling, anything between a few months and a few years, many fine wines seem to close up, to become surly, to lose their aroma without having gained a bouquet. Their dimensions can be sensed but little else (see TASTING). A variable number of years afterwards, they begin to smell like wine again and to have considerably more palate LENGTH. After this they enter into their most satisfying stage at which the bouquet seems fully developed and astringency has receded, making the mouthfeel attractive, so that the wine is delightful in terms of flavour, texture, length, and all-important BALANCE. (Many serious white Rhône wines are particularly prone to this sort of midlife crisis.) If, however, wine is aged for too long (and no one, alas, can predict when this will be), it enters a stage of decrepitude during which the acidity starts to dominate. This unpredictable journey may help to explain apparently contradictory judgements of the same wine, from WINE WRITERS, wine professionals, and wine consumers alike.

Artificial ageing

This winemaking technique has been practised with varying degrees of enthusiasm according to the demands of the market. Current FASHION dictates that wine should be as 'natural' as possible (and, increasingly, that it should be youthful rather than mature), and so very few table wines are ever subjected to artificial ageing (even if many modern WINEMAKING techniques such as MICRO-OXYGENATION are in fact designed to hasten some natural processes). Wine can be artificially aged by exposing it to oxygen or extremes of temperature, by shaking it to encourage effects of dissolved oxygen, or by exposing it to radiation or ultra-sonic or magnetic waves. The making of MADEIRA and some other RANCIO wines deliberately incorporates exposure to high temperatures, while storing wine in some modern domestic conditions can expose wine to high temperatures rather less deliberately.

This century is seeing considerable experimentation with unusual storage conditions for ageing. Those deliberately storing bottles of wine under water (see UNDERWATER AGEING) have been encouraged by the condition of even century-old champagne dredged up from the Baltic (see record prices in AUCTIONS), while others are seeing what happened when wine is stored at especially high ELEVATIONS or at a variety of TEMPERATURES and HUMIDITIES.

agglomerate corks, developed in 1891 by an American businessman, John Smith, occasionally called 'agglo', consist of ground-up cork granules glued together to form a cylinder. These are sold by most cork companies and can perform somewhat similarly to intact cork, though the smallest, poorly made agglos are used on the cheapest bottles. Another inexpensive alternative are colmated corks: one-piece corks in which blemishes and lenticels are filled with a mixture of cork dust and adhesive, then painted.

More recently, companies such as Diam, Amorim, and Cork Supply have offered 'technical' corks, closures made from carefully produced cork particles mixed with an elastic component. The particles are flushed with supercritical CO_2 (in the case of Diam) or undergo other processes to remove TCA (see CORK TAINT), and can have defined OXYGEN TRANSMISSION RATES. Because of this improved performance, technical corks are becoming increasingly popular with winemakers. Diam's Origine uses a plant-based binder and beeswax rather than oil-derived products. Agglomerate corks with discs of natural cork at each end, such as Twin Top from the world's biggest cork supplier Amorim, are also very popular and the standard for SPARKLING WINE.

A.L.W.

Agiorgitiko, also known as Aghiorgitiko and occasionally St George, most planted and admirably versatile Greek red grape variety native to Nemea in the Peloponnese, whose wines may be made from no other variety. There were 2,185 ha/5,400 acres in Greece in 2021. It blends well with other varieties and can also produce good-quality rosé. The wine produced by Agiorgitiko is fruity but can lack acidity. Grapes grown on the higher vineyards of Nemea can yield fresher, long-lived reds. DNA PROFILING has suggested a parent–offspring relationship with the Greek table grape KORINTHIAKI.

Aglianico, a dark-skinned top-quality southern Italian grape variety long thought to be of Greek origin (the name was said to be a corruption of the word *Ellenico*, Italian for Hellenic), although DNA PROFILING has failed to find a relationship with any known Greek

variety. It retained the name Ellenico or Ellenica until the end of the 15th century, when it took its current name. First planted around the Greek colony of Cumae, close to present-day Avellino (home of TAURASI), it is today cultivated in the mountainous centre of Italy's south, in particular in the provinces of Avellino and Benevento in CAMPANIA, and in the provinces of Potenza and Matera in BASILICATA. Scattered plantings of this early-budding vine variety can also be found in CALABRIA, PUGLIA, MOLISE, and on the island of Procida near Naples. DNA profiling has suggested a possible half-sibling relationship with DUREZA and an avuncular relationship with SYRAH. Italy's total plantings were 9,627 ha/23,789 acres in 2015. The vine can ripen so late even this far south that grapes may be picked in November. Attempts to pick it earlier, or to increase yields, invariably lead to a failure to tame its rather ferocious tannins. The grape's best wines are deep in colour with full chocolate and plum aromas, fine-grained tannins, and marked acidity on the palate. Aglianico seems to prefer soils of volcanic origin and achieves its finest results in the two DOCs of Taurasi in Campania and AGLIANICO DEL VULTURE in Basilicata, where elevations are lower and the wines rather softer and earlier-maturing. Its nobility is so obvious that it is now grown in Australia, California, and Argentina.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Aglianico del Vulture, potentially superior wine, one of only a handful in BASILICATA, based on the tannic and ageworthy AGLIANICO grape planted on the slopes of Mt Vulture, an extinct volcano. The DOC zone consists of close to 570 ha/1,408 acres in the north-west of the zone benefiting from cool nights at an ELEVATION of 450–600 m/1,970 ft. The area was given its own DOC in 1971, while the Superiore and Riserva versions of the wines were elevated to DOCG in 2010. Minimum VINE DENSITY for both DOC and DOCG is a low 3,350 plants/ha, while the high permitted YIELDS of 10 tons/ha for the DOC

is lowered to 8 tonnes/ha for the DOCG. Quality-focused producers, however, demand much lower yields from their vines to produce the sturdy, classic red wine with a real propensity for extended cellaring.

Both DOC and DOCG wines must be 100% Aglianico, but styles can differ wildly, with an emphasis on winemaking rather than on the vineyard. The DOC version may not be released on to the market prior to the September following the year of harvest, while the DOCG requires 24 months of ageing, of which 12 must be in oak. French BARRIQUES still feature heavily, but the best wines tend to be aged in large oak casks. Vineyard districts, called CONTRADE, some 70 in total, may feature on labels, but the zone would benefit from more refined geographical DELIMITATION, specifically a much smaller CLASSICO zone to distinguish the HILLSIDES from the many vineyards on the plain.

W.S.

www.consorzioaglianico.it

agricultural treatises are the source of much of our evidence for wine in ancient GREECE and ancient ROME. HESIOD was the first Greek to write on agriculture, in the 8th century BCE. CATO, VARRO, COLUMELLA, PLINY, and VIRGIL were all important Roman writers.

agriturismo, late 20th century phenomenon in rural Italy whereby unused or under-used farm buildings, a significant proportion of them on wine farms, are converted, typically with state aid, for TOURIST accommodation, thereby exposing many thousands of visitors each year to the practicalities of wine production. Spain has seen a similar *enoturismo* initiative, and farm stays have since become popular worldwide.

agrochemicals, the materials used in agriculture to control pests and diseases. The term includes FUNGICIDES, insecticides, HERBICIDES,

bird repellents, plant GROWTH REGULATORS, rodenticides, and soil fumigants and is not limited to synthetic chemicals. A broader definition might also include FERTILIZERS.

Viticulture requires fewer agrochemicals than some other field crops, partly because such a high proportion of vines are grown in warm, dry summer environments in which FUNGAL DISEASES are relatively rare, and also because vines require fewer fertilizers than most other crops (see VINE NUTRITION). However, vines grown in humid, warm summers may require regular SPRAYINGS. Vine-growers, like other farmers, are in general becoming more aware of their use of agrochemicals because of increased environmental concerns (see SUSTAINABILITY) and as alternative approaches become available. Some diseases, notably BOTRYTIS BUNCH ROT, develop tolerance to the repeated use of some chemicals, and so their use is subject to resistance-management strategies. Alternative approaches may take the form of INTEGRATED PEST MANAGEMENT (IPM) programmes, which aim to reduce reliance on agrochemicals through understanding and managing the host–pathogen interaction. The adoption of some form of SUSTAINABLE, ORGANIC, or BIODYNAMIC VITICULTURE restricts the use of agrochemicals to a prescribed list of permitted inputs.

The use of agrochemicals in viticulture is strictly regulated by governments in order to provide better protection for humans and the environment. Advances in analytical methods and an improved awareness of chemical risks has led to the removal of some chemical control options. The products that replace them have to pass stringent registration criteria, including an analysis of the effect the product may have on FERMENTATION. For example, RESIDUES of elemental SULFUR, which is used to protect vines against POWDERY MILDEW, may result in the formation of unpleasant aroma compounds if applied too close to harvest.

Such registrations are therefore lengthy, exacting, and costly. They specify, for example, withholding periods that must elapse between the last application and when the crop is harvested to allow residues of the agrochemical to diminish to suitably low concentrations. To

save money, some manufacturers do not register chemicals with all governments, with the result that small and emerging wine industries, like that of the UK, are disadvantaged by having access to only a limited range of products.

When regulations governing agrochemicals are not harmonized across countries, trade barriers may result. For example, the fungicide iprodione was deregistered in 2017 for use on any crop grown in Europe. If it is used elsewhere on products destined for the EU, the official maximum residue limit (MRL) is set at the lower limit of what can be quantified analytically, thus affecting the way fungal diseases are managed worldwide. The *Codex Alimentarius* ('food code' in Latin) was established by the Food and Agricultural Organization (FAO) and the World Health Organization (WHO) to upgrade and simplify international food regulations and to avoid such situations. *Codex* MRLs have been set for some agrochemicals in a range of crops, and several countries accept *Codex* MRLs in the absence of their own.

Although an agrochemical may be present in formulations bearing different proprietary names, it usually has a single common name that is recommended by standards organizations. For example, the fungicide Scala® (from manufacturers Bayer) contains the agrochemical pyrimethanil that is also the active constituent of several other fungicides.

See also RESIDUES. R.E.S. & M.E.

Mollah, M., and MacGregor, A., 'Review of the potential for agrochemicals used in viticulture to impact on the environment' (2002), GWRDC Project CRV 01/04.

Agroscope, the Swiss centre for agricultural research, affiliated to the Federal Office for Agriculture, conducts wide-ranging research, from the vineyard to sensory analysis, at sites in Changins, Pully, Leytron, Cugnasco, and Wädenswil. The challenging landscape of the vineyards and the structure of the industry (see SWITZERLAND) incur

high production costs for high-quality wine, making such research essential.

Current priorities include CLONAL SELECTION to safeguard the diversity of INDIGENOUS VARIETIES and the breeding of high-quality DISEASE-RESISTANT VARIETIES such as DIVICO and Divona to drastically reduce the use of AGROCHEMICALS. In order to achieve the maximum potential of the Swiss wine-producing regions, cultivation techniques and farming systems have been developed to ensure the best possible match between soil, climate, and grape variety.

Research in plant protection offers practical solutions for problems caused by pests, diseases, and weeds in the vineyards, including methods of prediction, prevention, and treatment. Agroscope's AgroMeteo platform publishes meteorological information useful for managing phytosanitary problems, while collaboration with companies, institutes, and winegrowers has resulted in the development of natural alternatives and innovative strategies for applying plant-protection products.

Research in oenology and analytical chemistry is focused on improving and adapting winemaking technology, taking into consideration changes brought about by CLIMATE CHANGE and consumer trends. Other priorities include microbiology, oxygen management, and the COLLOIDAL stability of wine. Besides maintaining and improving wine quality, research also addresses questions of food safety and sustainability. C.C.

Ahr, diminutive but increasingly prestigious German wine region of 562 ha/1,389 acres in 2019, specializing in SPÄTBURGUNDER (Pinot Noir) and named after the river which flows east from the hills of the Eifel to join the Rhine near Remagen (see map under GERMANY). The most westerly vineyards hug a circuitous, dramatically rocky stretch of river between Altenahr and Dernau, its steep sides sometimes narrowing to the dimensions of a gorge. Ahr vineyards are variously underlain with BASALT, SLATE, and clay-rich sandstone known as GREYWACKE, whose fast-warming and heat-retentive capabilities, along

with shelter from winds and 69% of vine surface exceeding 30° inclination, more than compensates for an unusually northerly location at 50–51° LATITUDE and for ELEVATIONS of up to 300 m/980 ft; indeed, Spätburgunders in excess of 14% natural alcohol are not uncommon. Spätburgunder gained ground steadily here during a German red-wine boom that began in the 1990s, reaching 65% of regional vine surface by 2019. PORTUGIESER, prevalent after the Second World War when Ahr reds were mostly pale, soft, and slightly sweet, is in sharp decline, while FRÜHBURGUNDER retains popularity (with a 6% share). Riesling makes up 9% of vine surface, favouring slate soils, its wines evincing a tropical fruit character reminiscent of those from the MITTELRHEIN.

During the night of July 14–15, 2021, unprecedented rains turned the Ahr into a raging flood that destroyed the region's infrastructure and most of its wine facilities and, in many instances, wine stocks. Prime vineyards remained largely above water, so, thanks to timely helicopter-spraying against fungus and an enormous influx of volunteers from throughout Germany, much of the region's 2021 crop was harvested, then vinified off-site. Infrastructural recovery will take years. It remains to be seen how many of the region's 50-plus estate bottlers—not to mention roughly 1,100 small vine-holders who supply the Ahr's four CO-OPERATIVES (representing in 2019 some three-quarters of its grapes)—will elect to continue growing grapes.

D.S.

AI. See ARTIFICIAL INTELLIGENCE.

Aïdani, floral-scented variety grown on SANTORINI and other Greek islands, typically for blending with ASSYRTIKO. DNA PROFILING has shown that Aïdani Mavro is not a dark-skinned mutation. J.V.

air drainage, important topographical and hence climatological consideration in VINEYARD SITE SELECTION. Cold air flows, or 'drains', downhill, and so a continuous slope or HILLSIDE is much less prone to

FROST and WINTER FREEZE than a hollow. In regions at risk from these phenomena, zones which accumulate cold air should be avoided as vineyard sites. In general, a vineyard site near the top of a free-standing hill is ideal since no cold air is imported from above. R.E.S.

air dried. See BARREL MAKING.

Airén is planted at such a low VINE DENSITY in its central Spanish homeland that it is planted on just over 20% of all Spanish vineyard and covers more area than any other white wine variety in the world. Its 2020 total of 204,699 ha/505,822 acres is dramatically reduced from its 2004 total of 305,000 ha/753,350 acres, however, thanks to vigorous VINE-PULL SCHEMES, particularly in LA MANCHA and VALDEPEÑAS, where it has traditionally been blended with dark-skinned Cencibel (TEMPRANILLO) grapes, which are steadily replacing Airén, to produce light red wines. It is increasingly vinified as an inexpensive white wine, however, to yield crisp, neutral, dry white wines for early consumption. In several ways, therefore, Airén is the Spanish equivalent of France's UGNI BLANC. Airén vines are trained into low bushes and have remarkable resistance to the DROUGHTS which plague central Spanish viticulture. The variety is also grown around MADRID.

Aix-en-Provence, Coteaux d'. Mainly dry rosé and some red wines are made from the varied but often spectacularly situated vineyards in this PROVENCE appellation. Stretching from the western frontier with LES BAUX DE PROVENCE as far as east as the Coteaux VAROIS, it includes ELEVATIONS varying from nearly sea level to over 400 m/1,312 ft with considerable TEMPERATURE VARIABILITY. A total of 4,127 ha/10,198 acres of vineyards in 2020 produce serviceable if generally unsophisticated reds and pale pink wines for early consumption. CO-OPERATIVES are relatively important here, but a number of estates such as Chx Calissanne, Revelette, Pigoudet, and Vignelaure are working at promoting a regional and distinctive style

from GRENACHE grown at cooler elevations. Cinsaut, Mourvèdre, Counoise, Syrah, Carignan, Cabernet Sauvignon, and small amounts of CALADOC are also allowed. A little white is made from a wide range of grape varieties, mainly VERMENTINO.

ORGANIC VITICULTURE has established a significant hold in this arid, MEDITERRANEAN climate. E.A.G.

Ajaccio. See CORSICA.

Alarije, white grape grown in the EXTREMADURA region of Spain. Called Malvasia Riojana in Rioja and Subirat Parent in Cataluña, it has been shown by DNA PROFILING to be a natural offspring of Gibi and Tortozón. J.V.

Alaska , far north-western state of the United States where Bell's Alaskan Vineyard & Winery in Anchorage successfully makes wine from VITIS VINIFERA planted in the ground but under greenhouse. Because of the cool climate, FRUIT WINES are more common. E.C.B.

Alba, culinary capital of Italy's LANGHE, famous for its red wines and white truffles, and where in the past, before estate bottling became the norm, producers would sell their grapes to bottlers and NÉGOCIANTS on the Piazza Savona immediately after the harvest. Since 2010 it also is the name of a, at least for the moment, rather irrelevant DOC for Nebbiolo-Barbera blends covering all of Roero, Barolo, Barbaresco, and Dogliani. See also ROERO and NEBBIOLO D'ALBA. W.S.

Albalonga, originally described as a 1951 RIESLANER × SILVANER cross but now shown by DNA PROFILING to be Rieslaner × MÜLLER-THURGAU. Grown to a very limited extent in Germany (13 ha/32 acres in 2019), notably in Rheinhessen and the Pfalz, and to an even more limited extent in England. J.V.

Albana, Italian vine made famous by the over-promoted ROMAGNA ALBANA. Now widely planted in the EMILIA-ROMAGNA region, its chief claim to fame is being mentioned in the 13th century by medieval agricultural writer PETRUS DI CRESCENTIIS. Most Albana is late ripening, thin-skinned, and prone to rot, but the Albana Gentile di Bertinoro clone has thicker skins than most and results in relatively deep-coloured white wines with marked acidity, which is useful in the best, long-lived sweet versions. Total area planted had declined to 818 ha/2,021 acres by 2020.

Albana di Romagna. See ROMAGNA ALBANA.

Albani, Colli, white wine DOC from the hills south-east of Rome based on MALVASIA Candia (maximum 60%) with up to 50% TREBBIANO (Giallo, Toscano, or Soave) and/or 5–45% of Malvasia di Lazio). Wines can be sparkling or still, dry or sweet. For more information, see CASTELLI ROMANI.

Albania , Mediterranean country situated on the Adriatic coast between MONTENEGRO and GREECE that claims one of Europe's longest histories of vine-growing. French historian Henri Enjalbert considered Albania, the Ionian Islands of Greece, and southern Dalmatia in what is now BOSNIA AND HERZEGOVINA possibly the last European refuge of the vine after the Ice Age. Wine production is believed to have been practised by the inhabitants of Albania in the Bronze Age, and there are written accounts of vines being cultivated in Illyria (as Albania was known in Classical times) as early as the 8th century BCE. Until the Ottoman invasion in the late 15th century, vines were grown in every region, and every parish church had its vineyard. The Ottoman occupation of Albania (1479–1913), the two World Wars, and the isolationist communist regime suppressed the development of the Albanian wine industry, but there is a very considerable level of

viticultural potential in this small country, particularly due to its distinctive INDIGENOUS VARIETIES.

Albania is now a parliamentary republic with a population of 2.83 million inhabitants in 2021 and a total land area 28,000 km square, slightly smaller than Belgium. It has a typically MEDITERRANEAN CLIMATE: cool and wet in winter, warm and dry in summer. It is a mountainous country, with only a quarter of its land suitable for agriculture, but over half its population lives off the land, on farms with an average size of 1.14 ha/2.8 acres. Viticulture is an important sector. Nearly half of all the 12,002 ha/29,657 acres of vines are trained on PERGOLAS.

The principal vine-growing regions are Elbasan, just south of the capital Tirana; Fier and Vlorë close to the Adriatic Coast, and Gjirokastër in the far south. French vine varieties such as Merlot, Cabernet Sauvignon, and Chardonnay collectively make up 42% of the vineyard area, but Kallmet, known as KADARKA in Hungary, is locally considered the country's noblest red, valued for its juicy blackberry-vanilla flavours. More attention is also being paid to indigenous varieties such as Cëruja, a high-acid, floral white-wine grape, and Shesh i Zi ('Black Shesh'), a low-yielding variety originating from Shesh, near Tirana, that produces ageworthy, lightly tannic red wines with tart, fragrant plum notes. Viticultural research in Albania is focused on the collection, characterization, and preservation of these and other varieties, including Pulës i Zi, Vlosh, Serina e Zezë, and Debinë e Bardhë, as many can still be found growing wild near pre-Ottoman archaeological sites such as those at Rozafa Castle, Berati town, and Byllis. L.S. & E.S.

Enjalbert, H., *Histoire de la vigne et du vin* (1975).

alberese, a name used in parts of TUSCANY for pale-coloured, marly soils that are more CALCAREOUS and poorer in clay than GALESTRO. Although both albarese and ALBARIZA soils are high in calcium carbonate, they are geologically different. A.J.M.

Albariño, Spanish name of the distinctive, aromatic, high-quality vine grown in Galicia (and as ALVARINHO in the north of Portugal's Vinho Verde region). The grapes' thick skins help them withstand the particularly damp climate and can result in white wines notably high in alcohol, acidity, and flavour. Albariño was one of the first Spanish white grape varieties produced as a VARIETAL and encountered on labels. Most common in Spain in the RÍAS BAIXAS zone, it has become so popular (and expensive) that it represents 96% of all plantings in the DOP. Sometimes oak-matured, and increasingly aged for several years in stainless-steel tanks before release, it can age better than most light-skinned Spanish grapes however it is made. Occasionally it is blended with LOUREIRA, TREIXADURA, or CAÍÑO BLANCO. Spanish plantings had grown to 5,936 ha (14,668 acres) by 2020. Its wines are so widely exported that it is now also grown in California, Oregon, Washington, Australia (although see also SAVAGNIN), New Zealand, and Uruguay and has been allowed in France since 2010.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties Including Their Origins and Flavours* (2012).

albariza, strikingly white soil in the area around JEREZ de la Frontera and SANLUCAR DE BARRAMEDA, ANDALUCIA, south-west Spain, well suited to growing PALOMINO FINO vines.

Soils derived from white siliceous MARL constitute the whole western part of the Guadalquivir river region. Their local names reflect differing proportions of siliceous and CALCAREOUS microfossils, CLAY minerals, and QUARTZ. Albariza consists of 50% or more of calcareous microfossils (including coccolithophores; see CHALK) and clay minerals. Albariza subtypes such as *tosca de barajuelas* have been classified by García del Barrio Ambrosy.

The soil is humus-poor and light in texture, providing healthy aeration and easy root penetration. Its microporosity gives excellent water storage, enhanced by the swelling clay montmorillonite. The

slow release of this stored winter moisture is invaluable during Andalucia's arid growing season. A.J.M.

García del Barrio Ambrosy, I., *La Tierra del Vino de Jerez* (1979).

Albarola, neutral white grape disappearing from the Cinqueterre zone of LIGURIA in north-west Italy. Known as Bianchetta Genovese around Genoa.

albedo. See REFLECTION.

alberello, Italian term to describe free-standing BUSH VINES trained according to the GOBELET system.

Albillo, name of several different pale-skinned grape varieties grown and sometimes confused in various parts of Spain, most notably Albillo Mayor in Ribera del Duero and other parts of CASTILLA Y LEÓN, Albillo Real in CASTILLA-LA MANCHA and around MADRID, where some old vines yield honeyed dry wines of real substance, and Albillo de Albacete in MANCHUELA. However, considerable confusion is caused by the use of plain Albillo in Spanish statistics and wine regulations. Both Albillo Mayor and Albillo Real produce wines that are generally low in acidity, full-bodied, and aromatic.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

alcohol, the common name for ETHANOL. The term 'alcohol', which can be applied to any of the ALCOHOLS, derives from the Arabic *al-kuhl*, meaning 'the fine powder used to stain eyelids' (today's kohl), and thus by extension any kind of fine impalpable powder that represents the concentration, or quintessence, of the raw material involved. It was then more widely applied to fluids that represented

the essence, or spirit, of something, and thus to any product of distillation.

alcoholic strength, an important measurement of any wine, is its concentration of the intoxicant ethyl alcohol, or ETHANOL. It can be measured in several different ways, the most common being the DEGREE first defined in France by Gay-Lussac in 1884. This was the number of litres of pure ethanol in 100 litres of wine, both measured at 15 °C/59 °F. Later a more precise definition, using 20 °C/68 °F as the reference temperature and some other minor refinements, was adopted in France and by most international organizations. The degree of alcohol is equivalent to its percentage by volume and is sometimes referred to as 'abv', alcohol by volume. In most countries it is mandatory to specify the alcoholic strength of all wines on the label, although it may be written either % or occasionally ° (see also LABELLING INFORMATION).

The alcoholic strength of wine that has not had alcohol added by FORTIFICATION is usually 9–16%, with the great majority of wines being 12.5–14.5% alcohol—considerably higher than as recently as the 1980s thanks not only to CLIMATE CHANGE but also to FASHIONS, a desire for riper PHENOLICS, and the resulting tendency to later picking after extended HANG TIME. A significant proportion of high-quality wine made today in warmer climates is deliberately subjected to some form of ALCOHOL REDUCTION to make it more palatable—high-alcohol wines may taste 'hot' and are likely to be less aromatic because ethanol can mask aromas and flavours—or to satisfy some legal requirement. However, higher-alcohol wines may reduce the perception of TANNINS because alcohol can prevent them from binding with salivary tannins (see ASTRINGENCY).

In Europe, fermented grape juice should usually reach at least 8.5% alcohol (9% in specified warmer zones) before it legally constitutes wine, although exceptions are made for PDO or PGI wines that have traditionally been low in alcohol such as some German wines with PRÄDIKAT and Italian MOSCATO, and EU regulations that

came into force in 2023 permit the term DE-ALCOHOLIZED WINE. The technical European legal maximum alcoholic strength for wines that have had no alcohol added is 15%, but derogations are frequently made at this upper limit too (as long as they have not been ENRICHED), not least for Italy's strongest wines such as AMARONE. In the United States, grape-based 'table wine' must legally be between 7 and 14%, while those between 14 and 24% technically qualify as DESSERT WINES.

Since alcohol is the product by FERMENTATION of grape sugar, itself the product of PHOTOSYNTHESIS driven by sunlight, the alcoholic strength of a wine is, very generally, proportional to the proximity of its provenance to the equator and to the precosity of the variety, although many other factors play a part, especially the intentions of the winemaker. High vineyard ELEVATION, poor WEATHER in a particular year, high YIELD, and any RESIDUAL SUGAR are just some of the factors which may decrease alcoholic strength. Severe PRUNING in the vineyard and cellar techniques such as ENRICHMENT, CONCENTRATION, and fortification allow winemakers to manipulate alcoholic strength upwards. Some OLOROSO sherries, for example, can reach alcoholic strengths approaching 24% after EVAPORATION. (See also DRIED-GRAPE WINES.)

There is an important distinction between actual alcoholic strength, as defined above, and potential alcoholic strength, which refers to what the concentration of alcohol in a wine would be if all the sugars were converted to alcohol. Total alcoholic strength is the sum, post fermentation, of the actual alcoholic strength and the potential alcohol of any remaining fermentable sugars. Natural alcoholic strength refers to the alcoholic strength of a wine prior to any form of enrichment.

Regulation (EU) No 1308/2013 of the European Parliament and of the Council of 17 December 2013, *Official Journal of the European Union*. .

alcohol reduction typically refers to the removal of alcohol from fully fermented wine using physical separation processes. The aim is to retain all other desirable components, but such techniques are likely to affect the volatile composition of the wine and its sensory profile. The most extreme form is de-alcoholization, resulting in a wine with an ALCOHOLIC STRENGTH of less than 0.5%. Alcohol reduction is used for a number of purposes.

Full-strength wines with excessively high alcohol levels may be adjusted or 'corrected' by a few degrees to improve BALANCE. In some jurisdictions, there is a maximum limit for such adjustments if the product is to be sold as 'wine'. In the EU, for example, the alcoholic strength can be reduced by a maximum of 20% of the original alcohol content and cannot be reduced below 9% (8.5% in the coolest regions). Beyond those limits, from 2023 the product must be sold as a 'wine-based drink', or as DE-ALCOHOLIZED WINE or PARTIALLY DE-ALCOHOLIZED WINE.

Alcohol reduction is carried out using various mechanical methods based on temperature, pressure, and concentration, sometimes in combination. These include the use of a vacuum distillation technique such as the SPINNING-CONE COLUMN, membrane separation techniques such as REVERSE OSMOSIS, ELECTRODIALYSIS, EVAPORATIVE PERSTRACTION, PERVAPORATION, ULTRAFILTRATION, and NANOFILTRATION, as well as the more 'traditional' method of HUMIDIFICATION.

Non-mechanical methods of alcohol reduction such as harvesting earlier or choice of YEAST strain have also shown some success. See LOW-ALCOHOL WINE.

alcohols, those organic chemicals, the simplest members of which consist of carbon, hydrogen, and oxygen atoms arranged so that there is an –OH group present. Many different alcohols are used in commerce and industry, but the most common is ethyl alcohol, or ETHANOL, the alcohol that is the important, and intoxicating, ingredient in wines and spirits. The presence of ethanol in foods and beverages, commonly referred to simply as 'alcohol', is the product of yeast FERMENTATION of natural sugars.

Other alcohols with more than two carbon atoms of ethanol are also the product of fermentation, and these are sometimes called higher alcohols, or FUSEL OIL. The higher alcohols separated from ethanol by DISTILLATION are normally used as solvents in industrial processes. The major constituent of fusel oil is the five-carbon isoamyl alcohol. P.J.W.

aldehydes, a class of chemical compounds midway between the ALCOHOLS and the organic ACIDS in their state of OXIDATION. They are formed during any phase of processing in which an alcoholic beverage is exposed to air. ACETALDEHYDE is the aldehyde of most interest to wine producers. Some aldehydes have quite potent odours, even if they are usually present in only trace concentrations in wines and spirits. As such, aldehydes contribute harmoniously to the overall character.

Those aldehydes containing more than the two carbon atoms of acetaldehyde are in general much more palatable. VANILLIN, for example, is a complex aromatic aldehyde present in the vanilla bean and in many other plants, including some grapes, where it is present as a GLYCOSIDE and is a FLAVOUR PRECURSOR. Vanillin also occurs as a component of the lignin structure of OAK. If new oak casks are used

for wine maturation, some of this vanillin is extracted from the wood into the wine (see also OAK FLAVOUR).

One of the most important functions of SULFUR DIOXIDE is to bind with aldehydes, which can make a wine seem flat if present in excess. Once bound, the aldehydes can no longer be tasted, making the wine seem fresher.

See also HERBACEOUS for the part played by leaf aldehydes.

P.J.W. & M.J.T.

Aleatico, Italian red grape variety with a strong MUSCAT aroma. DNA PROFILING has shown a parent–offspring relationship with the classic MUSCAT BLANC À PETITS GRAINS, hence the Muscat flavour. Aleatico certainly has the potential to produce fine, if somewhat esoteric, fragrant, usually pale red from the Italian 2015 total of just 149 ha/368 acres. Two DOCs enshrine the word 'Aleatico' in the wine lexicon of LAZIO and PUGLIA, but the variety is becoming increasingly rare even if it is still found in TUSCANY, the MARCHE, and UMBRIA. Sweet red Aleatico is one of the few wines to be exported from the Tuscan island of ELBA, and the variety is grown on the island of Corsica. Aleatico is also surprisingly popular in the central Asian republics, notably KAZAKHSTAN and UZBEKISTAN. J.V. & J.E.H.

Alella , town near Barcelona in CATALUÑA (see map under SPAIN) which gives its name to a small Spanish DOP making mainly white wines in increasingly urbanized countryside. To compensate for the loss of agricultural land, the DO was extended northwards in 1989, but by 2021 there were only 227 ha/560 acres of vineyard, a fraction of the area planted in 1956 when Alella was first awarded DO status. The zone used to be known for cask-aged, medium-sweet white wines. Today, it is better known for both sparkling CAVA and dry, still white wine. The chief grape variety is Pansa Blanca, the local name for XARELLO, which is now grown along with CHARDONNAY on granitic sandy soils known as *sauló*. V. de la S. & F.C.

Alenquer, small DOC in a sheltered valley in LISBOA, and seat of boutique modern winemaking using Portuguese and French varieties. Its strength is fuller-bodied red wines.

Alentejo, DOC and VINHO REGIONAL (known as Vinho Regional Alentejano) in southern PORTUGAL corresponding to the province of the same name.

DOC wines, including VINHO DE TALHA, must come from one (or more) of eight subregions which may appear on labels: PORTALEGRE, BORBA, REDONDO, and REGUENGOS de Monsaraz are located in the southern part of the Alentejo, north of the Vidigueira fault (an escarpment); GRANJA-AMARELEJA, VIDIGUEIRA, ÉVORA, and MOURA are located to the south. Many good producers prefer to label wines VR Alentejano, however, while some outside its DOC regions (notably in Beja) must be labelled VR Alentejano, despite their wines' evident high quality.

The sparsely populated Alentejo represents one-third of mainland Portugal, and, in contrast to the north, cereal farms and cork plantations (*latifúndios*) stretch as far as the eye can see. For centuries, the Alentejo's main link with wine was CORK. Around half the world's cork supply is grown in Portugal, nearly all stripped from Alentejo's cork oaks. Southern Portugal bore the brunt of the military-led revolution that rocked the Lisbon establishment in 1974–75 and the economy of the Alentejo was still in disarray in the early 1980s. However, financial assistance from the EU has allowed the CO-OPERATIVE wineries in the towns of Portalegre, Borba, Redondo, Reguengos de Monsaraz, Granja-Amareleja, and Vidigueira to improve wine quality and develop exports. Moreover, it resulted in an increase in the number of ambitious, privately owned estates from 45 to 260 between 1995 and 2010. By 2010 Alentejo not only commanded the biggest share of the domestic market in quality wines (in volume and value) but had also charmed export markets with its generous, fruit-led wines. In 2019, vines were planted on more than 22,000 ha/54,363 acres, and 40% of the vineyards were

certified under Wines of Alentejo's pioneering Sustainability Programme (WASP) by 2021.

Large farms offer considerable economies of scale compared with the smallholdings (*minifúndios*) of northern Portugal. This and Alentejo's consistent climate—sunshine hours average over 3,000/annum—hold the key to its bedrock of smooth, easy-going reds. Where summer temperatures frequently exceed 35 °C or even 40 °C/104 °F, conditions can be challenging for top-end wines. Cooler locations such as Portalegre and Borba (elevated), Costa Vicentina (coastal), and Alentejo's water-retentive bands of SCHIST help—especially for white wines, which are a growing strength. So does modern technology: TEMPERATURE CONTROL and IRRIGATION supplements an annual rainfall that rarely totals 600 mm/23 in. Conversely, TALHA wines have put the spotlight on traditional DRY-FARMED grapes. Red wines dominate, making up three-quarters of production—principally blends from ARAGONEZ, TRINCADEIRA, ALICANTE BOUSCHET (which flourishes here), Syrah, and TOURIGA NACIONAL. Several producers make impressive white blends of ANTÃO VAZ, ROUPEIRO, and ARINTO. VERDELHO, ALVARINHO, and VIOGNIER also look promising. S.A.

Alexander Valley, California wine region and AVA in northern Sonoma County north-east of Healdsburg and south of Cloverdale. See SONOMA.

Alfrocheiro, one of the most promising red grapes in the DÃO region of Portugal. Its well-constructed blackberry- and strawberry-flavoured wines have such appeal that it can now also be found in the ALENTEJO, TEJO, and BAIRRADA. National plantings in 2020 were 1,198 ha/2,960 acres. It is very susceptible to POWDERY MILDEW and

GREY ROT and is not therefore as popular with growers as with winemakers. However, it yields reasonably well, ripens early, and produces deep-coloured wines with good alcohol and acid balance. DNA PROFILING has suggested that Alfrocheiro is the natural parent of at least 20 varieties in the Iberian Peninsula, including CASTELÂO and MENCÍA. Also known as Alfrocheiro Preto, in the Douro it may sometimes be called Tinta Bastardinha, Baboso Negro on the Canary Islands, and Albarín Tinto in Asturias. R.J.M. & J.V.

Algarve, located at the southernmost tip of Portugal and sheltered from northerly winds by the Serra de Monchique, has a long winemaking tradition (of principally FORTIFIED wines). The entire province is designated as a VINHO REGIONAL, with four DOCs, from west to east: Lagos, Portimão, Lagoa, and Tavira. While it shares the high sunshine hours (over 3,000 per year) and warm Mediterranean climate of the ALENTEJO, its northern neighbour, the Algarve does not benefit from the cool respite of pronounced diurnal or seasonal TEMPERATURE VARIABILITY, and vineyard sites must be carefully selected. West of Faro, the land is more exposed to cooler, humid Atlantic influence (Lagos additionally to northern winds); the east is warmer and drier. The Algarve's DOCs used to be centred around local CO-OPERATIVES, but by 2021 only one remained and private investment had grown, allowing for a greater interrogation of individual terroir with both popular Portuguese and French grapes and local grapes Negra Mole (see NEGRAMOLL) and Crato Branco (SÍRIA). Most boutique players focus on domestic sales, but in 1998 the British singer Sir Cliff Richard led the export charge when he established a vineyard and winery near the resort of Albufeira. It was acquired by a Portuguese-French businessman in 2021 following a decade during which Algarve exports quadrupled. Al-Ria in Tavira, founded in 2013 by Lisboa-based Casa Santos Lima, is now the Algarve's biggest producer. Quinta da Aveleda of Vinho Verde has also invested heavily, establishing the Villa Alvor brand in the western Algarve in 2019. S.A.

Algeria was for much of the 20th century one of the world's leading wine producers. Annual output sometimes reached 20 million hl/525 million gal, most of it exported to France, of which it was then a colony. Changes following Algeria's independence in 1962 have reduced production to a figure typically nearer 500,000 hl/13 million gal.

History

As seen in mosaics and Saint Augustine of Hippo's *Confessions*, wine was produced in Algeria in classical times, but viticulture became less evident once ISLAM established itself as the primary form of worship. In the first few decades after French colonization began in 1830, officials typically discouraged viticulture in favour of 'tropical' crops that France did not grow, such as cotton, but such experiments mostly failed. It was not until France's PHYLLOXERA crisis of the 1870s that large-scale wine production in Algeria received official approval and gained momentum. Taking place on lands from which indigenous Algerians had largely been displaced, colonial Algeria's viticulture boom reflected the diverse European origins of its settler population; industry pioneers included colonists of Maltese, Majorcan, and Swiss extraction as well as many regions of France.

Though phylloxera reached Algeria in the 1880s, hitting growers in the east especially hard, by the 1900s Algeria was supplying three-quarters of France's wine imports and was the fourth largest producer in the world. Wealth from the industry, which required extensive vineyard labour as well as work in barrel workshops and ports, had also helped shore up a fragile colonial economy. CO-OPERATIVE wineries were embraced by smaller growers, while bigger producers found influence over the colony's affairs. Muslim Algerians of Arab or Berber ethnicity increasingly performed the basic manual tasks in the vines, though colonial producers often undercut requests for higher wages by using convicts or cheaper labour from neighbouring MOROCCO.

France came to rely on Algerian wine to provide its everyday blended red (and some smarter wines) with strength, colour, and concentration—attributes lacking in the ARAMON then grown so prolifically in the LANGUEDOC. Yet southern French vignerons increasingly perceived Algerian production as unfair competition as the colony's vineyard underwent a major expansion in the 1920s. Colonial representatives in the French parliament successfully resisted the southern wine lobby's attempts to impose a quota on imports,

which entered France duty-free as Algeria was considered an integral part of France. Meanwhile the first wine tankers, introduced in the mid 1930s, sparked opposition among port and barrel workers in Algeria and in French receiving ports such as Rouen and Sète, who saw these ships as a threat to their livelihoods. Following the Second World War, tankers would ship most of Algeria's wine across the Mediterranean in steel containers.

Vineyards reached their greatest extent of 400,000 ha/988,400 acres in 1935, and in the final decades of French rule wine often accounted for close to half of Algeria's exports by value. The interruption of maritime traffic to France during the Second World War, however, underlined the industry's dependence on the metropole, while labour disputes revealed a restless Algerian workforce as anti-colonial nationalism spread. During the war for independence that began in 1954, vineyard operations often took place under armed guard as vines became a target of insurgents. French forces sometimes detained Algerian suspects in wine vats, resulting in several instances of mass suffocation. Yet protective measures continued to ensure healthy profits for big producers.

Some wealthier owners had already bought vineyards in choice regions of France before 1962, but a near-total European exodus followed Algeria's independence that year. The eastern plains of CORSICA proved one popular destination for colonists eager to continue large-scale viticulture. Algeria's vineyards were nationalized and passed into a form of collective agriculture, but the sudden loss of expertise and ageing vines hurt production, and political disputes made the French market unreliable. A 1968 deal with the Soviet Union offered an alternative outlet, but the agreement did not reflect production costs. As oil and gas provided new streams of revenue, in 1971 Algeria's government began a major project of uprooting vines. In 1985, the country failed to produce more than one million hl/26.4 million gallons for the first time in a century, while Islamists placed new pressure on growers to abandon viticulture during the country's civil war of the 1990s.

Geography, climate, and industry structure

Algeria's climate is similar to much of southern Spain, with mild winters and hot, dry summers, indeed increasingly so due to CLIMATE CHANGE. In colonial times a high proportion of the wine was produced on plains such as the Mitidja south of Algiers, but the vines that remain—less than 75,000 ha/186,000 acres in 2021—are often in hillier areas in the vicinity of towns such as Aïn Témouchent, Mascara, Mostaganem, Sidi Bel Abbès, and Tlemcen in the west and Médéa in the centre. High-volume, heat-tolerant varieties favoured by colonists such as CARIGNAN, CINSAUT, and ALICANTE BOUSCHET continue to predominate but have been joined by INTERNATIONAL VARIETIES such as Syrah and Cabernet Sauvignon. The former state wine company, which helped rescue the industry during the civil war, continues to operate as SOTRAVIT (Société de Transformation des Produits Viticoles), but a private company, Grands Crus de l'Ouest, shows more dynamism, producing wine in facilities built in the colonial era. The derelict wineries that are a common sight along the country's roads, however, represent a truer picture of the industry's fall. Once the world's biggest wine exporter, since the 2010s Algeria has become a net importer. O.W.

Alicante , city on Spain's Mediterranean coast long associated with strong, rustic wines which now gives its name to a denominated but shrinking wine zone of 9,100 ha/21,800 acres. This DO extends from the city towards YECLA on the foothills of Spain's central plateau (see map under SPAIN) and allows eight styles of wine including DOBLE PASTA, fortified wines, and a SOLERA-aged wine called FONDILLÓN, a speciality of the region made from very sweet, deliberately overripened grapes. A coastal subzone, the Marina Alta, produces mostly white MUSCAT-based wines. The climate becomes progressively hotter and the landscape more arid away from the coast and YIELDS rarely exceed 20 hl/ha (1.1 ton/acre). The principal grape variety is the red MONASTRELL (Mourvèdre). Other red varieties well suited to the

MEDITERRANEAN CLIMATE include GARNACHA and BOBAL. Ninety per cent of the region's wine is produced in CO-OPERATIVES.

Alicante is also a synonym for Garnacha Tintorera, or ALICANTE BOUSCHET, in Spain and is even sometimes used as a synonym for GRENACHE. R.J.M., V. de la S. & F.C.

Alicante Bouschet, often known simply as Alicante and sometimes as Alicante Henri Bouschet, is the most widely planted of France's red-fleshed TEINTURIER grape varieties although total French plantings had declined to 2,460 ha/6,079 acres by 2018, mainly in the Languedoc and Roussillon.

It was bred between 1865 and 1885 by Henri BOUSCHET from his father's crossing of Petit Bouschet with the popular Grenache, then often known as Alicante, and was an immediate success thanks to its deep-red flesh.

Alicante Bouschet also played a major role in late 19th and early 20th century viticulture as parent of a host of other *teinturiers*, the products almost exclusively of crossings with non-VITIS-VINIFERA varieties. In the second half of the 20th century it profited from its status as the sole *teinturier* to be a *vinifera*, and it is therefore officially sanctioned by the French authorities.

Outside France it is most widely cultivated in Spain, where it is also known as Garnacha Tintorera and where plantings totalled 35,562 ha/87,876 acres in 2020. It is particularly common in CASTILLA-LA MANCHA and GALICIA. The total area planted in Portugal is much smaller (6,458 ha/15,958 acres in 2020), but the variety seems more at home here than in France and can make wines as celebrated as Mouchão in the ALENTEJO.

Alicante is widely grown around the world but nowhere else in any great quantity.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Aligoté, Burgundy's 'other' white grape variety, may be very much Chardonnay's underdog, but it is clearly a beneficiary of CLIMATE CHANGE. In a fine year, when ripeness can compensate for its characteristic ACIDITY, Aligoté is not short of champions, most notably Les Aligoteurs, an association of producers established in 2018. It is one of the many PINOT × GOUAIS BLANC natural crosses, therefore a sibling of Chardonnay, and was recorded in Burgundy at the end of the 18th century.

The vine is vigorous and its yield varies enormously according to the vineyard site. If grown on Burgundy's best slopes on the poorest soils in warmer years, Aligoté could produce fine dry whites with more nerve than most Chardonnays, but it would not be nearly as profitable.

In the CÔTE D'OR it is far less important than Chardonnay and Pinot Noir, but there was still a total of 1,974 ha/4,878 acres in greater Burgundy in 2018, including 616 ha/1,522 acres in the Côte d'Or. It was largely relegated to the highest and lowest vineyards, where it produced light, early-maturing wines allowed only the Bourgogne Aligoté appellation and traditionally mixed with blackcurrant liqueur as a KIR. However, ambitious producers, treating it with greater respect, are making outstanding wines with long ageing potential. Only the village of Bouzeron in the Côte CHALONNAISE, where some of the finest examples are produced, has its own appellation for Aligoté, in which the maximum yield is only 45 hl/ha (2.5 ton/acre) as opposed to the 60 hl/ha allowed for Bourgogne Aligoté. A little is grown by burgundy enthusiasts in the New World, but it is extraordinarily popular (and rarely tart) in Eastern Europe, where Moldova, Romania, Ukraine, and Bulgaria grow thousands of hectares of it, and it is also a common feature in Russian and Kazakhstani vineyards. J.E.H. & J.V.

Alisos Canyon, young California AVA (2020) of sandy hills just south of the town of Santa Barbara specializing in SYRAH and other Rhône varieties. See SANTA BARBARA.

allergies and intolerances. A key difference between allergy and intolerance is that allergic reactions have an immunological basis, while those due to other mechanisms are classed as intolerances. Intolerance of wine is far more common than true allergy to wine or grapes. The most common allergens, substances capable of causing an allergic reaction, are proteinaceous compounds. Among possible allergens in wines are traces of natural PROTEINS not precipitated and removed with the dead yeast cells after FERMENTATION, and traces of proteins from FINING agents used to clarify and stabilize the wine. Pollen-food allergy syndrome affects those severely sensitized to pollens which cross-react with similar proteins in fruit skins, causing oral itching. Grape allergy appears to be largely found around the Mediterranean, associated with specific heat- and acid-stable plant proteins. Even traces of wasp venom found in wine have been reported to cause reactions.

BIOGENIC AMINES, including HISTAMINE, tyramine, and putrescine, are produced chiefly by LACTIC ACID BACTERIA not ordinarily involved in MALOLACTIC CONVERSION. Above individual toxicity thresholds, these compounds can trigger a wide range of wine intolerance symptoms including headache or migraine and are typically at higher concentrations in red wines.

SULFUR DIOXIDE may be a cause of so-called 'white-wine allergy' (strictly speaking an intolerance), and some percentage of asthmatics are particularly sensitive to SULFITES. Although sulfur dioxide is used in both red and white wines, whites typically have both higher sulfite levels and more acidity (which increases its release from solution), resulting in airway irritation and wheezing for those sensitive to this.

Some people, particularly members of certain ethnic groups, experience symptoms such as facial flushing and rapid pulse after consuming even limited amounts of ETHANOL in any form. This alcohol intolerance is due to genetic variations in one or both enzymes involved in the metabolism of alcohol, alcohol dehydrogenase and acetaldehyde dehydrogenase, which together less efficiently process ethanol, resulting in adverse effects of intermediate toxic metabolites.

Allier is the name of a *département* in central France best known in the world of wine for its OAK, although it is also home to the wines of ST-POURÇAIN.

alluvium, a type of sediment which is deposited by flowing water on floodplains, in riverbeds, in deltas, and in estuaries, often derived from many different and distant sources. Soils formed on alluvial sediments are typically fertile and varied in texture, with particle sizes ranging from CLAY to SILT, SAND, and sometimes GRAVEL or boulders. Variations in DRAINAGE and age can often be seen over a few metres of distance and a few centimetres of depth. Where these soils are stony or sandy, with rapid drainage and generally low water-holding capacity, they are highly valued for viticulture, as in the MÉDOC region of France and Marlborough in NEW ZEALAND. However, vineyards planted on these soils are often variable in VIGOUR, making their management more difficult. Alluvial fans are formed when a side stream emerges from the mountains flanking a valley and abruptly slows down, depositing alluvium in a fan-shaped area.

R.E.S. & R.E.W.

almacenista, from the Spanish word *almacén* meaning 'store', is the term for a SHERRY stockholder who sells wine to shippers. In the last decades, as the supply needs of the big houses diminished due to low sales and as the requirements for putting wine directly in the market loosened up, most almacenistas began bottling their wines under their own labels. It has been used as a marketing term by the

sherry firm of Lustau, who sells a range of wines under the Almacenista label. J.B.

Almansa, DOP in the eastern corner of CASTILLA-LA MANCHA in central Spain (see map under SPAIN) with 7,200 ha/17,792 acres under vine. It borders the regions JUMILLA and YECLA, which produce similarly strong, sturdy red wines, traditionally used for blending but increasingly sold in bottle, principally from MONASTRELL and GARNACHA TINTORERA grapes, although SYRAH is increasingly planted. The climate is extreme, with temperatures of 40 °C/104 °F in summer and below freezing in winter. V. de la S. & F.C.

Aloxe-Corton, a small village of charm at the northern end of the Côte de BEAUNE in Burgundy. First references to vineyards in Aloxe date back to 696, while in 775 CHARLEMAGNE ceded vines to the Abbey of St-Andoche at Saulieu. Aloxe is dominated by the hill of Corton, planted on three sides with vineyards including the GRANDS CRUS Corton (almost all red) and Corton-Charlemagne (white).

Corton is the sole grand cru appellation for red wine in the Côte de BEAUNE and covers several vineyards which may be described simply as Corton or as Corton hyphenated with their names. While all Corton wines tend to be dense and closed when young, those from Bressandes are noted for their comparative suppleness and charm; Renardes for rustic, gamey character; Perrières for extra finesse; and Clos du Roi for optimum balance between weight and elegance. Other Corton vineyards are Le Charlemagne, Les Pougets, and Les Languettes, all of which more often produce white Corton-Charlemagne, and Les Chaumes, Les Grèves, Les Fièvres, Les Meix, La Vigne au Saint, and part of Les Paulands and Les Maréchaudes. Further Corton vineyards extend into LADOIX-Serrigny.

Although Corton is planted almost entirely with Pinot Noir vines, a small but increasing amount of white Corton is made, including the HOSPICES DE BEAUNE cuvée Paul Chanson.

The great white wines, however, are those made within the Corton-Charlemagne appellation (58 ha/143 acres), which stretches in a narrow band around the top of the hill from Ladoix-Serrigny, through Aloxe-Corton to PERNAND-VERGELESSES, where it descends down the western edge of the hillside. The MESOCLIMATE governing Corton-Charlemagne is fractionally cooler than that of Corton and the soils are different. Whereas red Corton is mainly produced on reddish chalky clay, the soil at the top of the hill and on the western edge is lighter and whiter, its stoniness believed locally to impart a gunflint edge to the wines of Corton-Charlemagne. Chardonnay has entirely replaced the once widely planted Pinot Blanc, Pinot Beurot (see PINOT GRIS), and ALIGOTÉ, though some would favour a return of the latter.

A great Corton may seem ungainly in its sturdiness when young but should have the power to develop into a rich wine with complex, gamey flavours at eight to ten years old. Cortons should, with POMMARD, be the most intense and longest-lived wines of the Côte de Beaune. Corton-Charlemagne also needs time to develop its exceptional character and racy power. Needing a minimum of five years, a good example will be better for a full decade in bottle.

Although more than half the vineyard area is given over to the grands crus, Aloxe-Corton also has its share of PREMIER CRU and village vineyards producing mainly red wines which can be supple and well coloured but mostly do not justify their significant premium over the wines of SAVIGNY-LÈS-BEAUNE. Apart from Les Guérets and Les Vercots, which are adjacent to Les Fichots in the commune of Pernand-Vergelesses, the premiers crus of Aloxe-Corton form a band just below the swathe of grand cru vineyards, extending into Ladoix-Serrigny.

See CÔTE D'OR and map under BURGUNDY. J.T.C.M.

Chapuis, C., *Aloxe-Corton* (1988), in French.

Alpilles, IGP for still red, rosé, and white wines covering the craggy LIMESTONE slopes of the Alpilles massif near St-Rémy-de-Provence in

the Bouches-du-Rhône *département* of France. The IGP has received particular attention in recent years thanks to leading producer Domaine de Trévallon, whose use of a robust amount of Cabernet Sauvignon in their wines makes them ineligible for the local AOC, LES BAUX DE PROVENCE.

Alpine Valleys in Australia's North East Victoria Zone lies immediately east of KING VALLEY and encompasses inter alia the Ovens, Buffalo, Kiewa, and Buckland Valleys. Annual rainfall is surpassed only by parts of TASMANIA. Main varieties are Prosecco (aka GLERA), Chardonnay, and Pinot Noir. See VICTORIA. E.N.H.M.

Alsace, historically much-disputed region now on the eastern border of France, producing a unique style of largely VARIETAL wine, about 90% of which is white. For much of its existence it has been the western German region Elsass. Now separated from Germany by the river RHINE and from the rest of France by the Vosges Mountains, the language and culture of Alsace owe much to both origins but are at the same time unique. Many families speak Alsacien, a dialect particular to the region, quite different from either French or German.

Of all the regions of France, this is the one in which it is still easiest to find villages outwardly much as they were in the Middle Ages, with traditional half-timbered houses and extant fortifications. The hilltops of the lower Vosges are dotted with ruined castles and fortresses, witnesses to past invasions.

Of more than 4,000 grape-growers, about 950 bottle wine, but more than 60% of total production is sold by one of the 20 biggest NÉGOCIANTS and CO-OPERATIVES. Even the large companies are usually family-owned, however.

All still Alsace wines are, by law, bottled in the region of production in tall bottles called *flutes*.

History

For details of the history of the region pre-17th century, see GERMAN HISTORY. Annexed by France in the 17th century, Alsace was reclaimed, with part of Lorraine, by the new German empire in 1871. Shortly after, the twin crises of oïdium (POWDERY MILDEW) and PHYLLOXERA struck. In the aftermath, winegrowers largely abandoned the HILLSIDE sites and planted HYBRIDS on flat, easily accessible land to give large, trouble-free crops.

It was not until after the First World War, when Alsace returned to French rule, that up to one-third of the hillside sites were replanted with VITIS VINIFERA varieties. A setback occurred with the Second World War, when export was impossible, and the area was once more overrun by Germany. Replanting of the better sites gathered momentum in the 1960s and 1970s, when Alsace again started to build up export markets.

Geography and climate

Alsace lies at LATITUDE 47.5–49° N, allowing for a long, cool growing season. The region's vineyards are largely confined to a narrow strip running 100 km/62 miles from north to south along the eastern flank of the Vosges Mountains (see map under GERMANY), spanning the two *départements* of Haut-Rhin and Bas-Rhin. Most large producers are based in the more southerly Haut-Rhin, which is generally associated with better quality, especially for Alsace's characteristic Gewurztraminer (spelt Gewürztraminer in Germany) and Pinot Gris.

Thanks to the protection of the mountains, average annual RAINFALL is one of the lowest in France: 594.4 mm/23.4 in in Colmar, the region's centre. Most vineyards are at an ELEVATION of 175–550 m/574–1,804 ft, above which level much of the mountainside is covered with pine forests. Autumn humidity allows for the production of late-picked VENDANGES TARDIVES and SÉLECTION DE GRAINS NOBLES wines (see below) in good vintages.

Within the wine region, there are at least 20 major soil formations, covering several eras. Higher, steeper slopes of the Vosges have thin topsoil, with subsoils of weathered GNEISS, GRANITE, SANDSTONE, SCHIST, and VOLCANIC sediments. The gentler lower slopes, derived from the Rhine delta bed, have deeper topsoils, over subsoils of CLAY, MARL, LIMESTONE, and sandstone. One of the most important subsoils is the pink *grès de Vosges*, Vosges sandstone, which was used extensively in the construction of churches and cathedrals and which is much in evidence in Strasbourg. The plains at the foot of the Vosges are of ALLUVIAL soils, eroded from the Vosges, and are rich and fertile, generally more suited to the production of crops other than vines.

Winters can be very cold, spring is generally mild, and the summer is warm and sometimes very dry, with heavy HAIL and thunderstorms possible in summer and autumn. In some vintages summer DROUGHT can be a problem, and younger vines planted in the drier, sandy soils can suffer, whereas vineyards on the water-retentive clay soils have an advantage.

As a general rule, the heavier clay and marl soils give a wine with broader flavours and more body and weight, while a lighter limestone or sandy soil gives more elegance and finesse. Flint, schist, shale, and slate soils tend to give wines a characteristic oily, minerally aroma reminiscent of petrol and sometimes described as ‘gunflint’, especially those made from the Riesling grape.

Vine varieties

At the beginning of the 20th century, the many varieties planted in Alsace were divided into 'noble' and others. Today the region produces seven major VARIETAL wines: RIESLING, Gewurztraminer (Gewürztraminer in German), Pinot Gris, Pinot Noir, Pinot Blanc, Muscat, and Sylvaner. CHASSELAS is also planted but is generally used for blending, and only a handful of producers still bottle it as a varietal wine. AUXERROIS is usually blended with and labelled as Pinot Blanc. There is also a small amount of Chardonnay, forbidden by law but tolerated when labelled as Pinot Blanc or used in the sparkling wine CRÉMANT d'Alsace. Savagnin Rosé is allowed only in KLEVENER DE HEILIGENSTEIN.

Riesling Riesling is Alsace's most esteemed and widely planted variety, accounting for 21% of the area under vine in 2019. It is nearly always presented in a bone-dry style. Young Riesling can display floral aromas, although it is sometimes fairly neutral. With age it takes on complex, gunflint, mineral aromas, with crisp steely acidity and very pure fruit flavours.

Gewurztraminer Gewurztraminer is grown on almost as much land as Riesling but usually represents a smaller percentage of the production; its average yield is the smallest of all the varieties. The largest plantations of Gewurztraminer are in the Haut-Rhin. Its wines are usually dry to off-dry, but its low ACIDITY, combined with high alcohol and GLYCEROL, often gives an impression of sweetness. Gewurztraminer has a distinctive aroma and flavour, floral and spicy, with hints of lychee and grapefruit. Its naturally high sugar levels make it ideal for late-harvest sweet wines, and this is the most frequent variety used in Vendange Tardive wines. Poorly made examples can be blowsy, flat, over-alcoholic, sometimes oily, but the finest can be firm and full-bodied, with notes of bacon fat, leather, and roses.

Pinot Gris Once known as Tokay-Pinot Gris or Tokay d'Alsace, Pinot Gris has been the only permitted name on labels since 2007 according to an agreement between Hungary and the EU. The pink-skinned grape accounted for more than 16% of plantings in 2019. Young Pinot Gris is reminiscent of peaches and apricots, with a hint of smoke, developing biscuity, buttery flavours with age. With its firm backbone of acidity, it can make particularly successful Vendange Tardive wines.

Muscat Alsace grows both MUSCAT BLANC À PETITS GRAINS, known as Muscat d'Alsace, and MUSCAT OTTONEL, which together make up barely 2% of vineyard area. Wines labelled Muscat d'Alsace tend to be a blend of the two and are always dry, with a fresh grapey aroma and flavour. Low in alcohol and acidity, it rarely ages well but makes a

charming aperitif. Because of its sensitivity to poor weather at flowering, yields can vary considerably from year to year.

Sylvaner Sylvaner has been losing ground to Riesling, as it is difficult to grow, needs a good site and a warm vintage, yet fetches comparatively little money. By 2019, it accounted for only 5% of Alsace's vineyard area, with higher proportions in the Bas-Rhin than the Haut-Rhin. Good Sylvaner has a slightly bitter, slightly perfumed flavour, with very firm acidity. It has moderate alcohol and is at its best when it is young and fresh.

Pinot Blanc Also labelled Clevner or Klevner, Pinot Blanc is the workhorse of Alsace. As well as forming the base wine for Crémant d'Alsace, Pinot Blanc can produce very good, clean, dry white that is not particularly aromatic but has good acidity, with moderate alcohol. Pinot Blanc and the more common Auxerrois, with which it is frequently blended, accounted for 21% of Alsace's vineyard area in 2019.

Edelzwicker German for 'noble mixture', Edelzwicker indicates a blend of more than one variety, vinified together or separately. Contrary to the name, it is generally one of the cheapest wines in the range, with Chasselas, Pinot Blanc, and Auxerrois common ingredients.

Gentil This term is reserved for AOC Alsace wines comprised of at least half Riesling, Muscat, Pinot Gris, and/or Gewurztraminer, with the make-up Chasselas, Pinot Blanc, and/or Sylvaner. Also, unlike Edelzwicker, each variety must be vinified separately before blending, and the wines must be vintage-dated.

Pinot Noir Pinot Noir represented 11% of the total vineyard area in 2019. It has been deepening in flavour and colour thanks to CLIMATE CHANGE. It is currently the only red grape allowed as a varietal wine in AOC Alsace, though several producers, led by René Muré, are now growing SYRAH, bottling it under the generic VIN DE FRANCE.

See also KLEVENER DE HEILIGENSTEIN.

Viticulture

The varied styles of training in use depend partly on the steepness of the vineyard. Either single GUYOT, with up to 15 buds left on the cane, or double Guyot, with up to eight buds on each cane, may be found, with a VINE DENSITY of 4,400–4,800 vines per ha (1,940 per acre). There are also some CORDON-trained vines, with SPUR PRUNING, generally on older vines. Yield limits vary by variety and denomination.

Vines are generally trained at a height of 60–90 cm/35 in above ground, depending on the site. Vines on the plain are generally trained high to avoid FROSTS, while sloping vineyards can be trained closer to the ground, benefiting to the maximum from the available SUNLIGHT.

The steepest vineyard slopes may be TERRACED, as for example the GRAND CRU sites of Rangen and Kastelberg, or vines may be planted in rows either following the contours of the slope or vertically from top to bottom, depending on the risk of SOIL EROSION. COVER CROPS may be planted to prevent erosion and to give more of a grip to tractors on moderate slopes.

Although MECHANICAL HARVESTING is common on the plains, many vineyards are too steep for machines, and many grapes are still hand-picked. The vintage is always protracted, with varieties ripening at different times. Generally, harvesting starts in mid September and often continues well into November.

A few growers have experimented with late-picked, BOTRYTIZED wines, not merely for the four varieties permitted for the late-harvest wines described below but also with such diverse varieties as Auxerrois and Sylvaner, which can make outstanding wines. One or two growers produce a small quantity of VIN DE PAILLE, from healthy, ripe grapes picked in October and dried on straw over the winter months. There have also been experiments with EISWEIN, from healthy grapes picked in December or even early January.

Winemaking

As in Germany, winemakers measure the sugar content of the grapes, or MUST WEIGHT, in degrees OECHSLE. CHAPTALIZATION, always outlawed for late-harvest wines (see below) and, since 2011, for AOC Alsace Grand Cru, is now relatively rare, even for AOC Alsace, thanks to CLIMATE CHANGE. Indigenous YEASTS are generally sufficient, and few winemakers add yeast cultures, except in an abnormally wet vintage. ACIDIFICATION is not practised.

The number of different varieties, all to be vinified separately, can present a logistical problem. Small operations with one PRESS (usually a bladder press, which gives cleaner juice) will organize picking to allow each variety sufficient time in the press before the next variety is picked.

For white wines, most winemakers prefer to prevent MALOLACTIC CONVERSION by keeping them cool and lightly sulfured, although this is changing, as winemakers have found that it does not seem to alter the quality or keeping ability of the wines. Pinot Noir needs to go through malolactic to soften and STABILIZE the wine and is therefore often kept in an isolated part of the cellar to prevent cross-contamination from LACTIC ACID BACTERIA.

Because over 90% of the wine is white, and because winemakers are emphasizing the primary grape flavours, most wine is vinified and stored in inert containers. Traditional cellars have large oval wood casks, many over 100 years of age, literally built into the cellar. Traditionally the same cask will be used each year for the same varietal. The build-up of TARTRATES forms a glass-like lining to the cask, and there is no likelihood of oak flavours masking the wine's character. If a cask has to be replaced, the new cask will be well washed out to remove as much as possible of the OAK FLAVOUR and will be used for Edelzwicker until all oak flavours have disappeared. A few growers are experimenting with BARREL MATURATION, most widely for Pinot Noir but also occasionally with Pinot Blanc, Pinot Gris, Auxerrois, and even Sylvaner.

The cellars are generally quite cold by the time FERMENTATION is taking place, so many have no cooling system. Winegrowers have found that the BOUQUET and AGEING potential of Riesling, Sylvaner, and Muscat can be enhanced by fermenting at 14–16 °C/61 °F, while Gewurztraminer will take a warmer temperature of up to 21 °C/70 °F. Most wines are bottled within a year of the vintage to retain freshness.

Most Alsace wines are fermented dry. Around the turn of the 21st century some of these supposedly dry wines had perceptible RESIDUAL SUGAR that was difficult to predict from the label, but starting with the 2021 harvest all Alsace wines indicate SWEETNESS on the label, whether in words or an indication on a visual scale. The residual sugar content for *sec* (dry) wines must be less than 4 g/l; *demi-sec* range from 4 to 12 g/l; *moelleux* run from 12 to 45 g/l, and *doux* exceed 45 g/l.

The late-harvest wines

While Alsace winegrowers very occasionally make VIN DE PAILLE and *vin de glace* (see EISWEIN), most late-harvest wines fall into two styles, Vendange Tardive and Sélection de Grains Nobles, defined by law in 1983.

Vendange Tardive, or Vendanges Tardives Late-picked wines have always been produced in Alsace in small quantities in outstanding vintages. To be labelled as Vendange Tardive, a term to which Alsace producers claim exclusive rights in France, a wine must come from a single vintage, from one of the four permitted varieties Riesling, Muscat, Gewurztraminer, or Pinot Gris. The wine must not be ENRICHED in any way, and the minimum sugar concentration at harvest must be 244 g/l (93 °Oechsle) for Riesling or Muscat, and 270 g/l (103 °Oechsle) for Gewurztraminer or Pinot Gris. Picking must take place after a certain date, determined annually by the authorities, who must be informed beforehand of the grower's intention to pick a Vendange Tardive wine and may inspect the vineyard at the time of picking to check the sugar concentration and quantity produced. The wine must also undergo an analysis and tasting after bottling, before the label is granted. Vendange Tardive wines do not have to be BOTRYTIS-affected. The most common variety for Vendange Tardive wines is Gewurztraminer, which can easily attain very high sugar levels. Muscat is the rarest of all and is only possible in occasional vintages. Vendange Tardive wine is not necessarily sweet and may vary from bone dry to medium sweet. Quality varies as widely as sweetness levels.

Sélection de Grains Nobles SGN is a further refinement of Vendange Tardive, where the grapes have reached even higher sugar levels. Wines labelled as Sélection de Grains Nobles, however, nearly always contain a proportion of grapes affected by botrytis, or NOBLE ROT, picked by hand, generally involving several passages through the vineyard. The same four varieties are permitted, with minimum sugar levels of 276 g/l (105 °Oechsle) for Riesling and Muscat, and 306 g/l (117 °Oechsle) for Gewurztraminer and Pinot Gris. The same legislation as for Vendange Tardive governs production (see above). Sélection de Grains Nobles wine is always sweet, although there is a variation in richness and quality, depending on the grape and the grower.

The appellations Alsace was awarded AOC status in 1962, with the one regional appellation Alsace, or Vin d'Alsace. In 2011 a further two appellations were introduced which may complement the general AOC Alsace:

AOC Alsace communales This denomination is stricter than the regional appellation, and specifies grape variety, VINE DENSITY, PRUNING, VINE TRAINING, and ripeness levels (MUST WEIGHTS). YIELDS for white wines are also lower than those for the general Alsace AOC, at 72 hl/ha as opposed to 80; reds are the same, at 60 hl/ha. The following 13 communes, or inter-communal entities, may be mentioned on the label, alongside 'AOC Alsace': Bergheim, Blienschwiller, Côtes de Barr, Côte de Rouffach, Coteaux du Haut-Koenigsbourg, KLEVENER DE HEILIGENSTEIN, Ottrott, Rodern, St-Hippolyte, Scherwiller, Vallée Noble, Val St-Grégoire, and Wolxheim.

AOC Alsace lieux-dits These are wines which express combinations of grape variety and certain terroirs and have stricter requirements than the AOC communales, including lower yields for white wines (68 hl/ha). Wines from these *lieux-dits* express primary fruit characters of individual grape varieties with nuances specific to the terroir.

Alsace Grand Cru The Alsace Grand Cru classification was first defined in 1975 with Schlossberg, a steep, south-facing site above Kayserberg with a history of grape-growing that dates to Roman times. Originally, an Alsace Grand Cru wine had to come from a single named vineyard site, or *lieu-dit*, and a single vintage, and it also had to be made from Riesling, Muscat, Gewurztraminer, or Pinot Gris. Subsequent expansions in 1983, 1992, and 2007 have seen 51 vineyards granted Grand Cru status; blends may also be allowed at the discretion of each Grand Cru's management committee. In 2022, Pinot Noir became eligible for Grand Cru status as well, in the Kirchberg and Hengst vineyards.

The wines from these vineyard sites make up only 4% of Alsace's total production but are the subject of some vigorous debates. Some grand cru sites are of only moderate quality or cover an unreasonably large area, including a number of soils and ASPECTS, some greatly superior to others. Much depends on the attitude of the grower, too: Many growers and co-operatives are producing wines of average quality, cashing in on the grand cru name. Because of this, some winegrowers have eschewed the appellation in favour of their superior brands. Beyer's Riesling Cuvée Particulière, from the Grand Cru Pfersigberg, and Trimbach's Clos Ste-Hune, grown in a parcel within the Rosacker Grand Cru, are prime examples.

Crémant d'Alsace The appellation Crémant d'Alsace was created in 1976 and amended in 2011, formalizing the sparkling wines that had long been made in the region. By 2020 Crémant d'Alsace represented 29% of all AOC wines made in Alsace. Pinot Blanc is by the far the most significant ingredient, although Pinot Gris, Auxerrois, Riesling, and Chardonnay are also used, and Pinot Noir is the only variety allowed for Crémant d'Alsace rosé. As with the late-harvest wines, growers have to identify before the start of harvest which parcels of vines are destined for Crémant d'Alsace production. See also CRÉMANT.

Alta Langa. See LANGHE.

Alternaria, vine disease. See BUNCH ROTS.

alternative packaging for wine is slowly becoming more common, for reasons of convenience, economy, and/or SUSTAINABILITY. Glass BOTTLES are still by far the most common, but see also BOXES, CANS, CARTONS, KEGS, PAPER BOTTLES, PLASTIC BOTTLES, and POUCHES.

alternative varieties, Australian name for VINE VARIETIES other than the best-known INTERNATIONAL VARIETIES. They even have their own wine SHOW in Australia.

Altesse, SAVOIE's finest white grape variety, once known as ROUSSETTE, the name of several associated wines in Savoie and BUGEY.

The variety buds early and is therefore frost-prone, but it ripens late. It resists rot well, and the wine produced is relatively exotically

perfumed, has good acidity, and is well worth ageing. Total plantings had grown to 424 ha/1,048 acres by 2019.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (London, 2012).

altitude, a term commonly used to describe the ELEVATION of a vineyard. While the terms are used interchangeably, altitude—used typically by pilots—actually refers to height above the Earth's surface whereas elevation refers to the height above sea level.

Alto Adige, the alpine and most northerly part of Italy which shares with its neighbour TRENTINO a preponderance of INTERNATIONAL VARIETIES and the absence of a detailed DOC system. With the Austrian Tyrol to the immediate north, its culture is firmly Germanic and its first language is German. Officially known as Südtirol–Alto Adige, and part of Austria until it was annexed by Italy after the First World War, the region owes the Italian part of its name to the River Adige (Etsch), flowing south-east to the Adriatic. At the capital Bolzano the Adige is joined by the Isarco (Eisach) River from the north-east, forming a y-shaped valley on whose slopes viticulture has been practised for millennia. Vineyards are planted at 300–1,000 m/3,280 ft, while the valley floor is reserved for large-scale apple production, which has become so lucrative it has begun to supplant vineyards on lower-lying slopes, too.

Viticulture at dizzying heights is a serious option since the Alps protect Alto Adige from cold winds from the north, while the steepness of the slopes creates excellent ASPECTS for long, slow grape ripening. Due to CLIMATE CHANGE, several producers, notably Franz Haas, campaign for a general allowance for vineyards over 900 m, which, with few exceptions, are outlawed. Marked DIURNAL TEMPERATURE RANGE helps to retain acidity in the grapes, resulting in the fresh, appetizing whites for which the region is especially known. Some districts, notably around the towns of Merano and Bolzano

where the dark-skinned LAGREIN and especially Vernatsch (SCHIAVA) are cultivated, even enjoy a sub-MEDITERRANEAN climate.

International grape varieties, introduced in the 19th century under Hapsburg rule, are the norm here. Pinot Grigio, with 662 ha/1,635 acres, is the region's most planted variety, at the cost of Vernatsch (635 ha), closely followed by GEWURZTRAMINER, CHARDONNAY, and PINOT BIANCO. Although KERNER claims only 115 ha/284 acres, it is set to become the next big thing, with a reputation for high-quality white wines.

Over the last 40 years, red wines have lost ground to white wines, which now make up 62% of production. Lagrein, at 486 ha/1,200 acres, has been taken over by Pinot Noir, here called Blauburgunder (494 ha). Its growing popularity has put the spotlight back on Schiava, which once produced pale, early-maturing red wines as a result of overproduction and irrigation but, in the hands of a new generation, now turns out elegant, complex reds, often produced from single vineyards and with WHOLE-BUNCH FERMENTATION.

Nearly two-thirds of Alto Adige production is controlled by CO-OPERATIVES, which process the harvest of hundreds, sometimes thousands, of grape farmers. The power of the co-ops is such that they can dictate the cultivation of certain grape varieties considered marketable. This is the main reason why Alto Adige's INDIGENOUS VARIETIES still receive scant attention. The regulations permit YIELDS up to 14 tonnes/ha, and, although high yields were still the norm in the early 2010s, improvements in the vineyard—primarily reduction of aggressive irrigation and use of fertilizers—has led to increased wine quality. While there has been a move from PERGOLA to lower-yielding GUYOT training systems, many old local varieties remain pergola-trained.

Alto Adige has only three DOCs and no DOCG. Valdadige DOC includes the whole of Alto Adige and neighbouring Trentino. Alto Adige DOC exists for the production of international varieties, while five of its six subregions—Colli di Bolzano, Meranese, Santa Maddalena, Valle Isarco, Valle Venosta—are historic Schiava zones,

and the sixth, Terlano, produces exclusively white wines. Lago di CALDARO/Kalterer DOC, south of Bolzano, is exclusively for Schiava.

In a region dedicated to the production of international varietal wines, matching suitable varieties to subzones was never a priority, although there are some exceptions. Bozner Gries, near Bolsano, is locally considered a Lagrein CRU, and Mazzon, near Egna, is considered a Pinot Noir cru, though it is in danger of becoming too hot due to CLIMATE CHANGE. Girlan, its west-facing vineyards immediately south-west of Bolzano, shows increasingly more confidence with Pinot Noir, too. Terlano and VALLE ISARCO have deservedly risen to prominence: the first because of its long-lived Pinot Bianco, the latter because of a handful of small estates producing crystalline wines from vineyards up to 1,000 m. Termeno/Tramin claims to be the cradle of TRAMINER.

In an effort to emphasize the notion of terroir, a list of official *Lagen* or single-vineyard zones, called *menzione geografica aggiuntiva* (MGA) in Italian, has been created, permitting only certain authorized grape varieties. The controversial list more or less reflects the current situation. Producers can still produce any variety they like and bottle it under the plain Alto Adige denomination.

To further strengthen its image as a quality producer, the region has introduced an overarching quality designation, called Gran Alp. Analogous to Gran Selezione in CHIANTI CLASSICO, Gran Alp represents the pinnacle of the quality pyramid of both red and white wines, with more stringent rules on yields and obligatory ageing. But even before it was introduced, its relevance was questioned by the growing number of so-called 'super cuvées', tiny-production, stratospherically priced white wines meant to represent the top of a producer's range as well as of the region as a whole.

Alto Piemonte is the area to the north of Barolo and Barbaresco in Italy's PIEMONTE encompassing a string of small historic denominations producing wine based on NEBBIOLO, often called Spanna here. See also BOCA, BRAMATERRA, CALUSO, CAREMA, FARA, GATTINARA, GHEMME, LESSONA, and SIZZANO. W.S.

Alvarelhão, dark-berried vine planted all over northern Portugal, especially in Dão, Douro, Beiras, and to a limited extent Vinho Verde country. In GALICIA it is also known as Brancellao and makes pale aromatic reds for early drinking.

Alvarinho, the Portuguese name of a distinctive white grape variety grown around the town of Moncão in the extreme north-west of Portugal's VINHO VERDE country (and, as ALBARIÑO, in neighbouring GALICIA). The grapes' thick skins help them withstand the particularly damp climate and can result in wines relatively high in alcohol (12–13%), acidity, and flavour. Alvarinho was one of the first Portuguese varieties to appear on the labels of VARIETAL whites and is therefore one of the best known. Portuguese plantings had reached 3,345 ha/8,266 acres by 2020.

Amador , California county. See SIERRA FOOTHILLS.

Amarone, powerful, red DRIED-GRAPE WINE in the DOC VALPOLICELLA in Italy's north-east. The wine, made of the same grape varieties as Valpolicella, consists of 45–95% CORVINA and/or CORVINONE and 5–30% RONDINELLA. The percentage of Corvinone, more resistant to hydric stress than Corvina, was previously limited to 50% but has been increased as a strategy to mitigate the effect of CLIMATE CHANGE. The blend may also contain up to 25% of other red varieties

authorized in the province of Verona, with a maximum of 10% for each variety.

Strictly speaking, Amarone is a *recioto scapata*, literally a RECIOTO that has escaped and fermented to full dryness when the intention was to produce a sweet wine. The yeast, already struggling with the high sugar content in the MUST, would normally stop working because of rising alcohol levels and before all the sugar had been converted. Stylistically, Recioto della Valpolicella and Amarone are similar, but the latter must be dry with no more than 9 g/l RESIDUAL SUGAR (RS) at 14% alcohol, further allowing an additional 0.1 g RS for every 0.10% between 14% and 16%, and 0.15g for every 0.10% above 16%. The pleasant, bitter (*amaro*) aftertaste explains its name. Amarone is a style; its name must be suffixed by 'della Valpolicella' and can be followed by one of the two subzones, CLASSICO or Valpantena, on the label. By law Amarone must be aged for at least two years, four for wines labelled RISERVA.

Amarone has been produced in commercial quantities only since the 1950s. From the 1980s it has been a roaring success, especially in Scandinavia, Germany, and the United States, and production soared from 8.5 to 15 million bottles between 2005 and 2020. The total Valpolicella vineyard area has also increased, from 5,719 ha in 2000 to 8,200 ha/20,263 acres in 2020. Producers are allowed to transform up to 65% of their total grape production into Amarone, regardless of the quality or provenance of the grapes within the Valpolicella zone, which has resulted in wide quality variation. But proposals to restrict Amarone's production to HILLSIDE sites, and/or reducing production on the plains, have not come to fruition.

By law the grapes for Amarone must be dried at least until the first of the December after the vintage. The drying process results in a metabolization of the acids in the grape and a POLYMERIZATION of tannins in the skins, which explains the richness of good Amarone. The wine should be made from selected superior whole bunches, which are dried or raisined in special drying lodges. Traditionally, the drying of grapes was restricted to the Valpolicella hills, above the autumn fog line, where thermal fluctuation warded off the

development of BOTRYTIS. Grapes were spread out on mats or wickerwork shelving or strung up from the ceiling or rafters. Today, however, most producers pick the grapes directly into plastic crates and dry them in a temperature- and humidity-controlled warehouse. This technical approach, which ensures minimal handling of the grapes, minimizing the risk of damage and consequent development of rot or mould, has resulted in cleaner, more balanced, but also rather formulaic wines, while encouraging the current industrial-scale production of Amarone.

Traditionally, the wines were aged in large BOTTI, although today BARRIQUE ageing is the norm, resulting in wines with a distinctly international style. In the 2010s the pendulum started to swing back, away from heavy OAK influence and towards lower alcohol and little or no residual sweetness (although reportedly only Bolla produces an Amarone with no residual sugar), while also the first AMPHORA-fermented Amarones have appeared on the market. amateur winemaking. See HOME WINEMAKING.

ambient yeast are those that are present in the vineyard and winery, as opposed to inoculated, cultured YEAST.

amelioration, which strictly means 'improvement', is a euphemism for chemical intervention in winemaking with the express purpose of compensating for nature's deficiencies. Thus in cooler wine regions the term is commonly used interchangeably with ENRICHMENT or

CHAPTALIZATION. 'Amelioration' is sometimes used more widely, to include both ACIDIFICATION and DEACIDIFICATION, and sometimes for any chemical adjustment to the constituents naturally present in grape juice or wine. See also MANIPULATION.

American hybrids, group of vine HYBRIDS developed in the eastern United States, mainly in the early and mid 19th century and in some cases earlier but also much more recently with cold hardiness in mind. Brianna, for example, was developed in 1983 by the American private breeder Elmer Swenson and involved no fewer than 93 distinct parents from eight different species. The term includes hybrids between native AMERICAN VINE SPECIES of the genus VITIS and a variety of the European vine species VITIS VINIFERA, resulting in such varieties as Black Spanish (JACQUEZ), NORTON, CONCORD, NIAGARA, HERBEMONT, DELAWARE, and Othello. The hybrids' most common parents are the American species VITIS LABRUSCA and *Vitis aestivalis*, along with *vinifera*.

These varieties are used for wine production, for unfermented GRAPE JUICE and jelly, and for TABLE GRAPES. The fruit is typically highly flavoured, and palates accustomed to the taste of *vinifera* varieties find the FOXY character of products made from many American hybrids strong and objectionable.

See UNITED STATES, history, for more background. Following the devastation wreaked by the pest PHYLLOXERA in Europe at the end of the 19th century, the French began experimental hybridizing of *vinifera* with American species, producing the so-called FRENCH HYBRIDS or 'direct producers'. American vines, loose term for both AMERICAN VINE SPECIES and AMERICAN HYBRIDS.

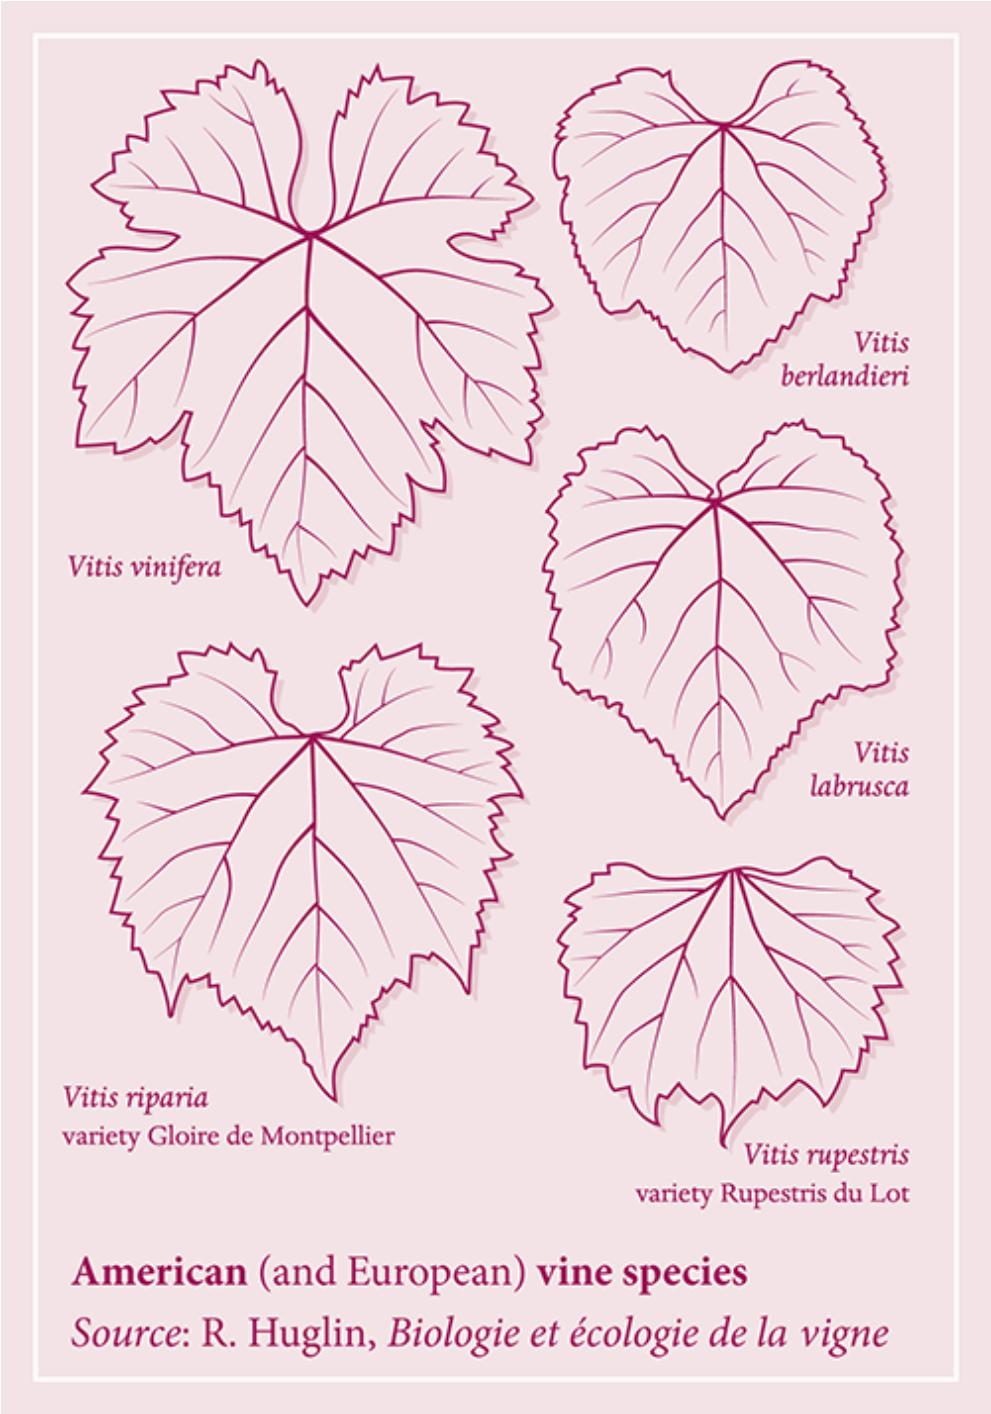
American vine species, those members of the grapevine genus VITIS which originate in North and South America, including Mexico and the Caribbean. About half the vine species of the world are native to America, but they are poorly suited to WINEMAKING. However, when all efforts to grow European vine species VITIS VINIFERA in North America failed through pest, disease, or climatic extreme (see UNITED STATES, history), wine was made in North America of necessity from these species, detailed below.

After the development of AMERICAN HYBRIDS and the successful cultivation of *vinifera* vines in CALIFORNIA and elsewhere in the Americas, native vines were rarely used for wine. A notable exception is *Vitis rotundifolia*, particularly the SCUPPERNONG and related bronze- and black-fruited varieties used for a sweet, musky wine popular in the southern United States, where they are both grown and cultivated.



Vitis vinifera has varied leaf forms among its many varieties, not always with five distinct lobes as shown here.

The most important role for the American species has been to provide the genetic basis for ROOTSTOCKS on to which *vinifera* vines

may be grafted (see MUNSON). This became a necessity in most of the world's wine regions by the end of the 19th century to counter the impact of PHYLLOXERA, native to America and to which most American vine species developed resistance or tolerance. The species *Vitis berlandieri*, VITIS RIPARIA, and *Vitis rupestris* are particularly important as sources of protection against phylloxera, and the great majority of the world's vineyards now grow on rootstocks derived from them.

These are some of the more important American vine species (although others are listed under VITIS):

Vitis labrusca Vine species found in the north-eastern United States producing highly aromatic and strongly flavoured berries sometimes described as FOXY. The berries fall easily from the cluster when mature and are called 'slip-skin', in that a berry squeezed between fingers will eject the flesh as a complete ball (non-slip-skin varieties, which are more usual, are squashed when squeezed in this way). Most of the fruit of this species is black, and the leaves are large, thick, and covered on the lower surface with dense white or brown hairs. *Labrusca* is a common parent in American hybrids, including CONCORD and CATAWBA.

Vitis aestivalis Vine species found in the southern and eastern United States which, like *labrusca*, is a common parent in American hybrids. The fruit, typically black, is not strongly aromatic, and the berries adhere to the cluster when mature. This species shows good resistance to DOWNY MILDEW and POWDERY MILDEW and is therefore a common parent in VINE BREEDING programmes. NORTON, which has a reputation for high-quality wine in VIRGINIA, where it was bred, is a hybrid derived from *aestivalis*. Early Spanish settlers of north-eastern MEXICO made wine from WILD VINES of this species as early as 1597.

Vitis riparia This vine species is widely distributed in eastern North America, from Canada to the Gulf of Mexico. The grapes are not strongly aromatic, with black skin and highly acidic juice. *Riparia* is used directly as a rootstock and as a parent of many commercially important rootstocks; the species typically imparts low to moderate vine size to SCIONS and provides protection against phylloxera.

Vitis rupestris Unusual vine species that grows as a small shrub, found typically on gravelly banks of streams or in watercourses in Texas, Oklahoma, Arkansas, and Missouri. The leaves are small and kidney-shaped, and roots tend to grow vertically downwards rather than spreading horizontally. It is a common parent of many commercially important rootstocks because of its phylloxera tolerance or resistance and deep-rooting habit, which can provide protection against drought.

Vitis berlandieri Vine species found on the limestone soils of Texas and Mexico. The grape is black, and its juice is high in sugar and acid without strong flavours. This species is known for being difficult to root from cuttings, but, because of its high phylloxera and lime tolerance or resistance, it is a common parent of many commercially important rootstocks.

Other American species include *Vitis cinerea*, *Vitis vulpina* (*cordifolia*), *Vitis mustangensis*, *Vitis shuttleworthii*, *Vitis acerifolia*, *Vitis californica*, *Vitis arizonica*, *Vitis monticola*, *Vitis palmata*, *Vitis biformis*, and *Vitis tiliifolia.* See VITIS. P.C.

American Viticultural Area. See AVA.

Amerine, Maynard (1911–98), pre-eminent American OENOLOGIST, teacher, and writer, was trained as a plant physiologist at Berkeley in California before joining the revived Department of Viticulture and Enology at DAVIS in 1935. There he participated in some of the most important branches of its work, including the

assessment of VINE VARIETIES for the different regions of California and the re-education of the wine industry to restore and advance the technical knowledge lost during PROHIBITION.

With A.J. WINKLER, Amerine developed the system of classifying wine regions by measuring heat summation (see CLIMATE CLASSIFICATION). The list of his publications extends to nearly 400 items. He served as chairman of his department from 1957 until 1962 and retired from the University in 1974. T.P.

Amigne, rare Swiss white grape variety and a speciality of Vétroz in the Valais used for dry, semi-sweet, and sweet wines. DNA PROFILING has established that Amigne is a likely grandchild of PETIT MESLIER, a rare variety of Champagne. The wine produced is either a powerful dry white with distinctive linden aromas or a sweet (see FLÉTRI) wine with flavours of citrus fruits and bitter almonds. J.V.

amino acids, the basic building blocks of PROTEINS, chemicals essential to all living systems. There are 20 amino acids involved in constructing thousands of proteins of living materials. When these proteins act as catalysts for specific biochemical reactions, they are called ENZYMES.

In ripe grapes, NITROGEN-containing compounds constitute about 1 g/l of juice, of which amino acids make up about half. The most common are proline, arginine, and glutamic acid (see UMAMI). During grape RIPENING, the concentrations of amino acids increase, arginine and proline especially; proline increases more than arginine if the fruit is exposed to light. High concentrations of arginine, resulting from soils with a high nitrogen content, present the danger of production of the carcinogen urethane (ETHYL CARBAMATE) in wine.

YEASTS are able to make most of the amino acids they require, but they will also use intact amino acids from the medium in which they find themselves if they are available. Thus FUSEL OIL is formed in wine as a by-product of the nitrogen metabolism of the yeast cells living in

grape juice. After fermentation has finished, yeast proteins break down, secreting smaller peptide units and amino acids into the wine if it is left in the presence of the LEES or dead yeast cells.

Bottle-fermented SPARKLING WINES owe some of their special flavour to the presence of substances associated with yeast breakdown, peptides, and amino acids (see AUTOLYSIS). B.G.C.

Rantz, J. M. (ed.), *Proceedings of the International Symposium on Nitrogen in Grapes and Wine* (1991).

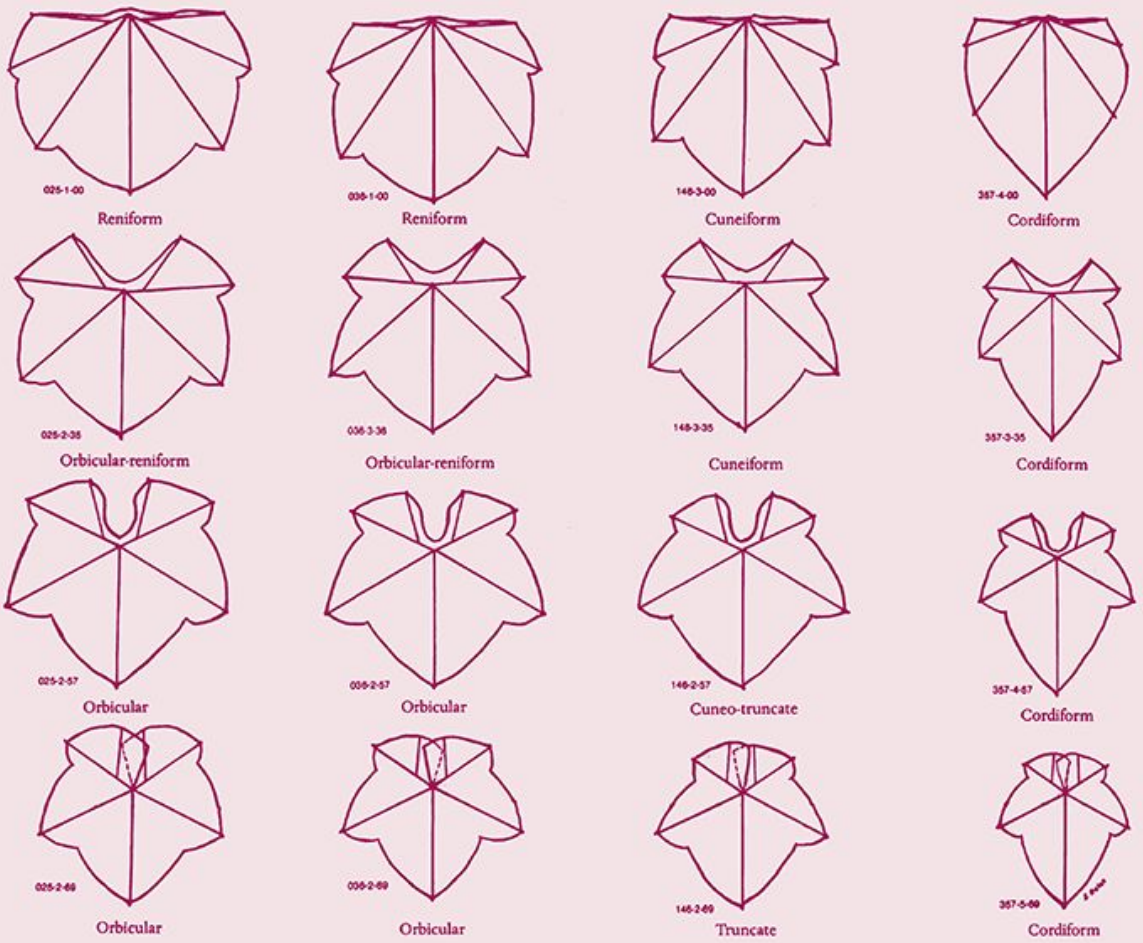
amontillado, Spanish word which etymologically means sherry (or the equivalent wine from other wine regions in ANDALUCÍA) made in the style of MONTILLA. A FINO becomes *amontillado* when the FLOR yeast dies and the wine is exposed to oxygen, becoming amber in hue and richer and nuttier in flavour. This happens if the alcohol exceeds 17%, whether through FORTIFICATION or natural ageing, since the flor yeast cannot work in such an alcoholic environment. A true Amontillado-style sherry is therefore an aged Fino. Cheaper wines created by blending and sweetening used to appear on the market as Amontillado but now must be labelled as Medium. Amontillados are always bone-dry. For more details, see SHERRY. J.B.

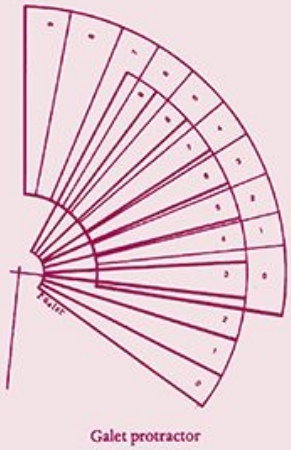
ampelography, the science of description and identification of the vine genus VITIS and its cultivated VINE VARIETIES. A volume of vine descriptions is also called an ampelography, the word coming from the Greek *ampelos*, meaning 'vine', and *graphos*, meaning 'description'.

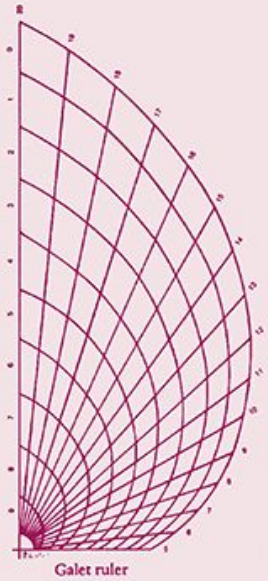
While an awareness of the differences between vine varieties can be seen in the writings of PLINY the Elder, and regional ampelographies emphasizing the aptitudes of various cultivated varieties already existed in medieval Europe, the term 'ampelography' was not coined until 1661, in Philipp Jakob Sachs von Löwenheim's *Ampelographia*, published in Leipzig. The term was not used again

until 1807, when Simón de Roxas Clemente y Rubio published a Spanish ampelography.

Some system of distinguishing between grapevine varieties was clearly necessary, since the choice of variety has a fundamental impact on the organoleptic characteristics of a wine and since the same variety often goes by different names in different regions. In addition, when serious vine diseases and pests were introduced to Europe from America (POWDERY MILDEW in 1845, PHYLLOXERA in 1863, DOWNY MILDEW in 1878, and BLACK ROT in 1885), it became essential to identify those species and varieties which showed most resistance to these hazards. Such species were soon used for VINE BREEDING and as ROOTSTOCKS.







Galet's **ampelographic** codes for some basic vine leaf shapes and the ruler and protractor used to measure them.

Several large regional ampelographies were published near the turn of the century, including Pulliat (1888) and Viala and Vermorel (1901–10) in France; Goethe (1878) in Austria; Rovasenda (1877) and Molon (1906) in Italy; and Hedrick (1908) and MUNSON (1909) in the US.

The most famous modern ampelographer, the late Dr Pierre GALET of MONTPELLIER, began his studies in 1944 by inspecting rootstock plantings, and this led to the publication of a distinguishing key in 1946. These studies were extended to include wine and table grape varieties, and in 1952 his *Précis d'ampélographie pratique* was published, followed by, among other works, *Cépages et vignobles de France*. Galet's comprehensive quantitative description of leaf shape, attained by measuring the lengths and angles of the veins, the ratio of length to width, and the depth of sinuses, is highly objective.

Other characteristics have been considered for identification, including the timing of phenological or development stages such as BUDBREAK, fruit maturation, or even LEAF FALL. Such features are known to be controlled by the climate, however, and can be used only in a relative sense for vine varieties in a single region.

The disadvantages of these classification techniques are that, while some characteristics are quite stable, others, such as leaf shape, can vary markedly even on one vine. Major differences can be caused by environmental factors (see EPIGENETICS), but also, and to a lesser degree, by variation between different CLONES, plant age, and the influence of pests and vine DISEASES. There are, however, five characters which are quite stable: sex of the flower; grape skin colour; pulp colour; the taste of berries; and the presence of seeds.

Experience has shown that ampelography is a field of systematic botany requiring very specialized observational skills and interpretative ability, as well as an extraordinary memory. Very few people can walk into any vineyard and unequivocally identify varieties. Some modern acknowledged experts apart from Pierre Galet have included his colleague Paul Truel and successors Jean-Michel Boursiquot, Thierry Lacombe of Montpellier, Anna Schneider of Italy, and the late Allan Antcliff of Australia.

A complex ampelographic procedure was proposed by the Office International de la Vigne et du Vin (OIV) in 1951, based on 65 morphological characters. The International Board of Plant Genetic Resources (IBPGR) and l'Union Internationale pour la Protection des Obtentions Végétales (UPOV) have also produced lists of descriptors, and all three international systems have been harmonized by the introduction of numeric codes. Ampelographic studies have recently been facilitated by the application of computers and electronic data storage and retrieval (e.g.

www.vivc.de), but final identification still relies heavily on the judgement of ampelographers.

Attempts were therefore made to develop objective, laboratory-based tests for vine identification, including isozyme analysis and gel electrophoresis of enzyme banding patterns, but DNA PROFILING has proved by far the most successful and effective.

Unfortunately, misnomers are common, especially in the New World, in government collections as well as in commercial nurseries and thus vineyards. Some of the early introductions of vine cuttings to these regions were made before European vine-growers had correctly identified their own varieties. Sometimes name tags on bundles of vine cuttings, all of which look remarkably similar, were simply misplaced or transposed. In other cases, confusion was caused by different synonyms in different European regions. James BUSBY's celebrated vine collection introduced to colonial Australia in 1832, for example, probably contained CINSAUT cuttings under seven different regional synonyms and CHENIN BLANC under three. Paul Truel studied a large collection of French varieties at Domaine de Vassal on the Mediterranean coast (see INRA) in the 1960s and 1970s and found that as many as six distinct varieties grown in different parts of France were a single variety under different names, and there is even more variation in nomenclature between countries. The GRACIANO of Spain, for example, is the same as France's Morrastel, while the

Ottavianello of Italy is the same as Cinsaut of France, but more complex examples abound. A labelling error in a Spanish vine collection, perpetuated in France and then again in Australia, led many growers to label their SAVAGNIN BLANC wines as Albariño.

Because its nursery has been able to provide virus-free, high-health vines, the FOUNDATION PLANT SERVICES at the University of California at DAVIS has been an important source of varieties for many NEW WORLD countries. Naming mistakes in this collection were legion and caused inconvenience for both the California wine industry and importers of plant material from Davis. Some examples of such errors cited in California by French ampelographers GALET and Boursiquot, in Australia by Truel, and in New Zealand by Zuur include: Petit Verdot (Gros Manseng), one CLONE of Pinot Noir (Gamay Beaujolais), Négrette (Pinot St George), Valdiguié (Napa Gamay), Melon (Pinot Blanc), Muscadelle (Sauvignon Vert), Tempranillo (Valdepeñas), a clone of Sauvignon Blanc (Sauvagnin Musqué), Trousseau Gris (Grey Riesling), and Touriga (Alvarelhão).

Generally rootstocks are more difficult to differentiate as they do not often fruit, so it is not surprising that problems have also occurred with their naming. In the 1990s, California growers were forced to replace the rootstock AXR1 as it succumbed to phylloxera. This replanting effort was thwarted by finding that the rootstock thought to be SO 4 was in fact 5C Teleki, and Riparia Gloire was mixed with Couderc 1616.

Today ampelographers can rely on the accuracy of DNA PROFILING to identify not only varieties but also CLONES. R.E.S. & J.V.

amphora, Latin word from the Greek for a vessel with two handles. The term is normally used to describe the large pottery containers which were used for the BULK TRANSPORT of many goods and liquids, including wine, in the Mediterranean world throughout classical antiquity (see ancient EGYPT, for example). (See DOLIUM for the vessels used by the Romans for FERMENTATION.) Despite the considerable variety of shape in amphorae, they mainly shared the characteristics of the two handles, a mouth narrow enough to be stoppered, and a bottom which tapered to a point (only a few, notably those of southern France, had flat bottoms). When full, many amphorae were a considerable weight, so the spike on the bottom served as a third handle when lifting and pouring. To carry wine, the inner surface of the porous amphora was sealed with a coating of pine resin (see RESINATED WINES). To stop the mouth, either CORK or a lid of fired clay was pushed down the neck and then secured with a sealing of mortar. Many amphorae were stamped with the name of the potter—not that of the winemaker, as some have suggested—before firing. Modern study of ancient amphorae began after the Second World War, when the use of the aqualung led to the discovery of many wrecks carrying cargoes of amphorae (see CELTS, for example). Scientific study of the clays used, and the detection of tartaric residues as evidence of wine (see ORIGINS OF VINICULTURE), are currently helping to identify the date and origin of the wine. As a result, a much clearer picture of the pattern of trade in goods, such as wine, has emerged. The term 'amphora' also became an expression of capacity, a cubic Roman foot, about 26 l/7 gal, although the actual vessels did not by any means conform to this. Indeed, it is likely that goods, such as wine, were frequently sold wholesale by weight and there were formulae for converting the weight of different goods into capacity. J.J.P.

Demesticha, S., *Per Terram, Per Mare: Seaborne Trade and the Distribution of Roman Amphorae in the Mediterranean* (2015).

University of Southampton, *Roman Amphorae: A Digital Resource* (2014).

Modern usage

Even though the Roman amphora was used exclusively for the transport of wine, the term is now generally used to refer to a vessel used for FERMENTATION (what the Romans called a DOLIUM) and AGEING of wine. Partly inspired by the likes of Gravner and Radikon in FRIULI (see ORANGE WINES), and traditional winemaking techniques in Georgia (see QVEVRI), winemakers have been experimenting with CLAY or, occasionally, CONCRETE 'amphorae' that are typically bigger, more rounded, and handleless. Concrete may provide a less oxidative environment and is easier to use and maintain, but the level of oxygenation depends more on the size of the vessel, the width of the opening, and how it is sealed. Winemakers may design their own shapes. The more traditional amphora shape, with a narrow base, allows less LEES CONTACT and better SETTLING and results typically in more vibrant wines than those whose shape is closer to that of CONCRETE eggs, which tend to produce richer wines. Amphorae are generally free-standing in a cellar, but some producers bury them, emulating Georgian traditions. Small amphorae with narrow necks are particularly difficult to clean. Ideally the pores of the clay should be very fine, giving a smooth surface that is easier to clean and is less permeable to liquid, although they may also be treated inside, for example with beeswax. Some producers use local clay with the aim of maximizing the possible local footprint on the resulting wine. See also TINAJA, TALHA, and PITHARI.

Amtliche Prüfnummer. See AP NUMBER.

amurensis. See VITIS AMURENSIS.

Amyndeo is the coolest wine region in GREECE, famous for wine from the XINOMAVRO grape. It lies on the north-western slopes of Mount Vermio, on the other side from NAOUSSA, on a plateau at 650

m/2,100 ft in ELEVATION. In the rain shadow of the Vermio, Vitsi, and Voras mountains, the region has cold, snowy winters and relatively dry summers, as well as five lakes that help moderate the temperature. An Amyndeo PDO wine must be a pure Xinomavro, whether red, rosé, or rosé sparkling wine, which has been much in vogue since 2010. The red wines can be full-bodied with admirable COMPLEXITY, especially from centenarian vines in sandy, PHYLLOXERA-free soils. Many international grape varieties have found a welcome home here, too. A blend of Xinomavro, Merlot, and Syrah is becoming a regional speciality, while, in white wines, ASSYRTIKO, CHARDONNAY, MALAGOUSIA, and even several Italian varieties can give impressive results. Nevertheless, these labels qualify only for the regional PGI Florina or PGI Macedonia. The area has been attracting serious investments from producers both inside and outside of the region.

K.L.

analysis of grapes, must, and wine is a regular and important part of the WINEMAKING process.

Grapes and must

Traditional analysis of grapes and must is chiefly concerned with just three components: sugar, acid, and PH. For TABLE WINE, for instance, the grapes should ideally contain SUGARS capable of producing wines with an ALCOHOLIC STRENGTH of 10–14% by volume, which means that the grapes should have 18–25% fermentable sugar by weight (see MUST WEIGHT for the various ways in which this can be measured).

The ACIDITY of the grapes or must should also ideally be such that the TOTAL ACIDITY is in the general range of 7–10 g/l expressed as tartaric acid. Some acid is always lost during winemaking, primarily as the alcohol content of the wine increases and the solubility of wine acids decreases. Acidity may be further reduced by MALOLACTIC CONVERSION and cold STABILIZATION. It is therefore necessary to start with more acid in the grapes than is eventually wanted in the wine. However, it should be noted that the production of SUCCINIC ACID during fermentation may occasionally lead to a very slight increase in total acidity.

The chemistry of AGEING is strongly influenced by pH, and, although there is a relationship between pH and total acidity, it is important to measure pH separately. Two samples with the same acidity can have different pH readings because of different POTASSIUM levels and due to differing organic acid profiles.

Sugars are most simply measured by determining the DENSITY of a sample of CLARIFIED grape juice. Measurement of the juice's index of refraction (see REFRACTOMETER) can also provide a close estimate of its sugar content. In establishments with particularly well-equipped laboratories, modern chromatography can provide an extremely accurate sugar measurement. This gives an indication of timing of HARVEST, the POTENTIAL ALCOHOL, and any need for ENRICHMENT, but harvest decisions are often also governed by grape flavour profiles.

In warm wine regions, the accumulation of sugars poses a different problem: in hot, dry weather, sugar synthesis (see

PHOTOSYNTHESIS) and acid loss occur so rapidly that picking decisions have to be taken fast, and frequent field analysis may be necessary, normally involving a hand refractometer for sugar.

On arrival at the winery, harvested grapes may also be tested with a probe linked to an autoanalyser. This will typically analyse for sugar content, total acidity, MALIC ACID, pH, and yeast-available NITROGEN. INFRARED SPECTROSCOPY may be used for rapid analysis of ANTHOCYANINS in red grapes.

See SOIL TESTING for the analysis of soils. R.D.

Wine

Analysis of wine involves the measurement of various characteristics which relate to wine quality, stability, and legal requirements, ideally in a well-equipped laboratory. In most specialist wine laboratories, wine analysis also includes a critical tasting to ensure that the wine conforms to type and quality. Wine analysis is also used to help assess blends, estimate shelf life, and ensure that BLENDING and PACKAGING operations have been successfully performed.

Common measurements include those of alcoholic strength, total acidity, VOLATILE ACIDITY, pH, density, RESIDUAL SUGAR, microbiology, and SULFUR DIOXIDE. Laboratories in larger wineries may also be equipped to test for mineral elements such as IRON, COPPER, SODIUM, and potassium. All these parameters either play an important part in assessing quality and stability or are limited by law.

Not all wineries determine all these constituents, and many of the smaller ones have no laboratory at all and have to rely on samples sent to professional analysts.

Wine analysis advanced considerably in the early 21st century with the development of powerful specialist high-tech equipment such as Inductively Coupled Mass Spectrometry (ICPMS), Liquid Chromatography Mass Spectrometry Mass Spectrometry (LCMSMS), and Gas Chromatography Mass Spectrometry Mass Spectrometry (GCMSMS).

ICPMS is a powerful technique which enables the simultaneous measurement of 60 or more different elements (e.g. metals, trace metals) and can be used to help monitor authenticity (see AUTHENTICATION), for example to make sure that wines or batches of allegedly the same wine are, in fact, identical.

Chromatography in very general terms is an analytical technique for separating, then identifying and quantifying the various components and chemicals within liquids such as wine. Of the various types of chromatography, the two most commonly used in wine analysis are complementary: liquid chromatography, generally used

to separate non-volatile compounds; and gas chromatography, for separating volatile compounds. The techniques have evolved into very sophisticated analytical tools and can now include a double mass spectrometer: the first confirms the mass of the compound separated; the second breaks down the compound into its components, enabling detection at lower levels, and more certain identification, than previously. Sub-nanogram per litre quantification is now possible. This is important because wine taints such as TCA can be detected by the human nose at nanogram per litre level.

LCMSMS is typically used for SUGARS, TANNINS, PHENOLICS, certain ACIDS, etc.

GCMSMS is typically used for anisoles (TCA, TBA, etc.), BRETTANOMYCES markers such as 4-ethyl phenol, pesticide RESIDUES, aroma profiling for varietals such as Sauvignon Blanc, etc. An additional adaptor, called an odour port or sniff port, can be used to enable simultaneous nosing (smelling) and identification. These are extremely powerful tools available to the modern wine analyst.

Stability prediction tests for TARTRATES, PROTEIN, COLOUR sedimentation, and microbiology are also crucial analyses to ensure a commercially sound and stable product.

Modern analytical methods based on INFRARED SPECTROSCOPY are able to perform rapid multi-parameter analyses, from grape to packed wine, comparing the samples with a pre-established databank. The equipment is therefore an invaluable tool for large-scale wineries and bottling facilities, but for some wine styles, including sparkling wine, it is important to compare the results with those obtained by more traditional methods.

See also NUCLEAR MAGNETIC RESONANCE, and see AUTHENTICATION for the development of non-invasive analysis using spectroscopy.

Reynolds, A.G. (ed.), *Managing Wine Quality 1: Viticulture and Wine Quality* (2nd edn, 2022).

Anatolia, much of modern TÜRKIYE, the land lying between the Black Sea and the Mediterranean. In ancient Asia Minor, grapes were harvested in September and October. In business documents of the Old Assyrian trading colonies in Asia Minor (dating to approximately the 19th century BCE), this season of the year was called *qitip karānim*, or 'grape picking'. The locations of the ancient vine-growing areas are uncertain, but they were probably established in suitably warm, well-watered regions throughout the peninsula, as they are today along major river valleys and along the coasts.

Among the Hittites, the Anatolian civilization in central Turkey in the second millennium BCE, a grape-harvesting festival took place every year. Viticulture was certainly important during the Hittite Old Kingdom (*c.*18th–15th centuries BCE). The king's merit in the eyes of the storm god (who was regarded as the owner of the land) was reflected in the produce of the vineyards and in grain and livestock production. Wine was under the control of royal officials who distributed 'good wine' to certain pensioners (who complained when the quality was not satisfactory). Certain officials during the Old Kingdom bore a title which can be translated as 'wine chief', originally supervisor of the vineyards but later an exalted military rank comparable with general or field marshal.

In Hittite laws (also of the Old Kingdom), the price of grapes was regulated, together with the prices of barley and emmer (a species of wheat). One law makes provisions for damage caused to vines: the offender has to take the damaged vine himself and let the plaintiff take grapes from one of his own good vines at harvest time.

Another law prescribes penalties for the theft of a vine: six shekels of silver for a free man, three if the offender was a slave. Previously the fine was lower, but the offender had been obliged to undergo corporal punishment in addition. Six shekels was also the fine for a free man who damaged another's vine by fire. Viticultural images were used in ritual magic. In an archaic ritual performed during the foundation of a new palace, for example: 'They lay out a vine tendril and say, "Just as the vine puts down roots and sends up tendrils, so may the king and queen put down roots and send up tendrils!" '

Similarly in so-called 'vanishing god' texts we read: 'O Telepinu [a god of agriculture], hold goodness in your mind and heart, just as the grape holds wine in its heart!'

Ancellotta, Italian red wine grape valued for its deep colour as a blending ingredient, up to 15% in some types of LAMBRUSCO and up to 60% in REGGIANO. It is also widely used throughout central and northern Italy to add colour to wines deemed too pallid. Total Italian plantings were 1,700 ha/4,201 acres in 2015 with almost all of it in EMILIA-ROMAGNA. It is also grown in Brazil and the Valais in Switzerland.

Ancenis, Coteaux d', small, schistous AOC zone on both sides of the LOIRE between Nantes and Angers producing mainly off-dry whites from Pinot Gris (locally called Malvoisie) and reds and rosés from Gamay.

ancient vine varieties. THEOPHRASTUS (*c.*370–*c.*287 BCE) remarked that there were as many kinds of grapes as there were kinds of soil (*Historia plantarum* 2. 5. 7; also *De causis plantarum* 4. 11. 6). He does not elaborate, but his remark shows how difficult it is to discuss VINE VARIETIES in the classical world. Are varieties that classical authors describe as different really different varieties, or are they examples of the same variety behaving differently in different conditions? Soil is only one factor; climate and winemaking methods are others. We cannot resort to tasting samples or nursery

specimens; all we possess are CLASSICAL TEXTS written by authors who were not modern, scientifically trained AMPELOGRAPHERS.

The Greeks did not write systematic treatises on wine, so we must turn to the Latin writers on agriculture and natural history, particularly VIRGIL, PLINY, and COLUMELLA. Virgil's treatment, in *Georgics* 2. 98–108, is the briefest and least systematic of the three, and he does not distinguish different wines, such as Lesbos, from different grape varieties, such as Aminean and Bumastus (the latter primarily a TABLE GRAPE). There are so many varieties, he concludes, that no one knows the number.

Only Democritus knew how many grape varieties existed, Pliny says (14. 20), but his account does not survive. Pliny himself announces that he will give us only the most important vine varieties. Pride of place among the Italian grapes goes to the Aminean, which has five subvarieties, then to the Nomentan, and third comes the Apian, which has two subvarieties and is the preferred grape of Etruria. All other vine varieties, Pliny asserts confidently, are imports from GREECE. Of these, the Graecula, from Chios or Thasos, is as good as the Aminean. Eugenia is good but only when planted in the Colli ALBANI. Elsewhere it does not produce good wine. The same goes for Rhaetic, which grows well in a cool climate, and the Allobrogian, which apparently ripens well in frost. These last three grape varieties produce wines which go lighter with age. The remaining varieties Pliny mentions are ones that he judges to be without distinction as wine grapes.

Columella agrees with Pliny for the most part, but there are differences (3. 2. 7–31). He regards the Aminean as the best grape and puts the Nomentan second. He also recommends the Eugenian and Allobrogian wines, with the same reservation as Pliny, and the Apian. Then he mentions other varieties which are noted for their productivity rather than for their flavour. He does not think highly of the Rhaetic, and he does not rank the Graecula with the Aminean. Vines were still being imported: Columella mentions three grapes which have only lately come to his notice so that he cannot give an opinion on their wines and also another grape which he says is a

recent Greek import named Dracontion. Columella's aim is not to give a long and comprehensive list, for that would be impossible (he quotes Virgil's words, *Georgics* 2. 104–6). One should not quibble about names, he concludes, and, knowing that a variety can change out of all recognition if it is planted somewhere new, one should not approve a new grape until it has been tried and tested.

Columella's remarks indicate that farmers were prepared to experiment with new varieties, some of them imported from Greece. Some varieties were probably brought over with the Greek colonists from the 8th century BCE onwards; others were growing in Italy long before they arrived. A Greek name is not a guarantee of Greek origin: some Greek names may be names given to Italian grapes which the Greeks of Sicily and southern Italy used when they started producing wine in their colonies. If so, these names reflect no more than the fact that the Greeks exploited the potential of these grapes commercially before the natives did. H.M.W.

ancient world. See ANATOLIA, ARMENIA, CAMPANIA, CANAAN, CHINA, EGYPT, ETRUSCANS, GREECE, INDIA, IRAN, MESOPOTAMIA, PHOENICIA, ROME, SUMER.

Andalucía, or Andalusia, the southernmost of Spain's autonomous regions, encompassing eight provinces and the DOP regions of JEREZ, MÁLAGA, MONTILLA-MORILES, SIERRAS DE MÁLAGA, GRANADA, LÉBRIJA, and CONDADO DE HUELVA (see map under SPAIN). Andalucía is one of the

hottest parts of Spain and has traditionally been associated with strong, alcoholic wines which have been exported from the Atlantic port of Cádiz since the PHOENICIANS first established their trading links around 800 BCE (see SPAIN, history). There is evidence of grapes being cultivated during seven centuries of Moorish domination, but wine drinking was seriously punished, and there are doubts whether there was clandestine winemaking. Once the Muslims were expelled from western Andalusia in the mid 13th century, international commerce flourished. By the early 16th century, Andalucía had become one of the most exciting parts of the world, and it would remain so for a few centuries to come. The harbours of Sevilla, Cádiz, and the sherry town of Sanlúcar were key in the expeditions to the New World. It was from Sanlúcar de Barrameda where the first trip around the world took place in 1519, led by the Spanish sailor Juan Sebastián Elcano.

Many wines of Andalucía bear a strong resemblance to each other, and particularly to SHERRY, which has fashioned the region's wine industry. Most are FORTIFIED, although grapes from the arid plateau around Córdoba and Jaén are often so rich in natural sugar that they do not require the addition of spirit to reach an ALCOHOLIC STRENGTH of 14–18%. Until laws were tightened up following the foundation of the Jerez Consejo Regulador in 1934, wines from other parts of Andalucía would frequently find their way into sherry blends.

Since the late 1990s, fine-wine estates have sprouted on the slopes of Sierra Nevada mountains in GRANADA and around Ronda in the province of MÁLAGA. The region also has several VINO DE LA TIERRA appellations. Some of the most compelling wines come from the IGP Vino de la Tierra de Cádiz, which covers a wide range of international and local varieties grown north and east of the port town of Cádiz. Especially exciting are the non-fortified, flor-aged white wines made from PALOMINO FINO, as well as dry red wines made from Tintilla de Rota (GRACIANO).

R.J.M. & F.C.

Anderson Valley. Scouts for Louis ROEDERER of Champagne say they hunted in CALIFORNIA until they found somewhere with weather as bleak as Roederer's home in north-eastern France, and that the coast-hugging Anderson Valley in MENDOCINO fitted their requirement perfectly. Anderson's rolling hills are cut through by the Navarro River, and almost all vineyards are planted on some degree of slope. The region has the distinction of being one of California's rare transverse valleys. Running approximately east–west, this orientation allows the cool ocean fog and breezes to penetrate far inland. That said, though Anderson Valley is hardly 1.6 km/10 miles end to end, a steady rise in elevation from 244–396 m/800–1,300 ft combined with a rising wall of hills makes the inland end at Boonville warmer and sunnier than the oft-befogged area between Philo and Navarro, where most of the vines grow.

Redwood logging, sheep, and apples reigned here until grapes came, a little wave of them in the 1970s and a bigger one in the 1980s. In the 1990s, leading producers such as Littorai and William-Selyem drew attention to the region through high-quality single-vineyard bottlings. Though many locals feel the region's true strengths lie in its sparkling wines and aromatic whites, it was the rising popularity of Pinot Noir in post-SIDEWAYS America that resulted in Anderson Valley's growing fame. Today, over 70% of the AVA is planted to Pinot Noir, and nearly all of Mendocino's fine dining and luxury accommodations are located here. While most wineries are small outfits, major players such as Duckhorn have also taken up shop. The result is that Anderson Valley is now better known than the county that claims it. K.W.

Angelica, a historically important type of MISTELA produced during the earliest part of CALIFORNIA's development, named after the city of Los Angeles, where it was a primary product of Mission-period winemaking in the region. It is traditionally made by adding brandy to unfermented or partially fermented grape MUST of the MISSION grape. A.Y.

animals can cause serious damage in the vineyard, most obviously but not exclusively by eating grapes and foliage. Any reductions in foliage can prejudice fruit RIPENING and wine quality, and encourage sunburn.

Most mammals may be kept out by fencing, but fences have to be sunk into the soil for smaller, burrowing animals and be high and cantilevered for animals as large and mobile as kangaroos. Deer, rabbits, rodents, raccoons, and wild boar are some of the most common vineyard animal pests, but baboons can pose a threat in South Africa and ETHIOPIA, as can monkeys in JAPAN, hippos in Ethiopia, elephants in Thailand, bears in Canada, kangaroos and rabbits in Australia, and badgers in the UK, while rattlesnakes can present a danger to vineyard workers. Some vine-growers in New Zealand, on the other hand, deliberately use a combination of electric fencing and sheep to achieve judicious LEAF REMOVAL. Animals of relevance to wine production other than HORSES are referred to in VINE PESTS. See also BIRDS. R.E.S.

Bettiga, L. J., (ed.), *Grape Pest Management* (3rd edn, 2013).

Anjou, major, revitalized, and diverse wine region in the western LOIRE centred on the town of Angers, whose influence once extended all over north-west France. Anjou was the birthplace of Henri II, and its wines were some of France's most highly regarded in the Middle Ages (see LOIRE, history). It was the DUTCH WINE TRADE, however, that developed the sweet white wine production of the region in the 16th and 17th centuries. White grapes, especially CHENIN BLANC, predominated until the 19th century, when the Anjou vignoble reached its peak and PHYLLOXERA arrived. Subsequently a wide variety of grape varieties were planted, yet the evolution of the market over the 20th century led to the predominance of CABERNET FRANC, while Chenin plantings, as well as the total vineyard, with its communal AOC, shrunk by half its peak to 15,484 ha/38,260 acres.

The region's climate is quite mild, being influenced by the Atlantic and protected by the Mauges hills to the south-west. Rainfall is low, with an average of 570 mm/22.4 in. These climatic conditions explain why Anjou offers the largest stylistic diversity of the whole Loire.

Wines claiming the Anjou name predominantly come from the black, metamorphic part of the area, as SAUMUR AOC is usually used for wines on TUFFEAU territory. The terroir of SCHIST with VOLCANIC veins influences wine style, and wines can be rustic when tannins and ripeness development are not handled carefully.

The GROLLEAU vine, mostly used for Rosé d'Anjou, is in retreat, although better vineyard management has resulted in better quality. In the same vein is the most produced AOC of the whole Loire, the rosé Cabernet d'Anjou, made from Cabernet Franc or, seldomly, Cabernet Sauvignon. It can be quite sweet, and usually has high acidity and discernable tannins which can preserve it for decades, yet its long-lasting potential is rarely realized.

Cabernet Franc is increasingly favoured, encouraged by the commercial trove of off-dry rosé as well as by the creation in 1987 of the serious red-wine appellation Anjou-Villages. The best area for such reds immediately south of Angers in the Coteaux de l'Aubance was given its own appellation Anjou-Villages Brissac in 1998. It overlaps the Coteaux de l'AUBANCE AOC. Juicier reds are produced as Anjou Gamay, while Anjou Rouge is the catch-all appellation for lighter, often fresh, red wines, with some peppery PINEAU D'AUNIS added to the blend.

Despite the current enthusiasm for Chenin Blanc, still Anjou Blanc and sweet variations are produced on a modest scale, as are Anjou MOUSSEUX. Anjou Blanc is the most common and for a long time was considered an afterthought. It must contain at least 80% Chenin Blanc, with Chardonnay and Sauvignon Blanc allowed in the blend. An exciting development since the late 1990s has been the emergence of a new, high-quality style of dry Chenin paired with the development of a strong ORGANIC and BIODYNAMIC movement that often revives prime, historic sites to produce healthy grapes picked by hand in TRIES at full maturity. BARREL FERMENTATION and MALOLACTIC

CONVERSION are common, and successful, yet a significant proportion of top growers chose to declassify their production in VIN DE FRANCE. Anjou-Coteaux de la Loire near SAVENNIÈRES, once a key area, makes minuscule amounts of sweet Chenin Blanc.

See also the Anjou appellations Coteaux de l'AUBANCE; BONNEZEAUX; Coteaux du LAYON; QUARTS DE CHAUME for sweet wines; and SAVENNIÈRES for dry wines. P.Le.

annual growth cycle. See VINE GROWTH CYCLE.

año, Spanish word for year. Some wines, particularly RIOJA, were once sold without a VINTAGE year but with the number of years' AGEING prior to bottling indicated on the label. Ano is the Portuguese word.

Ansonica, alternative name for Sicily's white INZOLIA grape used particularly in the Tuscan Maremma, where it can produce wines of real character.

Antão Vaz, white grape increasingly favoured by winemakers in the ALENTEJO, southern Portugal, especially in the cooler subregion of Vidigueira, where it produces full-bodied VARIETAL wines with notable longevity and is also blended with tarter varieties such as ARINTO. Total 2020 plantings were 1,425 ha/3,521 acres.

anther, the pollen-bearing part of the STAMEN of a flower such as that of the vine. Each of the five anthers of the grape has sacs in which a large number of pollen mother cells develop into pollen grains, about two to three weeks before FLOWERING. The small, dry grains of POLLEN are released, possibly before the CALYPTRA or flower caps have fallen (see POLLINATION). In deliberate VINE BREEDING

stamens and caps are removed early, before caps would normally fall, to prevent self-pollination and permit deliberate cross-pollination.

B.G.C.

anthesis, another word for FLOWERING.

anthocyanins, members of a complex group of natural phenolic GLYCOSIDES (see also PHENOLICS and FLAVONOIDS) responsible for the colour of black and red grapes. They are also responsible for the colour of red wines, both as wine components and as precursors of PIGMENTED TANNINS and other derived pigments which are formed through reactions of anthocyanins with other wine components. Anthocyanins are common in the plant world and are responsible for the red to blue colours of leaves, fruits, and flowers. The word comes from *anthos*, Greek for 'flower', together with the Greek-derived 'cyan', blue.

The particular anthocyanins found in grapes are limited in number, with mixtures of pigment molecules varying from species to species and from grape variety to grape variety. Indeed, chemical determination of the particular mixture of pigments present in an unidentified grape berry can aid vine identification. Pure VITIS VINIFERA varieties have mostly anthocyanin pigments with only one molecule of glucose (monoglucosides), while many of the AMERICAN VINES used in breeding ROOTSTOCKS and AMERICAN HYBRIDS also have significant amounts of anthocyanins with two molecules of glucose (diglucosides; a fact which greatly aided detection of non-*vinifera* wine in France in the mid 20th century; see University of BORDEAUX).

Anthocyanins have another important characteristic. They are capable of changing form, depending upon the PH, or degree of ACIDITY, of the medium in which they are dissolved, the different forms being red, blue, and colourless. In general, the more acid the grape juice or wine, the greater the degree of ionization of the anthocyanins (giving a higher proportion of the red flavylium cation) and the brighter red the colour; as the acidity decreases, the proportion of colourless and blue forms increases. In mildly acidic

conditions, anthocyanins are also bleached by SULFUR DIOXIDE. At wine pH values, grape anthocyanins should be mostly in colourless forms unless the pigments are stabilized by CO-PIGMENTATION or through conversion to derived pigments including pigmented tannins (see below).

The anthocyanin pigments are formed in the grapevine by a sequence of metabolic steps and are first visible when the berry begins to expand. The onset of this stage in the vine's metabolism is called VERAISON and is characterized by rapid growth and accumulation of sugar in the berry together with the first flush of colour in the berries.

The concentration of the pigments in the grape skin increases as the level of sugar increases in the grapes during ripening. The increase is intensified if sunlight falls on the berries—that is, if the berries are in an open CANOPY MICROCLIMATE. Anthocyanin production during ripening is very temperature-dependent and is also strongly influenced by the MACROCLIMATE. During veraison the anthocyanin pigments are formed and sequestered in the berry skins' outer cell layers in all but a few dark-berried grape varieties which have a portion of the pigment present in the pulp of the berry as well as in the skin (see TEINTURIERS).

One important operation during the FERMENTATION of most red wines, therefore, is to transfer the anthocyanin pigments from the skin cells to the wine. Colour transfer is achieved by keeping the skins adequately mixed with the fermenting wine (see MACERATION).

One might reasonably expect that the pigments in the new wine would be identical to those found in the grape skin. This may be the case for a few hours, but once the anthocyanins are mixed with the other phenolics as well as the many products of fermentation, they begin a series of reactions leading to a great diversity of derived pigments and colourless molecules. Derived pigments are classically assimilated to pigmented tannins arising from the addition of tannins to anthocyanins, either directly or through condensation reactions with ALDEHYDES. However, they also include rather small molecules

formed by the reaction of anthocyanins with other wine constituents such as ACETALDEHYDE or PYRUVIC ACID, or hydroxycinnamic-acid derivatives. Moreover, most of these reaction products are themselves unstable, and the list of derived pigments found in wine keeps expanding, covering a wide range of colours. Within a few years, only traces of the relatively simple monomeric anthocyanins remain. With wine AGEING, polymers containing anthocyanin molecules may become larger and form aggregates so that some of them exceed their solubility in the wine and are precipitated as SEDIMENT. See AGEING. B.G.C. & V.C.

anthracnose, one of the FUNGAL DISEASES of European origin which affects vines. It is also known as bird's eye rot or black spot. The disease is spread worldwide but is a particular problem in humid regions, as in the eastern UNITED STATES. Before the introduction of DOWNY MILDEW and POWDERY MILDEW, it was the most serious grape fungal disease in Europe, but since BORDEAUX MIXTURE was introduced in 1885 it has been controllable. The disease is caused by the fungus *Elsinoe ampelina*. Small black lesions are produced on the leaves, and this area can die and drop out so that the leaves look as though peppered with gunshot. Small dark-coloured spots are also produced on young shoots, flower cluster stems, and berries. Anthracnose can

reduce both the YIELD and quality of the fruit. The disease can be controlled by FUNGICIDES applied early in the growing season. R.E.S.

Antinori, one of Italy's most important wine producers, based in TUSCANY. The modern wine firm was founded by brothers Lodovico and Piero Antinori in 1895, although the Antinori family can trace their history in the wine trade back to 1385, when Giovanni di Pietro Antinori enrolled in the Vintners Guild of Florence. Like the vast majority of the Florentine nobility, the Antinori were, for centuries, producers of wine on their substantial country properties.

The work of the 19th-century brothers was continued by Piero's son Niccolò, who extended the house's commercial network both in Italy and into foreign markets and purchased the Castello della Sala estate near ORVIETO in Umbria. The house developed a certain reputation for its white wines, sold under the Villa Antinori label, and for its Chianti, made in a soft and fruity style. Although the family fortunes flourished, Antinori was only a medium-sized operation in 1966 when Piero Antinori, the son of Niccolò Antinori, took over.

By the early 1990s, he had increased the annual production fifteen-fold, giving the house a commanding position in Tuscany, based on both the quality of all the firm's wines at various price levels and, above all, the innovative work of Antinori and its OENOLOGIST the late Giacomo Tachis in creating Tignanello, the prototype SUPERTUSCAN; Solaia, which, together with SASSICAIA (initially marketed by the Antinori and whose development was assisted by Tachis), showed the potential for outstanding Cabernet in Tuscany; and Cervaro, a white wine produced at the Castello della Sala based on Chardonnay grapes and, then unusual for Italy, BARREL FERMENTED.

Although it is firmly anchored in Central Italy, where its vineyard holdings were 2,800 ha/6,919 acres in 2019, Antinori has expanded steadily, securing holdings in every important or upcoming Italian wine region: Montenisa in FRANCIACORTA; the historic house of Prunotto in BAROLO; and Tormaresca, a large-scale operation in PUGLIA. In 2021 it bought a majority stake in the Jermann estate in FRIULI and

acquired both the Villa di Cigliano near their own modern winery in San Casciano and Tenuta Rubbia al Colle in BOLGHERI, where they also own Guado al Tasso. Further estates in the Antinori portfolio include Pian delle Vigne in MONTALCINO, La Braccesca in MONTEPULCIANO, Tenuta La Farnete in Colli Senesi, and Le Mortelle and Tenuta Monteloro in the MAREMMA.

Internationally Antinori spread its wings quite early on, often through JOINT VENTURES, the most important of which was Antica on Atlas Peak in NAPA Valley in 1993. This was followed in 1995 by Col Solare in a joint venture with Ste. Michelle, in WASHINGTON State. In 2007, again in a joint venture with Ste. Michelle, the legendary Stag's Leap Winery of Napa Valley was acquired. Tuzko Bátaapáti in Hungary had been acquired in a joint venture with Fonterutoli's Lapo Mazzei in 1991. Meridiana on MALTA, producing INTERNATIONAL VARIETIES, was established in 1992, followed by Vitis Metamorfosis, a joint venture with Halewood in ROMANIA, and Haras de Pirque in CHILE's Maipo Valley.

Piero's brother Lodovico Antinori independently created the internationally famous Supertuscans Ornellaia and the all-Merlot Masseto at his own estate near Bolgheri (subsequently owned by the Antinoris' great rivals the FRESCOBALDI). With their sister Ilaria, the brothers have developed the Tenuta di Biserno project at Bibbona just north of Bolgheri with Michel ROLLAND consulting and increasing attention paid to Cabernet Franc. Lodovico, long a fan of Sauvignon Blanc, independently produces one in MARLBOROUGH, New Zealand, with Mount Nelson Estates. W.S.

antioxidants. For their role in protecting must and wine against the effects of OXYGEN during winemaking and wine AGEING, see GLUTATHIONE, SULFUR DIOXIDE, ASCORBIC ACID, NITROGEN, and CARBON DIOXIDE. For their importance in the effects of wine consumption on HEALTH, see FLAVONOIDS and RESVERATROL.

anti-transpirant, a natural film-forming polymer (di-1-*p* menthane) applied to the grapevine CANOPY around VERAISON, known to reduce PHOTOSYNTHESIS and TRANSPIRATION and hence delay berry RIPENING. Trials in Europe, Australia, and New Zealand have shown promising results: lower sugar concentration, lower acidity, enhanced wine flavour, and improved YIELD. This new technique could be useful in the production of lower-alcohol wines and to mitigate the effects of HARVEST COMPRESSION and CLIMATE CHANGE. R.E.S.

Previtali, P., et al., 'A systematic review and meta-analysis of vineyard techniques used to delay ripening', *Horticulture Research* (2022).

ants, more specifically leafcutter ants belonging to the genera *Acromyrmex* and *Atta*, can pose a serious problem in South America, especially in Argentina, where *Acromyrmex* spp. are particularly damaging to young leaves in newer vineyards close to indigenous vegetation and in sandy and stony soils, for example in MENDOZA's Gualtallary subregion. As their name suggests, they cut the leaves and other parts of the vine, taking the spoils to their underground nests to feed the mutualistic fungi that live there. While ants play an essential role in regulating other pests and increasing soil ORGANIC MATTER, they are also capable of defoliating an entire vineyard row in less than a week, and they can severely reduce yields as they are most active between BUDBURST and FLOWERING. They can be controlled with insecticides, but organic alternatives are limited to destroying the nests and distracting the ants with other plants.

AOC stands for *appellation d'origine contrôlée*, often shortened to *appellation contrôlée*, France's famous denomination for its best wines. In 2010, as a result of EU reforms introduced in 2008, this was superseded by *appellation d'origine protegée* (AOP), France's PDO, but many continue to use the term 'AOC'. This much-imitated, prototypical, and inherently protectionist system of designating and

controlling the country's all-important geographically based names applies not just to wines but also to spirits such as cognac, armagnac, and calvados, as well as to many foods. It is administered by the INAO, a powerful Paris-based body which also controls the less restrictive denomination *indication géographique protégée* or IGP (formerly VIN DE PAYS). AOP/AOC wines represented approximately 60% of French wine production in 2020, IGP around 30%.

History

France's role as a wine producer had been gravely affected by the viticultural devastation caused by POWDERY MILDEW, DOWNY MILDEW, and PHYLLOXERA in the second half of the 19th century (see FRANCE, history). Fine wines were available in much-reduced quantity, but the LANGUEDOC and ALGERIA had become vast factories for the production of very ordinary wine at very low prices. Laws passed in the first two decades of the 20th century were aimed at bringing an end to the ADULTERATION AND FRAUD that was by then widespread. These were based simply on the principle of geographical DELIMITATION and specified particular areas within which certain wines had to be produced. Bordeaux, Banyuls, and Clairette de Die were among the first; disagreement about exactly which districts should be allowed to produce France's most famous sparkling wine led to riots (see CHAMPAGNE, history).

It rapidly became clear, however, that France's famous wines depended on more than geography. The wrong grape varieties and careless winemaking would not result in a suitable expression of these carefully delimited TERROIRS. By 1923, Baron le Roy, the most influential and well-connected producer of CHÂTEAUNEUF-DU-PAPE, was implementing in his part of the southern Rhône a much more detailed set of rules including not just geographical delimitation but a specification of permitted VINE VARIETIES, PRUNING and vine-TRAINING methods, and minimum ALCOHOLIC STRENGTH.

The French *appellation contrôlée* system evolved into a national reality in the 1930s when economic depression, widespread cultivation of HYBRIDS, and a serious wine surplus increased the incentive for wine merchants to indulge in nefarious blending. The producers of genuine Pommard, for example, had a very real interest in limiting the use of their name to themselves. In 1935 the INAO was created with the express mission of drawing up and enforcing specifications for individual AOCs, which broadly followed the Châteauneuf prototype, and in principle banned hybrids from AOC

wine. The great majority of the appellation regulations for France's most famous wines and spirits are therefore dated 1936 or 1937, although they have been continuously revised since.

The legal powers of the INAO, both within France and in its dealings with the EU and beyond, were strengthened substantially in 1990, when it took the conscious decision to try to build the future of French wine on the concept of geographical appellations (eschewing even the mention of vine varieties on the main label) and adopted the specific aim of preserving agricultural activity in certain zones. But in 2004, when France's wine exports were clearly in significant decline and domestic sales stagnant, this policy was dramatically modified to make French wine labels easier to understand and the wines themselves more competitive in the global market. The aim was to raise the average quality of AOC wines and introduce some new regional Vin de Pays categories (most now rebadged as IGP). The INAO continues to wage war on all misused GENERIC wine and spirit names, but, as an increasing number of French wine producers find the detailed AOP/AOC regulations too restrictive, the supremacy of the AOC system is no longer unchallenged orthodoxy.

The regulations' scope

The INAO's detailed regulations for its more than 360 AOP/AOCs are voluminous and constantly revised, covering the following aspects for each appellation. The regulations for the IGP category (with 74 listed in 2020) are similar but generally less restrictive.

Production area All those communes allowed to produce the wine in question are listed, but within each of these communes only certain plots of land are deemed worthy, details of which are lodged with each commune's all-important *mairie* or administrative centre. Vines grown elsewhere within the commune are normally entitled to be sold only as a less specific appellation, an IGP, or VIN DE FRANCE.

Vine varieties The permitted grapes are specified in great detail, along with permitted maximum and minimum proportions in the vineyard (known as the *encépagement*) and in any wine that is a blend (the *assemblage*). Vineyards will generally be inspected to ensure that the correct varieties are planted. Many appellation regulations include half-forgotten but once-significant local varieties. White grape varieties are permitted to a certain extent in some red-wine appellations. See full details in Appendix 1.

Ripeness and alcoholic strength Specific minimum MUST WEIGHTS are generally cited for freshly picked grapes before any CHAPTALIZATION, given in g/l of sugar and as potential NATURAL ALCOHOL. A maximum ALCOHOLIC STRENGTH may also be specified for appellations in which chaptalization is permitted.

Yields Control of YIELDS is a fundamental tenet of the *appellation contrôlée* system even if the maximum yields cited in the regulations were almost routinely increased by about 20% throughout the 1970s and 1980s thanks to a special derogation, now abolished, known as the *plafond limite de classement* or PLC. The regulations now specify a base yield (*rendement*) and a maximum yield (*rendement butoir*), so it is still possible to request a derogation allowing a higher yield if the application can be justified—by the VINTAGE weather conditions, for example.

This section usually includes information on a minimum VINE AGE allowed for AOP/AOC production.

Viticulture This usually specifies a minimum VINE DENSITY, the approved PRUNING regime down to the number of buds, and the permitted vine-TRAINING SYSTEM. In some southern appellations the (limited) extent to which IRRIGATION is allowed may be outlined.

Winemaking This long section may well specify such aspects as compulsory DESTEMMING, or the method of ROSÉ WINEMAKING that must be used (usually by SAIGNÉE), although there is generous use of the vague phrase *usages locaux*.

Pros and cons

France's *appellation d'origine contrôlée* designation is in general a more reliable guide to the country's best wines than, for example, the QUALITÄTSWEIN category of supposedly superior wines in Germany, the liberally applied DOC designation in Italy and Portugal, and its DOP counterpart in Spain (all of the last three modelled on the AOC system). The French system is by no means perfect, however, since it was drawn up not with a clean slate but to legitimize the best current practices. Policing remains a problem, and the Direction Générale de la Concurrence, de la Consommation et de la Répression des Fraudes (DGCCRF) is probably understaffed. Contraventions of the regulations, particularly over-chaptalization, or chaptalization and ACIDIFICATION of the same wine, are difficult to detect (although a complex bureaucracy controls over-production). Misdemeanours are only very rarely publicized, and then usually only as a result of local politics.

A more serious disadvantage of the *appellation contrôlée* system is the extent to which it stifles experimentation. In dramatic contrast to the New World, vine-growers may plant only certain vine varieties. Those wishing to experiment are often restricted to selling the wine not merely as an IGP but as Vin de France.

It is also fanciful to suggest that every wine produced within an appellation inevitably uniquely betrays its geographical provenance. Few blind tasters would unhesitatingly identify a Côtes du MARMANDAIS, for example. And then there are the catch-all appellations such as BORDEAUX AOC, ALSACE, and CHAMPAGNE, whose quality variation is simply frustrating.

The full regulations for every appellation, its *cahier des charges*, can be found online:

SEE WEB LINKS

www.inao.gouv.fr.

AOP stands for *appellation d'origine protegée*. See PDO.

Aosta, or the Valle d'Aosta (Vallée d'Aoste to the region's many French speakers), is Italy's smallest region (see map under ITALY). The long, narrow valley formed by the River Dora Baltea as it courses through the mountains of Italy's extreme north-west is Italy's connecting link to France and Switzerland and to the north of Europe beyond. Consequently, wine labels may be written in either Italian or French.

In this rugged alpine landscape, the vineyards, planted on HILLSIDES flanking the Dora Baltea, are frequently TERRACED on dizzyingly steep slopes. In an average year, no more than 19,000 hl/501,926 gal of wine qualifying as DOC is produced from a total of 469 ha/1,158 acres of vines, with 339 ha qualified to produce DOC wines (the balance traded as VINO DA TAVOLA). Despite such minuscule production levels, the region has no fewer than seven subzones suffixing a single overarching DOC, Valle d'Aosta, while a host of INTERNATIONAL and local varieties may appear on labels as single varietals.

At the crossroads between northern and southern Europe, the Valle d'Aosta has found itself with an extremely rich diversity of vine varieties. The three most important local varieties are the red grapes PETIT ROUGE (90 ha/222 acres) and NEBBIOLO (43ha/106 acres) and the white PRIÉ Blanc (38 ha/94 acres), which together account for more than one-third of the region's DOC production. Increasingly important are the ARVINE of Switzerland, called Petite Arvine here, as well as FUMIN. Other native regional and Italian varieties include VIEN DE NUS, Prëmetta, and Moscato di Chambave. French varieties include PINOT NOIR, GAMAY, SYRAH, PINOT GRIS or Malvoisie, PINOT BLANC, and CHARDONNAY.

Production has mainly been in the hands of CO-OPERATIVES, which have a good reputation but have been joined by an association of small producers, Viticulteurs Encaveurs Vallée d'Aoste, aiming at reviving ancient local viticultural practices and favouring INDIGENOUS VARIETIES.

The most interesting wines are the Nebbiolo-based Donnas or Donnaz and the neighbouring Nebbiolo-based Arnad-Montjovet, as well as the family of fruity Petit Rouge reds such as Enfer d'Arvier, Torrette, and Chambave Rosso. But in the early 21st century its delicate alpine Chardonnay drew attention, as well as the minerally Blanc de Morgex et de La Salle from Prié Blanc grown at ELEVATIONS of up to 1,200 m/3,937 ft. The latter is made from UNGRAFTED vines (PHYLLOXERA does not survive at such high altitude) trained in a low PERGOLA. Thanks to the elevation, the grapes retain acidity well, and fine TRADITIONAL METHOD sparkling wines are made. This acidity is also key to the region's relatively numerous sweet wines. The region's main challenge for the future is to retain its highest-quality steep vineyards when faced with an ageing population. W.S.

www.docvalledaosta.it

Gallino, F., *Vino in Valle* (2013).

aoûtement, French term for CANE RIPENING derived from *août*, French for August, the month in which it generally takes place in the northern hemisphere.

Apalta, warm, sunny DO on the banks of the Tinguirica River in the heart of Chile's COLCHAGUA Valley known especially for old-vine CARMENÈRE planted on GRANITE soils.

Apera, registered in 2012 as the name to replace Sherry for Australian wines previously thus named. At the same time, Fino, Amontillado, and Oloroso were replaced by the more prosaic, but decidedly less Andalucian, Dry, Medium Dry, Medium Sweet, Semi-Sweet, and Sweet.

aperitifs, drinks served before a meal to 'open' (from the Latin *aperire*) the digestive system and stimulate the appetite, of which VERMOUTH and similar drinks are archetypal. Wines commonly served as aperitifs are dry, white, and not too alcoholic: CHAMPAGNE or any dry SPARKLING WINE; FINO and MANZANILLA sherry; MOSEL wines up to SPÄTLESE level of sweetness; less rich ALSACE whites; and MUSCADET, CHABLIS, and virtually any light, dry, still white wine without too much oak or alcohol. Customs vary nationally, however, and the French customarily serve spirits, FORTIFIED WINES, VINS DOUX NATURELS, VINS DE LIQUEUR, and sweet wines such as SAUTERNES before meals. A common all-purpose aperitif, apparently acceptable to French and non-French alike, is the KIR, or *vin blanc cassis*, as well as a blend of white wine and sparkling water sometimes known as a spritzer. The port trade serves white PORT as an aperitif, sherry producers a dry oloroso or fino, too many amateurs a full-bodied Chardonnay.

aphids, small insects of the *Aphidiodae* family that feed by sucking the juices from plants. Several species of aphids attack grapes but seldom cause serious damage in vineyards. See also PHYLLOXERA, often referred to as the grape root aphid.

apical dominance describes plant growth which is greater at the apex of a stem or shoot, suppressing lateral growth further away from the apex, a physiological attribute which helped grapevines survive by climbing in forest habitats in previous millennia (see ARBOREAL VITICULTURE). In viticulture, the term is also used to describe preferential BUDBREAK for the two buds nearest the cut end of the

cane, which grow earlier and more strongly than those below. The botanical term 'acrotony' describes a similar phenomenon whereby dormant buds higher up the cane can suppress bursting of lower ones. To encourage fruiting along the entire cane and avoid staggered RIPENING, some viticulturists use an arched cane TRAINING SYSTEM to promote mid-cane budbreak, bending the cane so that the middle section is higher than the base and the apex, but the benefits are not universally acknowledged. Movement of HORMONES in the cane prior to budbreak affects these growth responses. R.E.S.

AP number, written 'A.P. Nr.' on wine labels, short for Amtliche Prüfnummer, adorns the label of every bottle of German QUALITÄTSWEIN. This 10- to 12-digit number is an outward sign that the wine has passed official testing procedures, which involve submitting samples for ANALYSIS and a BLIND TASTING test. Some 95% of wines submitted eventually receive approval. The first digit signifies which of the country's testing stations awarded the AP number. The next code signifies the location of the vineyard. The penultimate pair of digits is the bottler's own code, which supplies the unique identification of a particular lot. If a winegrower has bottled two or more wines of otherwise identical labelling (same site, PRÄDIKAT, and degree of dryness) this number is often referenced as a means of distinguishing them. The final two digits signify the year in which the wine was tested, which for white wines is usually the year following harvest. Austrian Qualitätswein also receives a roughly comparable registration number, known officially as a Staatliche Prüfnummer. D.S.

apoplexy, vine disease. See ESCA.

appassimento, Italian term for the process of drying grapes off the vine, used, for example, in the production of AMARONE and DRIED-GRAPE WINE.

appellation, or appellation of origin. See CONTROLLED APPELLATION.

appellation contrôlée, short for *appellation d'origine contrôlée*. See AOC.

apps, wine. See SOCIAL MEDIA.

Apremont, CRU just south of Chambéry whose name may be added to the eastern French appellation SAVOIE. This is Savoie's largest cru and its wines are typically light, dry, floral, or minerally whites made from the local JACQUÈRE grape. W.L.

Apulia, Anglicized form of the Italian region PUGLIA.

Aquileia. See FRIULI AQUILEIA.

Arab poets. The classical period of Arab civilization spawned a rich corpus of BACCHIC poetry which had its roots in pre-Islamic Arabia (530 CE until the emergence of ISLAM). Wine was celebrated as one of a number of standard topics in the composite odes of pre-Islamic poetry. In its treatment, wine was underpinned by the rigid ethical code (*Muruwwa*, approximately *virtus*) that predicated the desert *Weltanschauung* and thus gave voice to exaggerated notions of generosity. It was in this period, when wine was often compared to the saliva of women (to represent a kiss), that the seeds of the erotic register of later Arabic wine poetry were sown. Interestingly one such simile is even contained in the ode composed by Hassān Ibn Thābit, the Prophet's bard, to celebrate the conquest of Mecca shortly before Muhammad's death in 632 CE. Traditional Muslim commentary, basing itself on the Islamic injunction against the consumption of wine, suggests that the simile is interpolated. But this argument is not entirely convincing; for Islam, while criticizing aspects of the culture

of poetry, seems to have had little effect in censoring the poetic repertoire.

The essential model provided by this bedouin canon, which constituted the cornerstone of Arabian cultural and tribal identity, was absorbed virtually in its entirety into the nascent Islamic/Arab community; for this reason wine survived as a theme. Soon its treatment came to stand independently from the composite ode; while the descriptive elements of Bacchic verse were based around a core of inherited imagery, a new defiant and anti-religious attitude was introduced that is reflected in a verse by the poet from al-Tā'if, Abū Mihjan al-Thaqafi: 'If I die bury me by the vine, so that its roots may satiate the thirst of my bones.' This solipsistic dirge, showing the poet to have acquired notions of life after death, ignores the new imposing religious eschatology of the nascent Islamic community.

Islam did, of course, have a profound effect on the poets of Bacchism: after a time, usually with the onset of old age, they would repent of their erring in pious Islamic terms. To replace them there was always a new generation of libertines, commonly men of high standing such as governors and even, during the Umayyad period, caliphs. Al-Walīd ibn Yazīd, one of the last Umayyad caliphs (d. 744 CE), was a notorious hedonist (although perhaps maligned by later Abbasid propaganda) whose attitude in some Bacchic fragments is aggressively atheistic: 'Give wine [to drink] … for I know there is no Hell-fire!' In this period Bacchism became an urban phenomenon, notably among the libertines of Kufa (modern Iraq), and was eventually to gain a high profile in the Abbasid court circle of Baghdad, particularly during the reign of al-Amīn (reigned 809–13 CE). This son of Hārūn al-Rashīd is famous in literary history as patron and boon companion of the great ABU NUWAS (d. 814 CE).

In his wine poetry, Abu Nuwas synthesized a variety of impulses to produce sometimes complex poems which articulated all the issues relevant to the social dialectic of wine culture in an Islamic society: he expanded both the fantastical and mimetic descriptive repertoire of the *khamriyya*; he fused the Bacchic and erotic registers of poetry to create well-wrought seduction poems that gave voice to a sceptical

world view; he structured his poems in such a way as to support the simple rhetoric in defence of wine; finally, with literary sleights of hand, he reconciled the hedonistic ethic with Islamic dogma. It has rightly been said about the finest of these poems that they parallel the impulses and complexity of some English Metaphysical poetry.

From the descriptions of Abu Nuwas and other poets we gain a detailed picture of Bacchic culture: we are familiarized with the wine itself (its provenance, preparation, colour, bouquet, taste, and age—although here a mythological dimension enters into the poet's expression); its effects (physical, psychic, and spiritual); the personages (the boon companion, the pourer, the singing girl, the taverner (Jewish, Christian, or Persian), and the servant girl); the decorum of drinking (generosity, aristocracy, the quest for freedom, the Satanic pact, and, ultimately, belief in divine mercy); and the venues of drinking (the caliphal palace, the tavern, the monastery, gardens, and the vine itself); finally, we learn about the variety of vessels (for drinking: glass, silver and gold cups or goblets, ewers; for storage: jars, tanks or casks, and leather bottles).

After Abu Nuwas, poets who treated wine (throughout the Islamic lands, including al-Andalus in southern Spain) had little new to say; they simply reworked the imagery he had established, while discarding the careful structure of his finest poems. It was only among Sufi mystics that a new, important dimension was added to Bacchic poetry. Foremost among these was Ibn al-Fārid (d. 1235). For these ascetics DRUNKENNESS represented divine intoxication; they simply borrowed the imagery of Bacchic culture to articulate the otherwise ineffable states of mystical experience. Although Abu Nuwas himself was a ribald, Sufi sensitivity is perhaps foreshadowed in some of his most ethereal descriptions of wine:

[Last night I could not sleep] so give me to drink of the maiden wine who has donned the grey locks of old age whilst still in the womb;

A wine which [when poured] is replenished with youth …

One preserved for a day when its [seal] is pierced, though it is the confidant of Time itself;

It has been aged, such that if it were possessed of an eloquent tongue,

It would sit proudly among people and tell a tale of an ancient time …

P.K.

'*Khamriyya*', *The Encyclopaedia of Islam* (new edn), vol. iv (1978), 998–1009.

Aragón, known as Aragon in English. Once a powerful kingdom whose sphere of influence stretched from Spain to NAPLES and SICILY in Italy and Athens in Greece, Aragón is now one of Spain's 17 autonomous regions. In the north-east of the country, it spans the broad valley of the River Ebro which is flanked by mountains on either side (see map under SPAIN). The north is dominated by the Pyrenees, which feed water on to the arid Ebro plain. To the south and east the climate becomes hotter as the land rises towards the central Spanish plateau.

The wines of Aragón used to be strapping potions with natural ALCOHOLIC STRENGTH as high as 17–18%. Red wines, made predominantly from the GARNACHA grape, were mostly sold in bulk for blending. However, four DOP regions designated between 1980 and 1990 changed the profile of Aragón wines. SOMONTANO, in the lush Pyrenean foothills east of the city of Huesca, made the controversial choice to almost entirely forgo INDIGENOUS grape varieties, but south of the Ebro wines from the DOPs of CAMPO DE BORJA, CARIÑENA, and CALATAYUD have benefited from investment in modern winemaking technology, which has revolutionized the style of modern-day Garnacha, sometimes blended with Tempranillo or Syrah. Also promising is the IGP Valdejalón, an enclave just south of Campo de Borja pioneered by Fernando Mora MW at Bodegas Frontonio. Aragón also claims one VINO DE PAGO, Aylés, 47 ha/116 acres just south of Zaragoza.

R.J.M. & F.C.

Aragonez, once spelt Aragónêz, occasionally spelt Aragones, the traditional name for the Spanish red grape variety TEMPRANILLO in Portugal's ALENTEJO region, where it makes concentrated, deep-coloured reds. See under its northern Portuguese name TINTA RORIZ for more information.

Aramon, an offspring of GOUAIS BLANC, is now, happily, a remnant of French viticultural history, a vine variety that burgeoned throughout the LANGUEDOC in the second half of the 19th century (the many who made their fortunes from wine around Béziers were said to live in 'palais d'Aramonie') and was displaced as France's most popular only in the 1960s by CARIGNAN. For decades, particularly after the development of railway links with the populous north of France, Aramon vines were encouraged to spew forth light, everyday wine-for-the-workers that was with good reason called *petit rouge*.

Aramon's great attribute, apart from its prodigious productivity of up to 400 hl/ha (22.8 tons/acre), was its resistance to POWDERY MILDEW, the scourge of what were France's established wine regions in the mid 19th century. The variety was taken up with great enthusiasm and rapidly spread over terrain previously considered too flat and fertile for viticulture. GALET notes that its effects were particularly noticeable in the Hérault, where, between 1849 and 1869, the land under vine more than doubled, to 214,000 ha/528,800 acres.

Unless planted on poor soils and pruned extremely severely, Aramon produces some of the lightest red wine that could be considered red, notably low in alcohol, extract, and character. To render the *rouge* sufficiently *rouge* for the French consumer, Aramon had invariably to be bolstered one of the red-fleshed TEINTURIER grapes, most often ALICANTE BOUSCHET. This gave Aramon a grave disadvantage compared with the deep, alcoholic reds of North Africa, and its popularity began to decline in the mid 20th century, a trend exacerbated by its toll from the 1956 and 1963 frosts. Aramon suffers

from the twin disadvantages of budding early and ripening late and is therefore limited to hotter wine regions.

The total French area planted with Aramon shrank from 34,700 ha/85,700 acres in 1988 to 1,266 ha/3,128 acres in 2019.

Aramon Gris and Aramon Blanc, lighter-berried mutations, can still (just) be found, particularly in the Hérault.

Galet, P., *Dictionnaire encyclopédique des cépages* (2nd edn, 2015).

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties Including Their Origins and Flavours* (2012).

Arany Sárfehér, white grape of HUNGARY traditionally grown on the sandy Great Plain for table grapes and sparkling wines. Its 2021 total of 251 ha/620 acres produced light, tart wine.

Arbin, CRU on the steep, warm, south-facing slopes east of Chambéry whose name can be added to the eastern French appellation SAVOIE. Use of the Arbin cru name is restricted to wines from the local MONDEUSE grape, some of the region's finest reds.

W.L.

Arbois, the most important appellation in the JURA region in eastern France and named after the region's main wine town. The scientist Louis PASTEUR was brought up in the town and conducted observations here when invited to turn his attention to wine health. In the 20th century the town was made famous by wine producer Henri Maire, who did much for the revival of the Jura wine region after the Second World War and died in 2003. The wine company he founded still owns over 250 ha/618 acres of Jura's vineyards but left family hands in 2010 and in 2015 was taken over by BOISSET. Jura's largest CO-OPERATIVE, the Fruitière Vinicole d'Arbois, is based in the town. About 35% of Arbois production is red, making it the most important Jura red-wine appellation. The light-coloured POULSARD

grape is a speciality of the subappellation of Arbois-Pupillin, where it is named Ploussard, and TROUSSEAU is especially successful in the warmer sites around the village of Montigny-les-Arsures, home to several top vignerons, notably various members of the Tissot family. White wines are often VARIETAL Chardonnay made in unoxidized, Burgundian style, increasingly vineyard-designated. The old synonym *Naturé* is sometimes used for the local SAVAGNIN, to designate fresh, lemony, or so-called 'floral' white wines made from the variety, distinguishing them from the more usual OXIDATIVE styles. The oxidative styles, made from Savagnin on its own or blended with Chardonnay, culminate in the nutty and long-lived Savagnin-only VIN JAUNE. An Arbois 1774 was so much appreciated when tasted in 1994 that other bottles from the same lot have sold for enormous prices, one reaching €57,000 in 2011. VIN DE PAILLE is made under the Arbois appellation, whereas TRADITIONAL METHOD sparkling wine made is sold as CRÉMANT du Jura. See also MACVIN DU JURA.

Wines made from grapes grown within the commune of Pupillin have the right to the subappellation Arbois-Pupillin. Pupillin is home to one of the 'fathers' of the natural wine movement in France, retired wine producer Pierre Overnoy, whose estate is run today by Emmanuel Houillon. W.L.

Harvesting these 70– to 80-year-old CARIGNAN vines that climb up native trees on the Villalobos estate near the village of Ranguili in Chile's COLCHAGUA Valley is a team effort. The unpruned vines have never been treated with AGROCHEMICALS and YIELDS are extremely low. © Martín Villalobos Encina

Arbois Blanc is also a synonym for the MENU PINEAU vine variety of the LOIRE.

arboreal viticulture is probably the oldest and most traditional vine-TRAINING SYSTEM, or lack of one. It takes advantage of the natural inclination of the VINE to climb up trees towards direct sunlight without the need for any other support. Managing such vines is challenging, with ladders needed for most vineyard tasks, but recent research into this practice in southern BOLIVIA suggests the method has many advantages: greater biodiversity, including beneficial insects that protect the vine against diseases and other pests (see ECOSYSTEM), protection of the vine from climate extremes such as heat and FROST, and increased soil fertility and carbon sequestration, as well as less SOIL EROSION. Yields are likely to be lower than in a more intensely cultivated modern vineyard, and there may be increased competition for water. Examples of arboreal viticulture are also found in Portugal's Vinho Verde, in Georgia, Chile, Lebanon, in several regions of Italy (where it is known as *alberate*), and in France. In most cases, this looks more like a vineyard with trees to support the vines rather than the more extreme agroforestry seen in Bolivia, with vines co-habiting with trees in the forest.

Oller, P., et al., 'Structure and management of traditional agroforestry vineyards in the high valleys of southern Bolivia', *Agroforestry Systems*, 96 (2022), 375–86.

arbour, an overhead trellis structure used for VINE TRAINING, particularly in southern Italy. See TENDONE.

archaeology has been of great importance in tracing the ORIGINS OF VINICULTURE and plays a part in the ancient history of most wine regions. For a discussion of the techniques available and some of the more significant finds, see PALAEOETHNOBOTANY. For some more specific aspects, see also AMPHORAE and the CELTS.

Ardèche, French *département* on the right bank of the RHÔNE, much of which lies between the main concentrations of vineyards which constitute the northern and southern Rhône Valley, and now the name of an IGP for a wide range of generally VARIETAL wines. Chardonnay and Viognier have been particularly successful here for whites, Merlot and Syrah for reds which are typically light- to medium-bodied.

Areni, the characteristic red wine grape of ARMENIA, and also the name of a village on the border with Azerbaijan where the remains of a 4000 BCE winery were identified in 2011. Wines are medium-bodied with real zip, and the best have good ageing potential.

Argaman, ISRAELI 1972 cross of CARIGNAN and the Portuguese SOUSÃO which produces dark, light-bodied reds.

Argentina , has been the wine titan of SOUTH AMERICA for much of the 21st century, vying only with CHILE for the largest wine production in the continent. Of the country's 214,798 ha/530,777 acres of vineyard in 2020, 92% grew grapes for wine. Since the 1990s, Argentina has radically shifted to a focus on quality over quantity. Red wine, especially MALBEC, dominates, but white wines have a growing reputation for quality. Considerable investment in new vineyard areas, winemaking technology, RESEARCH, and innovation have all played a part in making Argentina a leader in the NEW WORLD.

History

Unlike North America, where explorers and early settlers found VITIS LABRUSCA growing in abundance, South America depended on the Spanish colonizers for imported European VITIS VINIFERA vines. The vine probably arrived in Argentina by four different routes. The first was directly from Spain in 1541 when vines are thought to have been cultivated, without great success, on the Atlantic coast around the Río de la Plata. A year later, grape seeds were germinated after an expedition from Peru to the current wine regions immediately east of the Andes. Another Peruvian expedition in 1550 imported vines to Argentina, and more vines came from Chile in 1556, just two years after the vine was introduced to Chile's Central Valley. (See SOUTH AMERICA, history, for more details.)

One of the most important grape varieties systematically cultivated for wine in South America was almost certainly the forerunner of Argentina's CRIOLLA CHICA, California's MISSION, and Chile's PAÍS, which were to be the backbone of South American wine production for the next 300 years. Although Argentina was settled from both the east and the west, it was in the foothills of the Andes that the Jesuit MISSIONARIES found the best conditions for vine-growing. The first recorded vineyard was planted at Santiago del Estero in 1557. The city of Mendoza was founded in 1561, and vineyards in the province of San Juan to the north were established on a commercial scale between 1569 and 1589. Soon after that, in 1595, King Felipe II of Spain, who ruled over most of Central and South America, banned the production of wine, except by the Catholic Church. This was intended to protect Spanish wine producers and their exports to Mexico and was therefore not particularly enforced in South America, so secular producers remained, and the wine industry thrived. Contrary to popular belief, this heralded a period of almost 300 years (from the second half of the 16th century to the beginning of the 19th century) of sustained growth, innovation, and a search for wine quality, largely thanks to the powerful MONKS AND MONASTERIES.

Wine soon became the main economic activity, with the wealthiest families of Cuyo and the north-west of Argentina—in what are today the provinces of Mendoza, San Juan, La Rioja, and Salta—engaged in wine production, whether secularly, through family members who were clergy, or both. Export routes to the cities of Buenos Aires, Córdoba, and Santa Fe to the east, to Bolivia to the north, and to Chile to the west were developed from the early 16th century, which created a dynamic proto-bourgeoisie, particularly in the Cuyo region. During this time, the most important grape variety cultivated was CRIOLLA CHICA (also called Uva Negra), and various MUSCATS were also widely grown. TORRONTÉS Riojano, a natural crossing of Criolla Chica and Muscat of Alexandria, dates from the 18th century. Other natural crossings that appeared in this period and are still widely grown include CEREZA and CRIOLLA GRANDE.

By the skilful use of dams and IRRIGATION channels originally established by the native population, the early settlers were able to produce sufficient wine to meet the needs of a growing population. The 18th century saw major changes. To ensure quality and ageing potential, particularly for wines that had to withstand the journey by cart from Mendoza to Buenos Aires, wines were FORTIFIED or sometimes heated, a precursor of PASTEURIZATION. Some wines were even made, like SHERRY, under FILM-FORMING YEASTS. Wine PRESSES changed from being made of leather and/or oak to being built with bricks, lime, and slate. The first record of FERMENTATION vessels made from OAK instead of the old clay AMPHORAE dates from 1740. The first AMPELOGRAPHIC studies were carried out during the second half of the century, and the government's first winery census took place in 1780. This was a period of dynamic growth, driven by solid institutions, commerce, peace, and the conjunction of a blooming bourgeoisie and the clergy's desire to make the most out of God's creation. By the end of the century, Cuyo was by far Argentina's most important wine region, with about 8,000 people in the cities of Mendoza and San Juan, almost 300 vine growers, and annual wine production of 13 million litres.

Then the wine scene began a decline that lasted nearly 100 years. In 1767 the Jesuits were expelled from Spain, and its colonies and their estates were either abandoned or seized by the Spanish crown. A civil war lasted for much of the early 19th century, and wine was no longer the most important economic activity of the region.

Some good things happened, however, such as the introduction of glass BOTTLES, from 1820. The best example is the well-documented story of General San Martín, the son of a vine-grower and probably Argentina's first wine CONNOISSEUR. After returning from leading a long campaign in Chile and Perú against the Spanish royalists, he went back to Mendoza and organized a dinner with some of the most important people of his time. At this meal, in 1823, he poured one of his favourite wines from Mendoza, and one from a renowned producer of Málaga—transposing the labels before doing so. By the end of the evening, when all attendees had proclaimed the virtues of the bottles with the Málaga label, he had demonstrated two things: that the wines from Mendoza compared well with those of Spain; and that they could age for eight years or more—which was the time his bottles had spent in his underground cellar during his crusade against the Spanish empire.

The second half of the 19th century saw Argentina enjoy a period of relative stability and prosperity built on exports of agricultural and cattle products. Many of those who had fled to Chile returned to Cuyo. Among them was Domingo Faustino Sarmiento, who subsequently became governor of San Juan and then president of Argentina. He campaigned for the creation of an agronomy school, including viticultural research and a vine NURSERY used to gradually improve vineyards, under the direction of a Frenchman exiled in 1851. Under his direction top-quality French varieties, including Malbec, were imported—before the arrival of PHYLLOXERA in Europe, incorporating much of the genetic material that was later lost in Europe. Thus Malbec, Sémillon, Cabernet Sauvignon, and many high-quality varieties were already established in Argentina before a significant wave of European immigrants of the late 1800s and early 1900s further enriched Argentina's viticulture.

In 1885 the RAILWAY between Buenos Aires and Mendoza was completed, lending still greater importance to the vineyards in the foothills of the Andes. The immigrants, many from wine-producing areas of Italy, Spain, and France, brought with them many new vine varieties and their own winegrowing skills. The foundations for Argentina's mammoth domestic wine industry were laid. This had interesting implications. Unlike many New World wine regions where winemaking was restricted to an elite, the origin of Argentina's modern era viticulture was popular and widespread among immigrant families. Even today there are over 23,000 vineyards, with an average size of 9 ha/22 acres. And the immigrants brought their wine-drinking culture with them, which turned Argentina into one of the largest domestic markets in the world. Today, Argentines drink about three-quarters of the national crop.

By the early 20th century, Argentina was the seventh wealthiest developed nation in the world, but the subsequent economic depression and political crisis led to a disastrous drop in the export price of its primary products and then a steep decline in foreign investment. The peso was often devalued. While the landowning classes continued to prosper for some time, or salted away their capital overseas, there was growing unrest among the largely disenfranchised, poorly paid urban masses. When General Juan Domingo Perón came to power in 1943 he appealed directly to the workers with promises of rapid industrialization, better working conditions, and organized, government-controlled unions. For a while Argentina's fortunes revived, but in the mid 1950s Perón and his ambitious and charismatic wife Eva were deposed by the military. From then on a succession of opportunistic military governments led the country into spiralling decline. The urban masses created an unprecedented market for wine so that quantity not quality became the imperative. In the late 1960s and early 1970s, at a time when the UK was drinking approximately 3 litres per capita annually and the Americans even less, the Argentines, despite all their troubles, were quaffing 90 litres of wine per head.

However, over the next two decades, Argentina grew increasingly isolated and suffered from social and political unrest, stifling

bureaucracy, corruption, war, and disastrous economic management. Accumulated inflation during the 1980s was over 8,000%, and wine consumption dropped dramatically. A VINE-PULL SCHEME reduced the total vineyard area by one-third, from 314,000 ha in the early 1980s to 205,000 ha/506,350 acres in 1993. A peak of hyperinflation in 1989, however, prompted President Raúl Alfonsín out of office; he was replaced by Carlos Menem, inaugurating a period of political and economic stability not experienced for decades. Under his administration, business confidence in Argentina's future was revitalized, encouraging investment in a wine industry where time had stood still (see also CHILE). Producers began to give serious consideration to the possibilities of exporting.

From the mid 1990s onwards Argentina entered a new wave of high-quality viticulture. Using new CLONES of international varieties and MASS SELECTIONS of some of Argentina's oldest varieties, new vineyards were planted in higher density and with DRIP IRRIGATION. This led not only to a leap in quality but also to an expansion of wine regions, as drip irrigation now made it possible to plant on the rocky, steep slopes of the Andean foothills. The Uco Valley has been at the forefront of this quality boom since the early 2000s. By 2012 Argentina was exporting over US$1 billion (a number which has stabilized at around US$820 million since).

Geography and climate

Argentina's wine regions are widely dispersed—spanning over 3,700 km/2,299 miles from Jujuy in the north to Chubut in Patagonia, and ranging from latitudes 23 to 45° S—but are almost entirely confined to the foothills of the Andes. In this western strip, Argentina's climate is CONTINENTAL, with the four seasons clearly defined. The Cuyo region, where the climate is semi-desert, accounts for 95% of plantings.

Summer temperatures vary from 10 °C/50 °F at night to as much as 40 °C/104 °F during the day. Summers are hot in the regions of San Juan (except for the high-elevation valleys of Pedernal and Calingasta), La Rioja, Catamarca, and the east of Mendoza (Santa Rosa, Rivadavia, San Martín, and Lavalle). In the Calchaquí Valley (Cafayate), upper Mendoza (Luján de Cuyo), Uco Valley (Tupungato, Tunuyán, and San Carlos), and Río Negro, summers are TEMPERATE to warm, making them Regions II and III in the Winkler system of CLIMATE CLASSIFICATION, although the coolest sites in the Uco Valley are Region I. In winter, temperatures can drop below 0 °C/32 °F with occasional light snowfalls. Heavy winter snow in the high Andes is important as this ensures plentiful supplies of pure water for IRRIGATION.

Rainfall is concentrated in the summer months, which encourages growth, but it seldom exceeds 300 mm/12 in annually, making irrigation essential. Early summer HAIL is the main risk to the vines—as many as 6% of Argentine vineyards are netted against hail—together with FROST. It is customary in Mendoza to own vineyards in different parts of the province to minimize the risk of hail damage. As a result, and even though single-vineyard and TERROIR-driven wines are increasingly important, blends of wines from different parts of the province are also common.

The air is dry and particularly unpolluted. Vine FLOWERING may occasionally be adversely affected by a hot, dry, very strong foehn wind called *zonda*, which blows down from the west mainly in late

spring and early summer. The lack of humidity reduces the risk of FUNGAL DISEASES, and vineyards are typically sprayed much less often in Argentina than elsewhere, making ORGANIC VITICULTURE relatively easy although only 6,000 ha/14,826 acres were certified organic by 2019. Full RIPENESS is easily achieved and CHAPTALIZATION is not allowed.

Regions

See map.

Mendoza In the far west of the country, only a (substantial) mountain range away from Santiago in Chile, this is by far the largest and most important winegrowing province in Argentina, accounting for more than 70% of the country's wine production. The Andes dominate the western skyline, with Mount Aconcagua, at 6,960 m/22,837 ft, the highest mountain in the Americas. With vineyards planted at elevations of 600–1,600 m/1,970 to 5,249 ft, and very varied aspects, soils, and mesoclimates, the region turns out a wide variety of wines, best described by subregion. See MENDOZA for more detail.

San Juan Argentina's second biggest wine-producing region had 44,923 ha/111,007 acres of vineyards in 2020. The capital of the province, San Juan, is 150 km/90 miles north of Mendoza. The climate at these lower elevations and latitudes is much hotter than that of Mendoza, with summer temperatures of 42 °C/107 °F not uncommon and rainfall averaging only 100 mm/4 in per annum.

Long the home of high-yielding pink varieties, especially Cereza, San Juan has gradually moved from quantity to quality production, especially for red grapes such as Malbec and Syrah, San Juan's most planted varieties. Good-value basic reds are also made with Bonarda and Cabernet Sauvignon, but the region is better known for Torrontés and good-value Viognier. It also provides the base for most of Argentina's brandy and VERMOUTHS. The vast majority of San Juan's wine comes from Tulum Valley at an elevation of 650 m/2,132 ft just south of the capital city. Better-quality wines can be found further west at higher elevations, in the Ullum-Zonda Valley at 850 m/2,788 ft and the Pedernal (1,100 m/3,608 ft) and Calingasta (1,500 m/4,921 ft) valleys.

La Rioja Historically the oldest of Argentina's wine-producing provinces, La Rioja is Argentina's third largest region with 7,707 ha/169,044 acres of vineyard in 2020, 20% of which is planted to Torrontés Riojano. La Rioja is little-known abroad, partly because almost the entire production of the province is crushed by the giant CO-OPERATIVE La Riojana. A handful of small-scale producers have started to produce more interesting wines in higher-elevation areas such as Famatina and Chañar Muyo.

Salta, Jujuy, Tucumán, and Catamarca These far north-western provinces are in the Calchaquí Valley, a high valley spanning latitude 24–26° S where vines benefit from more than 300 days of sun per year, as well as lots of wind and ULTRAVIOLET RADIATION. Even the lower vineyards in Salta are at 1,650 m/5,413 ft; the highest, Ayni in Jujuy, sits at 3,329 m/10,921 ft. Because of this elevation, the vines tend towards lower YIELDS and the grapes develop thick skins, the combination producing concentrated, full-bodied, fragrant wines. Promising varieties include Malbec, Cabernet Sauvignon, Bonarda, Syrah, and, particularly, TANNAT, which expresses itself quite differently here compared with those of URUGUAY and MADIRAN. For white wines, Torrontés Riojano is very much at home. Salta has the most vines, with 3,347 ha/8,270 acres of vineyards. Other areas such as Tolombón, Colomé, Molinos, Yacochuya, and Tacuil also have excellent potential.

Río Negro, Neuquén, and Chubut Located in southern Patagonia, these areas are much cooler than the better-known areas to the north and less developed, with 3,397 ha/8,394 acres under vine in 2020 split roughly equally between Río Negro and Neuquén, and just 87 ha in Chubut.

Río Negro has historically been Argentina's principal fruit-growing district, producing apples and pears as well as grapes. The valley is shaped by a river that runs from the west into the Atlantic, forming a green canyon surrounded by arid desert on both sides. Humidity and rainfall are markedly higher than further north. These growing

conditions, together with some seriously old vineyards, attracted both Countess Noemi Marone Cinzano and Piero Incisa della Rochetta, from the family that owns SASSICAIA, who respectively established their Noemía (with Hans Vinding-Diers) and Bodega Chacra projects in the province in the early 2000s. Both now practise BIODYNAMIC VITICULTURE, with exciting results.

Unlike Río Negro, the province of Neuquén had no winemaking tradition whatsoever until early this century when the authorities realized that the province was going to run out of its non-renewable mining resources. They constructed an extensive channel that could irrigate about 3,000 ha/7,413 acres of land on which vegetables, orchards, and vineyards have been planted. Bodega del Fin del Mundo led the project, and now several producers make millions of bottles in state-of-the-art wineries, filling them mainly with Sauvignon Blanc, Chardonnay, Pinot Noir, and Malbec.

Chubut, at latitude 42–43° S, was pioneered by the legendary Bernardo Weinert, from the eponymous Mendoza winery, in the late 1990s. Today the province boasts a handful of producers, including Argentine billionaire Alejandro Bulgheroni, who claims the world's southernmost commercial vineyard and winery, Bodega Otronia, with 50 ha planted at 45.33° S. The region's lean, low-alcohol, high-acid, cool-climate wines are redefining Argentine wine.

Buenos Aires, La Pampa, and Córdoba Of these three developing winegrowing areas, only Córdoba, which had 277 ha/684 acres of vines in 2020, has a long tradition of making artisanal wines. La Pampa, a province known more for its cattle, has 279 ha/689 acres planted on the northern border of Patagonia, half of that farmed by Bodega del Desierto, which started planting here in 2001. And Buenos Aires province had 149 ha/368 acres of vineyards planted on slopes near the Atlantic Ocean, where the MARITIME CLIMATE lends itself to Albariño, Pinot Noir, and Sauvignon Blanc.

Vine varieties

Red Malbec is king in Argentina. Accounting for 21% of all plantings and over 60% of Argentina's wine exports in 2020, it has come to seem more at home in Argentina than in its CAHORS homeland. Planted on a total of 45,657 ha/112,821 acres (up from just 9,770 ha in 1996), it tends produces deep-coloured, robust, fruity wines with enough alcohol, weight, and structure to benefit from OAK AGEING, with different expressions in each wine region. The second most planted red wine variety, with 18,153 ha/44,857 acres, is CHARBONO, called Bonarda in Argentina, which is used to make everything from fragrant sparkling rosés to supple red wines. Cabernet Sauvignon is right behind, having grown from less than 2,500 ha in 1990 to 14,129 ha/34,914 acres by 2020; it often appears in prestigious blends with Malbec. Syrah, at 11,797 ha/29,151 acres, is increasingly important, particularly in San Juan, north of Mendoza. A wide range of Italian and Spanish varieties, including TEMPRANILLO, CORVINA, and ANCELLOTA, were presumably brought to the country by the many European immigrants, but it is the French CABERNET FRANC, PETIT VERDOT, and TANNAT that are currently making waves, as well as PINOT NOIR, which seems to have found a home in Patagonia and the high elevations of the Uco Valley.

White Although steadily losing ground, PEDRO GIMÉNEZ (distinct from Spain's PEDRO XIMÉNEZ) is still Argentina's most planted light-skinned

grape variety, with 9,587 ha/23,690 acres grown in 2020, particularly in Mendoza and San Juan, where it is used mostly in basic blends. It is also used for making grape concentrate, which Argentina exports in vast quantities, particularly to Japan. Far more interesting is TORRONTÉS Riojano (7,659 ha/18,926 acres), which produces floral, aromatic wine made in a range of styles from dry and crisp to lusciously sweet LATE HARVEST wines. It is planted all over Argentina, but the best usually come from the Calchaquí Valley. Chardonnay, the next most planted white variety with 5,854 ha/14,466 acres, is responsible for both everyday table wines and some of Argentina's most celebrated white wines. Its own so-called Mendoza CLONE was developed at DAVIS in California and is widely planted in Australia and elsewhere. Other white wine grapes, in order of importance, are Moscatel de Alejandría (MUSCAT OF ALEXANDRIA), Sauvignon Blanc, Chenin Blanc, Torrontés Sanjuanino, and Ugni Blanc, although it is Sémillon that is leading Argentina's white wine revolution, with a good percentage of its 640 ha/1,581 acres being old vines capable of making distinctive, structured white wines. Sparkling wines also make up an important segment of Argentina's white wine production, ranging from easy-drinking TANK METHOD wines, usually made from Chenin Blanc, to rich TRADITIONAL METHOD wines based on Chardonnay.

Pinks Argentina's historically famous pink-skinned varieties are in sharp decline, representing 23% of wine-grape plantings by 2020. CRIOLLA GRANDE, CRIOLLA CHICA, and CEREZA are some of Argentina's oldest varieties and together account for 39,881 ha/98,548 acres. All three are extremely productive varieties and are typically planted in the hotter, flatter, most heavily irrigated vineyards: one bunch on a well-irrigated vineyard can weigh as much as 4 kg/9 lb. MOSCATEL Rosada is also important, with 5,330 ha/13,171 acres. The wine produced from these varieties is usually very deeply coloured white, occasionally pink, often sweet, and sold at the bottom end of the market, in bulk or in litre bottles or cardboard cartons. There is, however, a small Criolla renaissance taking place, with a new

generation of winemakers using the varieties to turn out light, juicy, fragrant red wines.

Viticulture

Argentine viticulture has been transformed since the 1990s, with better IRRIGATION techniques, CANOPY MANAGEMENT, methods and timing of HARVEST, incorporation of technology, clonal and MASS SELECTIONS, and studies of the impact of MICROBIAL TERROIR and ULTRAVIOLET RADIATION, for example.

Most vines in Argentina are UNGRAFTED because the biotype of PHYLLOXERA present is a relatively mild one, perhaps because there is a relatively high proportion of SAND in vineyard soils. Some varieties that are vulnerable to NEMATODES, however, tend to be grafted. ANTS can also pose a problem, especially to young vines. Rainfall is so low in most of the country that irrigation is a necessity. Traditionally, water was distributed by an intricate network of canals and ditches that date to the 16th century and then by FLOODING or furrows. In more recent times, the channels of water that flow from the snow-capped peaks of the high Andes have been augmented by deep boreholes. These take water from between 60 and 300 m/984 ft below the surface and can produce as much as 250,000 l/66,000 gal per hour. They are used with the more efficient DRIP IRRIGATION systems that now operate on about 20% of Argentine vineyards. In this unique landscape the cultivated areas resemble green oases in the scorched desert surroundings (as in the irrigated vineyards of Australia but with the majestic Andes as a backdrop). The vast majority of the soils are of alluvial origin, quite poor, and mostly made of sand and stones. Their structure varies from region to region, but a loose greyish sandy texture predominates with substrates of GRAVEL, LIMESTONE, and CLAY. Different forms of CALCAREOUS soils are found in some of the finest terroirs of the Uco Valley, such as Paraje Altamira, Gualtallary, and Vista Flores, as well as Pedernal in San Juan.

Although the immigrants who arrived in the early 20th century brought with them the vertical *espaldera* TRAINING SYSTEM of low training of vines along three wires, the need for greater volume led most vineyard owners to adopt the productive *parral cuyano* trellis system in the 1950s and 1960s (see TENDONE). As in Chile, however, the classic method is increasingly favoured once more in order to facilitate both CANOPY MANAGEMENT and drip irrigation, although Cereza and Criolla Grande vines are still likely to be *parral* trained. By 2020 roughly half of all vines were *parral* trained, and most of the rest were trained with either high or low VSP (see VERTICAL TRELLIS) *espaldera* systems. Over 28% of vineyards were 40 years old or more, and in Salta there is even a vineyard planted in 1862. Only 18% of vines are under 10 years old.

From BUDBREAK to HARVEST takes an average of five months, and the long ripening season normally ensures full maturity. The national institute sets the date of the harvest, which usually begins in mid February and, depending on variety and region, extends until late April. Special permits must be obtained to pick any later than the prescribed end date, mostly for late-harvest wines. MECHANICAL HARVESTERS are slowly becoming more common.

Winemaking and labelling

Since the 1980s Argentina has had an influx of international CONSULTANTS and significant investment and modernization in winemaking technology, giving the country a dynamic winemaking scene. With a diverse network of over 20,000 vine-growers and 800 wineries, Argentina has both boutique and industrial-sized wineries, and winemaking techniques range from artisanal, foot-crushed wines to large-scale productions with state-of-the-art technology. Fermentation vessels are typically stainless steel, concrete, or oak, and both oak-aged and unoaked wines are popular in white and red wines. Argentina also has a booming sparkling-wine industry, both in TANK METHOD and TRADITIONAL METHOD styles. There is also a new wave of PET-NAT and ORANGE WINES emerging from the new generation of winemakers. This generation of winemakers is particularly keen to learn and collaborate, and many work vintages in the northern hemisphere to learn from other wine regions, too.

In terms of labelling, a varietal wine must contain at least 85% of the variety cited, while any variety mentioned on the label must constitute at least 20% of the blend. Wines are classified either IP (Indicación de Procedencia) for table and regional wines, IG (Indicación Geográfica—see GEOGRAPHICAL INDICATION) for *vinifera* wines made from a specific region with certain minimum quality standards, or DOC (Denominación de Origen Controlada) for high-quality wines in which restrictions related to alcohol, winemaking techniques, yields, ageing, and other criteria apply. In 2022, Argentina had two DOCs—Luján de Cuyo and San Rafael—and roughly 100 IGs. A.R. & A.B.

www.winesofargentina.org

argilo-calcaire, French term commonly used to describe soil that is a mixture of LIMESTONE (*calcaire*) and CLAY (*argile*).

argols, another word for TARTRATES.

Arinarnoa, 1956 INRA cross of Tannat × Cabernet Sauvignon (although it was originally presented as Merlot × Petit Verdot) of which just over 171 ha/423 acres grew in the Languedoc in 2019, typically producing strong, dark-red wines. It is planted to a very limited extent elsewhere, for example in Uruguay and Brazil.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Arinto, more precisely Arinto de Bucelas, historic Portuguese white grape variety most commonly encountered in BUCELAS, in which it must constitute at least 75% of the blend. It is also grown in many other parts of Portugal, notably Tejo and Lisboa. Arinto is respected for its high acidity and citrus flavours and in Bucelas in particular can yield wines which gain interest and complexity with age. As an ingredient in VINHO VERDE it is known as Pedernã. Total plantings in 2020 were 6,351 ha/15,694 acres.

Arinto do Dão is a synonym for MALVASIA Fina in DÃO. Arinto dos Açores is an unrelated, high-quality variety indigenous to the Azores. Arinto Tinto is a Portuguese synonym for Aragonez, or TEMPRANILLO.

Aristophanes , Greek writer of comedies at the end of the 5th century BCE. In his plays he extols the hard-working peasant farmer in the fields around Athens. One of his characters is a vine-dresser, or early vineyard worker (Trygaios in *The Peace*), and the goddess of

peace is called wine-loving and 'giver of grapes'. Aristophanes criticizes the young for idling and drinking too much. Women also come in for criticism as topers in several of his plays. H.H.A.

Arizona, south-western state in the United States that boasted more than 120 wineries in 2021. The area's winegrowing history dates to the 1600s, when Spanish settlers and missionaries began planting vines in what was then MEXICO. Its modern history began in the south-eastern corner of Arizona in 1976, first in the Sonoita area then moving into nearby Willcox by the 1980s. Both are now federally recognized AVAs. In the 1990s, winegrowing was also established in the Verde Valley at the centre of the state, although as of 2022 its status as an AVA remained pending. As with COLORADO and NEW MEXICO, Arizona's vineyards are grown at high ELEVATION, where the extremes of the state's arid and semi-arid climate are moderated. Even so, the Willcox and Verde Valley areas are considered zone V, or 'very hot' on the Winkler Index (see CLIMATE CLASSIFICATION), while Sonoita counts as Zone IV 'hot.' Summer months bring plenty of sun and warmth, but by autumn monsoon season begins, making early ripening a must. Both WINTER FREEZE and spring FROST are also concerns. Sonoita vineyards sit around 5,000 ft/1,524 m in elevation, while Willcox sites begin at 4,000 ft/1,219 m and climb as high as 7,000 ft/2,134 m. The Verde Valley is comparatively lower, with vineyards at elevations between 3,500 and 5,000 ft/1,067–1,524 m. Incredibly, LIMESTONE can be found throughout all three regions as ancient Arizona once hosted an enormous inland sea. While land is far more available in both Willcox and Sonoita, the two AVAs suffer from less water availability. The Verde Valley benefits from the Verde River, but most land has been given to ranching rights. Though Arizona wine was established originally on Cabernet Sauvignon and Syrah, today the most successful wineries are experimenting with Spanish and Italian varieties. MATARO, GARNACHA, TEMPRANILLO, and MALVASIA do particularly well. PETIT MANSENG made in a dry style has also proven uniquely successful. E.C.B.

Arkansas, southern state of the United States that traces its winemaking history back to the 1880s, when Swiss and German immigrants settled in Altus, a town in a high valley along the Arkansas River, and began making wine from the local CATAWBA and Cynthiana (NORTON) grape varieties. Fifteen years later, a group of Italians settled further north, in Tontitown, in the foothills of the Ozarks, and began producing wine from CONCORD and Cynthiana. The industry grew to include 150 wineries before PROHIBITION, which hit Arkansas particularly hard: even in 2022, 34 of the state's 75 counties are 'dry', prohibiting alcohol sales. Nevertheless, in 2022, the state produced 1,210,910 litres/266,363 gal of wine, placing it 17th in wine production in the US. Winegrowing is focused in the cooler north-western corner of the state, particularly in Altus, now an AVA. There, the sandy soils and a protected position between the Boston and Ouachita mountain ranges allow for the growing of VITIS VINIFERA such as RIESLING, CHARDONNAY, and ZINFANDEL. In the surrounding Arkansas Mountain AVA, WINTER FREEZE can be a risk, putting emphasis on HYBRIDS such as CHAMBOURCIN and Cynthiana, the official state grape, sometimes called the 'Cabernet of the Ozarks'. In the state's southern reaches, heat, humidity, and a risk of PIERCE'S DISEASE make MUSCADINIA the favoured choice. The state's winegrowers are supported by the University of Arkansas's grape breeding programme, focused on creating cold-hardy varieties such as Opportunity, a white grape with RKATSITELI parentage, and Enchantment, a TEINTURIER variety with ALICANTE BOUSCHET parentage.

Arlanza, DOP created in SPAIN in 2008 for land between RIOJA and RIBERA DEL DUERO along the Arlanza River, with 350 ha/865 acres under vine in 2020. Closer in climate to Rioja, it is the source of fresh, fragrant wines from old, often mixed vineyards (see FIELD BLEND).

arm, viticultural term for that part of the vine's woody framework which is more than one year old and from which the CANES and SPURS arise. The location and length of the arms depends on the vine-TRAINING SYSTEM used. Arm is used interchangeably with cordon in some regions, but if both are present, the arm is the shorter and the cordon is the longer. R.E.S.

armazém, Portuguese for 'warehouse' or 'store'. In the towns of Vila Nova de Gaia (see OPORTO) and Funchal (see MADEIRA), *armazéns* (plural form) are the long, low LODGES where PORT and madeira are left to age.

Armenia, relatively small, mountainous, ex-Soviet republic in Transcaucasia with a proven winemaking history dating back at least 6,000 years. Vineyard ELEVATIONS of up to 1,750 m/5,741 ft compensate for its southerly latitude. In 2020, Armenia officially had 15,200 ha/37,560 acres of vineyard and produced 264,000 tonnes/291,010 tons of grapes giving 110,130 hl/2.9 million gal of wine and 391,910 hl of brandy.

History

The Transcaucasian region, including Armenia, is one of the world's oldest centres of viticulture and may be the cradle of grapevine domestication. Ancient Armenia was much bigger than modern Armenia and in classical times included much of eastern TÜRKIYE, AZERBAIJAN, and GEORGIA in the area between the Black Sea and the Caspian Sea. Fossil evidence of the wild vine VITIS VINIFERA subsp. *silvestris* has been identified in the region from the late Pliocene, and carbonized grape pips have been found at several Neolithic sites in the Caucasus. These findings, along with the current populations of wild grapevines and diversity of cultivated material, support this hypothesis.

In 2011, it was announced that the earliest 'winery' in the world had been discovered in the karst Areni-1 cave. Dating back to *c.*4000 BCE, it showed that winemaking was already large-scale, organized, and linked to human ritual. The cave has a rudimentary grape press surrounded by clay wine jars (*karas*) in which traces of grape pigments, alcohol, and grape material have been confirmed by chemical analyses. The atmosphere of the cave has preserved organic material incredibly well, and other finds include a six-millennia-old human brain and a leather shoe from 5,500 years ago. See PALAEOETHNOBOTANY and ORIGINS OF VINICULTURE.

Archaeological evidence has also revealed irrigation canals, wine cellars, wine presses cut into rock, and large *karas* dating to the Iron Age. Argishti I (785–753 BCE), the king of Urartu (an ancient state which is regarded by modern Armenians as a predecessor of their homeland), made his capital Tushpa into a pleasant garden city planted with vineyards. An inscription of his descendant Rusa II (680–639 BCE), who built Teishebaini (today's Karmir Blur) south-west of Yerevan states: 'By command of the god Haldi I have planted these vineyards.' Grape seeds resembling varieties grown today were unearthed during excavations of the Teishebaini fortress from the 8th century BCE. There were also wine cellars, with more than 400 *karas*

stamped with the year of production and volume of wine. Discovery of SULFUR close by suggested knowledge of its use in preserving wine. Herodotus (*Histories* 1. 194, see ancient GREECE) described the river trade on the Tigris by Assyrian merchants shipping wine downstream from Armenia.

In 301 CE Armenia became the first nation to adopt Christianity as its official state religion. The Christian faith shaped Armenian culture intimately, and wine became not only an intrinsic part of religious rituals (see EUCHARIST) but also was used for medicinal purposes. The biblical story of Noah is closely linked to Armenia. According to Genesis, Noah made landfall on the slopes of Mt Ararat (in Türkiye today) then planted vines on the foothills in Armenia and made wine. Old manuscripts confirm Armenia's high level of viticultural development, and many regard this period (to 500 CE) as a golden age of winemaking. The next 1,500 years saw waves of invasion and wars that meant wine suffered periods of decline, though it hung on even through the Ottoman period (see ISLAM).

Armenia became part of the Russian Empire in 1828 and saw an increase in grape-growing, winemaking, and distillation for brandy and vodka. Brandy developed particularly strongly in the late 1800s as it was more stable to transport over Armenia's inhospitable mountains. Prior to the First World War, Armenia was the leading brandy producer in the South Caucasus, led by the Yerevan Brandy factory. Vineyards covered 10,800 ha/26,687 acres, providing a living for 100,000 people in holdings typically less than 1 ha. After the First World War, Armenia had a brief period of independence but was invaded by the Soviet army in 1920, becoming the Armenian Soviet Socialist Republic. Private wineries were nationalized and amalgamated into the large Ararat wine trust, followed by establishment of the Hayginkoop agricultural CO-OPERATIVE. Stalin subsequently designated the country as a brandy producer, wine production fell, and vineyards were increasingly planted with neutral and high-yielding grape varieties for distillation.

Modern history

After independence in 1991, Armenia was left impoverished, and winemaking only started to recover in the late 1990s with the first new-era private wineries, often established by returning members of Armenia's considerable diaspora. This accelerated after 2011 with the appearance of genuinely premium quality wines. By 2020, the industry counted 110 registered wineries, but only 40 are serious producers and members of Armenia's Vine & Wine Foundation. Nearly a quarter of production was exported, with the Russian Federation a key market, but quality improvements have gained customers in 34 other countries.

Viticulture and vine varieties

Armenia is a mountainous, largely VOLCANIC landscape with LIMESTONE outcrops, growing vines commercially at 400–1,750 m/1,300–5,580 ft, the elevation moderating the climate, which is dry and CONTINENTAL to dry subtropical. Average annual rainfall is 550 mm/22 in, and summers are dry so IRRIGATION is widespread. Winters are sufficiently severe for 85% of vineyards to need WINTER PROTECTION, and there is risk of spring and autumn FROST. PHYLLOXERA is present only in the Ararat Valley so most of the country's vines are own-rooted (see UNGRAFTED VINE). Trellising is widely used, except for old BUSH VINES in remote areas such as Vayots Dzor that escaped collectivization; such vines can be more than 100 years old. Armenia claims at least 400 indigenous varieties though only 30 or so are used in commercial winemaking. Approximately 20% of the harvest goes for wine, with 70% for brandy and 10% as table grapes. The country has recently set up a nursery project to identify and conserve 350 indigenous varieties with 171 passported accessions planted so far. Area by vine variety is not available until the vineyard register is complete, but important red varieties include the indigenous and highly sought-after ARENI, plus Kakhet, Haghtanak, Sireni, and Karmrahyut. Important white grapes include Voskehat, Kangun, Garan Dmak, Mskhali, Chilar, Lalvari, and Khatun Kharji.

Armenia has five viticultural zones: the Ararat Valley (4,800 ha/11,861 acres), Armavir (5,600 ha), Aragatsotn (1,000 ha), Vayots Dzor (2,000 ha), and Tavush (1,800 ha). The predominantly ethnic Armenian self-declared Republic of Artsakh/Nagorno-Karabakh shrank from 1,380 ha to *c.*700 ha after the 2020 war. C.G.

armillaria root rot, worldwide FUNGAL DISEASE which lives in woody plant materials in the soil and attacks a wide range of plants including vines. It is sometimes called the mushroom, oak, or shoestring root rot. It is typically a problem on land where vines have replaced trees, and it is frequently seen in vineyards where oak trees grew previously. Infected vines tend to occur in groups and slowly decline or sometimes die suddenly. The causal fungus, *Armillaria mellea*, produces white fungal mats with a distinct mushroom-like smell under the bark of the vine's lower trunk and roots. The land can be fumigated to ward off this fungus, for which there are no tolerant ROOTSTOCKS. R.E.S.

Arnaldus de Villanova , sometimes called Arnaud de Villeneuve, was a Catalan who died in 1311. He taught MEDICINE at MONTPELLIER, the most important medical school, with Salerno, in medieval Europe. He had an eventful life, attending the sickbeds of popes and kings and engaging in theological controversy. He was an influential physician, and his writings were still reprinted in the 16th century.

Arnaldus is not interested in wine for its own sake: his concern is with the medical proprieties of wine. One of his books, the *Liber de vinis* ('Book on Wines'), deals exclusively with wine as medicine, but references to wine appear throughout his works. The *Liber de vinis* is short: in the 16th-century editions of the complete works, it occupies no more than 10 folio pages. To a modern reader it is bound to appear a strange mixture: GALEN and the Arab philosopher Avicenna; alchemy and astrology; some first-hand observation. Arnaldus' medicine draws heavily on the voluminous writings of Galen (129–99 BCE), physician to the Emperor Marcus Aurelius, but Galen was a far better scientist. Galen wrote in Greek, but knowledge of Greek was rare in the medieval west: some of his works were, however, translated into Arabic and thence into Latin. Through Moorish Spain, Arabic influence on European influence was strong: hence Arnaldus' references to Avicenna and other Arabic authors.

Arnaldus praises wine as a remedy against melancholy and says that it is good for the liver, the urinary tract, and the veins, because it

purifies the blood. He recommends it to the old, especially in winter, because it warms the kidneys as well as the entire body, reduces the swelling of haemorrhoids, is beneficial to digestion, gives one a healthy complexion, comforts the mind, and, best of all, slows down the greying of one's hair. Most of his remedies, however, do not involve the drinking of neat or watered wine. He uses wines flavoured with rosemary or borage, recipes which go back to classical antiquity and which were supposed to cure a wide variety of ills; he exploits the antiseptic quality of wine for making poultices and, since the water was not usually reliable, to dissolve other medical substances.

One would not have been safe in Arnaldus' hands. An aside about making wine is spot on, however: the wooden casks in which wine was kept should be clean and free of odours, the grapes should mature properly, and any unripe grapes must be discarded.

He is popularly credited with introducing the first still to France, probably from Salerno, and he was granted a patent for his discovery of MUTAGE (which spawned wines such as those now known as VINS DOUX NATURELS) in 1299 from the powerful king of Majorca.

Arneis, white grape variety and dry, scented VARIETAL wine of PIEMONTE in north-west Italy. Originally from ROERO, it was traditionally used to soften the red NEBBIOLO grape. Although the wine has a certain history in Piemonte, it seemed on the verge of disappearing in the early 1970s when only two houses, Vietti and Bruno Giacosa, were bottling Arneis. In the 1980s, however, thanks to growing demand for white wine in Piemonte, particularly from houses more renowned for their BAROLO and BARBARESCO, there was an explosion of interest in Arneis, and plantings totalled 1,108 ha/2,738 acres by 2015. This low-yielding variety ripens in the second half of September

and gives wines with subtle if interesting perfumes. Modern winemaking has, in the best cases, dealt with the variety's inherently low acidity. The best examples tend to be unoaked and drunk young. It is not planted anywhere else in Italy but is grown to a very limited extent in California, Oregon, Australia, and New Zealand.

Arnsburger, white wine variety developed at GEISENHEIM for sparkling wine and exported to the island of MADEIRA due to an EU-funded project (with a German consultant). Planted on the north side of the island, the productive, disease-resistant variety is used to make rather tart, unfortified, dry white wine with limited local appeal.

aroma, imprecise tasting term for a relatively simple smell such as that of a grape, fermenting MUST, or young wine. Originally from the Greek word meaning 'spice', it has evolved so that in generally current English it means 'pleasant smell' (as opposed to odours, which may be distinctly nasty). Wine-tasting professionals tend to use the word 'aroma' to distinguish the smells associated with young wines from the more complex aromatic compounds which result from extended BOTTLE AGE, sometimes referred to as BOUQUET. In Australia, the word 'aroma' is often used to refer specifically to VARIETAL characteristics rather than those associated with winemaking or AGEING. Those who distinguish between 'aroma' and 'bouquet' differ as to the point in a wine's life cycle which divides the use of the two terms. For tasters schooled at the University of BORDEAUX, bouquet includes fermentation smells, for example, as well as all those associated with oak ageing and bottle ageing. Others, particularly Burgundians, may refer to grape aromas as primary aromas, fermentation and oak ageing aromas as secondary aromas, and bottle-ageing aromas as either tertiary aromas or bouquet. See also FLAVOUR, AROMA WHEEL, FLAVOUR COMPOUNDS, and ESTER. A.D.W.

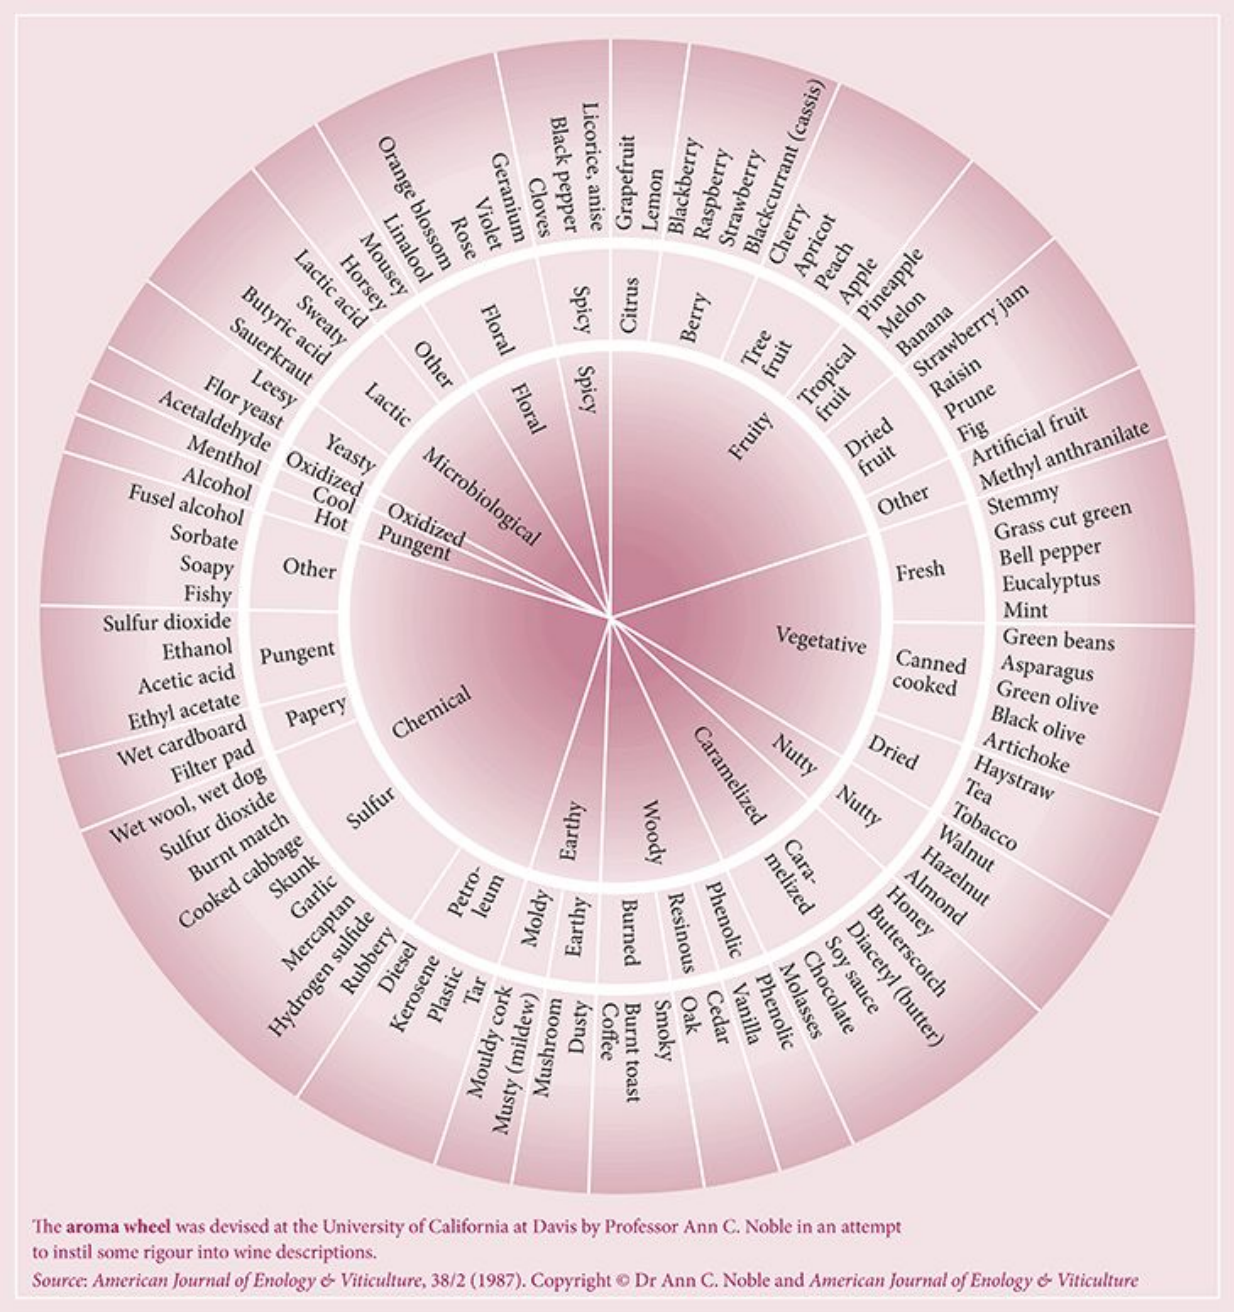
aroma compounds. See FLAVOUR COMPOUNDS.

aromatics, informal category of white wines made from particularly aromatic grape varieties, a term commonly used in AUSTRALIA and NEW ZEALAND. Typical examples are VARIETAL Gewürztraminer, Pinot Gris, and Riesling. Other particularly aromatic grape varieties include Sauvignon Blanc and Viognier.

aromatized wines. See FLAVOURED WINES.

aroma wheel, graphical representation of TASTING TERMS used for AROMA, devised at the University of California at DAVIS by Ann C. Noble and others in the early 1980s. Her research into sensory evaluation of wine had indicated that there was no general agreement either on terminology or on its application. The aroma wheel was developed to provide a standardized lexicon which can be used widely to describe wine aroma in non-judgemental terms, grouping specific terms which can be defined to provide a basis for communication. In its attempt at clarification and categorization it is used by professionals and provides a good basis on which tasting terms for aroma can be taught to novices, even if, with experience, most individuals tend to develop their own terms, which may be just as precise and descriptive. The aroma wheel does not include terms which describe the physical dimensions of a wine (such as 'full-bodied' or 'tart').

The extensive use of the wine aroma wheel led to the development of an analogous mouthfeel wheel to describe the TEXTURE and MOUTHFEEL sensations of red wines.



The **aroma wheel** was devised at the University of California at Davis by Professor Ann C. Noble in an attempt to instil some rigour into wine descriptions.

arrachage, French term for GRUBBING UP vines. The *prime d'arrachage*, payment for participating in the European VINE-PULL

SCHEME, made its mark on the southern French landscape from the late 1980s.

Arribes, Spanish DOP in the provinces of Salamanca and Zamora on the border with Portugal, with vineyards flanking the steep, deep canyons of the Duero River. The indigenous dark-skinned JUAN GARCÍA dominates the 337 ha/833 acres of vineyards, although Bruñal (ALFROCHEIRO) is increasingly valued. Whites are made mainly from Malvasía Castellana (DOÑA BLANCA).

arrope, a syrup used for sweetening wine in Spain, especially SHERRY and MÁLAGA, made by boiling down and unfermented grape juice. See GRAPE CONCENTRATE.

Arroyo Grande Valley, California wine region and AVA. See SAN LUIS OBISPO.

Arroyo Seco, California wine region and AVA. See MONTEREY.

Arruda, DOC subregion in central LISBOA in Portugal. Production, focused mostly on BULK reds, is dominated by the CO-OPERATIVE. An ambitious new project by Monte Bluna is revealing the quality potential on Jurassic LIMESTONE at ELEVATION. S.A.

Arrufiac, also known as Arrufiat, is a light-skinned, quite tannic grape variety enjoying a modest renaissance in Gascony in SOUTH WEST FRANCE, where there were just 31 ha/77 acres in 2018. An ingredient in PACHERENC DU VIC-BILH and ST-MONT, it was rescued from obscurity in the 1980s by André Dubosc of the Plaimont CO-OPERATIVE. It is typically blended with the MANSENGS, COURBU BLANC, and PETIT COURBU.

Artémis Domaines, the wine division of entrepreneur François Pinault's Groupe Artémis. His first wine acquisition was first growth Ch LATOUR in 1993. This was followed by Domaine René Engel, renamed Domaine d'Eugénie, in VOSNE-ROMANÉE, acquired in 2006; CHÂTEAU-GRILLET in the northern Rhône Valley (2011); Araujo Estate, renamed Eisele Vineyard, in Napa Valley (2013); and Clos de Tart in MOREY-ST-DENIS (2017). In 2022 the group absorbed Champagne Henriot, Champagne Jacquesson, and BOUCHARD PÈRE ET FILS.

artificial intelligence (AI) is being developed and used in four main areas of viticulture and winemaking in order to tackle a wide range of challenges, from CLIMATE CHANGE to COUNTERFEIT WINE. Based on historical developments and recent technological advances, research has been focused on the following potential applications of AI:

- Viticulture management, such as the exploitation and integration of data provided by the tools and techniques of PRECISION VITICULTURE, for example REMOTE SENSING and PROXIMAL SENSING. Applications of AI include the assessment of nutrient and water requirements, early detection and better management of pests and diseases to use resources more efficiently, and bud/grape berry recognition to obtain quality traits and predict yields.
- Estimation of grape composition and prediction of final wine quality, including possible smoke contamination of grapes in the vineyard and SMOKE TAINT in wines due to WILDFIRES.
- Measuring consumer acceptability of wines using biometrics for sensory analysis, including non-invasive physiological assessments such as heart rate, blood pressure, respiration rate, skin-temperature changes, and emotional response from face recognition and AI.
- Counterfeiting and PROVENANCE assessment using digital and non-invasive technology through bottles, such as near-infrared spectroscopy.

These digital technologies based on AI for viticulture and winemaking can also be implemented to develop smart systems (i.e. digital twins, which are a 'virtual model' or a digital counterpart to the viticulturist's/winemaker's decision-making process). These smart systems can be deployed as autonomous tools to invigilate all the processes between vineyard management (based on DRONES and remote sensing), wine production (based on 'electronic noses' and optical sensors), and consumer acceptability (based on biometrics from consumers and emotional response). The aim is to produce targeted wines or maintain styles determined by consumer preference that also maximize use of resources such as nutrients, water, and labour by implementing AI tools throughout the process.

Grape-growers' main concern in the digital era is who owns the data and whether data from their vineyards could be used to improve the viticultural and winemaking practices of competitors. However, this concern is based on the misconception that AI modelling techniques recognize patterns from the actual data. In fact, pattern recognition is created within the AI modelling techniques themselves or the machine, not from the data. Hence data contributes to incorporating site-specific factors which benefit all grape-growers using these technologies. Fuentes and Gago (2022) proposed that agricultural data should be treated as currency using BLOCKCHAIN technology to regulate its usage and management. In fact, it follows the Game Theory principle and therefore benefits the individual grape-growers and the industry as a whole.

AI in viticulture, and in agriculture more generally, could become a turning point in efforts to mitigate and adapt to the challenges posed by climate change, population growth, and reduced arable land on Earth. S.F.

artists' labels, wine LABELS illustrated by works of art, often a different one for each vintage. Baron Philippe de ROTHSCHILD commissioned the Cubist Jean Carlu to design a mould-breaking label for the 1924 vintage of Ch MOUTON-ROTHSCHILD, the first to be CHÂTEAU BOTTLED. He instituted this as an annual custom from the 1945 vintage, with the result that collectors may seek particular labels, thereby adding value to Mouton Rothschild even in lesser or earlier-maturing vintages (of which most bottles tend to have been opened). Since then, vintages of Mouton have enjoyed particular réclame in countries associated with the artist responsible for that year's label. Wine producers all over the world have since emulated this practice, notably Leeuwin Estate of WESTERN AUSTRALIA and Nittardi in CHIANTI CLASSICO, although none to such clever effect.

Mouton Rothschild: Paintings for the Labels (1995).

Arvine, also known as Petite Arvine, the finest of the INDIGENOUS VARIETIES of the Valais in Switzerland. The wines tend to be nervy with considerable EXTRACT and, often, a vague suggestion of grapefruit and salt. Wines vary in sweetness between dry, mi-FLÉTRI, and downright sweet. Switzerland had 235 ha/581 acres of this grape by 2020.

ascorbic acid, vitamin C, one of the first VITAMINS to be discovered and a winemaking additive used chiefly as an antioxidant. As well as being essential to the human diet, it is involved in plant metabolic processes. The green grape contains significant levels of vitamin C, but much is lost during fruit ripening and winemaking. In a wine

context, ascorbic acid (or its isomer erythorbic or iso-ascorbic acid) is of chief importance not to the wine drinker but to the winemaker as a permitted ADDITIVE, within limits, for its ability to prevent OXIDATION by reacting directly with OXYGEN. The EU limit in a finished wine is 250 mg/l.

The chemistry of ascorbic acid in preventing oxidation in white juices and wines is complex, and this has led to confusion about its effectiveness. When used alone as an antioxidant, ascorbic acid reacts very rapidly with oxygen and thus retards oxidation. However, the reaction of ascorbic acid with oxygen produces oxidative products that, in the absence of free SULFUR DIOXIDE, will in turn oxidize wine components. Thus ascorbic acid alone is not a suitable antioxidant in winemaking.

Free sulfur dioxide does not react rapidly with oxygen, thus it is not a good oxygen scavenger and does not fully control wine oxidation. However, the combination of ascorbic acid with free sulfur dioxide is a very effective antioxidant, even in the long term, provided that a level of free sulfur dioxide is maintained in the wine. The ascorbic acid reacts rapidly with any OXYGEN present, and the oxidative products in turn react with the sulfur dioxide and are eliminated.

In combination, ascorbic acid and sulfur dioxide can be used throughout the white winemaking process, from grape crushing and pressing to BOTTLING. In red winemaking, ascorbic acid is not used as some oxidative modification of PHENOLIC compounds, including TANNINS, is usually desirable. P.J.W. & T.J.

aseptic bottling. See STERILE BOTTLING.

Asia . Until the 1990s it was assumed—quite wrongly, as it turned out—that this most populous of continents would never play an important role in the world of wine. This assumption was rapidly disproved in the mid to late 1990s when the world's AUCTION prices were inflated at an unprecedented rate thanks largely to sudden

interest from buyers in Hong Kong, Singapore, and Taiwan. Thanks to a boom in the so-called tiger economies, and the much-vaunted HEALTH benefits claimed for red wine, wine-drinking changed from an unusual foreign practice to status symbol in a remarkably short time in countries as varied as Thailand, Taiwan, India, Korea, and—the country with the greatest potential as both consumer and producer—China. Wine-drinking had already infiltrated Japan, and several other Asian countries have embarked on their own domestic wine industries, often based on TABLE GRAPES initially and sometimes bolstered by imported BULK WINE, since the early 1990s. For details of individual countries, see BHUTAN, CAMBODIA, CHINA, HONG KONG, INDIA, INDONESIA, JAPAN, KOREA, MYANMAR, NEPAL, SINGAPORE, SRI LANKA, TAIWAN, THAILAND, and VIETNAM. See also the ex-Soviet Central Asian republics of AZERBAIJAN, KAZAKHSTAN, KYRGYZSTAN, TAJIKISTAN, TURKMENISTAN, and UZBEKISTAN. Countries such as AFGHANISTAN, IRAQ, IRAN, JORDAN, PAKISTAN, and SYRIA devote most of their vineyards to the production of RAISINS but, in Western Asia, ARMENIA, CYPRUS, GEORGIA, ISRAEL, PALESTINE, LEBANON, and TÜRKIYE all have significant wine industries.

Asia Minor. See ANATOLIA.

Asian lady beetle. See LADYBUG TAINT.

aspect, the direction in which a slope faces, also referred to as exposure, an important characteristic of vineyard sites, especially in cool climates. The French equivalent, *exposition*, is often mistakenly used in wine writing in English. For more details, see TOPOGRAPHY.

Aspergillus. See BUNCH ROTS.

aspersion, French for sprinkling and therefore a measure to reduce FROST DAMAGE to vines; see SPRINKLERS.

Aspiran, officially but not popularly known as Rivairenc, is a very old dark-skinned grape variety of the LANGUEDOC which once represented about a quarter of all vines in the Hérault *département* but was rarely replanted after PHYLLOXERA because it is not particularly productive. The odd hectare that remains yields limited quantities of light but perfumed red wine, and it is a permitted grape variety in MINERVOIS. Its progeny Aspiran Bouschet is almost extinct in France but can be found in Mendoza and Chile. DNA PROFILING has revealed a parent–offspring relationship with CINSAUT.

Asprinio. See GRECO.

Assario, Dão synonym for MALVASIA Fina.

assemblage, French word for the important operation in the production of fine wines of deciding which lots will be assembled to make up the final blend. It plays a crucial role in SPARKLING WINEMAKING when some CUVÉES may be assembled from several hundred different components. Here the complementary nature of each component is of great importance, as is, for all NON-VINTAGE sparkling wines, adherence to a house style.

Assemblage is of almost ritual significance in BORDEAUX, where many CHÂTEAUX make their so-called GRAND VIN carrying the château name by selecting and BLENDING only the best lots. The rejected lots may either be blended to make a SECOND WINE (and occasionally even a third wine) or sold off in bulk to a NÉGOCIANT carrying only the local appellation (Margaux or St-Julien, for example).

This selection process typically takes place between the third and sixth month after the HARVEST (much later in SAUTERNES) and involves the MAÎTRE DE CHAI (winemaker), any OENOLOGIST regularly working for the property, and the proprietor, who must bear the considerable financial sacrifice of exclusions from the *grand vin*, which may sell for

three or more times the price of the associated second wine. It is at this stage that the decision is usually taken over whether to incorporate any PRESS WINE.

The normal procedure is to taste samples from each *cuve* or FERMENTATION VESSEL and then simply decide whether it is of sufficiently high quality for the *grand vin*. It has usually been assumed that any blend of wines from the same property is likely to be harmonious. In most other European wine regions, especially BURGUNDY, holdings are often too small to allow this selectivity, although Chave of HERMITAGE in the Rhône, for example, is notable for keeping lots from different PARCELS of vineyard separate until a final assembly just before bottling.

Such a TERROIR-driven approach is slowly becoming more common throughout the wine world, although it is more likely to involve the assembly of blends of various quality levels and character. In this case there may be extensive experiments with small samples of each lot—known as bench blending—before final blends are decided upon. Here the winemaker is concerned not just with each lot's inherent quality but also with its affinity with other components in the blend.

Assyrtiko, top-quality white grape variety grown increasingly widely in GREECE. Its origins lie on the island of SANTORINI, but its ability to retain acidity in a hot climate has encouraged successful experimentation with it elsewhere, notably on the north-eastern mainland around Halkidiki. Its severe mineral profile (see MINERALITY) has made it a successful blending partner for MALAGOUSIA, Sauvignon Blanc, and Sémillon. Its wines can age relatively well. So obvious is its quality that it is Greece's third most planted white wine vine with 2,015 ha/4,979 acres in 2021, and it has even been imported into Australia, France, South Africa, and California. High demand for the fruit of Santorini's low-yielding vines has led to significant price increases over the last decade.

Asti, town and province in PIEMONTE in north-west Italy whose name appears in local VARIETAL reds made from DOLCETTO, FREISA, GRIGNOLINO, MALVASIA di Casorzo, and, most famously, BARBERA. Unlike its counterpart Barbera d'Alba, made from vines traditionally planted in lesser sites where NEBBIOLO will not ripen, Barbera has always been given supreme vineyard sites in Asti. Barbera d'Asti was elevated to DOCG in 2010, with three superior subzones: Tinella, Colli Astiani or Astiano, and Nizza, the latter elevated to DOCG in 2019. Since 2014 the area has been recognized as a UNESCO World Heritage Site together with the Langhe.

However, Asti is most associated with the playful, aromatic, lightly sparkling wine with modest alcohol levels that was Italy's biggest-selling wine before the ascent of PROSECCO and PINOT GRIGIO. In 1993, along with the superior MOSCATO D'ASTI, Asti Spumante was elevated to DOCG status and renamed Asti, largely to distinguish it from the host of FRIZZANTE or sparkling wines produced in Italy from a wide range of grape varieties of very varying quality.

Both Asti and Moscato d'Asti must be produced from at least 97% Moscato Bianco (MUSCAT BLANC À PETITS GRAINS) in the provinces of Asti, Cuneo, and Alessandria, where vineyards total 9,700 ha/23,969 acres, of which 7,000 ha are on slopes, shared by 4,000 growers spread over 52 communes. Average vineyard size is just 2.45 ha/6 acres. Production has increased from 40 million bottles in the 1970s to 91.5 million bottles in 2020, made possible by a VINE DENSITY of 4,000 vines/ha and a permitted yield of 10 tonnes/ha. Large bottlers and NÉGOCIANT houses have traditionally dominated production, relying on the TANK METHOD. The combination of large-volume production and small-scale viticulture has necessarily made Asti a wine blended from many sources, masking geographical differences in sites. No efforts have been made to distinguish hill sites from lower areas by the creation of a CLASSICO zone. However, an increasing number of producers are bottling their own produce, resulting in more artisanal wines and more wines from SINGLE VINEYARDS and SORÌ (a site with more than 50% inclination). The subzones Santa Vittoria

d'Alba and Strevi may appear on Asti labels, and, since 2020, single-vineyard names may appear on all Asti and Moscato d'Asti labels.

Asti comes in several versions, each determined by its alcoholic content, RESIDUAL SUGAR, and intensity of sparkle. Asti differs significantly from Moscato d'Asti: it is more alcoholic (6–9.5% rather than Moscato d'Asti's maximum of 6.5%), and it is fizzier (at least 3 bar of pressure in the bottle rather than Moscato d'Asti's maximum of 2 bar). The best and ripest grapes are normally reserved for Moscato d'Asti.

In 2011 an Asti Spumante Metodo Classico category was introduced, requiring a minimum of 10% alcohol, second fermentation in bottle (see SPARKLING WINEMAKING), and nine months ageing on the lees. In 2017, in response to an international demand for a drier style and to counteract competition from Prosecco, Asti Secco, with 17–32 g/l residual sugar and at least 3 bar of pressure, was created. Since 2020 Asti Spumante may also produce Brut, Extra Brut, Brut Nature, or Pas Dosé versions in addition to the sweeter categories Demi Sec, Secco/Dry, and Extra Dry. W.S.

astringency is a complex of sensations resulting from the shrinking, drawing, or puckering of the tissues of the mouth. Earlier, astringency had been considered as one of the primary TASTE sensations, like sweetness, sourness, and particularly BITTERNESS, with which it has often been confused. It is now recognized as a tactile response not dependent on the taste receptors, however. The word is derived from the Latin *ad stringere*, meaning 'to bind', which presaged the finding that astringent materials could bind to, and precipitate, PROTEINS. The most important astringent materials are TANNINS, and it is these components of a wine that are responsible for the puckery, tactile sensation that is most noticeable in young red wines but can be sensed in a small but increasing proportion of white

wines too, particularly those from hard-pressed or SKIN-FERMENTED grapes, most notably in ORANGE WINES. An appropriate degree of astringency contributes very positively to the palatability of a wine, and astringency is central to TEXTURE and MOUTHFEEL. Some of the terms used by tasters to describe the astringency of a wine—for example, 'hard', 'soft', 'green', 'resinous', 'leathery', 'gripping', 'aggressive', 'supple'—are the same as those used to describe the tannins of the wine. The astringent sensation may be modified by ACIDITY, SWEETNESS, PHENOLICS, particularly tannins and PIGMENTED TANNINS, and even serving TEMPERATURE. The effect of these components on apparent astringency has been an area of active research in contemporary OENOLOGY.

Revelett et al. suggest that the 'stickiness' as well as the level of tannins is a factor in how astringent a wine tastes. P.J.W.

Revelett, M. R., et al., 'High-performance liquid chromatography determination of red wine tannin stickiness', *Journal of Agricultural and Food Chemistry*, 62/28 (2014), 6626–31.

Vidal, S., et al., 'Taste and mouth-feel properties of different types of tannin-like polyphenolic compounds and anthocyanins in wine', *Analytica Chemica Acta*, 513 (2004), 57–65.

Aszú, Hungarian term derived from an old form of the word 'dried' and now used solely to denote grapes affected by BOTRYTIS and naturally dried on the vine in TOKAJ. Tokaji Aszú, therefore, means a wine made from shrivelled, botrytized grapes in Tokaj, although the winemaking method is more complicated than that. See TOKAJ for more detail.

ATF, previously known as BATF. See TTB.

Athenaeus (flourished *c.*200 CE) was born in Naucratis, a Greek city in the Nile Delta in Egypt, and wrote in Greek. Nothing is known

about his life, and his surviving work, the *Deipnosophistae*, meaning 'The masters of the art of dining', can be dated only from internal evidence. It describes at length how 23 men dine together in ancient ROME and records their conversations; their two most frequent topics are HOMER and wine. Two of the participants are the physician GALEN and the lawyer Ulpian of Tyre; the others are not based on real persons. The work consists of 15 books, but the first two and part of the third survive only in excerpts.

Although wine is the second most frequent topic of the diners' conversation, Athenaeus shows little interest in CONNOISSEURSHIP and none at all in VITICULTURE. Rather than engaging in systematic discussion, Athenaeus assembles curious facts, makes lists, and proposes (often incorrect) etymologies: his enumeration of types of CONTAINERS for wine in Book 11 exemplifies all these tendencies. Most of the wines which he mentions do not belong to his own day (e.g. Coan, Chian, Mendaean, and Thasian). The famous passage attributed to Galen on the wines of Italy (26c–27d) promises to be a discussion of Italian wines in Galen's day, the second half of the 2nd century, but it has none of the rigour and acumen of the great medical writer; in fact, it is almost certainly not by Galen at all. The passage is a series of bald statements, telling us mainly whether a wine is sweet or dry and whether or not it was strong; it does not offer any comparison with wines of earlier periods or different regions. It gives some optimum drinking dates: Alban is best at 15 years old; FALERNIAN needs a minimum of 10 years' ageing, is best after 15 to 20 and, if any older, gives headaches. Falernian can be sweet or dry: we know from other writings (mainly Galen's own) that dry wines were popular in the 2nd century CE, whereas in PLINY's day good wines appear to have been sweet. Athenaeus himself gives us no such historical perspective, however: he is not a historian but a contented collector of snippets. H.M.W.

Brock, R., and Wilson, H., 'Wine in Athenaeus', in D. Braund and J. Wilkins (eds.), *Athenaeus and his World* (2000).

Athiri, vine grown widely in southern Greece with total plantings of 588 ha/1,453 acres in 2021. Its soft, lemony produce is often used for blending, notably with the even higher quality ASSYRTIKO.

Atlantique, one of six massive regional IGPs in France, covering its Atlantic coastal vineyards from the Charente to the northern end of the Lot-et-Garonne *département* and inland to the Massif Central. Over 100 grape varieties are allowed; Bordeaux varieties dominate.

Atlas Peak, CALIFORNIA wine region and AVA in the mountains on the eastern side of NAPA Valley.

atypical ageing (ATA) or untypical ageing (UTA), known as *untypischer Alterungsnote* in Germany, where it was first documented in the late 1980s, is a term used to identify a phenomenon found in white wines worldwide, although varieties such as MÜLLER-THURGAU, KERNER, and BACCHUS seem to be particularly susceptible. It should more accurately be described as a wine FAULT as it is not related to AGEING. Hot, dry conditions immediately before and after VERAISON resulting in extreme WATER STRESS can lead to the development of this aroma/flavour defect. Wines from hot, dry growing seasons and sites are more prone to developing ATA. Vine NITROGEN deficiency may also be a contributing factor, which is why excessive use of certain COVER CROPS that compete with the vines favours the development of this fault. The compound 2-aminoacetophenone (AAP), which is responsible for the FOXY flavour in VITIS LABRUSCA, is also primarily responsible for ATA and is thought to be formed from the precursor indoleacetic acid (IAA) within a few weeks or months of the first addition of SULFITES post-fermentation. Affected wines lose VARIETAL character, develop atypical aromas and flavours described as reminding of naphthalene (mothballs), a wet towel, or old furniture varnish, and may show an increase in bitterness. These characteristics are not exactly the same as those typical of wines

suffering from PREMATURE OXIDATION because different aromatic compounds are involved. Methods to minimize the development of ATA include avoiding extreme moisture stress around veraison, ensuring adequate plant nitrogen, and avoiding OVERCROPPING, which could delay maturity. ASCORBIC ACID additions (100–150 mg/l) in conjunction with proper SULFUR DIOXIDE levels in the wine may help to limit the extent of this phenomenon. J.E.H. & V.L.

Schneider, V., 'Atypical aging defect: sensory discrimination, viticultural causes, and enological consequences. A review', *American Journal of Enology and Viticulture*, 65/3 (2014), 277–84.

Aubance, Coteaux de l', small (barely 200 ha/500 acres) but potentially excellent sweet-white-wine appellation in ANJOU on the left bank of the River Loire just south of the town of Angers. It takes its name from the Aubance, a tributary of the Loire. With barely a century of recorded production, it still lives in the shadows of its famous and larger neighbour to the south, the Coteaux du LAYON. If dry white and red Anjou make up the bulk of volume in this zone, as the appellation overlaps the red Anjou-Villages Brissac AOC, the gentle, heat-retaining SLATE hills protected by the Beaulieu and Brissac forest produce vibrant sweet CHENIN BLANC, with more nuanced concentrations than other examples of the area. In exceptional years Coteaux de l'Aubance can be just as noble, if not always as long-lived, as the Loire's more famous sweet whites, and must owe their quality to a succession of TRIES through the vineyard, picking only the ripest grapes. According to the vintage, the wines may be PASSERILLÉS and/or BOTRYTIZED, and, when a higher concentration is reached by pure noble rot, may carry the term SÉLECTION DE GRAINS NOBLES. See also LOIRE, including map. P. Le.

Aubun, rather ordinary black-berried vine variety of the southern Rhône planted on just 282 ha/697 acres in France by 2019. It produces wine not unlike a softer version of CARIGNAN and formed

part of James BUSBY's original vine collection taken to Australia, where isolated plantings can still be found, as they can in California.

Auckland is the largest city in NEW ZEALAND, and its greater area is one of the country's oldest wine regions. Located on a fertile isthmus in the north, it is headquarters for some of the largest wine producers (Villa Maria, Delegats). Viticultural plantings have decreased to just over 300 ha/741 acres by 2021 due to increasing urban expansion and the success of wine regions further south. Kumeu, a GEOGRAPHICAL INDICATION (GI) in West Auckland, has a rich wine history and produces some of New Zealand's best Chardonnay. Matakana GI, 70 km/43 miles north of Auckland, and Waiheke Island GI, off the eastern coast, are home to fine Syrah and BORDEAUX BLENDS, with sales bolstered by a thriving metropolitan population.

S.P.T.

auctions of wine are the sale of wine by lots by an auctioneer acting as agent for the seller or, in certain instances, as the seller in his or her own right.

History

Auctions have long been an integral part of the wine TRADE. Wine was sold by auction in ancient ROME; in the Middle Ages, before it became commonplace for buyers to visit wine regions, wine shipped in barrel to its final destination (see CONTAINERS) was frequently sold by auction as well as by private contract. In Britain, wine auctions were common at trading ports such as Leith in Edinburgh, Scotland, where the auction room in The Vaults testifies to a once lively auction trade in casks of fine bordeaux. In Germany, the practice of selling wine by auction under the names of village and vintage became well established in the 18th century. The Nassauer'sche Domäne in the Rheingau was among the first to initiate the movement towards establishing conditions of sale by auction in the 1830s.

As wine trading became increasingly competitive with improved transportation and more sophisticated communications, the need for producers to sell their wine by auction diminished. Whereas historically wine auctions were used as a means of selling young or relatively young wine in barrel, today's commercial auction trade relies on bottled wines at all stages of maturity. Once wine was packaged in BOTTLES stoppered with CORKS from the end of the 17th century, it became capable of AGEING and full maturation. With, literally, a new lease of life for fine wine, exceeding decades and, in rare instances, even a century or more, fine wine transcended its previous status as a short-term commodity.

Once wine became capable of being traded across generations, it naturally attracted admirers, collectors, and investors (see INVESTMENT). It became something that, at its finest, could be regarded with the same admiration as a work of art or any other classic auction room collectible. Wine captured in bottle led to a market in older wines whose reputation, based on VINTAGE and name, created a comprehensible and measurable scale of values.

Sales of wine were generally held as part of house sales until wine departments were established in two of the world's leading auction

houses, Christie's and Sotheby's. Christie's established its wine department in 1966, when Michael BROADBENT was recruited to build up the department to meet the demands of an increasingly specialized and sophisticated international market. The first auction of the new era was held on 11 October 1966, and the first season achieved sales amounting to £220,634. Not to be outdone, Sotheby's entered the fray in 1970, holding the first auction of its newly formed wine department on 16 September 1970 in Glasgow.

While Christie's and Sotheby's dominated the wine auction scene for many decades, new auction systems and entrants have challenged the status quo. In the late 1970s, The Chicago Wine Company introduced and popularized the 'silent bid' wine auction system in the US. Archaic laws in New York State prevented the spread of wine auctions in one of the world's most lucrative markets until the late 1980s. Christie's and Sotheby's initially teamed up with local wine merchants until deregulation in the late 1990s. The French auction market was also deregulated in the late 1990s. After all taxes and duties on wine were removed in 2008, HONG KONG rapidly became one of the world's leading wine-auction hubs, frequently recording higher annual revenues than either the United States or Europe.

In 2021 global wine-auction revenues totalled US$582 million, a modest sum compared with the global fine-wine market overall, and dwarfed by the value of saleroom fine-art revenues. Inefficiencies in the auction wine market during the 1980s also led to increased competition from specialist FINE WINE traders, the great majority of them based in the UK. The dot.com boom in the late 1990s spawned electronic wine-auction houses, and online selling in some form has been adopted by most wine-auction companies, including online bidding at live auctions, online-only auctions, and the emergence of online-only auction houses.

Some notable annual auctions

Nevertheless, traditional auctions survive, most notably that of the HOSPICES DE BEAUNE. This former medieval hospice in Burgundy derives a substantial proportion of income for the modern hospital associated with it from the sale of wines produced from vineyards given as bequests over the centuries. At the traditional candle auction, the lots are named after the Hospices' benefactors, each comprising a number of new 228-l/60-gal barrels. Christie's partnered with the Hospices de Beaune between 2005 and 2020, organizing not just the annual sale but also tastings of the wines all over the world. From 2021 and the 161st edition, Sotheby's took over, with their inaugural sale achieving a record total of $15.3 million.

The success of the Hospices de Beaune auction in combining the sale of wines with the glare of publicity has been the role model for a number of latter-day imitators, from LIMOUX to the NAPA Valley.

A number of notable auctions in Germany, largely focused on special lots of Riesling with some Spätburgunder, include those of the VDP's GROSSER RING in the Mosel, VDP Rheingau at KLOSTER EBERBACH, and VDP Nahe-Ahr in Bad Kreuznach. South Africa's Nederburg enhanced its reputation as a wine producer by establishing the Nederburg auction in 1975, at which lots of its top bottlings and those of other producers are offered for sale. The Nederburg sale in turn spawned the annual auction of the Cape Winemakers' Guild, a group of largely independent cellarmasters who started selling small lots of top wines at auction in 1985.

In the United States, distillers Heublein established the first New World wine auction in Chicago in 1969. Since then a combination of strict licensing laws and tax advantages to buyers led to a boom in charity wine auctions in the United States, led by the now famous annual Auction Napa Valley and the Naples Winter Wine Festival in Florida. The prices paid at these charity events are often so inflated by goodwill and/or welcome exhibitionism, however, that they cannot be compared with the United States' thriving commercial auctions as reliable indicators of the market.

The professionals

Christie's is the oldest established wine auctioneer. Wine was a prominent feature in James Christie's first sale on 5 December 1766, which, along with household furniture, jewellery, and firearms, included the sale of 'a large quantity of Madeira and high Flavour'd Claret, late the Property of Noble Personage (Deceas'd)'.

Today's commercial auction scene is dominated by regular sales conducted by a number of professional auction houses, initially London-based. However, in the late 1990s wine auctions elsewhere, particularly in the United States, started to present an increasingly serious challenge to London's hegemony as American cellars became an increasingly lucrative source of supply. In the early 1990s, wine auctions were at long last permitted in New York, but only in association with an established retailer. As a result, Sotheby's established a presence in association with Sherry-Lehmann, holding its first sale in New York on 8 October 1994, while Christie's teamed up with Zachy's. The total value of wine sales in the US overtook the UK total in the mid 1990s.

The introduction of the silent-bid wine auction in the 1980s, followed by the deployment of internet auction technology in the late 1990s, has changed the auction format irrevocably. The vibrant cut and thrust of the live auction room is to a certain extent dwindling as internet trading becomes part of our daily lives.

In 2021, the major wine auctioneers, in declining order of revenues achieved, were Acker Merrall & Condit, Zachys, Sotheby's, Hart Davis Hart, Christie's, Baghera, and Heritage. Other major players were Besch, Bonhams, Steinfels, and Artcurial. Acker Merrall & Condit, Zachys, Sotheby's, and Christie's have become the major players in the all-important Asian wine-auction scene centred on Hong Kong. Asian buyers have also become extremely active in auctions all over the world. Commercial auctions are also held in France, Holland, Belgium, Switzerland, Italy, Singapore, and Australia.

After the bumper years of 2011 and 2012, and the decline in global auction revenues by 16% in 2013, total revenues rose by

5.5% in 2014, possibly affected by increasing concern about PROVENANCE and adverse reaction to the exorbitant en primeur pricing of the 2010 Bordeaux vintage combined with economic uncertainty, particularly in the EU. Auction revenues reached a new peak in 2018, followed by two consecutive years of decline in 2019 (−8%) and 2020 (−12%), the latter decline largely due to pandemic-related restrictions on live sales. This encouraged global auction houses to adopt alternative methods for selling wine during periods of lockdown, such as increased live video-streaming of sales, absentee or online bids, and timed online-only auctions. The average lot price at global live wine auctions in 2020 was $3,694, which nearly doubled in 2021 to $6,991.

Trade structure

Wine auction customers are broadly split between private individuals and the wine trade. Private buyers may have any number of different reasons for buying wine. They may be consumers, collectors, and/or investors (see INVESTMENT). Trade buyers also buy for investment, to fill gaps in a restaurant or merchant's wine list, or as brokers for trade or private clients. Reasons for selling wine vary equally, the traditional three d's of death, debt, and divorce having turned into four, as doctors' orders have also become a factor. Private customers may want or need to sell in order to realize the value of their cellar, or part of it, or to finance further purchases, or as executors selling on behalf of an estate. There is also the phenomenon of single-owner sales, and single-producer sales used for less personal promotion. The wine trade may sell to dispose of surplus or bankrupt stock.

Wines traded

Red bordeaux, or claret, was historically the staple of the wine auction rooms. It is long-lived, enjoys widespread appeal, and it is in relatively plentiful supply. And the relative value of a particular red bordeaux is more readily identifiable than that of any other wine style, the 1855 CLASSIFICATION providing some sort of easily comprehensible framework for evaluating the red bordeaux châteaux most widely traded in the saleroom.

The FIRST GROWTHS—Chx LAFITE, LATOUR, MARGAUX, MOUTON ROTHSCHILD in the Médoc, HAUT-BRION in Pessac-Léognan, Ch d'YQUEM in Sauternes, AUSONE and CHEVAL BLANC in St-Émilion, PETRUS, LE PIN and Ch Lafleur of Pomerol—are undisputed members of today's elite. Owing to the classification's rigid composition, a second leading group of properties has emerged, commonly referred to as SUPER SECONDS. Qualification for this group requires not only the strictest commitment to quality but also a record of consistently high prices which reflects that policy.

Pre-PHYLLOXERA clarets are extremely rare and among the most highly prized bordeaux wines in any sale catalogue. Unique GRANDS FORMATS (large bottles; see LARGE FORMAT) of old vintages, particularly of first growths, are much sought-after by collectors (see BOTTLE SIZE), although perhaps to a lesser degree than in the late 1980s. Specific VINTAGES play an important part, too, with the price of wines from consecutive years often fluctuating by a factor of three according to the reputation of the vintage. The most highly prized pre-war vintages of the 20th century are 1900, 1920, 1926, 1928, and 1929. In the immediate post-war period, the most sought-after trio are 1945, 1947, and 1949. In the latter half of the 20th century and early 21st century, 1953, 1959, 1961, 1982, 1990, 2000, 2005, 2009, 2010, and 2016 rank as the outstanding vintages.

In this century, prices for relatively recent vintages started to outstrip the prices of older vintages. Although the state of the global economy plays a part, much of this has to do with the taste, and the

ratings, of influential critics who tend to concentrate on young wines, a practice pioneered by the influential American critic Robert PARKER. There is also a global trend towards drinking wines younger, especially among American and Asian collectors.

Following its meteoric rise in popularity from about 2016 (and the ensuing price increases), burgundy has become the most valuable commodity sold at auction, with Domaine de la ROMANÉE-CONTI, Henri Jayer, Leroy, Rousseau, Leflaive, Comte Georges de Vogüé, Coche-Dury, Domaines Dujac, Roumier, and Jean-Frédéric Mugnier among the most sought-after names. Champagne too has become an auction-room collectible, notably KRUG, ROEDERER Cristal, Dom PÉRIGNON, and Salon. Vintage port is a saleroom regular, although demand for it has been relatively modest, with TAYLOR, FONSECA, GRAHAM, WARRE, DOW, and QUINTA DO NOVAL, the unofficial first growths, as it were, of a group of some 40 or more port houses. Rare MADEIRA makes an occasional appearance at auction.

Auction houses have played a key role in predicting and shaping the success of newer regions for collectible wines, such as Italy and Spain. Among Italy's blue chips, GAJA and certain wines from Giacomo Conterno, Bruno Giacosa, Rocche dei Manzoni, Luciano Sandrone, and Aldo Conterno represent solid collectibles along with the most famous SUPERTUSCANS. From Spain older vintages of VEGA SICILIA, Marqués de Murrieta, Marqués de Riscal, CVNE, and Viña Tondonia from Lopez de Heredia are increasingly seen at auction. The finest wines of the Rhône, notably Hermitage, Côte Rôtie, and Châteauneuf-du-Pape, may be sold at auction, but wines from Germany, Alsace, the Loire, and TOKAJ make only an occasional appearance.

The wines of the NEW WORLD, California and Australia in particular, are making an impact as their track record for ageing becomes more widely accepted and new wines appear on the secondary market. Demand for California wines is particularly strong in the US and is increasing elsewhere. While such older rarities as the 1941 Inglenook Cabernet can fetch very high prices, the focus today is on such

CALIFORNIA CULT names as Screaming Eagle, Harlan, Sine Qua Non, Colgin, Araujo (now Eisele), Dominus, Opus One, Shafer, Spottswoode, and Heitz.

It was a wine from Australia, PENFOLDS Grange, that was arguably the first New World wine to be recognized internationally as the equivalent of a Bordeaux FIRST GROWTH. Langton's Classification of Australian Wine, first published in 1990, is a reliable guide to the best-performing Australian wines at auction, now mostly conducted online. In 2022 top Exceptional billing was given to 22 wines, including the saleroom classics Penfolds Grange and Henschke Hill of Grace, Bass Phillip Reserve Pinot Noir, Clonakilla Shiraz-Viognier, Grosset Polish Hill Riesling, Cullen Diana Madeline Cabernet-Merlot, Jim Barry The Armagh Shiraz, Leeuwin Estate Art Series Chardonnay, Wendouree Shiraz, and Wynns John Riddoch Cabernet Sauvignon. While Barossa, McLaren Vale, and Clare Valley Shiraz, as well as Coonawarra and Margaret River Cabernet Sauvignon, enjoy the lion's share of the secondary wine market, there is an increasing interest in Tasmanian Pinot Noir and wines from cooler areas around Melbourne. Penfolds is the leading collectible brand, with rare Grange (vintages 1951 to 1959) and experimental bottlings, including 1962 Bin 60A, achieving the highest prices in the Australian auction market.

Record prices

Red bordeaux has traditionally been the pace-setter for wine auction PRICES. The record of £105,000 for a single bottle of 1787 Ch Lafitte (*sic*) bought for the late Malcolm Forbes at Christie's on 5 December 1985 survived much longer than the wine itself, which turned to vinegar when put on show upright under a bright light (see STORING WINE). It was Lafite again, on this occasion the 1869 vintage, which smashed through the barrier for a standard 75-cl. bottle when three bottles were sold at Sotheby's Hong Kong in October 2010 for HK$1.8 million ($230,000) each. In November 2010, a rare imperial (six-litre bottle) of Ch Cheval Blanc 1947 was sold for £192,000 at Christie's, Geneva, setting a world record for a single bottle, albeit an outsize one.

Since then, burgundy has overtaken bordeaux for record prices. The dizzying rise of Domaine de la Romanée-Conti in the early 21st century has seen records consistently broken by the wines of this exceptional Burgundy producer, while some sales records in recent years have had to be rescinded over allegations of COUNTERFEIT bottles. The most notable bona fide world record for a case of the GRAND CRU Romanée-Conti itself was the $783,619 paid at Sotheby's Hong Kong in November 2013 for 12 bottles of the 1978 vintage. Beyond Domaine de la Romanée-Conti, the world record for the most expensive case of burgundy was won by 12 bottles of Bouchard Père & Fils, La Romanée 1865, sold by Swiss auction house Baghera in April 2021 for $2,142,294.

Beyond bordeaux and burgundy, other rarities have achieved fabulous prices for varying reasons. Thus, individual bottles of the 1907 Heidsieck Champagne salvaged in 1998 from a ship torpedoed by a German submarine during the First World War made up to $275,000 at auctions around the world. The HK$992,000 paid for a special demijohn decanter of 1863 Niepoort port in an Acker Merrall & Condit sale in 2018 is the highest price ever paid for a bottle of FORTIFIED WINE. And in 2000 at Auction Napa Valley, the annual

charity fundraiser, an imperial of 1992 Screaming Eagle Cabernet Sauvignon made $500,000 (£297,000).

How to buy and sell at auction

The public forum of the auction room and the intrinsically competitive aspect of bidding for lots often creates an atmosphere of tension and excitement in the saleroom in which it is easy for inexperienced participants to get carried away. The online-only format—which attempts to replicate the live auction environment—differs in that all lots are sold at exactly the same moment. The excitement of an online auction sale is greatest in the last 30 minutes before the auction closes. All the information required about a particular auction is published in the auction catalogue, including details of the lots, estimated prices, conditions of sale, and other general information on such matters as delivery charges, premiums, and other additions to the hammer price such as taxes and duties payable where applicable. Most auctioneers charge a buyer's premium at a house rate that is normally between 10 and 22.5% of the hammer price, as well as a seller's premium which can be negotiated with the auction house and varies according to the amount sold. The internet auction format has taken catalogues one step further, providing potential buyers with instant information regarding vintage conditions, regional information, and tasting notes.

The wines to be sold are in numbered lots. In addition to a number and an estimated price band from lowest to highest, the description of each lot identifies the wine by name, bottle size, and vintage where applicable. Increasing concern about COUNTERFEIT WINES has heightened awareness of the importance of PROVENANCE by both bidders and (most) auctioneers. Given the importance of the condition of the wine, especially older wines, and since wines are not generally available for inspection, the catalogue specifies exact FILL LEVEL, or ULLAGE levels ('mid shoulder' or 'bottom neck', for example, levels illustrated in the catalogue), the condition of the LABEL, whether the wine comes in its original wooden CASE (sometimes abbreviated to 'o.w.c.'), and will generally mention if a cellar is of exceptional pedigree or in previously undisturbed condition. Auction-house policy may vary on inspection and the condition of the wine to be sold.

Some auctioneers offer pre-sale tastings of varying degrees of lavishness. Hong Kong has seen extravagant entertainment of potential bidders, usually including examples of the wines to be sold. New York sales often take place in smart restaurants with a meal laid on. Most London sales are arid, workmanlike affairs. Lots which are of particular interest may be supplemented by the auctioneer's tasting notes.

Bidders who are physically present in the saleroom during an auction may bid by raising a hand or by waving a numbered paddle to attract the auctioneer's attention; however, most bids today are conducted via telephone or digitally, through online auction house bidding platforms.

Advance commission bids form a substantial proportion of bids received, and more and more lots are being sold online. Commission, or absentee, bids are treated in exactly the same way as bids in the room. The successful bidders obtain their lot at one increment above the underbidder. In the event of two commission bids of the same amount, it is the one received first that takes precedence.

Unless otherwise stated, bidding is per dozen bottles.

See COOPERAGE for details of French OAK auctions.

A.H.L.R., C.A. & E.L.

www.winemarketjournal.com

Aude, IGP encompassing the area between the Côtes CATALANES to the south and the Hérault to the north, the Mediterranean to the east and the more CONTINENTAL CLIMATE of the Malepère massif in the west. A vast, diverse IGP, it is often employed for wines that fall outside the AOC rules of CABARDÈS, CORBIÈRES, Corbières-Boutenac, FITOU, LA CLAPE, LIMOUX, MALEPÈRE, or MINERVOIS.

Aurore, otherwise known as Seibel 5279, a complex FRENCH HYBRID once widely planted in North America and still found occasionally in

colder states as well as in Canada. Adaptable and productive, it ripens early but is prone to ROT, and its floral-scented wines are of no great distinction.

Ausbruch, German-language equivalent of the Hungarian ASZÚ, traditionally designating sweet wines made from BOTRYTIZED grapes. Historically best-known among wines so designated is RUSTER AUSBRUCH.

Auslese, a PRÄDIKAT that means literally 'selected harvest' but is officially defined by grape sugar at harvest. In Germany, specific minimum MUST WEIGHTS are laid down for each combination of vine variety and region, ranging from 83 to 100 °OECHSLE. In Austria, the minimum across the board is 21 °KMW (approximately 105 °Oechsle). By German wine law, since 1994 vintage grapes for Auslese should have been picked at least one week after a preliminary picking of less ripe grapes. In practice, an Auslese may well have been picked early in the harvest. At their finest, German wines of Auslese prädikat are long-lived, sweet, often BOTRYTIZED wines, generally from Riesling, and the finest BOTRYTIS frequently occurs early on. In Germany, dry wines are sometimes designated as 'Auslese trocken' (dry Auslese), but with decreasing frequency. Many winegrowers long preferred to use the designation 'Spätlese trocken' even for wine based on must weights far exceeding the minimum for Auslese; and the trend (now official policy within the VDP growers' association) is to dispense entirely with designations of Prädikat for dry wines. In Austria, any wine that is not legally trocken and reflects the relevant minimum must weight is liable to be labelled Auslese. D.S.

Ausone, Château, minuscule but exceptionally fine estate on the edge of the town of ST-ÉMILION. It was named in 1781 after the Roman poet Ausonius, who certainly had a vineyard in the Gironde but probably one facing the River GARONNE rather than in St-Émilion.

Recorded in the 1868 Cocks et Féret's *Bordeaux et ses vins* (see LITERATURE OF WINE) as belonging to M. Cantenats, it then passed to a nephew, M. Lafargue, and then to his nephew, Edouard Dubois-Challon, who raised the reputation of the château to the leading position in St-Émilion up to the 1920s, when it was challenged by Ch CHEVAL-BLANC, the only other château to be ranked 'A' in the official CLASSIFICATION of St-Émilion in 1955. From 1939 to the mid 1970s, Ausone was not, with a few exceptional vintages, producing wines of the longevity of their 19th-century predecessors, although there was a marked improvement after the arrival of a new RÉGISSEUR, Pascal Delbeck, in 1976. Until the late 1990s, 50% was owned by Mme Dubois-Challon, widow of Edouard, and 50% by Alain Vauthier, who married Edouard's daughter Cécile, an unsatisfactory arrangement which ended with Vauthier taking control of, and completely renovating, the extraordinary cellars in limestone caves originally excavated to provide stone for building the town. The wine itself has also been dramatically modernized, and the vineyard recuperated.

The estate consists of a mere 7 ha/18 acres—55% Cabernet Franc, 40% Merlot with some Cabernet Sauvignon and Petit Verdot—on the dramatically steep slopes of the Côtes (see ST-ÉMILION) that run along the right bank of the DORDOGNE just below the town. Alain's daughter Pauline makes the wine.

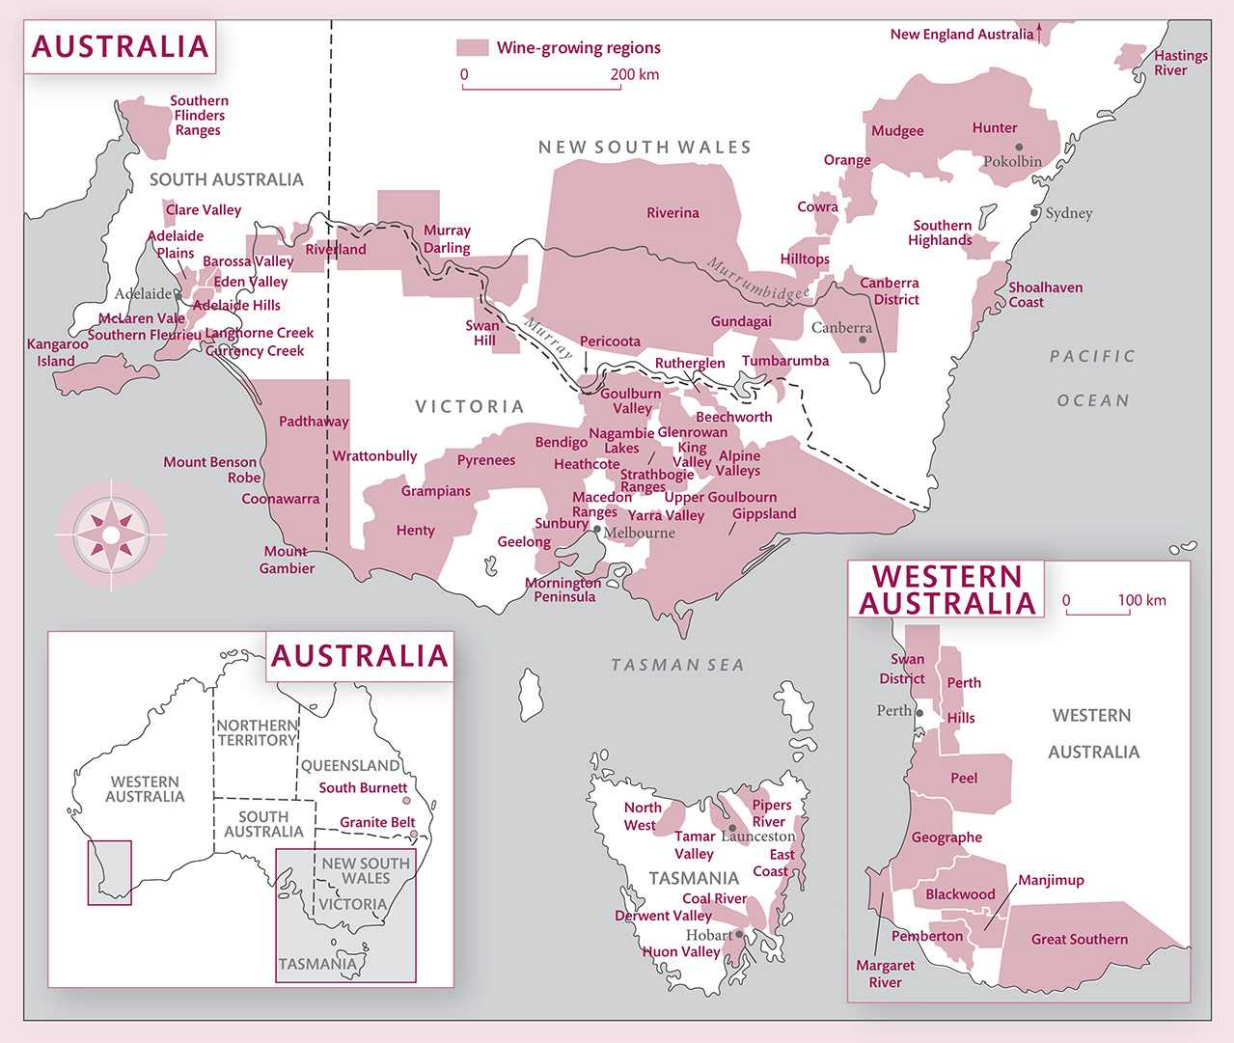
Australia became the world's sixth biggest wine producer in 2005, producing 14.7 million hl/388 million gal of wine in 2004, but by 2013 production had fallen to 12.31 million hl/324 million gal. A significant increase in the demand for Australian wine in China following the China–Australia Free Trade Agreement in 2015 saw Australian wine production peak in 2021 at 15 million hl/396 million gal, making it the fifth largest producer in that year.

Approximately 60% of Australian wine is exported, and in 2022 the UK was the largest export market by value and volume, followed by the US. Notwithstanding, with 40% of Australian wine consumed domestically, the domestic market is highly lucrative.

Australia's vineyard area has remained steady in recent times with a total vineyard area of approximately 145,000 ha/358,300 acres in 2022. As Australia's wine regulatory system does not dictate that specific varieties must be produced in specific viticultural areas, a vast array of wine styles are on offer, from aromatic, dry white table wine through to matured and rich fortified wines. Some of its wines—the unwooded Semillons of the Hunter Valley, the fortified TOPAQUES AND MUSCATS of north-east Victoria—have no direct equivalent elsewhere, but overall the wines manage to be at once distinctively Australian yet fit easily into the world scene.

History

On 24 January two bunches of grapes were cut in the Governor's Garden from cuttings of vines brought three years before from the Cape of Good Hope. The year was 1791, the chronicler Watkin Tench, and the site of the garden is now occupied by the Hotel Inter-Continental in Sydney's Macquarie Street.



Between 1820 and 1840, commercial viticulture was progressively established in NEW SOUTH WALES, TASMANIA, WESTERN AUSTRALIA, VICTORIA, and finally SOUTH AUSTRALIA. It was based upon comprehensive collections of VITIS VINIFERA vines imported from

Europe: there are no native vines in Australia, and neither CROSSES nor HYBRIDS have ever taken root. Italian immigrants (in Riverland and Riverina), Silesians (in the Barossa and Clare Valleys), Dalmatians (in the Swan Valley of Western Australia), and Swiss (Yarra Valley and Geelong in Victoria) all played key roles in the establishment of Australian viticulture.

By 1870, South Australia, Victoria, and New South Wales all had substantial industries: that year they produced 8.7 million l/2.3 million gal of wine. Twenty years later Victoria alone was making twice that amount, more than the other two states combined. PHYLLOXERA, first discovered in Victoria (near Geelong) in 1877, and later in New South Wales and Queensland, in 1884 and 1910 respectively, decimated the Australia wine industry, but strict quarantine measures employed in 1874 ensured that South Australia remained phylloxera-free, as have Tasmania and Western Australia.

Australia's production in the early 1900s was dominated by FORTIFIED wine, with the United Kingdom being established as a lucrative export market. From 1927 to 1939, Australia exported more wine to the United Kingdom than did France, mainly because of the Imperial Preference system which created trading advantages within the British Commonwealth. Export controls ensuring the quality, saleability, and merchantability of Australian wine were established at the request of industry in 1930 to ensure the protection of the reputation of Australian wine in overseas markets. Today, wine remains one of the only products for which a bespoke export approval process applies in Australia, with the policy intent being to maintain high quality, authenticity, and integrity.

By 1930, South Australia was producing over 75% of Australia's wine, and the Barossa Valley had become the centre of production, processing not only its own grapes but much of those grown in RIVERLAND.

The industry of today started to take shape in the mid 1950s. Cold fermentation of white wine in STAINLESS STEEL was pioneered (see REFRIGERATION), and the decline in fortified wine production and consumption contrasted with spectacular growth in the consumption

of red table wine (up to 1970) and thereafter white table wine. The 1970s witnessed the arrival of the wine cask, Cabernet Sauvignon, and Chardonnay; the phenomenon of the boutique winery; and the re-establishment of viticulture across the cool corner of south-eastern Australia, running east from Coonawarra and Padthaway right through Victoria.

Climate

With a land mass similar to that of the United States, winter snowfields larger than those of Switzerland, and viticulture in every state, it is hazardous to generalize about the Australian climate. However, there are two basic weather patterns, one affecting Western Australia, South Australia, Victoria, and Tasmania (the southern states), the other governing Queensland and New South Wales.

The southern states experience a winter–spring rainfall pattern, with a dry summer and early autumn. Ridges of high pressure, uninterrupted by mountain ranges, sweep across the southern half of the continent from Perth to Melbourne during the vines' growing season; daytime temperatures typically range between 25 and 35 °C/77–95 °F; however, heatwaves can send temperatures up to 48 °C/118 °F, particularly in the warm inland regions. Using the California heat degree system developed by Winkler (see CLIMATE CLASSIFICATION), the climate varies between region I and mid region III, with a preponderance in region II. Because of the lack of summer rainfall, IRRIGATION is considered as important for quality as for quantity.

The other, more northerly, weather system derives from the tropics. It provides a more even rainfall pattern, higher temperatures, and higher humidity. This system defines the subtropical climate for much of the Queensland wine industry and the coastal regions of New South Wales. The Hunter Valley is prone to receive rather too much of its annual rainfall during HARVEST, only to suffer the subsequent dual burden of winter and spring DROUGHT. Its redeeming feature is the humidity and afternoon cloud cover which reduces stress on the vines and mitigates the impact of its region IV heat load.

The Australian harvest is also heavily impacted by the climatic patterns in the Indian and Pacific Oceans, with El Niño conditions typically resulting in hot, dry growing conditions, and La Niña

conditions typically providing plenty of rainfall and mild ripening conditions.

Geography

Vine-growing in Australia is concentrated in its south-eastern corner. Just over 2,500 wineries are spread through the states of South Australia, Victoria, New South Wales, Tasmania, and Western Australia and in the Australian Capital Territory. South Australia has the highest production, accounting for just over 50% of the total production, while New South Wales accounts for approximately 30% and Victoria about 17%. Approximately 75% of Australia's total production is in the warm inland regions of Riverland, Murray Darling-Swan Hill, and Riverina. Australia's 20 largest wine producers contribute 70% of overall production.

For more detail, see under the state or territory names, which are, in declining order of production volume: SOUTH AUSTRALIA, NEW SOUTH WALES, VICTORIA, WESTERN AUSTRALIA, TASMANIA, and QUEENSLAND.

Viticulture

The first two decades of the 21st century have seen greater diversity in grape varieties and winemaking practices and a significant adoption of innovative technologies to increase quality and efficiency. SUSTAINABLE VITICULTURE has become increasingly topical, and the Australian wine industry is significantly invested in research and development into best practice biodiversity, soil management, pest and disease management, and water efficiency. There is a move away from FUNGICIDES, PESTICIDES, and HERBICIDES towards more 'natural' grape-growing (see ORGANIC VITICULTURE and BIODYNAMIC VITICULTURE).

New vineyards in premium areas, particularly those in cooler regions, are being established with VINE DENSITIES two or three times greater than traditionally used and with specifically adapted TRELLIS SYSTEMS. The aim is better-quality grapes, at yields which may in fact be greater than those of traditional plantings.

PHYLLOXERA has never entered the states of South Australia, Western Australia, and Tasmania, nor most of New South Wales (including the Hunter Valley), and it is not present in the BULK WINE-producing Riverland. Small parts of Victoria remain affected, but very strict QUARANTINE legislation, actively enforced and respected by viticulturists, prevented any spread from infested areas during the second half of the 20th century, with only one small exception.

In areas where phylloxera is present, it is common for vineyards to be planted on phylloxera-resistant ROOTSTOCKS, but in areas free from the pest most vineyards continue to be planted on their own roots. For example, in South Australia, 76% of vineyards are UNGRAFTED. However, there is a shift towards rootstocks for new plantings, with vine-growers citing drought resistance, salt tolerance, water efficiency, yield, and consistency of fruit set as significant factors for consideration. If a vine-grower wants to change a vine variety, TOP GRAFTING is commonly practised.

Winemaking

The typical medium-sized modern Australian winery is comprehensively equipped with modern winemaking equipment, and most wineries are equipped with laboratories capable of measuring basic analytes, including SULFUR DIOXIDE, sugar, MALIC ACID, PH, TITRATABLE ACIDITY, alcohol, and colour. Most wineries are fitted with powerful REFRIGERATION systems for cooling fermentation in insulated stainless-steel fermenters, as well as a must chiller to cool white grapes immediately after they have been crushed (unless they were machine-harvested at night). The CRUSHER, PRESS, and FILTRATION equipment is usually of French, German, or Italian design and fabrication; and it is highly probable that there will be several large ROTOFERMENTERS supplementing the normal array of FERMENTATION VESSELS, including the Australian-designed Potter fermenters.

Because grapes grown in the warmer regions reach chemical RIPENESS and PHYSIOLOGICAL RIPENESS with relatively low levels of acidity, it is usual for TARTARIC ACID to be added before or during the primary fermentation. In cooler areas, makers of white wines in particular endeavour to harvest the grapes with sufficient natural acidity to preclude, or at least minimize, acid additions. CHAPTALIZATION is prohibited; however, AMELIORATION of high sugar juice and must prior to fermentation is permitted provided the juice or must does not fall below 13.5 °Baumé.

Unlike countries in the EU, Australia does not regulate oenological practices but rather approves ADDITIVES and PROCESSING AIDS for wine and sets maximum limits on the presence of substances such as sulfur dioxide and VOLATILE ACIDITY. Permissions apply to the production of all Australian wine.

The Australian wine industry was built on FORTIFIED WINES, but the most celebrated survivors of this category are the TOPAQUES AND MUSCATS of Rutherglen and Glenrowan.

The twin problems of CORK TAINT and RANDOM OXIDATION have led to the mass migration of winemakers from cork to SCREWCAP. By 2014, 85–90% of bottled wine was sealed with a screwcap.

Vine varieties

In 2022, production of red wine made up 55% of overall production; however, there were strong indications leading into 2023 that the balance is likely to shift towards white wine in future years, with the white grape crush accounting for 45% in 2022.

Approximately 95% of production is attributed to the top ten red and white grape varieties. The following are the country's most widely planted red and white varieties, listed in descending order of volume of wine produced.

Shiraz is Australia's most planted wine-grape variety and is grown in most Australian wine regions. The variety is identical to the SYRAH of France and has a long Australian history. During the 1980s, the familiarity of Shiraz led to its being treated with a thoroughly undeserved degree of contempt. However, the old DRY-FARMED plantings of the Barossa Valley (producing voluptuously rich, potent wines) and the traditional Hunter Valley wines (which become silky with age) initiated a surge of popularity in both domestic and export markets. In 2022, there were 43,192 ha/106,730 acres of Shiraz, ranking Australia second behind France (60,000 ha) and well ahead of third-placed Spain (20,000 ha). Australia is home to the world's oldest continuously productive Shiraz vines, with some of the oldest plantings believed to date back to 1843.

Cabernet Sauvignon accounts for around 15% of the national CRUSH. Its thick skins and relatively loosely formed bunches provide a natural defence against DOWNY MILDEW and BOTRYTIS, which threaten many regions during the growing season. It is grown in most regions in Australia, though most of the best examples come from the cooler areas of GREAT SOUTHERN, South Australia's LIMESTONE COAST ZONE, MARGARET RIVER, and parts of central and southern VICTORIA. It is commonly blended with Shiraz and/or Merlot.

Merlot has been in Australia since the early 1800s, brought into Australia by John McArthur in 1817 and by James BUSBY in the 1830s; it became especially popular in the 1990s. It now extends some 8,115 ha/20,053 acres, with Langhorne Creek and Coonawarra in South Australia being the largest growing areas outside the warm inland 'river' regions. Merlot is popular for blending, particularly with Cabernet Sauvignon.

Pinot Noir thrives in Australia's cooler viticultural regions, such as Tasmania, Yarra Valley, and the Adelaide Hills. It is just as likely to end up in a classic TRADITIONAL METHOD sparkling wine as in a red table wine.

Petit Verdot first hit the statistical radar in 1999, when 110 ha/272 acres were bearing (and well over twice that were still to come into bearing). It excels in regions with long days and lots of sun, which describes many Australian wine regions. Over two-thirds of all Petit Verdot in Australia is grown in the South Australian RIVERLAND.

Chardonnay is Australia's most widely planted white variety, and second only to Shiraz overall. Australia has approximately 10% of the world's Chardonnay plantings and is the third largest grower of the variety after France and the US. It comes in many expressions—oaked or not, with or without partial or full MALOLACTIC CONVERSION.

Sauvignon Blanc accounts for one in every eight bottles of wine purchased on the Australian domestic off-trade retail market. The variety more than doubled in area from 2001 to 2010, becoming the second largest white wine grape variety after Chardonnay in 2014. It is grown across Australia, from the warmest 'river' regions to the cool climates of the Adelaide Hills and Tasmania, as well as in the maritime climate of Margaret River where it is often found in blends with Semillon.

Pinot Gris/Pinot Grigio is the third largest white variety, with 4,930 ha/12,182 acres in 2022 planted primarily in the warm inland regions and the King Valley.

Semillon (rarely written Sémillon in the New World) is predominantly grown in the RIVERINA. But the best Semillons are 100% VARIETAL, including unoaked versions from the HUNTER VALLEY with an alcohol level of 10.5 to 11%, and those fermented in French oak, with or without a percentage of Sauvignon Blanc, from the Adelaide Hills and Margaret River at more conventional alcohol levels.

Muscat Gordo Blanco (or Muscat of Alexandria, as it is more widely known outside of Australia) is the fifth largest white variety and eighth largest overall. It is almost exclusively grown in the warm inland regions: the Riverland, Riverina, Murray Darling, and Swan Hill.

It provides a more positively flavoured wine for cheap 'cask' blends than does SULTANA, and it often goes into lightly sparkling, low-alcohol, slightly sweet wines labelled MOSCATO, which in Australia can be made from any of the Muscat-flavoured varieties.

Another 100 or so varieties are grown, including Grenache and Mourvèdre (often called Mataro), which together with Shiraz often make up the red blends commonly referred to as GSM. In white wines, Riesling deserves special mention: although it has fallen drastically from its peak crush of 46,481 tonnes in 1985, top-quality examples can be had from GREAT SOUTHERN and the Clare (see CROUCHEN) and EDEN VALLEYS. Marsanne has been grown at Tahbilk in the GOULBURN VALLEY for well over 100 years, having been taken there from Yeringberg in the YARRA VALLEY (in turn having come from Switzerland). Much smaller plantings of Roussanne are mainly used to blend with Marsanne. Viognier is exciting a great deal of interest, for dry white wines but especially for the magic it works when CO-FERMENTED with Shiraz. And Verdelho, first imported in 1825 from Madeira by the Australian Agriculture Company, thrives in warm climates and yields well but not prodigiously, producing a popular, easy wine for relatively early drinking.

Increasingly, winemakers are exploring alternative varieties that are suited to dry climatic conditions and resist disease, hence decreasing water and chemical usage. Some varieties, such as ASSYRTIKO and SAPERAVI, are in the infantile stages of exploration by Australian winemakers, while others such as TEMPRANILLO and SANGIOVESE are gaining rapidly in popularity and are expected to become more mainstream in future years, particularly given Australian wine consumers' increasing propensity to drink lighter, more savoury wines and to experiment with different varieties.

Labelling laws

Wine labelling is strictly regulated in Australia in accordance with the Wine Australia Act 2013. Wine Australia maintains a register of GEOGRAPHICAL INDICATIONS (GIs) and other terms afforded protection under the Act such as APERA, the name for what was once called Sherry.

Within the GI scheme, each state is divided into zones: New South Wales and South Australia each have eight, Victoria six, and Western Australia five. There was—and is—no requirement of geographic or climatic particularity, no rules for the drawing of the zone boundaries. Within the zones are regions, which are sometimes further broken down into subregions, each of which must be substantially discrete and have substantial homogeneity in grape-growing attributes in regard to its size. This includes the uniformity of natural characteristics such as rainfall, soil type, geology, and other viticultural characteristics. In total, the country has 114 GIs in 2022.

EU geographical indications and traditional expressions are protected in Australia by virtue of a bilateral agreement between the EU and Australia on trade in wine. That agreement was replicated following the departure of the UK from the EU in the Agreement on Trade in Wine between the Government of Australia and the Government of the United Kingdom of Great Britain and Northern Ireland.

Australia's blending rules require that where a single vintage, variety, or geographical claim is made with respect to a wine, at least 85% of the blend must be comprised of such vintage, varietal, or geographical indication. Blending wines of differing vintages, varieties, or origins is allowed. If more than one variety or region are specified, then they are listed in descending order. Thus Cabernet–Shiraz means the wine has more Cabernet Sauvignon grapes than Shiraz; Shiraz–Cabernet the reverse. Wines can claim no more than three GIs.

In accordance with Australia's Label Integrity Program, all parties in the supply chain must keep records verifying vintage, variety, and

geographical indication claims. Failure to keep records, make records, or verify label claims with records amounts to an offence that carries a maximum penalty of two years' imprisonment.

Wine trade organization

The Australian wine sector is supported by Wine Australia, a statutory body established by legislation enacted by the federal government to control the export of Australian wine, ensure the truthfulness of Australian wine labels, promote the consumption and sale of Australian wine both domestically and overseas, and invest in grape and wine research and development. Research into improvements in grape and wine quality is led by the Australian Wine Research Institute (see AWRI) and CSIRO. Further, the sector is supported by universities such as CHARLES STURT UNIVERSITY in Wagga Wagga and the University of ADELAIDE where many of the country's most famous winemakers were educated.

Wine is traded freely between Australian states and territories. There are no commercial restrictions on importers, winemakers, distributors, and retailers engaging in trade and commerce directly, and the state and regional wine bodies do not play a regulatory role in the production or sale of wine. The state and territory health authorities are responsible for ensuring compliance with the Australia New Zealand Food Standards Code which sets out the rules pertaining to allergen statements, alcohol, and standard drinks labelling, as well as compositional requirements pertaining to the use of additives and processing aids.

Australia is a member of the OIV and the WORLD WINE TRADE GROUP, both of which provide useful forums for progressing mutual acceptance of oenological processes and harmonization of regulatory practices with a view to facilitating the international wine trade.

One of the particular freedoms of Australia is the BYO restaurant, BYO standing for Bring Your Own. Many restaurants across Australia generously encourage patrons to bring their own wine, including those holding liquor permits, who may charge a CORKAGE fee to offset the reduction in profit margin. Australian influence on wine production, marketing, and even distribution is difficult to overestimate. Its VITICULTURISTS (notably the viticulture editor of this *Companion*) pioneered sophisticated CANOPY MANAGEMENT techniques and all sorts of tricks such as niceties of irrigation (see PARTIAL ROOTZONE DRYING) and high-tech SOIL MAPPING. Australia's winemakers travelled the world—especially the northern hemisphere where the HARVEST conveniently takes place during the southern hemisphere lull—quietly infiltrating all manner of wineries with Australian technology, obsession with HYGIENE, and record water usage (see FLYING WINEMAKERS). Graduates of oenology and viticulture courses at Australian universities such as ADELAIDE and CHARLES STURT UNIVERSITY are now dispersed around the world, and the AWRI (Australian Wine Research Institute) is recognized as one of the most important, and practical, forces in ACADEME. It is significant that the world's largest and canniest wine company, E. & J. GALLO of California, deliberately recruited an Australian to lead its wine research

department into the new millennium. Australia overtook France to be most important exporter of wine to the UK, one of the world's most significant wine importers, at the beginning of the century; it went on to perform the same trick in the US, but Australian wine was this popular only temporarily with Americans. The spectacular success of YELLOW TAIL tarnished its image so that it came to be dismissively associated with 'critter brands'. Such was Australia's late 20th century success at developing and selling BRANDS to suit the modern international marketplace that for many years it was seen as a model even by such experienced wine exporters as the French. Alliances between Australian companies and global players in the drinks trade have been a notable feature of the GLOBALIZATION of the wine trade (see AUSTRALIA, Wine trade organization).

Australian Wine Research Institute. See AWRI.

Austria produces an average of 2.4 million hl/63 million gal wine a year but is more famous for the quality rather than the quantity of its wines, especially dry and sweet whites, and also reds from the dark-skinned grapes grown on more than one-third of Austria's vineyard area. Average yields are relatively low, around 50 hl/ha (3 tons/acre).

History

Austria is among many places into which CELTIC tribes are thought to have introduced grape-growing, but historical records begin with the ROMANS. That Austria suffered under DOMITIAN's notorious 92 CE edict prohibiting viticultural expansion can only be assumed. But this much is documented: Emperor Probus, in rescinding that edict two centuries later, expressly encouraged new plantings both in Gaul and in Pannonia—the Great Plain that incorporates today's eastern Austria. From his 5th-century base in the Roman garrison town of Mautern, St Severin is said to have sought solitude amid WACHAU vineyards. Control of the subsequently burgeoning vineyards west of Vienna passed largely to a collection of Bavarian ecclesiastical institutions in the wake of Charlemagne's and his son's victories over Avars and Slavs in the late 8th and early 9th century. That ecclesiastical legacy lives on in more than just physical structures that include the Wachau's towering stone terraces of Mediterranean inspiration, begun in the 11th century. Stift Göttweig, a huge winegrowing MONASTERY that dominates the landscape south of Krems, was founded by a bishop of Bavarian Passau in 1083; yet-larger KLOSTERNEUBURG dates from soon afterward; the Freigut Thalern and Schloss Gobelsburg wineries originated with early 12th century Cistercian monasteries; and the Salomon family of Krems-Stein's Undhof have for two centuries been renewing a land-for-wine rental contract with a charitable institution in Passau that first acquired those vineyards around 1200.

An Austrian tradition of small vineyard-holders dispensing their wine—institutionalized eventually as HEURIGER—is often said to have Carolingian origins; and by the Middle Ages, Vienna was notorious for copious production and consumption of wine, for which the Romans named it Vindobona. The evolution of viticulture in what was then westernmost Hungary led to several Neusiedlersee vineyard sites, notably in Jois and RUST, coming under direct royal control, and by the mid 16th century barrels of wine were being branded for those places of origin. Successive waves of Ottoman invasions in the 17th

century did not halt the expansion of vineyards. Moreover, many of the 'new settlers' for which the Neusiedlersee is named—waves of Croatians and southern Germans who arrived to repopulate its shores—became winegrowers.

The so-called Biedermeier era of Austrian stability that followed Napoleon saw the emergence not only of a prosperous, wine-drinking middle class but also—thanks especially to efforts by Archduke Johann (1782–1859) in Styria and a series of pioneering agronomists—of vine science and vine nurseries, so that by the mid 19th century the Hapsburg empire had become internationally renowned as a source for viticultural expertise and BUDWOOD. In 1860 a national school of viticulture and winemaking was established at Klosterneuburg. This was also a period of international success for Austrian wine, curtailed by PHYLLOXERA, identified relatively early by Klosterneuburg scientists. Meticulous wine historian Franz Schams identified many of the villages and vineyards that are still considered Austria's best as early as the 1830s, even if they often grew vine varieties different from those found there today. Such was still the case as recently as the mid 20th century, when plantings of GEMISCHTER SATZ (field blends) remained widespread, Silvaner still flourished (under the name 'Österreicher'), while GRÜNER VELTLINER dominated only in selected sectors and Riesling remained a rarity.

The 20th century's world wars visited disaster on Austria, each with different viticultural consequences. Following the collapse of the Austro-Hungarian empire in the wake of the First World War, vast wine regions were shed, including those of Moravia in what is now CZECHIA, FRIULI, CROATIA's Dalmatian Coast, SLOVENIA, SLOVAKIA, and much of today's ROMANIA. The Second World War brought significant physical devastation to Austrian vineyards and the widespread plundering of wine cellars by Soviet occupying troops. In rebuilding Austria's vineyards in the 1950s and 1960s, considerable attention was devoted to efficiency and, where possible, MECHANIZATION (see LENZ MOSER).

After four hard decades of vineyard revival, characterized by the remarkable ascendance of GRÜNER VELTLINER as Austria's national

grape, an explosion of ZWEIGELT plantings, and the international re-emergence of the Thermenregion and of the Neusiedlersee's sweet-wine culture, Austria suffered yet another viticultural calamity, this time of its own making. In 1985, dessert wines from the Burgenland region were found to have been laced with diethylene glycol, added by a handful of unscrupulous winegrowers or merchants to imitate the unctuous characteristics imparted by BOTRYTIS. While nobody is known to have been poisoned, the Austrian wine market was devastated. Vinous integrity demanded a completely fresh start. Implementation of stringent quality standards, combined with consumer consciousness of estate bottling and wine purity, led to a rebuilding of Austrian wine culture in ways nobody could have foreseen before the scandal. Through VINEA WACHAU, the Wachau's growers established quality benchmarks that went beyond Austria's new wine laws and set the stage for international prestige. SÜDSTEIERMARK emerged from a century of obscurity to national stardom. And a young Viennese pharmacist named Alois Kracher returned home to transform his family's estate into a beacon of quality, rescuing the reputation of BURGENLAND, the very region from which had emerged the wines that poisoned an industry. By the late 1990s, Austrian wine was enjoying unprecedented export success and prestige that has continued to this day.

Geography, geology, and climate

Austria's vineyards are concentrated in four states: NIEDERÖSTERREICH, WIEN, BURGENLAND, and STEIERMARK (Styria). Along a roughly 100-km/62-mile, almost continuously planted stretch of the Danube's left and occasionally right bank upstream of Vienna and north all the way to the Czech frontier lie those regions of Niederösterreich best known for Grüner Veltliner and Riesling—WACHAU, KAMPTAL, KREMSTAL, TRAISENTAL, WAGRAM, and WEINVIERTEL—which serves as a useful climatic touchstone. Niederösterreich is where Riesling feels at home: cool enough, but dry—like the Vosges rain shadow of ALSACE. Another feature common to most of this sector is wide, regular DIURNAL TEMPERATURE RANGE. Prominent here are soils originating in LOESS and in degraded crystalline rocks to which locals refer as URGESTEIN.

Wien—urban and suburban Vienna—serves as a sort of fulcrum of Austrian winegrowing. Its best-known vineyards, on the city's north-western edge, are dominated by Grüner Veltliner and GEMISCHTER SATZ but were historically renowned for Riesling. Two smaller concentrations of vines on Vienna's southern fringe feature red grapes as well as white and point towards the conditions that dominate in the adjacent Niederösterreich regions of THERMENREGION and CARNUNTUM, as well as in the four growing regions of Burgenland that hug Austria's border with Hungary. Here, warm air from Hungary's Pannonian Plain dominates the grape-growing season, although winters are often bitterly cold, and precipitation is even lighter than in the wine regions to the west. Most of Austria's red-wine vines (about one-third of the national total) are grown here, and Grüner Veltliner is less important than many other white grapes.

Steiermark (Styria), in Austria's south-eastern reaches, comprises three growing regions, the most important of which is SÜDSTEIERMARK, whose vineyards saturate a sector south of Graz and along a 40-km/25-mile stretch of the Slovenian frontier. Cool and well-watered, the steep hillsides here can support Riesling, but late 20th century

choices have led to a dominance of Sauvignon Blanc, Chardonnay, Pinot Blanc (WEISSBURGUNDER), WELSCHRIESLING, and MUSKATELLER.

Vine varieties

Given the huge number of grape varieties grown in Austria and how many are INDIGENOUS or at least little-known elsewhere, an overview is in order (reflecting plantings as of 2021). Among whites, GRÜNER VELTLINER—with roughly a one-third share of plantings nationwide—has become known as Austria's national grape, even though its role in Burgenland is only modest and in Steiermark practically non-existent. (Its thirstiness is also a concern for the future.) Austrian wines from this grape—virtually always dry—capture an otherwise unprecedented range of flavours, including those of lentils, green beans, mange-tout, cress, rhubarb, beetroot, roasted red peppers, tobacco, white and black pepper, citrus zest, iris, and nutmeg. A tactile 'bite' or pleasantly sizzling peppery astringency—referred to by Austrians as *Pfefferl*—is often treated as a varietal signature. Arguably also without precedent is this grape's ability to achieve satisfying ripeness and completeness at levels of POTENTIAL ALCOHOL ranging from as little as 10.5% to as much as 15%. Grüner Veltliner wines can reflect vineyard identity as well as mature impressively in bottle for decades. There can be enormous variation in size and colour of berry; size and shape of cluster; vine VIGOUR; and wine flavour. The painstaking MASS SELECTION undertaken by the Wachau's Franz Pichler in the mid 20th century did much to make possible today's quality, and interest in re-propagating old-vine selections has since increased.

RIESLING by no means takes a back seat to Grüner Veltliner in quality, although it occupies less than 5% of Austria's vineyards. As they do elsewhere, the wines vary considerably in strength and demonstrate an uncanny ability to reflect TERROIR. Most Austrian examples are dry and can tolerate alcohols over 13% rather better than their dry German counterparts, but, after a brief flirtation with strengths of 14% or more, most growers actively seek, through viticultural adaptation and slightly earlier harvest, to keep levels below 13.5%. Austrian Riesling is almost uniformly lower in acidity

and tends towards less effusive aromas than its German counterparts, but at its best it offers a crescendo of flavours on the finish. It tends to be leaner in texture than Alsace Riesling and to age a little faster than the best examples of Germany and Alsace or than Austria's best Grüner Veltliner.

WELSCHRIESLING, a traditional mainstay of Austrian viticulture but long in decline, is planted on half again as much land as true Riesling. It is prized commercially for light, bracing examples from Styria and considered a key player in Burgenland's botrytis belt. Some growers, especially in Südsteiermark and Südburgenland, render dry examples with considerable complexity, heralding an increase in respect for this drought-tolerant, acid-retentive variety. Pinot Blanc—here generally called WEISSBURGUNDER—is arguably one of Austria's hidden strengths, capable of subtle and seductive complexity while uniting natural creaminess with refreshing animation. It represents a bit more than 4% of Austrian vineyard, as does Chardonnay. Sauvignon Blanc is treated as a signature grape of Steiermark and is gaining in popularity elsewhere, gradually approaching 4% of total vine surface.

Gelber Muskateller—a variant of MUSCAT BLANC À PETIT GRAINS—has a long tradition throughout Austria and accounts for 3% of plantings. Light, bracing wines in Südsteiermark represent its instance of greatest commercial success. Roter TRAMINER (here typically labelled simply Traminer, as can be both its Gewürz-variant and a rare yellow Austrian strain) and Pinot Gris (here usually called GRAUBURGUNDER) are also grapes of long standing, albeit each represents well less than 1% of Austrian vine surface. ROTER VELTLINER and NEUBURGER are two highly distinctive indigenous varieties whose wines are capable of remarkable longevity. ROTGIPFLER and ZIERFANDLER are distinctive indigenous varieties associated with the Thermenregion. BOUVIER and SCHEUREBE (here also called Sämling 88) deserve mention for their role in sweet wines from the Neusiedlersee; and FURMINT for its recent revival, particularly in RUST.

Among red wine grapes, ZWEIGELT dominates Austria with a roughly 14% share of the national vineyard and (unlike Grüner

Veltliner) has a significant presence in every wine region. Best known for the forward fruitiness of its solo expressions, it also figures in some more ambitious wines, including when blended with other Austrian or Bordeaux varieties. BLAUFRÄNKISCH, while occupying only around 6% of Austrian vineyards (largely in Burgenland), is considered the country's most serious red wine grape. Black fruits, tobacco, resinous herbs, and black pepper are among the characteristics associated with this comparatively high-acid variety, which demonstrates striking ability to reflect its soils and sites of origin. Selections whose grapes are smaller-berried and thicker-skinned than the late 20th century norm are being actively sought and re-propagated, contributing to significant 21st-century improvement.

ST-LAURENT may or may not be an Austrian original, but it is today little known elsewhere, and—given the fragility and finicky temperament it seems to have inherited from Pinot Noir—its dwindling under 1.5% share of acreage signifies an insecure future. At their best, wines from St-Laurent display rich fruit allied to even plusher texture than Pinot Noir (Blauburgunder) which represented just 1.3% of Austria's vine surface. The Bordeaux red varieties are also grown to a limited extent, and, though uncommon, Syrah has some serious proponents in Burgenland and neighbouring Carnuntum. Two once-widespread red-wine varieties, Blauer PORTUGIESER and BLAUBURGER, have dwindled to just over 1% of Austrian vine acreage. Like MÜLLER-THURGAU among white grapes, with its rapidly diminishing share of Austrian acreage, these varieties are largely bereft of grower-champions, though a few strong cases are being made for Portugieser.

Wine labelling

Austria shares much of its wine vocabulary with GERMANY, but a term can vary significantly in both the extent to and meaning with which it is employed in each country. Austrian wine law enshrines the term 'Kabinett' for unchaptalized, dry QUALITÄTSWEIN (Austria's equivalent of PDO) of up to 13% alcohol and from grapes of at least 17 °KMW (84 °OECHSLE). But in practice the term is seldom employed. The term 'Spätlese' imposes a higher minimum MUST weight and may be applied to wine with perceptible RESIDUAL SUGAR. But in practice that term, too, is increasingly absent from Austrian wine labels save in Rust and the Neusiedlersee. With the advent of DAC legislation, the term 'Reserve' has effectively replaced Spätlese in those regions where that term was used for dry wines, while 'Klassik' is often used to refer to wines formerly labelled 'Kabinett'. The official Austrian PRÄDIKATS of Auslese, Beerenauslese, and Trockenbeerenauslese apply to wines of incrementally higher minimum must weights and with noticeable residual sugar. They most often apply in those sectors of Burgenland that specialize in BOTRYTIZED sweet wine, which is also where the more specialized categories of Strohwein (STRAW WINE), EISWEIN, and AUSBRUCH are almost exclusively used. It can be safely assumed that an Austrian wine tastes dry unless it is labelled prominently with one of these so-called Prädikats. The word 'trocken' (signifying less than 9 g/l residual sugar) is therefore seldom displayed with any prominence on Austrian labels.

All Austrian wines meeting the standards set for Qualitätswein wear the *Banderole*, a neck band or capsule top featuring the red and white stripes of the national flag, which serves not only as a guarantee that the wine has met federal production limits and quality controls, including any implied by the terms on its label, but also acts (by means of a long string of tiny digits) to track the wine. Qualitätswein from those regions to which a DAC appellation applies will either be labelled for that DAC or, if they are inapplicable or not submitted for DAC status, be labelled for their state of origin:

Niederösterreich, Wien, Burgenland, or Steiermark. The second decade of the 21st century witnessed finalizing of official vineyard names and boundaries as well as aggressive purging from wine labels of allegedly misleading geographical and topographical allusions or fantasy names that might be misconstrued as referencing places. Additionally, beginning in 2016, each authorized vineyard name utilized on a label must be preceded by the word *Ried* (meaning vineyard or site) as well as accompanied by the applicable communal (village) name.

Austrian SEKT (sparkling wine) has its own classification scheme, incorporating an upper tier with protected designation of origin (PDO) further subdivided into categories of Klassik, Reserve, and Grosse Reserve. These last two must be produced by the TRADITIONAL METHOD and spend a minimum of 18 and 30 months respectively on the lees. Reserve Sekt must be labelled for its state of origin, while Grosse Reserve entails a further specification of commune and an option of vineyard designation.

The former Austrian legal category Tafelwein, now simply Wein (see WINE WITHOUT GEOGRAPHICAL INDICATION), is produced in very small volumes, and virtually none is exported. Wines falling into the slightly more elevated official category Landwein, the equivalent of PGI, represent 5–7% of Austrian production. These are labelled for one of three broad geographical areas: Weinland (comprising the states of Niederösterreich, Wien, and Burgenland), Steierland (co-extensive with Steiermark), and Bergland (comprising Austria's five more westerly states). The Bergland designation may take on future significance, because, although little more than 200 ha/490 acres of vines currently qualify, significant pockets of revival are emerging in places where vines last flourished in the Medieval Warm Period, particularly in the state of Kärnten (Carinthia). Meanwhile, Weinland and Steierland are taking on increased prominence due to high-profile growers whose wines are either not submitted or fail to meet the criteria for approval as Qualitätswein. Growers who bottle Landwein relinquish the right to specify its state much less village or vineyard of origin. Some Landwein labels have become notorious for

the orthographic contortions and textual circumlocutions employed in attempts to circumvent that limitation. D.S.

authentication. The gripping tale of skulduggery arising from the Christie's 1985 AUCTION of the so-called 'Jefferson Lafite' was the first high-profile case in a subsequent litany of suspected COUNTERFEIT WINES, encouraged by skyrocketing fine-wine PRICES, increased global demand, and the initial complacency of wine producers, auctioneers, and FINE WINE traders. The resulting loss of revenues and the erosion of BRAND values and consumer confidence have highlighted a growing need for the authentication of fine wine in particular. This was emphasized in 2014 when the Indonesian-born fraudster Rudy Kurniawan, also known as Dr Conti, was jailed for 10 years for tricking collectors out of millions of dollars by selling cheap copies of many of the world's most famous wines cooked up in his Los Angeles kitchen.

The need for authentication is not confined to fine wine, however. Wine fraud (see ADULTERATION AND FRAUD) ranges from passing off, such as poor Chinese imitations of PENFOLDS labels under such names as Penfunils and Benfolds, to the sale of fake Chablis, Côtes-du-Rhône, and BULK WINE mislabelled Pinot Noir for GALLO's Red Bicyclette brand (see SIDEWAYS).

A need to reassure emerging markets, in Asia in particular, has led to a rise in the number of wine appraisal and authentication experts. In the US, Maureen Downey of Chai Consulting advised the FBI investigation into Rudy Kurniawan, while Michael Egan in Bordeaux testified for the prosecution. David Wainwright in Hong Kong and Siobhan Turner MW in the UK are also experienced authenticators. The authority of an expert is important because a certificate of authenticity can itself be a fake or relate to a different bottle.

There has also been much greater exploration by producers and collectors of methods of validating the authenticity of their wines. Anti-counterfeiting measures are limited to a certain extent, however, by a lack of coordinated effort that would result in shared industry standards and solutions such as education, investigation, and law enforcement.

One of the most popular security measures has been the development of the Prooftag Bubble Tag. This device, adopted by several high-profile producers, consists of a translucent polymer with a randomly self-generated constellation of bubbles. The Bubble Tag authenticates a bottle's origins and allows access to information on the producer's website. Its drawback is a tendency to peel off. Other traceability and authentication measures in use or development include proprietary paper with an ultraviolet signature, special and invisible ink, laser and other invisible product markings on bottles and/or labels, holograms with specific pieces of information, microwritings, watermarks, proprietary glass, and DNA codes such as beeswax (whose DNA can be tested and authenticated) under the capsule of DOMAINE DE LA ROMANÉE CONTI's wines.

The more different measures are adopted, the greater the layering and consequently the better the protection against fraud. BLOCKCHAIN is a promising technology but by 2022 was not fully operational for authentication use. Its benefits could be in both the primary and secondary markets—the first acting as a more secure form of some of the available bubble codes, and the latter as a means of guaranteeing the authenticity of a bottle. Research by the University of Adelaide into a technique of molecular fingerprinting of small wine samples

using fluorescence spectroscopy is also under way to bolster wine authentication, and Verivin of Oxford have managed optical fingerprinting using Raman spectroscopy of wine in bottles, although in both cases precision is as yet challenging.

No countermeasure though, however advanced, is yet known to be 100% proof against fraud, and so far none can be applied retrospectively to older vintages that are on the secondary market without the benefit of these technologies. A.H.L.R.

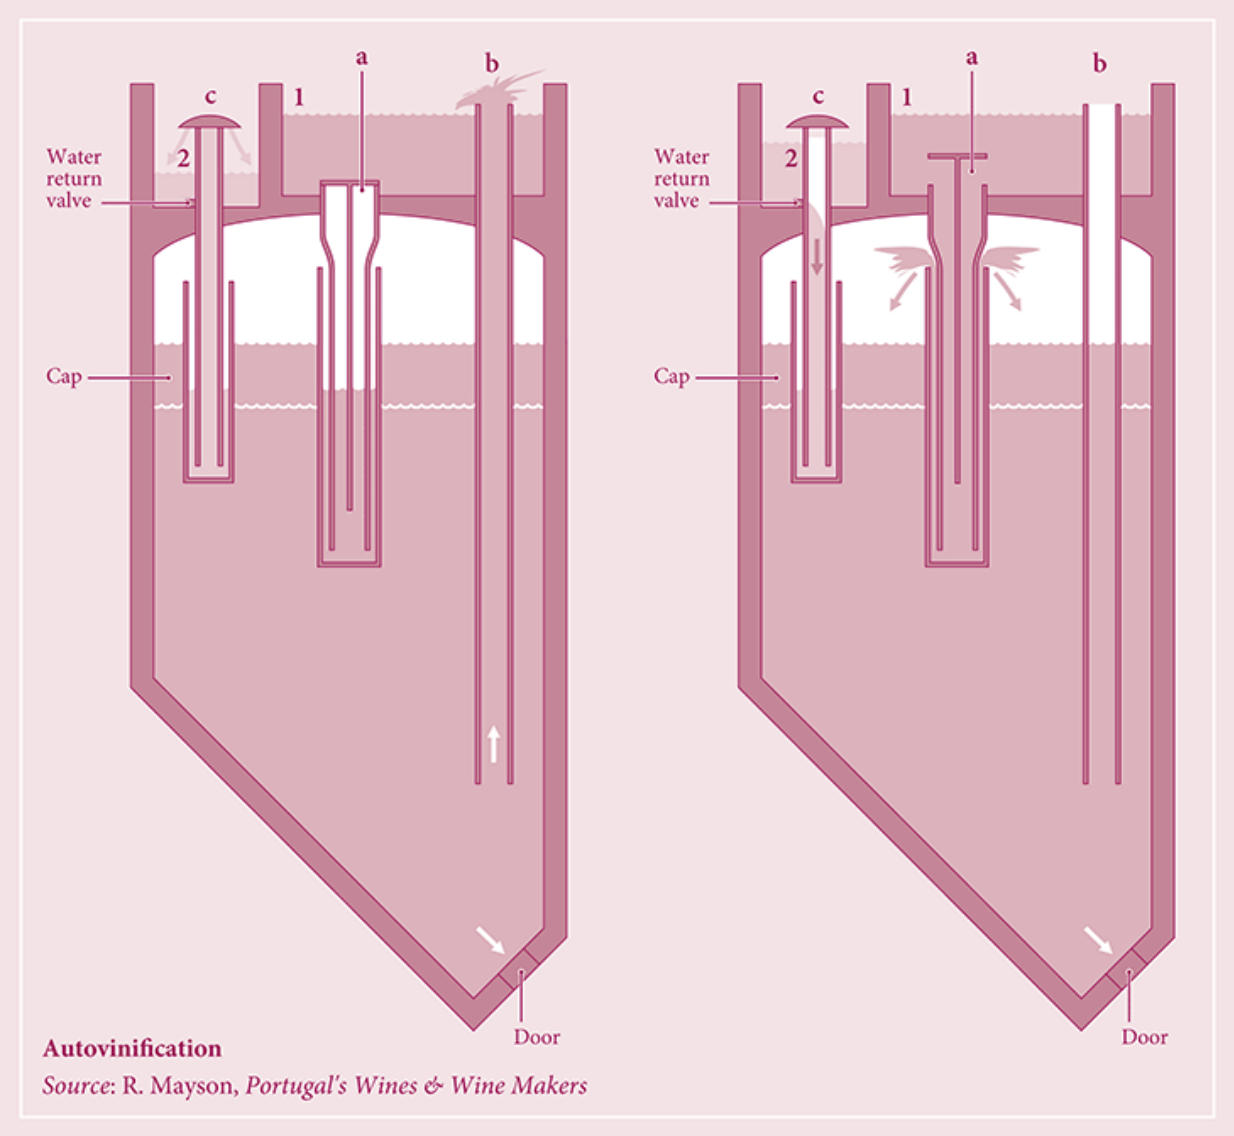
autochthonous varieties. See INDIGENOUS VARIETIES.

autolysis, the destruction of the internal structures of cells by their own ENZYMES. In a winemaking context, the term most commonly applies to the action of dead YEAST cells, or LEES, after a second fermentation has taken place during SPARKLING WINEMAKING. Its effects are greatest if wine is left in contact with the lees of a second fermentation in bottle for at least five years, and minimal if LEES CONTACT lasts for less than 18 months. MOUTHFEEL is improved through the release of POLYSACCHARIDES and peptides; OXIDATION is inhibited through the release of GLUTATHIONE and reducing enzymes; and the production of certain MANNOPROTEINS reduces TARTRATE precipitation and improves protein stability. In addition, there is an increase in amino acids, which may be the precursors of those flavour characteristics typically associated with CHAMPAGNE such as acacia, biscuity or bready notes, and other complex aromas from bottle AGEING.

Autolysis also occurs during ageing on lees of still white wines after fermentation. The changes in the chemical composition of such wines are highly desirable.

Alexandre, H., and Guilloux-Benatier, M., 'Yeast autolysis in sparkling wine: a review', *Australian Journal of Grape and Wine Research*, 12/2 (2006) 119–27.

autovinification, method of vinification designed to extract maximum COLOUR from red grapes and used primarily in the production of red PORT. Autovinification, a process involving automatic PUMPING OVER, was developed in ALGERIA in the 1960s, where it was known as the Ducellier system. Faced with a shortage of LABOUR in the 1960s, port producers were forced to abandon the traditional practice of treading grapes by foot in LAGARES. Many isolated QUINTAS had no electricity, and so shippers built central wineries. The power supply was erratic and too weak for sophisticated pumps or presses, so the shippers installed autovinification tanks in order to extract sufficient colour and TANNINS in the short FERMENTATION period prior to FORTIFICATION. Autovinification is a self-perpetuating process induced by the build-up of pressure; no external power source is needed.



Autovinification

Source: R. Mayson, *Portugal's Wines & Wine Makers*

Crushed and partially destemmed grapes are pumped into specially constructed autovinification vats (see diagram) which are filled to within about 75 cm/29 in of the top. The vat is closed and the autovinification unit (*a*) is screwed into place. As the fermentation begins, CARBON DIOXIDE is given off and pressure builds up inside the vat. This drives the fermenting must up an escape valve (*b*) which spills out into an open reservoir (1) on top of the vat. Eventually the pressure will also force the water out of a second valve (*c*) into a smaller, separate reservoir (2). When the water has been expelled, the carbon dioxide that has built up in the vat escapes with explosive force through valve (*c*). The fermenting must in reservoir (1) falls

back into the vat down the central autovinification unit (*a*), spraying the floating CAP of grape skins, so extracting colour and tannin. At the same moment, the water in reservoir (2) returns to valve (*c*), again sealing in the carbon dioxide, and the process repeats itself. The cycle continues until the winemaker judges that sufficient grape sugar has been fermented to alcohol and sufficient colour extracted, at which time the wine is run off and fortified just as described in PORT winemaking.

At the start of fermentation, when a small amount of carbon dioxide is given off, the autovinification cycle is slow. But when the fermentation is in full swing, the pressure build-up is such that the cycle takes only 10–15 minutes to complete.

Originally autovinification vats were built from epoxy-lined concrete. However, significant modifications have accompanied improvements in both winemaking technology and the power supply to the DOURO Valley, where port is produced. Modern autovinification tanks are made from STAINLESS STEEL and are equipped with REFRIGERATION units to prevent the must from overheating. Some shippers have resorted to traditional pumping over, although this generally provides insufficient EXTRACTION for better-quality port. Other shippers have successfully combined pumping over with autovinification, thereby giving the winemaker greater control over port fermentation than ever before, although lagares, including the new robotic ones, are preferred by many for top-quality ports.

R.J.M.

Auvergne, Côtes d', AOC in the Puy-de-Dôme *département*, which is part of the Auverge-Rhône-Alpes region. Nearly midway between Lyon and Limoges, the region features more than 80 volcanic craters, attesting to the VOLCANIC soils that underlie the region's vineyards. From fewer than 300 ha/750 acres of mainly GAMAY, occasionally Pinot Noir, and some Chardonnay vines, light reds and some pinks and whites are made with considerable skill from some of the many small enterprises in the region. Gamay has long been grown here and this was one of the most important wine

regions of France in the 19th century, before which Pinot Noir was grown in preference to Gamay. The names of the communes Boudes, Chanturgue, Châteaugay, and Madargue may be appended to Côtes d'Auvergne for reds, Corent for rosés. Most wines are consumed locally; none is expensive.

Auxerre , once an important city in the Yonne *département* of north-east France. Today CHABLIS is the Yonne's most famous and substantial wine appellation, but in the time of CHARLEMAGNE the region centred on Auxerre 20 km/12 miles west had many more vineyards, being a larger centre of population and conveniently situated on a river which leads directly into the Seine and thence to the PARIS basin. It is perhaps not surprising, given its historic importance, that so many vine varieties have the name or synonym AUXERROIS, meaning 'of Auxerre'.

Within the region, IRANCY has had its own appellation for Pinot Noir since 1999, ST-BRIS for its Sauvignon Blanc since 2002, and VÉZELAY for Chardonnay since 2017. There are also regional appellations for light reds made mainly from Pinot Noir and whites from Chardonnay sold as BOURGOGNE with one of these suffixes: Chitry, Côte St-Jacques, Côtes d'Auxerre, Coulanges-la-Vineuse, Épineuil (reds only), and (for whites only) Tonnerre.

Auxerrois is both a synonym for the black-berried MALBEC in CAHORS, where it is the dominant vine variety, and the name of a relatively important white-berried variety in Alsace. And as if that were not confusing enough, Auxerrois Gris is a synonym for PINOT GRIS in Alsace, while Chardonnay, before it became so famous, was once known as Auxerrois Blanc in the Moselle—as distinct from Auxerrois de Laquenexy, which is the variety today called Auxerrois in north-east France (including Alsace) and LUXEMBOURG.

In 1999, DNA PROFILING at DAVIS showed that this Auxerrois is a progeny of PINOT and GOUAIS BLANC. There are still minuscule plantings

of Auxerrois in the Loire, but today it is most important in Alsace, the French Moselle (including Côtes de TOUL), and Luxembourg, where it is most valued, particularly for its low acidity. If yields are suppressed, which they rarely are, the variety can produce excitingly rich wines that are worth ageing until they achieve a bouquet with a honeyed note like that of mature Chablis, the wine which today could be described as 'from AUXERRE' or, in French, *Auxerrois*.

Virtually all of the French 2019 total of 2,543 ha/6,262 acres is in Alsace, where Auxerrois is much more popular than Pinot Blanc even though it is rarely seen on a label. It produces slightly flabby, broad wines which are blended into, or may indeed constitute, many a wine labelled PINOT BLANC. Auxerrois is also a major ingredient in EDELZWICKER.

It is also planted to a limited extent in Germany, the Netherlands, and Canada.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Auxey-Duresses, a village in Burgundy producing medium-priced red and white wines not dissimilar to neighbouring VOLNAY and MEURSAULT respectively, although more austere in style. The vineyards, which include those of the hamlets of Petit Auxey and Melin, are located on either side of a valley subject to cooler winds than the main Côte de BEAUNE. Pinot Noir vineyards, including such PREMIERS CRUS as Les Duresses and Le Climat de Val, are on the south-east slope of the Montagne du Bourdon. White wines made from Chardonnay account for just above a quarter of the production, covering the slopes adjacent to Meursault. Some vines, atypically for Burgundy, are trained high.

In the past, wines from Auxey-Duresses were likely to have been sold under the names of grander neighbours. It is permissible, though now rare, to label the wines as Côte de Beaune-Villages.

See CÔTE D'OR and map under BURGUNDY. J.T.C.M.

auxins, one of a number of groups of natural HORMONES present in vines which regulate growth. They are produced in vine parts which are actively growing, such as shoot and root tips. Auxins favour cell growth over cell division but are also involved in inhibiting the growth of LATERAL SHOOTS. Many chemicals have been synthesized which are chemically related and have a similar biological function. For example, the compounds 2,4-D and 2,4,5-T are auxin-like and form the basis of some HERBICIDES, which are used widely in cereal production. Vines, like tomatoes and cotton, are very sensitive to 2,4-D vapours such as can drift over vineyards when neighbouring farmers use aerial spraying, even from considerable distances away. Most vine-growing regions have now enacted laws to protect vineyards from the effects of such hormone spraying. R.E.S.

AVA, the acronym for American Viticultural Area and the United States' answer to France's AOC system of permitted geographical designations. The US federal government began developing this system in the early 1980s through its Bureau of Alcohol, Tobacco, and Firearms (BATF; see TTB). AVAs are purely geographical, imposing no restrictions on varieties planted, vineyard practices, or winemaking protocols. The only requirement for their use is that 85% of the grapes in a wine labelled with an AVA come from that region; if the wine is a VARIETAL, the legal minimum of 75% of the named variety must come from the named AVA. (Unlike the AOC/DOC system, however, neither 'AVA' nor 'American Viticultural Area' appears on wine labels.)

Between 1983 and 1991, the BATF approved more than 100 AVAs in the country, more than 60 of those in California, but applications slowed to a trickle in the 1990s as producers were discouraged by the bureaucracy involved without any obvious commercial gain. Yet the 2000s saw a new rush of AVA applications and approvals, as winery marketers realized that Americans were beginning to care about where the grapes were grown and that labels from specific areas commanded more respect (and higher prices) than GENERIC

blends. By 2022, there were 266 AVAs in the US, 146 of which were in California.

The TTB website has a complete list of AVAs:
www.ttb.gov/appellation

Aveyron, IGP in SOUTH WEST FRANCE. Both inside and outside the AOC areas of MARCILLAC, ENTRAYGUES, and ESTAING, enterprising winemakers are producing original wines, partly from mainstream varieties and partly from local ones such as Négret de Banhars and Rousselet. Jurançon Noir also sometimes appears. Viticulture has reappeared in the west of the *département*, formerly bereft of vines. P.S.

Avesso, meaning 'contrary', a fitting description for this white grape planted in the VINHO VERDE region of northern PORTUGAL, notably in the warmer Baião subregion close to the lower reaches of the River DOURO, where it tends to produce wines of 12–13% alcohol, higher than those made from the other principal grape varieties in the region. It is now being produced as a VARIETAL wine. Plantings totalled 751 ha/1,856 acres in 2020. S.A.

AWRI (Australian Wine Research Institute) is the Australian wine industry's own research, development, and extension organization. Based in Adelaide and established in 1955, its governing board includes members elected by Australian grape and wine producers who pay the Wine Grapes levy. The AWRI's purpose is to support a sustainable and successful grape and wine industry through research, practical solutions, and knowledge transfer.

Research at the AWRI is designed to increase fundamental understanding while remaining responsive to the applied needs of producers and consumers. It has particular research strengths in wine chemistry, sensory science, microbiology, and molecular biology.

The AWRI has a strong track record of translating its research results into usable applications and fostering their adoption, as well as at communicating research and practical solutions from around the world. The organization's commercial arm provides specialized grape and wine ANALYSIS, benchmarking, and technical validation services, as well as export certificates and site audits.

The AWRI conducts a wide range of educational seminars and workshops and has published more than 2,200 papers and articles.

M.P.K. & E.M.C.R.

AXA, vast insurance group based in France whose wine division AXA-Millésimes is very small in the context of the company and very big in the context of fine wine in general and Bordeaux in particular. Claude Bébéar, the company's president and founder, was led to buy the small St-Émilion property Ch Franc-Mayne in 1984 as an indirect result of his friendship with Jean-Michel Cazes of PAUILLAC. Seeing the investment potential of good Bordeaux properties, he founded AXA-Millésimes in 1987, and it was managed by Cazes alongside his own wine holdings, including Ch Lynch Bages until 2000 when Cazes retired and Christian Seely took over. Initial acquisitions included Clos de l'Arlot in NUITS-ST-GEORGES, the CRU BOURGEOIS Ch Pibran, and, also in Pauillac, the second-growth Ch Pichon Baron, a fairy-tale château which has since been so lavishly refurbished and re-equipped that it regularly challenges the FIRST GROWTHS. In 1992 SAUTERNES first-growth Ch Suduiraut and the Disznókő vineyard in TOKAJ were added, a sweet triumvirate being completed by the acquisition and subsequent restoration of the QUINTA DO NOVAL port business in 1993. In 2018 AXA Millésimes acquired Outpost Vineyard at the summit of Howell Mountain in NAPA Valley, adding the neighbouring Henry Vineyard in 2020. AXA is by no means the only French insurance company to have invested in wine-related real estate, but it is the most wine-minded one.

AXR1, variety of ROOTSTOCK widely used in northern California until, in the late 1980s, it became fatally obvious that it was not resistant

to PHYLLOXERA, something French vignerons had known for many decades.

Ayse, sometime spelt Ayze, is an isolated CRU between Bonneville and Chamonix-Mont Blanc whose name may be added to the eastern French appellation SAVOIE. GRINGET is the principal grape variety used for the light white still and TRADITIONAL METHOD sparkling wines. The highly regarded Domaine Belluard accounts for half of production.

W.L.

Azal, one of the less aromatic white grapes grown to produce VINHO VERDE and recently showing its mettle in some steely, structured VARIETAL wines with flavours of green apple and grapefruit. Total plantings had fallen to 1,770 ha/4,374 acres by 2020. Azal Tinto is unrelated.

azeotrope, from the Greek 'to boil unchanged', a mixture of liquid chemicals which has a boiling point either higher or lower than any one of its components. The principal volatile components of wine tend to form azeotropes of two, three, or more components. Water, ETHANOL, volatile organic ACIDS, ALDEHYDES, ESTERS, acetals, and ketones, many of them powerfully aromatic, are among the azeotrope components in wines. The multiplicity of volatile compounds present in wine and our lack of detailed knowledge of all of the azeotropes possible makes it difficult to predict the composition of distillates (which depend on the varied boiling points of components).

Just as the formation of azeotropic mixtures in a liquid governs the boiling point and composition of the vapour during DISTILLATION, so it governs the composition of the vapours above a liquid in a glass at room temperature. When we smell a wine, our noses are recording the impression created by the azeotropic mixture rather than that of any single component.

A.D.W.

Azerbaijan, former Soviet Union state on the Caspian Sea. It also includes the Nakhchevan Autonomous Republic, an enclave surrounded by RUSSIA, GEORGIA, ARMENIA, IRAN, and TÜRKIYE. While the country grows only a fraction of the wine it produced before the fall of communism, vineyard plantings are increasing, with more attention paid to quality instead of quantity.

History

Grape-growing is likely to be one of the oldest branches of Azerbaijan's economy. Archaeology has revealed seeds of cultured grapes, stones for crushing grape berries, and stone fermentation and storage vessels dating back to the seventh millennium BCE at Shomu-Tepe and the second millennium BCE in the settlements of Kültan, Galabaglar, and Galajig.

HERODOTUS, describing a campaign of the Scythian chief Madyas in ANATOLIA in the 7th century BCE, mentioned that viticulture and winemaking were already developed in that region. The Greek geographer Strabo, in the 1st century BCE, reported on grape culture in 'Albania', the old name of part of Azerbaijan.

The Arabian historians and geographers Abulfedy, Masudi, Khaukal, and El Mugaddasi recorded that vineyards existed near the towns of Gianji and Bardy during Arab domination. Viticulture of that region declined in the periods of war and revived in the time of peace. Viticulture was on a commercial scale after 1814 and developed especially fast at the end of the 19th century when two railways were built which provided access to the enormous wine market of RUSSIA.

By the beginning of the 20th century, small viticultural farms were established in the Ganja-Gazakh region as well as much larger enterprises in specialized zones of commercial grape and wine production. In 1940, the total vineyard area was 33,000 ha/81,500 acres, mostly planted by German colonists who began settling in the region in the early 19th century. (In 1941, most all of them were deported to Kazakhstan and Siberia.) The Second World War had reduced this total to 21,000 ha/51,900 acres by 1947, but a subsequent vineyard expansion programme launched in the 1950s resulted in 1.1 million ha planted by the 1970s. Most of these plantings were doomed, however, by a combination of PHYLLOXERA, Mikhail Gorbachev's VINE-PULL SCHEME, and the economic turmoil after independence was declared in 1991. Only 8,000 ha were left in the

1990s. By 2020, plantings were up to 13,422 ha, with 20 wine companies.

See also ORIGINS OF VINICULTURE and PALAEOETHNOBOTANY.

Climate and geography

With its mountainous landscape, Azerbaijan has a very varied climate, from moderately warm with dry winters to cold with abundant rainfall. Annual rainfall in the low and premountainous parts of the country, where grapes are grown, is 250–600 mm/23 in. There are eight unofficial but widely recognized wine regions, with the greatest concentration in the north of the country, from Shirvan (5,343 ha) and Guba-Khachmaz (916 ha) in the north-east to Ganja-Gazagh in the north-west (4,274 ha), with Sheki-Zaqatala (833 ha) in between. Lankaran (4,274 ha) is in the far south-east; Karabakh (171 ha) and Nakhchivan (367 ha) are in the south-west, where temperatures fall low enough to necessitate WINTER PROTECTION for the vines.

Vine varieties

Azerbaijan claims to have more than 400 INDIGENOUS VARIETIES, but only a few are cultivated for wine production. In addition to INTERNATIONAL VARIETIES such as Merlot, Pinot Noir, and Cabernet Sauvignon, the most common local varieties for red wine are MATRASA, SAPERAVI, Tavkveri, Shirvanshahi, and Kindoghy. For white wines, the Georgian grape RKATSITELI makes up about 30% of production, while Bayanshira is the main autochthonous white wine grape. Kahetian MTSVANE is also grown, as well as Chardonnay, Pinot Blanc, and Viognier. In 2018, the government launched a development strategy aimed at expanding the country's vineyards with both indigenous and imported varieties. The country's main export market is the Russian Federation, but sights are set on the US, Netherlands, Ukraine, and China.

www.azerbaijanwine.com

azienda, Italian for a business. An azienda agricola is a farm, the equivalent of a French DOMAINE, and the phrase should appear on a wine label only if the grapes were grown and the wine produced on that estate; an azienda vinicola, on the other hand, may buy in grapes from elsewhere, while an azienda vitivinicola combines both activities.

Azores. New players from the mainland have sparked a winemaking revolution in this archipelago of nine Atlantic islands, an autonomous region of PORTUGAL. In 2004, a VINHO REGIONAL category Açores was created for light red and white wines produced throughout the archipelago from over 50 local, national, and international varieties. Three islands also have their own DOCs with

stricter regulations: GRACIOSA, BISCOITOS, and PICO, of which the latter is the most important quantitively and qualitatively. S.A.

B

BA, common abbreviation, used particularly by English-speakers, for the sweet-wine designation BEERENAUSLESE.

Băbească Neagră, Romania's fourth most planted red wine vine variety, whose name, meaning 'grandmother's black [grape]', compares directly with FETEASCĂ or 'young girl's [grape]'. It has long been grown in the east of the country, but total plantings had fallen to 2,569 ha/6,348 acres by 2021, typically producing light, fruity reds that are considerably less 'serious' than Fetească Neagră.

Babo, alternative name for KMW, the Austrian unit of MUST WEIGHT. See KLOSTERNEUBURG.

Bacchus, common name in ancient ROME for the classical god of wine whom the Greeks called Bacchos or, more usually, DIONYSUS. There was no official Roman festival of Bacchus: the Roman Senate suppressed the Bacchanalia in 186 BCE because it saw them not only as a danger to the state but also as a bacchanal in the modern sense, a scene of drunkenness and sexual licence. Bacchic poetry is verse with a vinous theme, a speciality of the ARAB POETS. Because the Romans concentrated on the vinous aspect of this much more complex god, and possibly because the word 'Bacchus' is considerably easier to say and spell than 'Dionysus', the Roman name is much more commonly used in modern times and is regarded as a word rich in wine connotations. The word is used emotively around the world to conjure up various conjunctions of wine and pleasure.

Dalby, A., *The Story of Bacchus* (2005).

Bacchus is also the name of one of the most important GERMAN CROSSES. It was bred from a Silvaner × Riesling cross and the lacklustre MÜLLER-THURGAU and in good years can provide growers in Germany with musts notching up the all-important numbers on the OECHSLE scale as well as powerful flavours and character, not unlike Sauvignon Blanc, and is therefore useful for blending with Müller-Thurgau. Unlike the more aristocratic and more popular cross KERNER, however, the wine produced lacks acidity and needs to be fully ripe before it can express its own exuberant flavours.

Bacchus's great allure for growers is that it can be planted on sites on which Riesling is an unreliable ripener and will ripen as early and as productively as Müller-Thurgau. Total plantings in Germany reached a peak of around 3,500 ha/8,650 acres in 1990. This total had fallen to 1,614 ha by 2020, mostly in Franken for straightforward fruity, aromatic wines and in Rheinhessen for BULK WINE blends. Its ability to ripen fully in cool years is a benefit in SAALE-UNSTRUT, as it is in the UK, where Bacchus is valued for its recognizable flavour and is the second most planted white grape, albeit way behind Chardonnay. With the UK's generally lower yields and higher natural acid levels, it does not suffer from the flabbiness of warmer-climate examples and was planted on around 175 ha in 2020.

Baco, François , was, like BOUSCHET, a nurseryman who saw his name live on in the names of some of the most successful of the vine varieties he bred. Baco's specialities were FRENCH HYBRIDS and his most successful was Baco Blanc, sometimes called Baco 22A, a hybrid of FOLLE BLANCHE and NOAH created in 1898 which was, for much of the 20th century until the late 1970s, the prime ingredient in armagnac—a role now occupied by UGNI BLANC. In 2019 there were 805 ha/1,989 acres in France, mainly in armagnac country.

Baco Noir, or Baco 1, resulted from crossing Folle Blanche with a variety of VITIS RIPARIA in 1902; it was at one time widely spread in France but today is best known for its light, fruity, non-FOXY reds in eastern Canada and, to a lesser extent, upstate New York.

bacteria, very small microorganisms which have serious implications in both viticulture and winemaking. Although not common pathogens of the grapevine, BACTERIAL DISEASES are potentially destructive and therefore very important. For beneficial bacteria in the vineyard, see SOIL BIOTA.

In winemaking just two groups of bacteria are important, ACETOBACTER and LACTIC ACID BACTERIA. Since grape juice and wine are both high in ACIDITY, the great majority of bacteria, with the exception of these two groups, are incapable of living in them and, if introduced, do not survive. (Drinks such as cider, perry, orange juice, and beer, which are all much less acid than wine, are subject to many forms of BACTERIAL SPOILAGE to which wine is immune, and therefore they lack wine's AGEING potential.) No known human pathogenic bacteria can survive in wine, however, which is one of the reasons it has been such a safe drink (safer than WATER at some times and in some places) through the ages.

Acetobacter (which do not harm humans) can turn wine, or any other dilute solution containing ETHANOL, into VINEGAR. They require OXYGEN for growth and survival, and they die in its absence (which is why care is taken to exclude oxygen from certain stages of winemaking and all stages of wine preservation—see LEFTOVER WINE).

Lactic acid bacteria produce LACTIC ACID and grow best in environments where there is a very small amount of oxygen. They are important as the agents of MALOLACTIC CONVERSION in wines, by which excess MALIC ACID is decomposed. R.E.S. & P.J.W.

bacterial blight, vine BACTERIAL DISEASE caused by the bacterium *Xanthomonas ampelinus*, so serious that it has led some Greek and

French growers to abandon stricken vineyards. It shows its presence by retarding and killing young shoots and is spread by rain, wind, and also pruning tools and increased MECHANIZATION. The disease can be controlled by removing and destroying infected plants and by disinfecting tools, as well as by COPPER sprays. It is present in parts of Europe, South Africa, Australia, and South America that have a MEDITERRANEAN CLIMATE. R.E.S.

www.cabi.org/isc/datasheet/56907

bacterial diseases, group of grapevine diseases caused by BACTERIA, small organisms which do not commonly attack vines but which can be deadly and are difficult to control. Of the bacterial diseases, PIERCE'S DISEASE is the most important, and QUARANTINE authorities around the world are anxious to stop it spreading from America, although it is now present and causing concern in Europe. In parts of North and Central America (southern California, Florida, eastern Texas, and Mexico, for instance), viticulture can be rendered commercially impossible by the natural presence of this disease. Other economically important bacterial diseases are BACTERIAL BLIGHT and CROWN GALL. R.E.S.

Szegedi, E., and Civerolo, E. L., 'Bacterial diseases of grapevine', *International Journal of Horticultural Science*, 17/3 (2011).

Wilcox, W. F., et al., *Compendium of Grape Diseases, Disorders, and Pests* (2nd edn, 2015).

bacterial spoilage, range of wine maladies or FAULTS including gas, haze, cloud, and off-flavours generated by the activity of BACTERIA in wine. These bacteria are either ACETOBACTER or LACTIC ACID BACTERIA. Acetobacter's tendency to transform wine into vinegar can be checked by keeping air away from wine, on the part of both

winemaker and wine drinker (see LEFTOVER WINE). Lactic acid bacteria are more varied in their effects, which include a wide range of unpleasant-smelling compounds, depending on the type of bacterium. These are relatively rarely seen today since great care is taken by winemakers (see STABILIZATION and HYGIENE) to guard against spoilage by lactic acid bacteria in the winery and to minimize the risk of bottling a wine with any spoilage bacteria (see FILTRATION, PASTEURIZATION, STERILE BOTTLING), but wines bottled unfined, unfiltered, and with little or no added SULFUR DIOXIDE are more at risk from spoilage (see MOUSY). If lactic acid bacteria do attack a wine in bottle, the results are usually detrimental to the taste and clarity of the wine, and gas is usually produced.

Baden, Germany's longest wine region, stretching over 400 km/250 miles from the border with FRANKEN in the north across the Rhine opposite ALSACE to Lake Constance (the Bodensee) and German-speaking SWITZERLAND in the south (see map under GERMANY). The general and local climate, the varying soils, and the ELEVATION have a marked effect on the wines of Baden's nine districts, or BEREICHE, which had a combined vineyard area of 15,836 ha/39,132 acres in 2019. In this southernmost growing region of Germany, SPÄTBURGUNDER, GRAUBURGUNDER, and Weissburgunder (PINOT BLANC) account for 34, 14, and 10% respectively of the region's vineyard area, making it Germany's Pinot stronghold, and total red wine production hit 40% in 2019. Warm, dry conditions and frequently steep, terraced sites of VOLCANIC origin typically combine to yield wines of naturally abundant alcohol, although, as in many other respects, this huge region harbours considerable diversity, and there are enough cooler sectors for growers so inclined to bottle Pinots that are downright delicate, as well as to support RIESLING. Around 70% of Baden's vine acreage is farmed by growers who belong to one of the region's 80 CO-OPERATIVES (*Winzergenossenschaften*), a number approaching half of Germany's total.

The Tauberfranken district covers 610 ha/1,507 acres that intermittently follow the Tauber River until its confluence with the Main at Wertheim. Plantings in this frost-prone area, 70% of them for white wine, have for many years been declining, and hardy MÜLLER-THURGAU represents 45% of all vines, distantly followed by fellow-crossings KERNER and BACCHUS. The wine is similar to that of FRANKEN and is also sold in its neighbour's flagon-shaped BOCKSBEUTEL.

East across the Odenwald, the vineyards of the Bereiche Badische Bergstrasse (400 ha/988 acres) and Kraichgau (1,250 ha/3,089 acres) run north and south of Heidelberg. The first district is simply a continuation of the HESSISCHE BERGSTRASSE. In both sectors, Müller-Thurgau and Riesling each hover around one-quarter of the hectarage, the latter capable of yielding distinctive, delicate results in GRANITE and SANDSTONE sites along the Bergstrasse.

The extensive Ortenau, Breisgau, and Kaiserstuhl districts that parallel the Rhine east of the Black Forest between Baden-Baden and Freiburg collectively comprise 53% of Baden vine acreage and are home to Baden's most prestigious estates, although, as elsewhere in this region, grower co-operatives account for a majority of production. Thanks especially to the opportunities afforded by cool sites south of Baden-Baden, Riesling accounts for around 28% of Ortenau vines, and Pinot Noir makes up 42%. Steep porphyry and BASALT sites around Neuweier are especially known for their Riesling. Some 15 km/9 miles south at Waldum, that grape—on weathered GRANITE—vies with Pinot Noir for attention; while a few kilometres closer to Offenburg, the village of Durbach, long a wine-trading centre, gives pride of place to Pinot, although Riesling (known here colloquially as Klingelberger) and Traminer (as Clevner) run close behind in importance and affection. Extending between Offenburg and Freiburg, parts of the Breisgau hug the Black Forest closely enough to benefit from more precipitation than neighbouring districts. Here CALCAREOUS soils promote firm, fruity acidity resulting in Pinot Noir that marries richness with vivacity and whose virtues have become increasingly evident over the past two decades, so that today many of the most intriguing red wines in Germany have Breisgau

addresses. Among those villages to have demonstrated outstanding site potential are (from south to north) Mundingen, Köndringen, Malterdingen, Hecklingen, and (in a side valley well into the Black Forest) Münchweier.

West of Breisgau, the primarily VOLCANIC vineyards of the Kaiserstuhl, rearing steeply up from the Rhine, are Baden's most famous and coveted, particularly for Pinots. Northwards from Breisach on the Rhine, Ihringen, Blankenhornsberg, Achkarren, Oberrotweil, and Burkheim harbour the most prestigious Kaiserstuhl vineyards. Largely on the basis of its calcareous LOESS rather than volcanic soils, the 1,033-ha/2,553-acre Tuniberg declared its independence from the Kaiserstuhl in 1991, though without having since then achieved significant independent reputation.

Hugging the Rhine in Germany's south-western corner from Freiburg to the Swiss frontier at Basel is the Markgräflerland, traditionally best known for its Gutedel (CHASSELAS), whose elegance and soil sensitivity can challenge that of Switzerland's best examples. Like the Breisgau, the Markgräflerland is becoming increasingly recognized for innovative winegrowers and excellent Pinot Noirs, some from the calcareous soils of Istein and Efringen-Kirchen along the Rhine just north of Basel being especially impressive. The Bodensee district, most of whose vineyards stretch along the northern shore of the huge eponymous lake, is nearly 100 km/62 miles distant from the Markgräflerland and even further from any other districts of Baden. While known inside Germany more for its tourism than its wines, and hardly known at all outside Germany, this outpost of diverse German viticulture, like its immediate Swiss neighbours around Schaffhausen and Konstanz, can boast some distinctively delicious results, especially with Pinot Noir. D.S.

Baga, red grape found throughout central PORTUGAL but mostly in the BAIRRADA region, where, unusually for Portugal, it accounts for about 80% of dark-skinned varieties and where plantings are increasing again. DNA PROFILING has shown a likely parent–offspring

relationship with MALVASIA Fina (under the synonym Arinto do Dão). It is a vigorous variety, resistant to POWDERY MILDEW but ripens late and has a tendency to rot in the damp Atlantic climate of Portugal's western seaboard, threatened by early autumn rains. This small, thin-skinned variety (*baga* means 'berry') produces dark, fairly acidic, tannic wines that can be undrinkably ASTRINGENT if the grapes are underripe. However, well-made wines are full of fruit and capable of long AGEING, and there are a growing number of lighter, more elegant examples. A large amount of Baga ends up as rosé: Sogrape, producers of MATEUS rosé, have a large winery in the Bairrada region. Portuguese plantings totalled 7,133 ha/17,626 acres in 2020.

J.V. & J.E.H

Baghdad , the capital of modern IRAQ, was founded by the first Abbasid caliph, al-Mansur, in 762 CE. Early in its history the city became the focus of a Bacchic culture (see ARAB POETS), celebrated most eloquently by the poet ABU NUWAS. Although wine was imbibed in the Caliphal court and some outlying districts of the city (al-Karkh, for example), most wine was consumed where it was produced, in the small monasteries and towns that lay outside the city in various parts of Iraq. Their names are preserved in poetry and other sources (ʿĀna, Hīt, Qutrubbul in the vicinity of the city, for example, and Tīzanabādh further south near Kufa). P.K.

bag-in-box. See BOXES.

Bagnoli Friularo, DOCG in Italy's VENETO on the plain immediately south of Padova dedicated to the production of the red RABOSO, locally known as Friularo. Due to their high natural acidity, the grapes for Bagnoli are dried and then fermented dry or almost dry. The wine resembles AMARONE, if slighter in style. W.S.

Bairrada, evolving DOC wine region in northern Portugal (see map under PORTUGAL). The coastal belt south of OPORTO has been producing wine since Portugal gained independence from the Moors in the 10th century. By the early 1700s, Bairrada's dark, tannic red wines were widely drunk in Britain, masquerading as or blended with PORT from the DOURO Valley to the north. Then in 1756, as part of his measures to protect the authenticity of port (see DELIMITATION), the Marquis of Pombal, Portugal's powerful prime minister, ordered that Bairrada's vineyards should be uprooted.

Despite the foundation in 1887 of the Escola Prática de Viticultura da Bairrada whose efforts to promote and develop the region included producing Portugal's first TRADITIONAL METHOD sparkling wine in 1890, it has taken Bairrada more than two centuries to recover.

For the best part of the 20th century, the merchant bottlers (see NÉGOCIANTS) and CO-OPERATIVES that still dominate production churned out cheap BULK wines for Portugal's African colonies. But this market collapsed in the wake of the 1974 revolution. Bairrada was awarded REGIÃO DEMARCADA (now DOC) status in 1979. Tapping new, more demanding export markets required the merchant bottlers to exert greater control over fruit sourcing and production through the acquisition of vineyards, buying grapes (instead of wine), and investing in winemaking facilities. Most of Bairrada's 2,400 growers own a very small area of vines even today, so most send their grapes either to a merchant or to one of the region's two remaining co-operatives. Around 900 of them alone sell their fruit to SOGRAPE for MATEUS rosé. Bairrada's main quality impetus has come from the handful of dynamic individual winemaking estates that emerged in the 1980s and the successive wave that has reinforced its number. Stalwart supporters of traditional varieties, notably BAGA, have progressively tamed its worst excesses (fearsome tannins and acidity) by optimal VINEYARD SITE SELECTION (warmer, better-drained CALCAREOUS-clay soils are best), trimming this productive grape's yields, and gentler EXTRACTION. Others have taken advantage of DOC rule changes which, from 2003, permitted blending with more

approachable, popular varieties such as Touriga Nacional, Cabernet Sauvignon, Merlot, and Pinot Noir. These incomers (sometimes with a dash of white grapes) have successfully fleshed out Baga and have even produced some very promising wines in their own right, especially the Bordeaux varieties, which are well-suited to Bairrada's MARITIME CLIMATE. Keen to reinforce the region's traditional varieties Baga, Maria Gomes, and Bical, from 2009 leading estate Luis Pato began once again to label its top wines Bairrada (as opposed to bottling all as Vinho Regional BEIRAS, now known as Beira Atlântico). In 2020, Baga represented only 40% of red grapes under vine (down from 90%) and 26% of land under vine. However, those who remain committed to producing VARIETAL Baga consistently make some of Portugal's leading reds. With riper, finer tannins and better fruit expression, modern Baga is broachable earlier than in the past and comes in many guises, ranging from easy-drinking GLOU-GLOU to FORTIFIED *vinho licoroso*. White grapes, mostly Maria Gomes (FERNÃO PIRES) and BICAL, once grown primarily by the merchants for TRADITIONAL METHOD sparkling wines, are increasingly valued by Bairrada's leading estates which make some remarkably TERROIR-focused, almost Burgundian whites and, more recently, artisanal traditional-method sparkling wines based on Baga. Sparkling-wine production remains important, representing around 50% of Portugal's output.

The Bussaco Palace Hotel owns a vineyard, Vinha da Mata, in Bairrada from which it has produced an impressively structured Baga-dominated red labelled VM since 2001. However, located on the cusp of Bairrada and Dão, it is best known for Buçaco red and white wines made from grapes sourced from both regions. Once regarded as some of the best table wines in Portugal, older vintages (dating back to the 1940s) are available only to guests dining at the hotel or one of its few associated establishments, apart from those few bottles that occasionally crop up at AUCTION. Baiyu, Chinese name for RKATSITELI.

balance is essential for quality both in vineyards and in wine.

Vines

Vine balance is a viticultural concept little appreciated by wine consumers yet one which is essential for producing grapes for premium winemaking. A vine is in balance when the amounts of fruit and vegetative growth are appropriate. One index of this is the LEAF TO FRUIT RATIO. Vine balance concerns VIGOUR and it can be managed by the VITICULTURIST, with BALANCED PRUNING and WATER STRESS the principal tools. One of the best measures of vine balance is the ratio of fruit yield to pruning weight, now often called the Ravaz Index after the French researcher who promoted it.

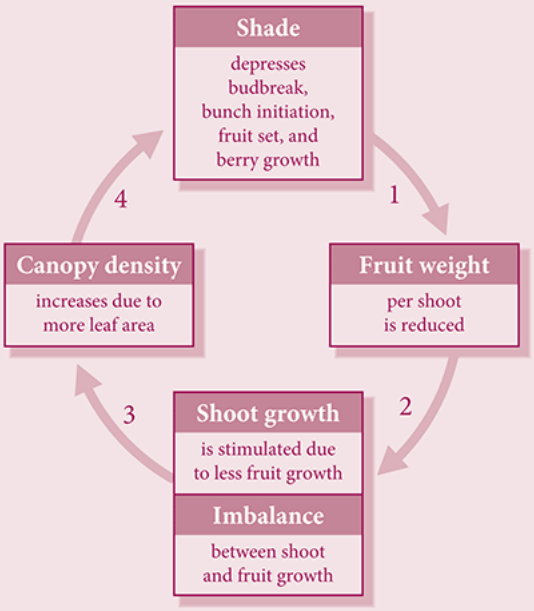
Balanced wine comes from balanced vines, a fact acknowledged even by those who were once critical of high YIELDS in any circumstances. A balanced vine has shoots of moderate vigour (thus medium pruning weight of around 35 g/1.23 oz per shoot) and no SHOOT TIP growth during fruit RIPENING. Leaves are of moderate size and number and shoots spaced in such a way as to avoid excess SHADE, with both leaves and fruit well exposed to sunlight. Unbalanced vineyards are either too vigorous (in which case poor ripening results from shading and competition between the ripening grapes and shoot tips for carbohydrates) or not vigorous enough (in which case there is insufficient leaf area for proper ripening). Monitoring shoot-tip growth is seen as an important management tool for vine balance.

R.E.S.

Balance

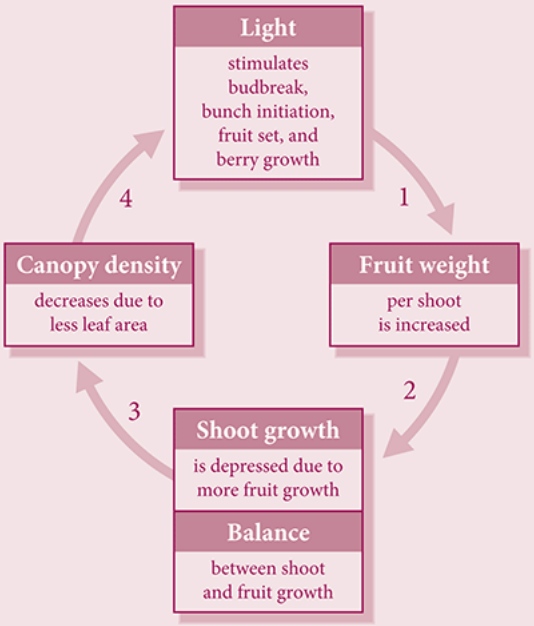
Vegetative cycle

Canopies tend to become more and more shaded and vegetative, leading to yield and quality reductions. Typical of vineyards on high potential soils with an inadequate trellis.



Balanced cycle

Light stimulates shoot fruitfulness leading to balance between shoot and fruit growth. Typical of vineyards trellised according to vigour.



Source: R. Smart and M. Robinson, *Sunlight into Wine*

Wines

Wine tasters say that a wine has balance, or is well balanced, if its ALCOHOLIC STRENGTH, ACIDITY, RESIDUAL SUGAR, TANNINS, and FRUIT complement each other so that no single one of them is obtrusive on the PALATE. (Young wines are expected to exhibit more marked tannins than mature ones, however.) This extremely important wine characteristic is unrelated to FLAVOUR, although see also HARMONY.

balanced pruning. The number of buds to be left on the vine at winter PRUNING will determine the vine's growth in the following season and should be assessed in relation to the vine's capacity to support shoot growth. In turn, a balanced pruned vine will produce sufficient shoot growth to ripen the fruit it carries. In practice, an experienced pruner will consider the amount of CANE growth of the last season and the bud number retained the previous year and then adjust the number of buds if the SHOOT growth was excessive or inadequate.

The amount of reserves, or stored CARBOHYDRATES, in the vine roots, TRUNK, and ARMS will determine the growth of developing shoots in the spring. An indication of the amount of vine reserves is the weight or mass of cane prunings removed; the greater the amount of shoot growth in summer, the higher will be the pruning weight and also the stored carbohydrate reserves.

Pruning weights are simply measured by weighing the cane prunings removed at winter pruning. This value is used to judge the appropriate number of buds to retain at winter pruning. For example, one common formula is to retain around 30 buds for each kg/2.2 lb of pruning weight.

If too few buds are left on the vine at winter pruning relative to the stored carbohydrates, then shoots in spring will grow quickly with leaves which are too large and stems which are too thick. The vine will have a high LEAF TO FRUIT RATIO, which may result in poor fruit set

(see COULURE). In any event, the leaf-to-fruit imbalance normally leads to a shaded CANOPY MICROCLIMATE and attendant problems of loss of YIELD and quality. Such a situation is common for vines planted too close together on fertile soil.

On the other hand, if too many buds are left at pruning relative to stored carbohydrates, then the resulting large number of shoots will develop only slowly in spring. The leaves will be small and the stems spindly. The danger here is that the leaf area may be too low for the weight of grapes, which will ripen slowly, and wine quality will suffer. This condition is often described as OVERCROPPING.

See also PRUNING. R.E.S.

Smart, R. E., and Robinson, M., *Sunlight into Wine: A Handbook for Winegrape Canopy Management* (1991).

Balearic Islands, *Illes Balears* in Catalan and *Islas Baleares* in Spanish, is an archipelago off Spain's east coast and one of its 17 autonomous regions. MALLORCA, the largest island, has the most significant wine industry, with two DOPS, Binissalem and Pla I Llevant, but there are also compelling VINO DE LA TIERRA (VdT) wines made on Formentera, Ibiza, and Menorca. All the islands share the commonalities of a warm MEDITERRANEAN CLIMATE with well over 2,700 sunshine hours yearly and low rainfall (around 400 mm/16 in annually, reaching 650 mm on the north-east coast of Menorca, the most easterly island). Monastrell, Tempranillo, Merlot, and Cabernet Sauvignon dominate plantings on all islands. Syrah is authorized in VdT Menorca and Ibiza wines, while FOGONEU, an indigenous red variety, is authorized for use in VdT Formentera. In white wines, Chardonnay, Malvasia, and Moscatel dominate.

Bali. See INDONESIA.

Ballard Canyon is the smallest AVA in SANTA BARBARA County, with less than one-tenth of its 3,116 ha/7,700 acres planted in 2021 but a strong reputation for Syrah, which makes up more than half its plantings. Cooling Pacific breezes, LIMESTONE and sandy soils, and a DIURNAL TEMPERATURE RANGE of up to 5 °C/9 °F combine for some of California's more elegant styles. M.D.K.

Balling, scale of measuring total dissolved compounds in grape juice and therefore its approximate concentration of grape sugars. It is very similar to the BRIX scale used in the United States. For more details, see MUST WEIGHT.

Bandol, the most serious wine of PROVENCE, typically a deep-flavoured, lush red blend dominated by the MOURVÈDRE grape. Like CHÂTEAUNEUF-DU-PAPE, Bandol produces quintessentially Mediterranean red wines which are easy to appreciate in youth despite their longevity.

The appellation is named after the port from which they were once shipped all over the world. Bandol is now a Mediterranean resort town with little to offer the wine tourist, and the vineyards are on south-facing terraces well inland, locally called *restanques*. As in the smaller appellation of CASSIS along the coast, the vines are protected from the cold north winds but have to fight property developers for their right to continued existence. Around 1,500–1,600 ha/3,700–3,954 acres were cultivated in 2020.

This particularly well-favoured southern corner is one of the few parts of France in which Mourvèdre, the characteristic grape of Bandol, can be relied upon to ripen. Other dark-berried varieties grown include GRENACHE and CINSAUT, much used for the local rosés, together with strictly limited additions of Syrah and Carignan. Despite Bandol's reputation for reds, since the early 2010s the proportion of rosé has risen steadily, accounting for more than 75% by 2020. A small quantity of white Bandol is made from CLAIRETTE blended with

Bourboulenc and Ugni Blanc (and no more than 20% Marsanne, Sémillon, Sauvignon Blanc, and/or Vermentino), but little of it escapes the region's fish restaurants.

Winemaking techniques are traditional but evolving. While some producers would like to introduce a red category with no OAK AGEING for a lighter, fresher style, current regulations stipulate that all reds must have at least 18 months in cask. Thanks to the high proportion of Mourvèdre (at least 50%), REDUCTION is a constant threat. Mechanical harvesting is banned. Domaine Tempier is one of the few domaines to have a well-established market outside France, but others such as Pibarnon, Pradeaux, La Bastide Blanche, and Vannières have a growing overseas presence. E.A.G.

Bannockburn, recognized in 2021, is the only subregional GEOGRAPHICAL INDICATION (GI) in Central Otago, NEW ZEALAND. A warm, dry area on the southern banks of the Kawarau River at the edge of Lake Dunstan in the Cromwell Basin, it is one of the first areas to begin harvesting, often four weeks ahead of the much cooler Gibbston. As elsewhere in Central, vineyards are planted overwhelmingly to Pinot Noir and have thrived in the complex soils that have been modified to a large extent by Bannockburn's strong gold-mining history. S.P.T.

Banyuls and Banyuls Grand Cru are the appellations for some of France's finest VINS DOUX NATURELS (VDN), made from vertiginous, terraced, black SCHIST vineyards above the Mediterranean at the southern limit of ROUSSILLON. The dry wines produced in the same vineyards are entitled to the appellation COLLIOURE, Banyuls-sur-Mer and Collioure being two of the four dramatic seaside communes included in these two appellations.

The VDN appellation divides into five colours: Blanc, Rosé, Grenat, Ambré, and Tuilé. For the red VDNs, GRENACHE NOIR must dominate the blend, constituting at least 50% of a Banyuls and 75% Banyuls Grand Cru, which also requires 30 months' OAK AGEING. Also permitted

are Grenache Gris, Carignan, Cinsault, Counoise, Mourvèdre, and Syrah. White and Ambré versions rely on GRENACHE BLANC and Gris with MACABEO and TOURBAT and can include small amounts of both Muscats, Marsanne, Roussanne, Vermentino, and Carignan Blanc. Yields are low and the grapes are picked with a high potential alcohol level, often as late as October. Alcohol is added, usually *sur grains*, on the skins, and then the wine is left to age in either a REDUCTIVE or an OXIDATIVE environment, depending on the desired style.

Traditionally Banyuls was an oxidative wine, aged in large old wood casks and often including an initial period of ageing outside in glass BONBONNES. The occasional reminder of the very austere RANCIO style of Banyuls, sometimes matured in a SOLERA system, can occasionally be found in the dustiest cellars. The more recently developed Grenat is a young red wine focused on fresh, heady red-fruit aromas. Banyuls Ambré and Tuilé, and Hors d'Age after five or more years of ageing, demonstrate the extraordinary levels of concentration that can be achieved by Grenache, heat, and time. Such wines are among the few that go well with chocolate, although many a French chef has created savoury dishes, often with a hint of sweetness, to be served expressly with a particular Banyuls. This is a rare appellation, once routinely prescribed medicinally, able to offer 20- and 30-year-old wines as a serious proportion of its total production. See also RIVESALTES and MAURY. R.E.G.

Barbaresco, firmly structured red wine based on the NEBBIOLO grape grown around the village of Barbaresco in the PIEMONTE region in north-west Italy. Long wrongly considered very much the junior of BAROLO in terms of its size and the structure and prestige of its wines, Barbaresco emerged from Barolo's shadow in the 1960s to win recognition of its own striking qualities of elegance and aromatic intensity.

The wine is, in fact, a younger one than Barolo, its name appearing on labels only from 1894 when Domizio Cavazza, professor at the Oenological School of ALBA, founded the Barbaresco CO-

OPERATIVE (now the much-admired Cantina di Produttori di Barbaresco). Before that the wines of Barbaresco were often blended with Barolo to add freshness to the latter. Barbaresco did not enjoy Barolo's connection with the House of Savoy and the nobility of the royal court in Turin, and it suffered relative commercial obscurity until the efforts of Giovanni GAJA and Bruno Giacosa in the 1960s demonstrated the full potential of the wine.

The production zone of Barbaresco is north-east and east of the city of Alba and only one-third the size of Barolo, but, as in Barolo, the area under vine has increased dramatically in recent years, from 484 ha in the early 1990s to 733 ha/1,811 acres in 2019. The wine is produced in the townships of Barbaresco, Treiso (formerly part of Barbaresco), and Neive, with a little made in a fragment of Alba. Neive calls itself 'the township of four wines' (the others being MOSCATO, BARBERA, DOLCETTO), and Nebbiolo consolidated its position there only after the Second World War. At the cost of Barbera and Dolcetto, today Neive has 265 ha/654 acres of the more lucrative Nebbiolo, up from 140 ha in 1995. Moscato has remained relatively unaffected by Nebbiolo's rise in popularity, making up half the planted area.

Although soil differences between Barolo and Barbaresco are regularly advanced as a major factor in the style difference, broadly speaking there are more similarities than differences. Barbaresco's soils can roughly be divided into two types. The CALCAREOUS clay of the Tortonion epoch is very similar to that in the Barolo communes of La Morra and Barolo, resulting in a perfumed, FRUIT-DRIVEN style. The second soil type, more compact and resembling somewhat the soils of the Barolo communes Monforte d'Alba and Serralunga d'Alba, is the so-called Sant'Agata fossil MARL, yielding more tannic wines.

Nebbiolo ripens earlier in some parts in Barbaresco than in Barolo, notably in vineyards closest to the River Tanaro, giving rise to the idea of Barbaresco as a lighter style. This is reflected in its ageing requirements: minimum 26 months, with at least 9 months in oak, and 50 months for Barbaresco Riserva, compared with Barolo's 38 months of which 18 are in oak, and 62 months for the Riserva. This

has led to the false assumption that Barbaresco is less ageworthy, which in recent past has unfortunately spurred some producers to attempt to emulate Barolo, ignoring Barbaresco's unique style.

Winemaking techniques, which had previously favoured prolonged MACERATION and CASK AGEING, changed in the 1970s and 1980s towards considerably shorter periods in French BARRIQUES in response to modern tastes for rounder, fruitier wines. This was scorned by more traditional winemakers who argued that French oak suppressed Nebbiolo's gentle perfume. Today, an increasing number of Barbaresco producers are returning to long maceration, often up to 40 days, and ageing in large oak casks rather than barrique. If Barbaresco is considered a lighter-bodied wine than Barolo (although these are wines which must have a minimum ALCOHOLIC STRENGTH of 12.5% and easily reach 13.5%), it is not lacking in the TANNINS and ACIDITY that mark the Nebbiolo grape; young Barbaresco is by no means an inevitably pleasurable glass of wine. The work done by the Produttori del Barbaresco, one of Italy's finest co-operatives, and by individual producers such as Angelo Gaja and Bruno Giacosa has helped to establish Barbaresco as a top-quality wine, while a number of smaller producers have begun converting to ORGANIC and BIODYNAMIC VITICULTURE and are using traditional winemaking techniques to produce highly original, long-lived wines with a muscular structure and perfumes of cherry, violets, and, with age, iron, tar, and orange peel.

In Barbaresco as in the rest of Italy, SINGLE-VINEYARD WINES are a relatively recent phenomenon, with the first, Prunotto's Barbaresco Montestefano, appearing in 1961, and there is a less firmly established written record of CRU designation here than in Barolo. Lorenzo Fantini's monograph on Piedmontese viticulture of the late 19th century indicates very few 'choice positions' in Barbaresco (and none whatsoever in Neive). The first attempts to list and rate the finest positions date from the 1960s (Luigi VERONELLI) and the 1970s (Renato Ratti).

NÉGOCIANTS' willingness to pay higher prices for grapes from certain vineyards, however, has established a certain consensus about which are the best: Asili, Montefico, Montestefano, and Rabajà in Barbaresco; Albesani and Gallina in Neive; and Pajorè in Treiso. A certain number of the most famous vineyards—San Lorenzo, Tildin, and Martinenga in Barbaresco, Santo Stefano in Neive—have gained their current prestige from the dedicated work and exacting standards of producers such as Gaja, Giacosa, and Alberto di Gresy. An official list of single vineyards, the so-called MGA (*menzioni geografiche aggiuntive*), was introduced in 2007, long before Barolo did the same in 2010. This list of single vineyards, also referred to as crus, has sensibly retained almost all the historically known vineyards, rarely absorbing them in more famous vineyard names for commercial reasons. barbarians, uncivilized ancient European people who were introduced to wine by CLASSICAL civilizations (see ROME and GREECE). See also CELTS.

Barbarossa, name used for many, probably unrelated, Italian red grapes, one of which may be identical to the rare Barbaroux of Provence.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Barbera, productive and versatile red grape variety widely planted in northern Italy. Total Italian plantings in 2017 were 18,431 ha/45,544 acres. Recent DNA PROFILING has shown that Barbera is most likely a progeny of Coccalona Nera, an almost extinct, inferior variety from south-eastern Piemonte known as Orsolina in Reggio Emilia and Rohrtraube Blaurot in Germany.

Barbera ripens relatively late, as much as two weeks after DOLCETTO, although in advance of the stately NEBBIOLO. Its chief characteristic is its high level of natural acidity even when fully ripe, which has helped its popularity in hot climates.

Piemonte

Barbera was once known as 'the people's wine' of Piemonte for its versatility and its abundant production. During the 1980s and 1990s, however, a proportion of Barbera underwent a significant metamorphosis as producers, in a parallel development to the Sangiovese-based SUPERTUSCANS, experimented with BARREL AGEING. The prototype was Giacomo Bologna's Bricco dell'Uccellone. New oak and lower yields substantially modifies the character of Barbera, adding a real spiciness to its aroma and a certain quantity of ligneous tannins, which firm up its structure and soften the impact of its acidity. In addition, the extra oxygenation of the wine has helped to curb the variety's natural tendency to REDUCTION. Today Barbera comes in a bewildering range of styles, from the young, cheap, light, and spritzy to powerful, intense, highly priced wines that need extended cellaring, reflecting both variation of producer vision and the extreme heterogeneity of the soils and MESOCLIMATES of the zones where it is planted.

Certain characteristics are constant nonetheless: a deep ruby colour (the wine was frequently used in the past to 'correct' the colour of Nebbiolo grapes grown in BAROLO and BARBARESCO); relatively low levels of TANNINS; and pronounced ACIDITY, which is aggravated by over-production, Barbera being a variety of exemplary VIGOUR and productivity. The DOC regulations permit generous yields (70 hl/ha in Alba, 63 hl/ha in Asti), relatively low ALCOHOLIC STRENGTH (12% in Alba and Asti, 11.5% in the Monferrato), and high minimum acidity. However, the combination of lower yields and the effects of CLIMATE CHANGE are making it ever harder to keep alcohol levels down and still reach PHYSIOLOGICAL RIPENESS.

ALBA, ASTI, and the MONFERRATO give their names to the three DOC zones of Piemonte, although the zones tend to sprawl across vast extensions of territory: there are 171 townships in the Asti DOC and 215 townships in the Monferrato DOC (with the two zones overlapping to a certain extent). The hills immediately to the north

and south of Alba and Monforte d'Alba in the Alba DOC and, in the province of Asti, the area from Nizza Monferrato north-west towards Vinchio, Castelnuovo Calcea, Agliano, Belveglio, and Rocchetta Tanaro are considered classic zones for Barbera. The finest wines tend to come from the DOCG Barbera d'Asti. Of the DOCG's three subzones, Nizza, one of the warmest parts of the Asti zone and historically producing the ripest Barbera, was promoted to its own DOCG in 2014. In Asti, Barbera is given the best vineyard sites, whereas in Alba these sites go to Nebbiolo.

An apparently unrelated Barbera Bianca is grown on 114 ha/282 acres, mainly in Acqui and Alessandria.

Elsewhere in Italy

Barbera dominates much of Lombardy, especially the vineyards of OLTREPÒ PAVESE, where it makes varietal wines of varying quality and degrees of fizziness, some fine and lively, with the best and most ageworthy coming from Buttafuoco. It is also blended with the softer local CROATINA or BONARDA Piemontese grapes. It is a minor, and decreasing, ingredient in Curtefranca (see FRANCIACORTA) and is found, as elsewhere in Italy, in oceans of basic VINO DA TAVOLA.

Barbera is also much planted immediately south-east of Piemonte in the Colli Piacentini, the hills above Piacenza, of EMILIA-ROMAGNA. Here too it is often blended with Bonarda, particularly in the Val Tidone for the sparkling and occasionally still red Gutturnio DOC. It is also planted in the Colli Bolognesi and Colli di Parma, where it may also produce a VARIETAL wine which rarely has the concentration of Piemonte's best and is regularly fizzy.

The variety was planted in Argentina many years ago and in California and Australia more recently thanks to a FASHION for Italian varieties and its suitability for warm climates. It is also found in Slovenia.

Barbera del Sannio is known in Campania while Barbera Sarda is grown on Sardinia, but neither is related to the Barbera of Piemonte.

Bardolino, generally modest but attractive light red wine from the south-eastern shores of Lake Garda in the VENETO region of north-east Italy. As in the other two important Veneto DOCs SOAVE and VALPOLICELLA, the original production zone known as CLASSICO (1,060 ha/2,619 acres encompassing Bardolino, Garda, Lazise, Affia, Costermano, and Cavaion) has been extended to a 1,580-ha zone whose wines are called simply Bardolino. The vineyard area of both zones combined is 2,640 ha, producing some 170,616 hl/4.5 million gallons annually. Like Valpolicella, the wine is made of CORVINA, CORVINONE, and RONDINELLA (Molinara is no longer obligatory), with the

possible addition of up to 20% of any authorized variety. Merlot is often used to bolster alcohol levels to the official minimum of 11% (9.5% for straight Bardolino DOC) so that after an additional year of ageing it can be labelled with the DOCG Bardolino Superiore. The rosé version, either still or sparkling, is called Chiaretto, while the NOVELLO indicates wines bottled before 31 December of the vintage year. In general, the determining factor of the wine's general blandness are the high permitted yields of 80 hl/ha. However, in 2021, three official subzones were created—Sommacampagna, La Rocca, Montebaldo—which require lower yields and later releases and forbid CHAPTALIZATION. Increased quality paired with growing demand for rosé has much improved Bardolino Chiaretto, while wineries such as Villa Calicantus and Le Fraghe clearly demonstrate Bardolino's potential. W.S.

www.ilbardolino.com

Barolo, often considered the most powerful and dramatic expression of the NEBBIOLO grape, takes its name from the village of the same name 15 km/9 miles to the south of the town of Alba in the region of PIEMONTE in north-west Italy.

The name Barolo started to appear on labels only in the mid 19th century, coinciding with the introduction of glass BOTTLES in the region around 1844. Before that it had been sold in cask only. Camillo Benzo, Count of Cavour, the architect of Italian unity, played a decisive role in Barolo's fortunes by modernizing his family's estate in Grinzane, with the introduction of a monoculture of vines, an idea that may have been inspired by his frequent travels to France. The French wine merchant Louis Oudart sought to work as his OENOLOGIST, and he is credited with creating the first modern, dry Barolo, although there is no written evidence of his winemaking practices. A decade earlier, Cavour had hired Pier Francesco Staglieno, who introduced fermentation in closed vats, which greatly

reduced PREMATURE OXIDATION and levels of VOLATILE ACIDITY in the wines. Staglieno's handbook, published in 1835, already stressed the importance of fermenting wine to complete dryness, which he repeated in correspondence with Cavour on specific casks to be sent to him for consumption.

Giulietta Falletti, Marquise of Barolo, allegedly engaged Oudart for her vast estate extending to La Morra, Barolo, and Serralunga although there are no records to substantiate this. Her wine, which attracted the attention of King Carlo Alberto di Savoia, allegedly inspired him to purchase and develop the estates of the castles of Verduno and Roddi for wine production, while Emanuele, Count of Mirafiori, Vittorio Emanuele II's son by the royal mistress Rosa Vercellana, developed the vineyards around the hunting lodge of Fontanafredda in Serralunga d'Alba. Due to this association with what was then Italy's reigning dynasty, Barolo earned the name 'the wine of kings, the king of wines'.

The core of Barolo has always been the townships of Barolo, La Morra, Castiglione Falletto, Serralunga d'Alba, and Monforte d'Alba, supplemented by outlying areas in a variety of other townships. The Agricultural Commission of Alba added Grinzano, part of Verduno, and a section of Novello in 1909, confirming the previous DELIMITATION work of the Ministry of Agriculture in 1896. This became the official definition of the zone in 1934, not without protests from Barolo and Castiglione Falletto, which considered themselves the true standard-bearers of authentic Barolo. Parts of Diano d'Alba, Roddi, and Cherasco were added in the DOC decree of 1966, then believed to be an error at least on paper, although a new generation of producers show that quality can be achieved. The villages of Roddi and Cherasco have respectively a mere 24.3/60 acres and 2.76 ha planted to Nebbiolo for Barolo.

Most of the Barolo zone falls within the five core townships mentioned above. This sensible demarcation of the zone, disciplined YIELDS (56 hl/ha maximum), and long AGEING requirements (38 months in total with at least 18 months in oak) make this DOCG one of Italy's most strict.

Although in the recent past Barolo was seen as powerful and concentrated, with pronounced TANNINS and ACIDITY, there are significant stylistic differences among the wines of the various zones which tend to roughly reflect the two major soil types conveniently separated by the Alba–Barolo road which runs along the valley floor, dividing La Morra and Barolo to the west from Castiglione Falletto, Monforte d'Alba, and Serralunga d'Alba to the east. The first soil type, calcareous MARLS of the Tortonian epoch which are relatively compact and more fertile, characterize the vineyards of the townships of La Morra and Barolo and, depending on the location of the vineyard, can produce softer, fruitier, aromatic wines. The second soil type, from the Helvetian epoch, with a higher proportion of compressed SANDSTONE, is less compact and less fertile, with the result that the townships of Monforte d'Alba and Serralunga d'Alba yield more intense, structured wines that mature more slowly. The vineyards of Castiglione Falletto are on a spur that divides these two valleys and produce wines that have some of the elegant and more forward character of the wines from Barolo combined with the structure and backbone of those from Serralunga.

All fine Barolo, however, shares certain traits: colour that is never deep (for Nebbiolo, like Pinot Noir, never produces opaque wines), ruby tending relatively rapidly to garnet or brick; and complex and expansive aromas of cherries and plums, evolving with time into dried cherries, rose petals, tar, liquorice, and—according to a few fortunate connoisseurs—the local white truffles. Full flavours are backed by substantial tannins, a dense texture, and lifted but never tart acidity.

One development that has marked contemporary Barolo is ESTATE BOTTLING and the fact that virtually all producers offer at least one SINGLE-VINEYARD WINE. Until 1960 the marketing of the wine was dominated by NÉGOCIANT houses, unsurprising in a production zone where the average property is less than 2 ha/5 acres. Estate bottling represented both an attempt by grape-growers to reap greater economic benefits from their vineyards and a desire to put their name, as well as that of their holdings, before the public. Négociant

houses, dealing in large quantities, necessarily blended the wines of different provenances into a house Barolo (just like their counterparts in BURGUNDY). When skilfully done, this did—and still does—accomplish the creation of balanced and harmonious wines which exemplify the general characteristics of Barolo. But certain privileged positions have long enjoyed greater prestige and given more distinctive wines in both the written tradition (from Lorenzo Fantini in the late 19th century to modern writers such as Luigi VERONELLI, Renato Ratti and, more recently, Alessandro Masnaghetti) and in the oral tradition of the zone, opinions made concretely significant by the higher prices paid by négociants for the grapes and wines of certain vineyards. While there is no absolute unanimity, most shortlists of the finest CRUS include Rocche dell'Annunziata, Brunate, and Cerequio in La Morra, spilling over into Barolo; Cannubi and Sarmazza in Barolo; Rocche di Castiglione, Villero, and Monprivato in Castiglione Falletto; Bussia, Ginestra, and previously Santo Stefano di Perno (now included in the unreasonably enlarged Perno, see below) in Monforte d'Alba; and Francia, Lazzarito, Ceretta, Arione, and Vignarionda in Serralunga d'Alba.

The multiplicity of single-vineyard bottlings from the 1980s, in the absence of an official CLASSIFICATION, has had the paradoxical result of focusing attention on and reinforcing confidence in single producers. The situation has, at least partially, been addressed by the introduction of the *Menzione Geografica Aggiuntiva* (MGA), an official list of registered single vineyards throughout the Barolo zone. They are not classified, but they are identified as 'crus', and Masnaghetti has attempted his own unofficial classification. Although most Barolo communes produced a historically faithful list, some, especially Monforte d'Alba, radically pruned the number of its vineyards by including swathes of them within more famous names. Bussia in particular has been unreasonably enlarged since the authorities failed to question this loss of historic vineyards and detail. This ruthless capitalization on famous vineyard names recalls the controversial creation of GROSSLAGE in Germany.

As the world of wine opened up in the 1960s, and as some of the producers in Barolo travelled further than Turin or Rome, they decided that their wines were badly in need of modernizing, triggering a move to TEMPERATURE CONTROL during FERMENTATION, a reduction in the length of MACERATION, a move to PUMPING OVER rather than SUBMERGED CAP in the belief that a lower tannin level and shorter time in barrel were steps in this direction. The leaders of the movement towards a softer style of Barolo were Renato Ratti, Paolo Cordero di Montezemolo, and Elio Altare. The use of ROTOFERMENTERS, allowing for speedy extraction of colour and a swift alcoholic fermentation (generally 7–14 days), as well as shorter ageing periods executed in new French oak barrels, resulted in less tannic, deeper-coloured wines.

The proponents of this new approach were termed 'modernists', while those who retained faith in the old methods were called 'traditionalists'. This rather facile distinction fascinated the wine world in the 1970s and 1980s, but by the beginning of the 21st century the differences between the modernists and traditionalists had come full circle. Some of the modernist versions aged in small French oak developed poorly in bottle, sometimes accompanied by premature oxidation, while the opulence of new-oak aromas tended to obliterate Nebbiolo's fine perfume. The traditionalists have seen their approach vindicated by a growing demand in the international market for their Barolos. Barriques are still in use, but a significant number of producers has returned to ageing in much larger casks, while increasing the total maceration on the skins to 30 and even 60 days in some cases, crucially without resulting in harsh tannins, bitterness, or oxidation. Arguably, better CLONAL SELECTION, lower yields, and higher plant density, combined with increasingly sophisticated knowledge of viticulture, has led to this increase of quality and, with that, an increase in the expression of variety and TERROIR, although CLIMATE CHANGE is putting these quality markers on their head.

An unparalleled series of exceptional vintages in the late 1990s and 2000s—such as 1996, 1997, 1998, 1999, and 2001, as well as the stellar 2010 and 2016—saw demand in the US, German-speaking

markets, and the UK grow exponentially and prices escalate. Plantings have increased in response, from 1,714 ha/4,285 acres 2004 to 2,208 ha/5,451 acres in 2020. This included Nebbiolo planted in sites that were traditionally reserved for varieties such as DOLCETTO and BARBERA, with most of the production not geared towards Barolo but LANGHE Nebbiolo, which has taken the market by storm as a kind of economy Barolo. Such is its success that other denominations, such as MONFERRATO, recently changed their wine regulations to allow for the variety to appear on labels (to a background of fierce protests from Barolo producers). Meanwhile, Barolo's neighbouring Dogliani DOCG is seeing Dolcetto, its historic grape variety, succumb to Nebbiolo, which guarantees producers a much higher return.

Baroque, sometimes spelt Barroque, is the intensely local grape variety associated with white TURSAN. Although it is now grown almost exclusively in the Landes *département* (46 ha/114 acres in 2019), it was at one time known throughout SOUTH WEST FRANCE and was valued by growers in the early 20th century for its resistance to POWDERY MILDEW. The best examples display the unusual combination of high alcohol and fine aroma, something akin to ripe pears.

Barossa Valley, arguably the most famous wine region in AUSTRALIA and the one in which most wine is produced, even if a high

proportion of it is shipped in from vineyards outside the valley itself. There is an increasing trend towards planting off the valley floor and on higher ground on the hillsides. On the other side of the coin, the incalculable value of the viticultural bank of Shiraz, Grenache, and Mourvèdre vineyards, up to 170 years old, DRY-FARMED and UNGRAFTED, makes this a heritage area which can be neither duplicated nor replaced. According to Australia's official wine geography, the Barossa Zone includes the Barossa Valley and Eden Valley GEOGRAPHICAL INDICATIONS. For more detail, see SOUTH AUSTRALIA.

barrel, cylindrical container traditionally made from WOOD and historically used for the storage and transportation of a wide range of goods. Today, barrels are used almost exclusively in the production of fine wines and spirits and are almost invariably made of OAK, although some have experimented with various combinations of STAINLESS STEEL, clay, CONCRETE, etc. The bulge, or bilge, of barrels means that they can be rolled and spun easily and that, when they are kept horizontal, any sediment naturally collects in one place, from which the wine can easily be separated by RACKING. The average worldwide production for wine and spirits (including cognac and brandy but not bourbon) is one million barrels, with more than half made in France.

Barrels come in many sizes (see BARREL TYPES) and qualities (see BARREL MAKING). The word 'barrel' is conventionally used for a wooden container small enough to be moved, while VATS are larger, permanent containers, sometimes with an open top. COOPERAGE is the collective noun for all wooden containers, whether barrels or vats (as well as the term for the cooper's business or premises), and the word CASK is used for wooden containers of all sizes.

BARREL AGEING is the term used in this *Companion* for ageing a wine in a barrel, while CASK AGEING has been used as a general term for keeping a wine in a larger wooden container. BARREL FERMENTATION is the technique of fermenting wine in barrel.

A barrel is made up of STAVES shaped into a bulging cylinder, with hoops round it, a flat circular head at either end, and at least one hole for a BUNG. See BARREL MAKING for details.

History

Although HERODOTUS refers to palm-wood casks being used to carry Armenian wine to Babylon in Mesopotamia, it is generally accepted that it was the Iron Age communities of northern Europe, notably the CELTS, who developed the wooden barrel for the large-scale transport of goods. Its origins cannot now be recovered, but Julius Caesar encountered barrels during his campaigns in France in the 50s BCE. In the second half of the 1st century CE, PLINY described transport barrels in GAUL in a way that suggests they would have been unfamiliar to his Roman audience. The Latin term *cupa*, which later came to mean 'barrel', at this time normally referred to wood storage tanks, the remains of one of which have been found at POMPEII, near Naples. Barrels or barrel staves have been preserved in waterlogged conditions on sites in Britain (at Silchester) and along the RHINE and the Danube. Famous monuments such as that from Neumagen on the German River MOSEL testify to the use of barrels for the transport of goods. When the Roman army served in northern Europe, it used barrels regularly; they are frequently illustrated in scenes from the columns of Trajan and Marcus Aurelius which commemorated the campaigns of these emperors in the 2nd century CE. There are increasing numbers of archaeological finds of barrels or barrel staves from Roman sites in Britain, along the RHINE, and in Western Europe. The presence of TARTARIC ACID residues in some cases may be evidence for the contents having been wine. (See PALAEOETHNOBOTANY.) The wood used was frequently silver fir.

From the middle of the 3rd century, references in literature and art to the use of barrels in Italy and, to a lesser extent, elsewhere in the Mediterranean are much more frequent. It is possible that the more widespread use of the barrel explains the disappearance of various types of AMPHORAE in this period. It also means that from this period on it is much more difficult to trace trade routes, since wood is much less likely to survive on archaeological sites. From the early medieval period, barrels were the normal means of transporting wine.

barrel ageing, also known as barrel maturation, is the winemaking operation of ageing wine in wooden BARRELS to create ideal conditions for the components of the wine to evolve and, in some instances, so that the wood imparts some OAK FLAVOUR to the wine, although the more obvious flavours of oak are today less sought-after than they were in the late 20th century.

Barrels were originally used for the TRANSPORT OF WINE, but winemakers, observing the way wines improved after time in barrel, developed techniques and cellars for deliberate barrel ageing, lasting from a few months for white wines to a year or more for reds.

White wines aged in barrels will often have been BARREL FERMENTED so the main goal is to prolong contact between the wine and the yeast lees (see LEES CONTACT) to enrich the wine with compounds released by yeast AUTOLYSIS. This may also involve LEES STIRRING to increase the exchanges between wine, lees, and wood.

The most obvious advantage of barrel ageing for both red and white wines is that it encourages CLARIFICATION and STABILIZATION of the wine in the most natural, if not necessarily the fastest, way.

When it comes to red wines, the aims are to clarify and stabilize their colour, to refine and soften their tannins giving more volume in the mouth and a longer aftertaste, and to increase the complexity of the aroma and flavour compounds.

The smaller volume of barrels compared with that of larger vats or tanks makes it easier to achieve clarity. Barrels are more sensitive to

the ambient temperature in the cellar, and when the temperature drops, salts, particles, and colouring matter (mostly ANTHOCYANINS and FLAVONOLS) precipitate and settle at the bottom of the barrel. The clear wine is separated from the lees and the more turbid wine at the bottom of the barrel by RACKING.

In addition to clarification, other chemical reactions occur during barrel ageing, changing the phenolic structure of the wines. Although some oak flavour may be extracted directly into the wine, one of the more obvious secondary flavour effects of maturing a wine in barrel results from the slow oxygenation of the wine and the oxidation–reduction reactions (see REDOX POTENTIAL) that take place in the barrel. When barrels are filled, stoppered, and rolled, they receive a small but significant amount of OXYGEN. Leaving barrels upright and topping up the evaporated wine weekly can triple the amount of oxygen the wine receives. In the Bordeaux area, the type of BUNG (glass, silicone, polymer, wood, and fabric) and its positioning (on the top or side) are also tools used to regulate the oxygen supply. This uptake of oxygen, however slow or fast, aids in the formation of PIGMENTED TANNINS with colours that are more stable and permanent than those of monomeric anthocyanins.

Oxygenation will also result in smoother, more stable tannins as they form complexes with POLYSACCHARIDES and PROTEINS. If the newly formed phenolic compounds become too large due to POLYMERIZATION, they will precipitate and form sediment. Temperature increases will favour these reactions, and cooling will accelerate precipitation.

MICRO-OXYGENATION in barrel or tank is seen by some winemakers (and accountants) as an attractive alternative to prolonged barrel ageing.

Maturing wine in wood can also add aromatic complexity to a wine thanks to aroma compounds derived from the barrels (see OAK FLAVOUR). WOOD INFLUENCE outlines the factors that govern the process of barrel ageing: size, age, and wood type of the barrel, techniques used in BARREL MAKING, storage conditions, characteristics of the vintage, winemaking techniques, and time. See also TOAST for details

of how this plays a part in providing a buffer between the alcohol and the wood's PHENOLICS.

Cellar conditions have a major impact on barrel-aged wine. The temperature in the cellar has an almost immediate impact on the temperature of the wine, which affects the volume of wine in the barrel, directly influencing the internal pressure of the barrel if it is well sealed with a bung. In addition, the relative humidity in the cellar, combined with temperature, has an effect on the wood of the barrel due to the hygroscopic properties of this material (see OAK). Both temperature and relative humidity have an effect on the oxygen supply, the wood aromas, tannin extraction, and even the microbiological balance of the wine. J.E.H. & R.T. du C.

barrel alternatives, common term for a group of materials and techniques, including the use of OAK CHIPS, BARREL INSERTS, and INNER STAVES (collectively known as oenological oak), sometimes in conjunction with MICRO-OXYGENATION, which are substitutes for BARRELS. Usually offcuts from cooperages or sawmills, toasted in convection ovens or infrared kilns, they save both money and space and have become increasingly sophisticated, offering the winemaker a choice of types of oak as well as different toast levels, but care is needed with the dosage and the length of time the products are in contact with the wine. The shape and size of the pieces influences the composition of the oak and the diffusion of oak compounds into

the wine. Since 2006 certain barrel alternatives have been permitted in the EU, although their use is forbidden in some PDO wines. A.P.

barrel fermentation, winemaking technique of fermenting grape juice or must in small BARRELS rather than in a larger FERMENTATION VESSEL. The technique is used principally for white wines because of the difficulty of extracting through a barrel's small bung-hole the mass of skins and seeds which necessarily remains after red wine fermentation, although in the late 1990s fermentation of red wine in barrel, said to improve oak integration and MOUTHFEEL, gained in popularity. In Burgundy, California, and especially Australia, however, some winemakers deliberately put pressed red wines which still retain some unfermented sugars into barrel, thus allowing completion of red wine FERMENTATION in barrel in an attempt to make softer, more approachable wines.

Encouraged by the success of this technique, a few winemakers are taking this further and fermenting small quantities of red grapes entirely in barrels, either by removing the barrel head for an open-top fermentation or by using a specially designed barrel in which the bung-hole in the side of the barrel has been replaced by a porthole in the head, sometimes with a paddle inside to help break up the CAP. If the barrels are stored on a racking system with rollers, barrels can easily be turned to keep the cap mixed with the fermenting must—rather like a mini wooden ROTOFERMENTER. Proponents claim that putting the must into barrel immediately after crushing results in softer tannins, increased stability, and better colour concentration, probably because of the MICRO-OXYGENATION that takes place in barrel.

Barrel fermentation seems particularly well adapted to wine made from CHARDONNAY grapes and some of the finest SWEET WINES. Its advantages are that it offers the possibility of extracting a controlled amount of OAK FLAVOUR into the wine and that, since barrels have a large surface-to-volume ratio, artificial mechanized TEMPERATURE CONTROL may not be needed. It also provides a natural prelude to

BARREL AGEING and LEES STIRRING since the lees and the wine are already in the same container.

White wine which is fermented and stored in oak with its yeast solids, or LEES, has a softened, less obvious, and more integrated oak flavour than wine that has been fermented in a larger container before being matured in barrels because the YEAST acts on the highly aromatic oak flavour molecules to transform them biochemically into much less aromatic substances (VANILLIN, for example, is transformed into vanillic acid, which has a higher perception threshold) and because of the adsorption of aromatic compounds on to the yeast cell wall. (The secondary fermentation aromas, however, such as result from ESTERS, fatty acids, and higher alcohols, are substantially unaffected by barrel fermentation.) FINING also removes some oak compounds. Fermentation in barrel also gives large increases in POLYSACCHARIDES, especially MANNOPROTEINS, which add richness and apparent LENGTH of flavour on the palate. The amount of yeast mass in the barrel and the frequency of stirring have a direct and considerable effect on the quantity of polysaccharides formed. The yeast also make and release ENZYMES that could reduce the stability of some aromatic compounds in the wine.

White wines fermented and matured for a few months on their lees in barrel usually have a much lighter colour than those put into barrel after fermentation to mature. Yeast cell walls adsorb certain PHENOLICS, a property that is useful for removing any unwanted colour in champagne, for example, by adding fresh lees.

Stirring up the lees in the barrel also affects oak flavour. If the lees are stirred, they act as an even more effective buffer between the wine and the wood, limiting the extent to which wood TANNINS, and colouring matter, are extracted into the wine. Wines subjected to lees stirring therefore tend to be much paler and less tannic than those whose lees are not stirred. Stirring also minimizes the effects of stratification in the barrel and is a more efficient way to bring wine components in contact with the lees and thereby increase extraction of materials from them.

Fermentation in barrel can also have secondary flavour effects due to temperature, lot size, and precise level of TOAST. The often higher temperature of fermentation in barrel rather than vat causes a change in wine AROMAS, depending on the grape variety. And because each fermentation even of identical juice has a slightly different flavour outcome, the larger number of small-volume lots that are common in barrel fermentation creates more complexity. A 10,000-l/2,642-gal lot would create one fermentation flavour if it were fermented in one tank, for example, but the same lot volume fermented in 70 barrels would produce a much more complex array of flavours.

The disadvantages of barrel fermentation are the relatively small size of the barrel and the time and effort required to clean, fill, and empty it, although the extra degree of complexity gained by the wine is usually worth any extra production costs. The cost of new barrels themselves is such, however, that the technique is restricted to higher-priced wines. With so many fermentations in a non-sterile material, it is always possible that some barrels may be infected with BACTERIA or undesirable yeasts, so extra vigilance is required to eliminate any defective wines.

Fermentation produces a protective blanket of CARBON DIOXIDE on the surface of the wine in the barrel. As fermentation slows and stops, the CO_2 will be displaced by air, allowing uptake of some oxygen from the HEAD SPACE into the wine. The larger ratio of head space to wine volume in barrels, and the permeability of wood to oxygen, will allow more oxygen to enter the wine than would occur if the same volume were in a large tank. However, it is important to keep barrels full (see TOPPING UP) to limit the amount of oxygen exposure so that the wine does not become OXIDIZED or affected by BACTERIAL SPOILAGE. Regular LEES STIRRING will also help to limit oxidation as the lees combine with oxygen.

When barrels are expensive and wine is not, winemakers and winery owners seek ways of economizing on barrel purchases. For alternatives to barrels, see INNER STAVES and OAK CHIPS.

barrel inserts, imprecise and expanding term for pieces of wood, usually OAK, added to a barrel too old to impart much OAK FLAVOUR. With larger pieces of wood, the barrel head has to be removed. A food-grade device reminiscent of the tray in an automatic dishwasher is inserted. This holds small oak planks which may be renewed every other year or so. Alternatively, small planks are linked together and attached to the bottom of the BUNG so that they dangle in the wine. For the use of inserts in a tank, see INNER STAVES. See also BARREL RENEWAL and OAK CHIPS.

barrel maintenance. BARRELS are an important investment for a winery, in terms of both their cost and their precious contents. The contents of a barrel may well have a wholesale value of thousands of dollars, while new barrels cost £250 to £1,100 (US$350 to US$1,500) each (for a 225-l barrel), depending on quality and origin. The preparation of new barrels and the maintenance of used ones is therefore an important activity for winemakers and can play a part in determining WOOD INFLUENCE. The costs associated with barrel ageing (buildings and their maintenance, cellar workers, energy, cellar tools and machinery, and loss of wine during handling or through evaporation) can be as much as the purchase price of the barrels.

Preparation for use

Barrels are treated prior to use both to check for leaks and to ensure that the barrel brings the right flavours to the wine. Typically, barrels are simply rinsed or filled with hot or cold water to check for leaks and so that the wood can be rehydrated after shipping and transportation, thus reducing initial leaks. The barrel may be spun and shaken so that, in theory, some of the rough TANNINS are washed out and leaks are revealed. Nowadays more wineries are using steam to check barrels, a method which saves water and time and reduces the risk of introducing microbial organisms such as bacteria into the wood. If a small leak is found, it can usually be plugged with an appropriately sized piece of wood. A leak near the head may indicate that some adjustment is necessary. Occasionally a STAVE may have to be replaced. However, the way the wood has been dried (see BARREL MAKING) has more influence on the tannins than the way the barrels are prepared for use.

In the past, it was not uncommon to treat the barrels with chemicals such as soda ash or ammonium to remove harsh tannins, but this also tended to remove the barrel's TOAST, and most winemakers now prefer to prepare their barrels with water or steam. At some point prior to first use, the exterior of the barrel is often coated with linseed oil or a mildewcide to combat MOULDS, although this is done principally for aesthetic reasons, and linseed is used mainly on larger vats.

Identification

At many wineries a card is attached to the head of the barrel to enable the winemaker to follow the life of each individual barrel. In larger wineries, it is not uncommon to see the sort of barcode used by supermarkets, along with computerized tracking (see INFORMATION TECHNOLOGY). Some coopers now deliver barrels with barcodes, making it easier to identify them and improving their traceability. In smaller wineries, a few letters may suffice. In Burgundy, for example, the chalked letters 'CM/R' might serve to denote 'Chassagne Montrachet, Ruchottes'. And in very small cellars, the single individual in charge may know every barrel so intimately that formal markings are unnecessary. Some wineries are now experimenting with Radio Frequency Identification (RFID) systems.

Cleaning

Barrels must be cleaned between uses and during RACKING, mainly to remove LEES and TARTRATES on the internal surface of the barrel and sometimes also to reduce the population of spoilage microorganisms such as BRETT or ACETOBACTER. Cleaning usually starts by removing tartrates using high-pressure jets of hot water. Harsher chemical treatments with citric acid or potassium carbonate may be needed but are generally avoided.

Steam is preferred for sanitizing the barrel and to remove spoilage microflora because it penetrates the wood, sterilizing not just the surface but also the deeper layers. The process is completed by rinsing the barrel with a solution of SULFUR DIOXIDE or by burning SO_2 inside the barrel.

Alternative techniques such the use of ultrasound, ultraviolet radiation, or dry ice exist but are much less common in practice.

Unused barrels and used empty barrels

Storage of unused empty barrels is problematic for several reasons: wood dehydration may lead to leakages; the oak may adsorb flavours such as TCA; and the wood could be colonized by mould in wet conditions. They are often sheathed in plastic before being shipped long distances to minimize spoilage. The storage of used empty barrels is even more problematic because they contain wine residues which could encourage the growth of harmful microorganisms such as ACETOBACTER and BRETTANOMYCES. To avoid these risks, empty barrels should be rinsed, carefully dried, treated with SULFUR DIOXIDE, and then bunged up every month. Overly long storage is not recommended since it entails excessive use of sulfur dioxide, and sulfuric acid will be formed. Barrels treated in this way must be stored under the same conditions of low temperature and high, but not too high, humidity as full barrels. High-pressure barrel washers can be used in combination with hot water or steam to sanitize barrels with little impact on wood quality, but the steam or water has to penetrate the staves sufficiently.

Most winemakers prefer to avoid the cost and risks associated with the long-term storage of empty barrels by ordering very precise quantities and filling them as soon as possible. See also BARREL RENEWAL and BARREL STORAGE. J.E.H. & A.P.

barrel making involves far more than mere mechanics and the ability to fashion a watertight container out of nothing but bent wood. As outlined in detail in WOOD INFLUENCE, every stage of barrel manufacture has an impact on wine matured in that barrel. First, the tree is cut down, usually during the autumn or winter when the sap is down. COOPERS usually buy long sections of trunk, ideally from trees

that are over 100 years old, and then the process that turns logs into stave wood begins.

Oak selection

Each oak tree is different, with its own sensorial properties, even among trees of the same species (see OAK for those species most important for wine). While the forest itself, often dominated by one species, was once the starting point for selection, in the 1990s research at BORDEAUX UNIVERSITY led to greater emphasis on GRAIN rather than specific forest. However, more recent research by Prida et al. has shown that the two species coexist in the same forest and that intra-specific variability is important for OAK FLAVOUR. Current more sophisticated selection is based on the analysis of individual trees or STAVES, using mainly gas chromatography–mass spectrometry (GC–MS) but also infrared spectrometry, so that a homogeneous lot of trees can be used to make more consistent barrels. This depends on research that elucidates the relationship between oak composition and a wine's sensory profile.

Cutting: sawing versus splitting

Logs of appropriate lengths are cut and then split into four lengthwise. The bark and sap wood are cut off so that staves may be cut from radial (rather than tangential) sections of wood.

Because American oak is so much less porous than European, staves of American oak can simply be sawn from each quarter to maximize the yield of each log. This is traditional quarter sawing. The mill worker tosses a quartered bolt on to a conveyor belt. A bandsaw parallel to the conveyor belt lops off a stave, which is sent on its way, while the rest of the log comes back on the conveyor belt to be sawn again.

European oak could well leak if thus sawn, however, and staves have to be cut, or split, much more carefully, minimizing the risk of leakage by following the oak GRAIN. Traditionally, therefore, European oak was split by hand so that the axe blade could follow the grain. Nowadays mechanically operated axes are guided through the wood sections and the resulting staves trimmed, still following the grain. Attempts to saw European oak in order to reduce wastage have largely been abandoned because of the issues with leakage.

In France, wood split by hand from logs for use as staves is known as *merrain* and the men who do this work are known as *merrandiers*. Traditionally this work was done near the forest, but nowadays many cooperages have their own stave-splitting facilities, either near the cooperage or in the forests.

Drying: air versus kiln

After the wood has been split or sawn, it must be dried to approximately 15% relative humidity. The drying process can be achieved either naturally in the open air or artificially using kilns, and the two methods are often combined. French oak has traditionally been air-dried one year for every 10 mm/0.4 in width so that it takes between 18 and 36 months to 'season' wood by drying it, in stacks of potential staves, in the open, preferably on a site far from any industrial activity or any other source of pollution. The optimum length of time varies according to the composition of the oak and the climate. Kiln drying, though quicker, may not give such high-quality results, but it is often used in order to homogenize a pallet of staves after air drying.

Many quality-conscious winemakers will pay a premium for wood dried in the open air, however, and some actually select and buy their own wood in advance of seasoning. Natural drying tends to reduce and modify the structure of the extractable compounds of the wood while heightening its aromatic potential. It has long been thought that, as wood is seasoned outdoors and turns grey, darkening the ground beneath it, harsh tannins are being leached out of the wood. Wine matured in air-dried wood certainly tends to taste less aggressively tannic than the same wine matured in kiln-dried wood. Australian research by Sefton and others, however, indicates that tannin levels in wood do not in fact change during seasoning but that their sensory effect does, with French oak tannins becoming much less noticeable with seasoning and American oak tannins more so.

In the late 1980s, many American cooperages realized that the wine-barrel market called for an entirely different barrel from that traditionally supplied to bourbon producers; they introduced air drying as well as offering barrels labelled with specific geographical origins, just like their French counterparts.

Studies by Nicolas Vivas of the University of BORDEAUX indicate that moulds and enzymes formed on and in the wood during air drying play crucial roles in the flavour of oak and any wine matured in it.

Moulds formed on the surface of the wood liberate exocellular ENZYMES, principally heterosidases. They permit the transformation of certain bitter components into molecules which taste more neutral. At the same time, glucose and POLYSACCHARIDES are liberated from the structural elements of the wood.

European oak must be cut following the GRAIN to avoid leakage. These 1-metre lengths at the Seguin Moreau STAVE mill near Bordeaux have been scanned to work out the best location for the radial cuts in order to get as many staves as possible out of each precious piece of wood. © Seguin Moreau

Vivas has also shown that natural air drying lowers the level of dry EXTRACT, total PHENOLICS, and ellagitannins and raises the level of lactones, vanillins, and eugenols (see OAK FLAVOUR). He cautions that

if oak is dried under warm and dry conditions such as those found in much of Australia and California, the results may be similar to those produced in artificial dryers.

Some cooperages maintain that it is not just the duration of the air-drying process that is important but the wood's exposure to rain and the temperature at which the wood is dried. Their wood may therefore be watered to simulate rain, but there has been little scientific analysis of results.

Spillman, P. J., et al., 'The effect of oak wood source, location of seasoning and coopering on the composition of volatile compounds in oak-matured wines', *Australian Journal of Grape and Wine Research*, 10/3 (2008), 216–26. Vivas, N., 'Recherches sur la qualité du chêne français de tonnellerie (*Quercus petraea* Liebl., *Quercus robur* L.) et sur les mécanismes d'oxydoréduction des vins rouges au cours de leur élevage en barrique' (PhD thesis, Bordeaux University, 1997).

Assembling

Once the staves are dry enough, they can be assembled into barrels. Barrel making is made possible by the fact that wood can be bent when it has been heated. If the staves are shaped properly, the result will be a barrel. All edges will meet properly, and the barrel will hold liquid without any agent other than the hoops which hold the staves together.

First, the staves are sized and trimmed into oblong lengths that might be called a double taper. Traditionally this work, known as 'dressing' the staves, was done by hand. The stave was 'listed'—that is, given the double taper shape—with a cooper's axe, known as a *doloire* in French. Then the inside of the stave was 'scalloped' with a two-handled hollowing knife to allow for easier bending. Finally the staves were joined on a jointer, known as a *colombe*. Here the staves were given their final shape—rounded at the bilge (the middle) and narrowed at the heads (the ends). Nowadays most of this work is done by machines, saving much time and energy.

Finally, the cooper fits the staves into a frame so that each barrel will have the same circumference. An especially strong and wide stave is chosen for the stave into which the bung-hole will eventually be drilled (see below). Then these staves are arranged around an iron 'raising up' hoop, the result looking like a skirt or a teepee splayed out from the hoop at the top. This job calls for great manual dexterity, although in many American cooperages machines can do much of this work.

Shaping and toasting

Research has shown that the heating process is one of the most important in barrel manufacture, modifying the wood's physical and chemical composition and profoundly influencing any wine stored in the barrel. Heating allows the cooper to shape the barrel. Toasting degrades the wood structure and thereby produces aromatic compounds. There is controversy as to which type of toasting is best, with some suggesting that slower toasting is better for both the flavour and the structure of a wine matured in that barrel. A deep medium toast produces the most desirable character for most woods, but there is variation in effect depending on the geographic origin of the wood, the seasoning of the wood, and the wine style. Ellagitannins from the barrel, which combine with phenolics in the wine to form new and softer tannin compounds and improve colour stability, are reduced by toasting. (See also OAK FLAVOUR and TOAST.)

Various sources of heat can be used to shape the barrel: natural gas, steam and boiling water, or the fire of pieces of oak (*écourtures*). Some cooperages combine techniques and shape the barrel with the aid of boiling water or steam, then finish the barrel with a fire toasting.

Coopers knocking down the hoops and bending the barrels over fire make an exciting spectacle, for a high degree of coordination is required. The would-be barrel is rolled over a cylindrical, vented metal firepot, known as a *chaufferette*, in which small pieces of oak are burned. The coopers walk round the barrel knocking down the temporary iron hoops. They pound the hammer on a hoop driver—a short block of wood with a flat metal end—while watering the wood to keep it from getting too toasted too quickly. After the top of the barrel has been shaped, the coopers wrap cables around the base of the barrel and use a capstan to cinch up the base.

Coopers often categorize the toasting and bending of staves in three stages: the warm-up (*chauffage*), the shaping (*cintrage*), and the toasting afterwards (*bousinage*). It is the last stage which

determines the level and depth of toast inside the barrel, which depends crucially on the right combination of humidity and heat.

Natural gas, boiling water, and steam will heat the wood effectively and allow the cooper to bend the staves. Many winemakers prefer this technique as the barrel is easier to clean. Other winemakers prefer barrels shaped over a fire of wood pieces, as the toast on the inside of the barrel provides an interesting 'toasty' flavour to the wine. These winemakers feel that any extra effort in BARREL MAINTENANCE is justified by the special flavour provided by this technique. The amount of time the barrel sits on the fire and the heat of the fire both have a dramatic impact on the appearance of the barrel's interior and on resultant wine flavour. Winemakers can order barrels toasted to their specifications. Some cooperages use an electric ambient heater or a wood fire to toast the heads too, although these are usually left untoasted.

The heads

After the body of the barrel has been formed, then the heads, or barrel-ends, must be made and fitted. Five or six head staves are fitted together with wooden dowels or stainless-steel gudgeons (headless nails). Some cooperages are now using a tongue-and-groove system. Then the head is cut to size, usually round but sometimes slightly oval in shape. Near each end of the body of the barrel, a groove, called the croze, is cut into the inside of the barrel. The head is cut at the edges so that it will fit into the croze.

Formerly all of this work was done by hand, but now virtually all of it is done on machines which have replaced an array of traditional cooper's tools with names (adze, chiv, etc.) to delight the dedicated Scrabble player. Finally the head is fitted into the barrel. To do this the hoops are loosened and the head is inserted into the croze.

Finishing

Before the barrel can be sold or shipped, its outside must be planed so that splinters will not dog cellar work. The barrel is tested for leaks, usually with steam or hot water injected through a small hole drilled in the bung stave. If the barrel passes the test, the small hole is drilled to bung-hole size and cauterized. The temporary iron hoops are removed, and the final ones, usually made of metal and sometimes of chestnut, are fitted.

Developments

The quality of barrels has increased dramatically since the 1990s through mechanization of tasks such as splitting the wood, the chemical analysis of trees to improve oak selection, and the customization of barrels according to the wine that will fill them, as well as the invention of new tools to monitor barrel ageing.

See BARREL INSERTS, BARREL RENEWAL, INNER STAVES, and OAK CHIPS for other ways of imbuing wine with OAK FLAVOUR without having to buy new barrels.

barrel maturation. See BARREL AGEING.

barrel renewal is a way of saving money on expensive barrels that depreciate very quickly. One method involves shaving the interior of the barrel, but BARREL INSERTS, INNER STAVES, and OAK CHIPS are more common alternatives. A cooper removes the barrel head and shaves off all the pigmented wood from inside the barrel with a plane or grouter. In some cases, the barrel is allowed to dry out a bit, and

then the cooper retoasts the inside in order to maintain the all-important buffer between the wine and the wood and seal the wood. This system is not perfect because it is difficult to toast wood that has been permeated by alcohol and is therefore not entirely dry. Retoasting seems most effective on relatively young (two- to three-year-old) barrels. Wine aged in shaved and retoasted older barrels rarely has the subtlety of wine matured in new barrels. Another technique involves removing the wine-soaked part of the barrel with dry ice.

barrel storage has both aesthetic and practical ramifications. In most wineries there are visitors to impress, although they tend to find efficient modern reality less impressive than cobwebbed tradition. Some much-visited wineries fill their barrels in full view of the tourists before trucking the wine down the road to a clinical modern barrel warehouse, carefully regulated for both temperature and humidity. In Bordeaux particularly, it is traditional to anoint the band around the middle of the barrel with wine, giving it a neat pink stripe—indeed, in some of today's most immaculate barrel cellars this is the only visible sign that a liquid called wine is involved at all.

Touristic considerations aside, most wineries usually employ one of the following techniques: (1) Barrels are placed on metal pallets and fork-lifted into place. This looks industrial but is easiest on the cellar staff. Barrels can be stored either rolled to the side or with the bung straight up. (2) Barrels are piled one, two, or even three high in neat rows. (3) Barrels are stacked in huge pyramids. These may look good, but the barrels are hard to work and clean as disassembling the stack is a daunting task. (4) A single row of barrels is rolled on to fixed barrel racks. This looks good but is often inefficient in terms of LABOUR costs and use of space. (5) Barrels rest on rollers, supported by a steel framework, making access to each one easier and reducing the need to move the barrels, which can be rotated *in situ* so that LEES STIRRING becomes unnecessary and barrels may be emptied or drained without being removed from the stack.

Storage conditions of full barrels are important (see BARREL MAINTENANCE for unused and empty barrels). If the cellar is too cold, the wine will not develop. If it is too warm, off-flavours and harmful bacteria may develop, and the wine may age too rapidly. If the cellars are too dry, too much wine can evaporate and the barrels themselves can dry out. The ideal temperature is usually around 14–18 °C/57–66 °F, with a relative HUMIDITY over 75%. Below 75%, water evaporates, but above that figure alcohol evaporates. In warm regions, winemakers like to keep the humidity high, but not so high that it becomes impossible to control the growth of moulds.

The winemaker must consider the dew point, that combination of temperature and humidity at which evaporation occurs. Storing empty barrels (and full ones too) at temperatures higher than 18 °C/65 °F invites problems, and storing barrels over 21 °C/70 °F for more than three weeks runs the risk of BACTERIAL BLIGHT and the formation of VOLATILE ACIDS. Constancy of temperature is not as important as it is in a cellar for full bottles, and a winter drop in temperature assists precipitation and therefore CLARIFICATION.

See also TOPPING UP.

barrel types vary considerably, and this list includes some terms used for COOPERAGE, or wooden containers, that are strictly speaking larger than BARRELS.

Before CONCRETE, STAINLESS STEEL, and other inert materials replaced WOOD as the most common material for wine FERMENTATION VESSELS and storage CONTAINERS in the 1960s, each wine region had its own legion of barrel types. Even today such terms as *feuillette*, TONNEAU, and FUDER may be used to measure volumes of wine long after the actual containers themselves have been abandoned. As recently as 1976, Jean Taransaud was able to list four pages of different barrel types used in various French wine regions (see below). By the second decade of this century there was a marked trend away from heavy OAK influence and towards using barrels larger

than the traditional sizes listed below, with capacities typically between 300 and 600 l (80 and 160 gal).

France

Barrel types, as most things French, are intensely regionalized. In many cases their capacity has changed over the years.

Bordeaux The barrique bordelaise, designated 225 l/59 gal for more than a century, is probably the most famous barrel of all and is used widely outside the region. It is about 95 cm/37 in high, and the staves are only about 20 mm/0.8 in thick (although the export version may be a centimetre or two shorter and have rather thicker staves). The traditional BARRIQUE, sometimes called the 'château' model, has a wooden crossbar at each head and a BUNG at the top and one for Rracking.

The TONNEAU, at 900 l/238 gal equivalent to four barriques, or 100 cases of wine, is much used as a measurement by the Bordeaux trade, even if this large cask is no longer common.

Burgundy Here the standard barrel is the 228-l (60-gal) pièce, which is relatively low (88 cm/37 in) and squat, supposedly for practicality, given the narrow doorways and small scale of many Burgundian cellars, and to provide a deeper bilge for the LEES which accumulate in this region where RACKING is generally less frequent than in Bordeaux, for example. The staves are usually notably thicker than those of barriques, about 27 mm. Traditionally these barrels had chestnut hoops or iron hoops painted black, although some domaines have followed the American taste for more workmanlike galvanized hoops, which need no repainting.

The traditional barrel in CHABLIS was the feuillette, at 132 l/35 gal about half the size of the *pièce*. This is still the unit in which prices are commonly given, even though the barrel itself is increasingly rare.

Some domaines on the CÔTE D'OR may still have their own size of *feuillette*, holding 114 l/30 gal, or even a quartaut holding 57 l/15 gal, used primarily for TOPPING UP or for the produce of a tiny holding in a GRAND CRU.

Cognac The standard cognac barrel now holds 350 l/92 gal, although in 1900 it held only about 275 l/73 gal and only 200 l/53 gal before the French Revolution. Cognac coopers make a wide range of barrels for various wine regions.

Champagne A 205-l/54-gal barrel is traditional here, but those few houses which persist with BARREL FERMENTATION may also buy in Burgundy barrels.

Elsewhere in France A wide range of barrel types is used in the Loire and the Rhône, from small new oak barrels to large wooden vats such as the 600-l/159-gal demi-muid used in Châteauneuf-du-Pape. In Alsace, large ovals, or foudres of varying capacities, are most common.

Germany

Although Germany formed its own group of daring iconoclasts, the Barrique Forum, in the early 1990s, most of the cooperage used until very recently has been large, old, and typically on the Mosel a Fuder holding 1,000 l/264 gal or on the Rhine a Stück of 1,200 l/317 gal. A Halbfuder and Halbstück are half these sizes respectively.

Spain

Spain's most characteristic barrel is the BUTT used for SHERRY. The American oak barrels used in RIOJA, and elsewhere, are 225-l/60 gal barricas bordelesas modelled on Bordeaux BARRIQUES. Spanish cooperage can vary considerably in size and shape, however, and new wood has only relatively recently been prized.

Portugal

The PIPE is Portugal's most famous wine measure. Portuguese cooperage, which can vary considerably in size and shape, may be made from French, American, or even Portuguese oak.

Italy

The large botti, or wooden casks, traditionally used in Italy are typically made from Slavonian oak and have varying but substantial capacities. The barrique, sometimes called a carato, is increasingly common, however, while the small barrels traditionally used for VIN SANTO are caratelli holding between 50 and 225 l/13–59 gal. Large upright wooden casks may be called tini.

Hungary

Gönci holding 136 l/36 gal are traditional in the production of TOKAJI and are named after the village in which they were usually made.

United States

Before the US became the world's best customer for exported French oak barrels (see COOPERAGE), American winemakers bought 50-gal/190-l American oak barrels produced for the whiskey business. A decline in bourbon sales in the 1980s led to American cooperages tailoring an increasing proportion of their output to wineries' needs, although variations on the *barrique* and *pièce* imported from France are the most desired, and most common, barrels used by American winemakers. Barrels holding 70 gal/265 l—with Burgundy-sized heads and Bordeaux-length staves—have become popular for both aesthetic and practical reasons.

Australia and New Zealand

Barriques of 225 l/59 gal have become the most commonly used barrel, and, if imported from France, are imported whole. Hogsheads of 300 l/79 gal and puncheons holding 450 or 500 l/118 or 132 gal are regaining popularity. While the latter are too large to manœuvre with ease and do not impart OAK FLAVOUR as fast as some winemakers desire, they are more suitable than *barriques*, for example, for some lighter wines and for the 21st-century trend towards more restrained use of oak. M.C.K. & J.R.

Taransaud, J., *Le Livre de la tonnellerie* (1976).

barrica, Spanish term for a barrel or BARRIQUE. A *barrica bordelesa* is the specific term for a Bordeaux *barrique*, the most common BARREL TYPE used in Spain.

barrique, the most famous of the BARREL TYPES, Bordeaux's relatively tall 225-l/59-gal wooden cask with thinner STAVES than the Burgundian *pièce* and most other barrels.

In the Middle Ages, the commercially acute Bordelais virtually trademarked their distinctive *barrique bordelaise,* carefully designating its dimensions and prohibiting its use outside the region. By the end of the 18th century, it had replaced the unwieldy TONNEAU for transportation as well as storage, and in 1866 it was officially decreed that one must hold 225 l/59 gal, rather than 215–230 l/57–60 gal as previously. Even as recently as this, it was common for some of the most highly regarded wines of Bordeaux to be shipped in *barrique* for bottling, if not by the NÉGOCIANTS of Bordeaux then by wine merchants outside France, particularly in northern Europe.

Today the word *barrique* is often used, particularly outside France, for all manner of wooden BARRELS. In Germany and Italy, for example, the word has been closely and emotively associated with those who

employ BARREL MATURATION in small, new OAK rather than traditional CASK AGEING in *botti*, large wooden casks.

Barsac, sweet white-wine appellation in the south-west part of the BORDEAUX region on the left bank of the River GARONNE, just over the climatologically important cool river Ciron from the larger SAUTERNES appellation. All wines produced within Barsac are also entitled to use the appellation Sauternes (though the reverse is not the case). In 2021, 333 ha/750 acres of vineyard were declared. It is traditionally said that the wines of Barsac are slightly lighter than those of Sauternes because of the soil—shallow red SAND over a deep LIMESTONE bedrock on a gentle slope going down to the river, as opposed to Sauternes' rolling hills of gravel over clay. But much depends on individual properties and their vineyard policies. For more details on viticultural and winemaking practices, see SAUTERNES. See also the Barsac properties included in the Sauternes CLASSIFICATION.

W.J.B.

Bartons, prominent family in BORDEAUX, originally from Lancashire in the north of England, who joined the Tudor Protestant Ascendancy in Ireland. Unlike most others who joined the BORDEAUX TRADE from abroad, the Bartons maintained their nationality, religion, and family connections. Thomas Barton arrived in Bordeaux in 1722, played a leading part in shipping fine CLARET back to Britain, and died in 1780 a very rich man. His son William (1723–99), with whom he bitterly quarrelled, formed his own company and was prominent in the trade on his own account. His son Hugh (1766–1854) married Anna, daughter of another prosperous merchant, Nathaniel Johnston. The association with Daniel Guestier of a Breton Huguenot family began in 1795, and the NÉGOCIANT Barton & Guestier was formed in 1802.

Highly successful, Hugh Barton bought Ch Langoa in ST-JULIEN in 1821 and acquired in 1826 part of the Léoville vineyard that was to become Ch Léoville-Barton, an even more prominent St-Julien. He died in England, having been succeeded by his son Nathaniel (1799–

1867). Barton & Guestier continued to play a leading role in the Bordeaux trade, but PHYLLOXERA, the consequent shortage of authentic bordeaux, and the slump in English demand prior to the First World War led to unprecedented problems. Nathaniel's son Bertram Francis (1830–1904) worked first in the London office but came in 1873 to live in Bordeaux rather than at Langoa. It was his third successor Ronald Barton (1902–86) who made Langoa his home. Business was difficult between the world wars, and on the fall of France in 1940 Ronald had hurriedly to leave Langoa, which was soon occupied by the Germans. They did not pillage the cellars as Daniel Guestier told them that the estate belonged to a neutral Irishman, who, however, volunteered for the British army. Although the quality and reputation of second-growth (see CLASSIFICATION) Ch Léoville-Barton and third-growth Ch Langoa-Barton steadily improved, the profitability of Barton & Guestier gradually declined, and in 1954 the American firm of Seagram took half the shares of Barton & Guestier and later acquired complete control.

Ronald Barton's nephew Anthony Barton (1930–2022) joined Barton & Guestier in 1951 and subsequently left to form his own merchant business. In 1986 he moved into Langoa and took over complete control of the two classed growths, whose wines are both made at Langoa and have become models of sensibly priced, classic CLARET made for the long term. Anthony's daughter Lilian Barton Sartorius bought Ch Mauvesin Barton in Moulis in 2011. She and her husband Michel, and their children Damien and Mélanie, run these much-admired properties. Damien is especially interested in SUSTAINABILITY. E.P.-R. & J.R.

Barton, A., and Petit-Castelli, C., *La Saga des Bartons* (1991).

basal buds, or base buds, the group of barely visible and compressed buds at the bottom of a SHOOT or CANE. Normally they do

not burst unless vines are severely pruned, and they are typically of low FRUITFULNESS. R.E.S.

basalt, a dark-coloured, fine-grained igneous rock (see GEOLOGY) dominated by the two minerals feldspar and pyroxene, though they are usually too fine to be discernible. They weather to provide a good range of potential NUTRIENTS. Dark rocks such as basalt are often said to reradiate warmth at night, but Pogue's study in the Columbia Valley in WASHINGTON and OREGON suggests that the thermal effects operate chiefly during the day.

Basalt is commonly found in association with VOLCANIC materials such as TUFF. In addition to the locations mentioned for them, basalt occurs in many other wine regions, for example VICTORIA (e.g. King Valley and Macedon Ranges) and the HUNTER VALLEY in Australia, the Galilee region of ISRAEL (including the Golan Heights), and in parts of HUNGARY such as Tapolca near Lake Balaton and Somló Hill, where it dominates vineyards. A.J.M.

Pogue, K., 'Influence of basalt on the terroir of the Columbia Valley American Viticultural area' (2010). people.whitman.edu/~pogue/soave.pdf.

Basilicata, a mountainous, virtually landlocked area of southern Italy, is the country's third least populated region. Its name has become synonymous with the extreme poverty in, and abandonment of, much of Italy's deep south, and the countryside has been drained by emigration since the end of the Second World War, while its unspoilt natural beauty still awaits any significant TOURISM boost to the regional economy. Little exists in the way of viticulture either; the region's total vineyard surface declined from 5,567 ha in 2010 to 5,000 ha/12,355 ha in 2020. The Basilicata has only four DOC wines and one DOCG. AGLIANICO DEL VULTURE is qualitatively the most

important DOC, with vineyards situated on the slopes of an extinct volcano 56 km/35 miles north of Potenza. The Superiore version was elevated to DOCG status in 2010.

Basilicata's other DOCs include Grottino di Roccanova (a 100% MALVASIA Bianca di Basilicata, with a rather less exciting provision for a SANGIOVESE-based red) and Matera, a hastily and rather generously designated DOC based on Malvasia and the potentially interesting GRECO BIANCO for whites and PRIMITIVO and Sangiovese for reds, while Matera Moro must contain at least 60% Cabernet Sauvignon. The Terre dell'Alta Val d'Agri DOC accommodates mainly INTERNATIONAL VARIETIES, for which demand is waning. W.S.

Belfrage, N., *From Brunello to Zibibbo: The Wines of Tuscany, Central and Southern Italy* (2nd edn, 2003).

www.vinobasilicata.it

Basque country (Euskadi in Basque, País Vasco in Castilian, and Pays Basque in French) produces wines in Spain and France on either side of the western Pyrenees.

Spain

País Vasco or Euskadi is the most ferociously independent of all Spain's 17 autonomous regions. This densely populated, heavily industrialized strip of country facing the Bay of Biscay is not normally associated with wine, even though the important RIOJA region stretches north of the River Ebro into the Basque province of Alava where the Rioja Alavesa subregion is located—home to such important estates as Marqués de Riscal, Contino, Artadi, Martínez Bujanda, Remelluri, and Remírez de Ganuza. The three wholly Basque DOs are the tiny region of Getariako TXAKOLINA on the coast 25 km/15 miles west of San Sebastián, the smaller Bizkaiko Txakolina around Bilbao, and the newest one, Arabako Txakolina.

France

See BÉARN and IROULÉGUY.

Bastardo, Portuguese name for the JURA red wine grape TROUSSEAU. As Bastardo it is a minor variety in the Douro Valley, Dão, and Beiras with total plantings of 591 ha/1,460 acres in 2020. Over the Spanish border in Galicia it is known as Merenzao.

Bâtard-Montrachet, great white GRAND CRU in Burgundy's CÔTE D'OR. For more details, see MONTRACHET.

bâtonnage, French term for the winemaking operation of LEES STIRRING, possibly the most frequently misspelt word in WINE WRITING.

Baumé, scale of measuring total dissolved compounds in grape juice, and therefore its approximate concentration of grape sugars (see MUST WEIGHT). It is used in much of Europe, including France, and in Australia; like other scales used elsewhere (see BRIX and OECHSLE), it can be measured with either a REFRACTOMETER or a HYDROMETER. The Baumé scale is particularly useful in winemaking since the number of degrees Baumé indicates the POTENTIAL ALCOHOL in percentage by volume. (Grape juice of 12 °Baumé, for example, would produce a wine of about 12% alcohol if fermented out to dryness.) The rate of fall in Baumé is one method used to follow the course of an alcoholic FERMENTATION, but it should be noted that its product, ETHANOL, has a low DENSITY and progressively depresses hydrometer readings. B.G.C.

bead, the progress of bubbles in a SPARKLING WINE. A fine bead denotes a steady stream of small bubbles. See also FIZZINESS.

bearer, viticultural term used when pruning for what is effectively the fruiting unit of the vine, the selected long CANES or shorter SPURS bearing the buds that will produce the next season's shoots and crop. See also PRUNING.

Béarn, AOC in SOUTH WEST FRANCE in two distinct sections, around Salies-de-Béarn and near Pau, for white, rosé, and red wines. MADIRAN growers can bottle rosé as Béarn (pink wines not being allowed under the Madiran label), and JURANÇON growers may make a red Béarn (their red wines cannot be sold as Jurançon). Rosés are the main event, but concentrated reds are made, mostly from TANNAT blended primarily with Cabernets Franc and Sauvignon and sometimes with COURBU NOIR, FER, and MANSENG NOIR. The rare, tangy white wines are made mainly from PETIT MANSENG, GROS MANSENG, and the local Raffiat de Moncade. Total vineyard area was 259 ha/650 acres in 2016, and most wines are made by the CO-OPERATIVE at Gan in Jurançon. The region benefits from the Atlantic climate but also enjoys Indian summers. P.S.

Beaujolais, wine region in east-central France, noted at one time for volumes of a fruity wine with wide popular appeal but increasingly for quality wine. For administrative purposes, Beaujolais is often included as part of greater BURGUNDY; this has roots in the politics and commerce of both regions, namely the long-time inclusion by Burgundy NÉGOCIANTS of Beaujolais wines in their line-ups. But Beaujolais is very much a place apart—in terms of climate, topography, soil types, and grape varieties—which has prompted a growing number of producers to frame the two as fully separate entities. Nearly all the region's wine is produced from a single red grape variety, GAMAY Noir à Jus Blanc, much of it by a distinctive winemaking method, CARBONIC MACERATION.

History

As Beaujolais is on the ancient Roman trade route up the RHÔNE and Saône valleys, it is hardly surprising that there are records of Roman vineyards in the region, notably on Mont Brouilly (Brulliacus) and in Morgon. Benedictine MONKS developed vineyards here as early as the 7th century; for much of the medieval period Beaujolais, in wine terms at least, was simply the southern neighbour of the great duchy of Burgundy.

Beaujolais is named after Beaujeu, the town in its western hills founded in the 10th century, and was ruled by the Dukes of Beaujeu before being ceded to the Bourbonnais for a time. The region's viticultural identity was forged in part when Philip the Bold issued an edict against the growing of Gamay in Burgundy proper. Yet Philip's decree would hardly define the fate of either region: Beaujolais also faced discrimination from its northern neighbours in the MÂCONNAIS, who decried Beaujolais wines as 'greatly harmful' for consumption, according to historian Roger Dion. More pointedly, they blocked northbound trade, which in turn would prompt Beaujolais wines to flow south via the Saône to Lyons, defining that city's wine culture. Even so, by the early 18th century, Beaujolais wines were also routinely being shipped to Paris—four million gallons each year, eventually. Indeed, even Philip's bias couldn't keep Gamay out of the CÔTE D'OR, where it flourished through the 19th century. Parisian thirst was only magnified as canal and RAILWAY routes were developed. And Beaujolais in the 1800s was a relatively prosperous place. The best of that era's Beaujolais was reputed on par with Burgundy: JULLIEN ranked Moulin-à-Vent (technically only a sliver of today's AOC) and Chénas on par with the wines of VOSNE-ROMANÉE, Fleurie with the wines of GEVREY-CHAMBERTIN.

A mix of PHYLLOXERA, outsized production, and economic misfortune would unravel much of this. Southern Beaujolais would expand plantings to less suitable, flatter, more fertile land and

eventually qualify for no more than basic Beaujolais AOC status, overshadowed by neighbours to the north.

After the Second World War, Beaujolais became associated with fresh, young PRIMEUR wines, shipped to Paris and Lyon where the simple, affordable style became a bistro staple. The wines became a worldwide phenomenon in the 1970s under the name Beaujolais NOUVEAU; at its peak in 1988, Nouveau made up more than 60% of production.

Already, however, a shift was under way towards higher-quality wines, attributed to several prominent producers known as the 'Gang of Four', led by winegrower Marcel Lapierre and mentored by the scientist and négociant Jules Chauvet. This cohort advocated better (typically ORGANIC) farming and minimal SULFUR DIOXIDE, precepts that would influence the NATURAL WINE movement throughout France. In the 2000s, several Burgundian producers acquired land in Beaujolais, including Thibault Liger-Belair and Michel Lafarge, marking a reversal from négociant-dominated trends of the past. These events also reflected shifting economic trends, namely overproduction in the late 1990s and early 2000s, when producers had to resort to compulsory DISTILLATION, plus a flattening of bulk prices paid to growers. That boosted the appeal for growers to make DOMAINE-BOTTLED wines. This increasing interest in TERROIR and quality got another boost with the availability, in the mid 2010s, of precise soil maps for the region's ten CRUS, which engendered a Burgundian level of discussion.

Today, the carefree vibe surrounding Beaujolais continues, amplified by its traditional service in Lyons and in Paris, in a special 46-cl/1 pint bottle known as a *pot*, as well as in sales of BULK WINE for immediate consumption. At the Beaujolais and Villages levels, this is an archetypal lubrication wine, drunk young and *gouleyant*, or gulpable, if served cellar cool. That said, more energy has turned to the crus, particularly Morgon, Moulin-à-Vent, Chénas, and Juliénas, which can improve in bottle for a decade or more. These wines have spiked in both price and quality, rivalling Burgundy at times.

Geography and climate

The total vineyard area of the Beaujolais region is slightly over 13,200 ha/32,600 acres and includes nearly 100 communes, with MÂCONNAIS on its northern boundary (indeed a number of villages service both Beaujolais and Mâcon-Villages AOCs, including ST-VÉRAN and Chaintré). The climate is TEMPERATE and semi-CONTINENTAL, with snow in the foothills of the Massif Central to the immediate west by the time Beaujolais Nouveau is launched and summers sufficiently hot for local houses to be shuttered from summer heat. Counting 1333 degree days (see CLIMATE CLASSIFICATION), the region's heat accumulation lands squarely between that of the Côte d'Or to the north and CÔTE-ROTIE to the south, although, with CLIMATE CHANGE, wines grown in some warmer MESOCLIMATES now routinely exceed 14% alcohol.

In the northern, narrower part of the region, TOPOGRAPHY is varied, the hills ranging from gentle to precipitous. Typically the discussion of Beaujolais soils has begun and ended with GRANITE, but recent soil maps have happily complicated this. The presence of SCHIST, especially in Juliénas and in Morgon, is significant, as is the volcanic soil known as TUFF, plus QUARTZ, SANDSTONE, and more. LIMESTONE appears in the north, at the edge of the Mâconnais, and again in the south, especially in the area known as Pierres Dorées.

And while the southern, flatter sector south of Villefranche is often considered too fertile for the best quality, a formal ranking published in 1893 by the industrialist and ampelographer Victor Vermorel and René Danguy, a prominent professor in Beaune, revealed exceptional LIEUX-DITS in the Bas-Beaujolais, in towns like Jarnioux. The extent to which the region succumbed to a later view as simple peasant wine reflects the deep cultural power of Nouveau, for good or ill.

The appellations

About half of all Beaujolais is sold under the basic appellation Beaujolais, which comes from the Bas Beaujolais plus the flatter land between the hills and the north–south autoroute around Belleville. The second most prolific Beaujolais appellation is Beaujolais-Villages, which must come from the hillier, northern part of the region, its vineyards pushing up into the foothills of the Massif Central. If a Beaujolais-Villages is the produce of just one village or commune, it can append the name of that commune. In the finest sectors of this northern part are the so-called Beaujolais CRUS, ten named communes whose wines had the best historical and commercial reputations.

For more details of individual crus, see, approximately from north to south, ST-AMOUR, JULIÉNAS, CHÉNAS, MOULIN-À-VENT, FLEURIE, CHIROUBLES, MORGON, REGNIÉ, and BROUILLY.

A small but increasing amount of Beaujolais Blanc and Beaujolais-Villages Blanc is made each year, mainly from Chardonnay grapes. Most is planted on patches of limestone in the north, thus a similarity to MÂCON Blanc, but increasingly growers are adding small amounts throughout the region. A modest amount of refreshing Beaujolais Rosé is made, too, and increasingly growers are harnessing more fertile vineyards to produce sparkling wines, often using a PÉTILLANT NATUREL method.

Basic maximum permitted YIELDS for both Beaujolais and Beaujolais-Villages now stand at 63 hl/ha, those for the Beaujolais crus to 56 hl/ha.

Viticulture

The GOBELET vine-training method is traditional in Beaujolais, somewhat mixed in with single GUYOT in the southern Bas Beaujolais, although even in the north BUSH VINES are often trained using rudimentary means to aid with harvest. For Beaujolais-Villages as well as the crus, PRUNING methods must be much more restrained, either gobelet or *éventail* (see TRAINING SYSTEMS). VINE DENSITY here has long been one of the highest in the world, 9,000–13,000 vines per ha. All picking must be manual because whole bunches are needed for Beaujolais's winemaking technique.

Vine varieties

Gamay Noir à Jus Blanc (so called to distinguish it from the relatively widely planted red-fleshed Gamay TEINTURIERS) accounts for about 98% of the Beaujolais vineyard, which makes Beaujolais the most *monocépagiste* (single-variety) region of any size in France. Virtually all the rest is Chardonnay, along with small amounts of ALIGOTÉ (permitted through vintage 2024) and MELON.

While there has been significant work on CLONAL SELECTION, with more than two dozen clones available today, many quality-minded growers often resort to MASS SELECTION, especially given the proliferation of old-vine material throughout the region.

ROOTSTOCKS used are SO 4, 3309, or (the Beaujolais speciality for granitic soils) Vialla.

Winemaking

Beaujolais is distinguished not just by the Gamay grape but also by its characteristic winemaking method, CARBONIC MACERATION or, more likely, SEMI-CARBONIC MACERATION. This technique has been used so widely in Beaujolais that a misperception has arisen that it originated in Beaujolais, and with Chauvet, when in fact it was pioneered in the mid 1930s by Michel Flanzy, director of the INRAE research station in Narbonne, and others prior to its broad adoption in Beaujolais.

What the region has popularized is a novel hybridization of the technique. Whole bunches arrive at the cellars and are emptied into concrete or stainless-steel FERMENTATION VESSELS generally of 40–300 hl/1,056–7,920 gal capacity. The bottom 10–30% of grapes are crushed by the weight above them and macerate and ferment in the normal way. This proportion increases with time. CARBON DIOXIDE is given off by this fermentation and leaves the upper grapes bathed in the gas so that they undergo intracellular fermentation, yielding the softer, fruitier aspects for which Beaujolais has often been known. This process can be halted after just four days for Nouveau but can continue for up to three weeks for cru wines, the maceration adding structure and density to the wines.

Most wine in the region undergoes MALOLACTIC CONVERSION, except for Nouveau, which typically must undergo STABILIZATION before a hasty bottling. The most long-lived crus receive extended CASK AGEING, often up to a year or more.

While it is tempting to describe carbonic as the region's traditional winemaking, the question of tradition is more complicated. Prior to the 20th century, vinification would largely have followed the same techniques found in Burgundy, and even today Beaujolais winemakers often talk of burgundian vinification—in the style of typical red burgundy. This method not only has endured for decades but also has been further revived by a new cohort of winemakers interested in longevity of their wines, and so it can be easier to think of winemaking on a continuum between the two methods, depending

on the producer's preference. The growing tendency towards domaine bottling and away from the négociant trade has only accelerated this, so that the fascination with Beaujolais as a pleasant peasant wine is fading into rear view, as the region relocates its one-time prestige. J.F.B.

Beaumes-de-Venise is a pretty village in the southern RHÔNE that produced such characterful Côtes du Rhône-Villages that in 2005 it was awarded its own AOC for spicy reds based substantially on Grenache and Syrah. In 2020, 22,735 hl/600,595 gal were produced from 680 ha/1,680 acres of vineyards.

The appellation has some excellent high-ELEVATION vineyards, but for centuries it was most famous for its unusually fragrant, sweet VIN DOUX NATUREL, Muscat de Beaumes-de-Venise. In 2020, 5,412 hl/142,970 gal were produced from 312 ha/771 acres of vineyards.

Like the Muscats of the Languedoc (see FRONTIGNAN, LUNEL, MIREVAL, and ST-JEAN-DE-MINERVOIS), this southern Rhône Muscat is made exclusively from the best Muscat variety, MUSCAT BLANC À PETITS GRAINS, and occasionally its darker-berried mutation which contributes colour to the rosé and red versions of the wine. Fermentation is arrested by the addition of alcohol to produce a wine with a minimum of 100g/l RESIDUAL SUGAR and 15% alcohol, yet Beaumes-de-Venise can be more delicate and refreshing than most Languedoc Muscats. Apart from the extremely rare and expensive Hermitage VIN DE PAILLE, the Muscat is the Rhône's only still sweet wine, along with small quantities of RASTEAU Vin Doux Naturel and tiny amounts of sweet CONDRIEU. M.C.W.

Beaune, vinous capital of BURGUNDY giving its name to the Côte de Beaune section of the CÔTE D'OR vineyards. Beaune was founded as a Roman camp by Julius Caesar, became the seat of the dukes of Burgundy until the 13th century, and, although losing political supremacy to Dijon thereafter, has always been the centre of the

Burgundian wine industry. In the 18th century, the first merchant houses such as Champy (1720) and Bouchard (1731) were established, and Beaune remains home to such leading NÉGOCIANTS as Louis JADOT, Joseph DROUHIN, Louis LATOUR, and BOUCHARD PÈRE ET FILS.

Beaune wines are mostly red, made from Pinot Noir grapes, although plantings of Chardonnay have increased since the 1990s. There is more SAND in the soil here than in most Côte d'Or villages so the red wines tend to be no more than medium-bodied, best drunk between five and ten years old. While neither as powerful as POMMARD nor as elegant as VOLNAY, Beaune wines are more supple than Corton (see ALOXE-CORTON) and can be a charming introduction to good burgundy.

Before the enforcement of AOC regulations, many local wines were sold as Beaune as a readily marketable label of convenience. Now the town has a good rather than great reputation for its wines, perhaps because there are few outstanding DOMAINES in an appellation dominated by merchants. However, Beaune is blessed with an unusually high proportion, nearly three-quarters, of PREMIER CRU vineyards. Indeed, those of village status are the exception, being limited to small parcels of land clinging to unsuitable upper slopes and some low-lying vineyards with richer soils. Otherwise the vineyards of Beaune form a broad swathe of premiers crus from the border with SAVIGNY-LÈS-BEAUNE to Pommard.

The finest vineyards are regarded as those situated almost directly between the town and the hill above: Les Grèves, Les Bressandes, Les Teurons, and Les Avaux. Beaune-Grèves includes Bouchard's noted Vigne de l'Enfant Jésus vineyard, while Beaune-Vignes Franches includes Louis Jadot's Clos des Ursules.

Other noted premier cru vineyards are Les Marconnets and Clos du Roi, near the border with Savigny, and Clos des Mouches abutting Pommard. Although the red wines from this vineyard are not always memorable, Joseph Drouhin makes a rich, complex, and ageworthy white Clos des Mouches.

Producers with a wide range of Beaune premiers crus (other than the négociants cited above) include Domaine des Croix and Albert Morot.

In 1443 Nicolas Rolin founded the Hôtel Dieu, Beaune's principal tourist attraction. For more details, especially of the famous annual auction, see HOSPICES DE BEAUNE.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

Beaune, Côte de . The Côte de Beaune is the southern half of the escarpment of the CÔTE D'OR, named after the important town and wine centre of Beaune. The greatest white wines of Burgundy and some very fine reds are grown on this stretch. The principal appellations, from north to south, are Corton and Corton-Charlemagne (see ALOXE-CORTON), BEAUNE, POMMARD, VOLNAY, MEURSAULT, PULIGNY-MONTRACHET, and CHASSAGNE-MONTRACHET. See also the separate entry under MONTRACHET.

Red wines from the lesser villages of the Côte may be sold under their own names or as Côte de Beaune-Villages. This appellation is available for the wines of AUXEY-DURESSES, Chassagne-Montrachet, CHOREY-LÈS-BEAUNE, LADOIX-Serrigny, Meursault, MONTHÉLIE, PERNAND-VERGELESSES, Puligny-Montrachet, ST-AUBIN, ST-ROMAIN, SANTENAY, and SAVIGNY-LÈS-BEAUNE. See also MARANGES.

Whereas wines labelled Beaune come from the appellation adjoining the town, there is a small group of vineyards on the hill above whose wines are sold under the confusing appellation Côte de Beaune. Of these the best known are Clos des Monsnières and Dessus des Marconnets. Both red and white wines are produced.

See also Côte de NUITS and map under BURGUNDY. J.T.C.M.

Becker, Helmut (1927–89), academic and exceptionally cosmopolitan VITICULTURIST who was chief of the GEISENHEIM Grape Breeding Institute in Germany from 1964 until his death. VINE BREEDING dominated his work. He emphasized the need for deliberate

cross-breeding for resistance to DOWNY MILDEW and POWDERY MILDEW. To achieve this end he used not only resistant genes from AMERICAN VINES, as many other vine breeders had, but also those from Asian species of VITIS, in particular *Vitis amurensis*. Under his leadership, the winemaking facilities of the institute were extended and became a model for small-scale winemaking in breeding stations around the world. The products of these micro-vinifications were filed like library books in the research institute's deep, cool cellar, in bottles closed with the CROWN CAPS, of which Becker was a great proponent. Here Professor Becker would regale visitors with tastings of fine, Riesling-like wine made from NEW VARIETIES which were effectively HYBRIDS because of their non-VINIFERA genes and therefore officially outlawed. (Some have since been officially embraced; see DISEASE-RESISTANT VARIETIES.)

He also intensified breeding of ROOTSTOCKS, aiming for complete PHYLLOXERA resistance rather than tolerance. R.E.S.

Beechworth, small but fashionable region in Australia with about two dozen producers in 2022 in the foothills of the Victorian Alps. Several are iconic, notably Giaconda and Castagna, in the North East Victoria Zone. See VICTORIA.

Beerenauslese, literally 'berry selection', refers to sweet Austrian or German wines, usually made from BOTRYTIZED grapes. By German wine law, minimum MUST WEIGHTS are laid down for each combination of vine variety and region and vary from 110 to 128 °OECHSLE. The iconic examples, often prodigiously long-lived, are complex and rich yet exhilarating Rieslings. In Austria, a minimum of 25 °KMW (approximately 127 °Oechsle) is stipulated, and wines bearing this PRÄDIKAT are very common only around the NEUSIEDLERSEE in Burgenland (and then from diverse grapes). D.S.

beetles, insects of the *Coleoptera* order, several of which attack grapevines as well as other horticultural crops and pastures. While particular species of beetles are often specific to a country or region, beetles are a pest to grapevines worldwide. Black beetles (*Heteronychus arator*) attack young vines in spring and can cause ring barking. They are native to South Africa and are also known as African black beetles, but they cause damage in other countries such as Australia, where the elephant weevil (*Orthorhinus cylindrirostris*) tunnels in the vine wood. Japanese beetles (*Popillia japonica*) cause problems by eating vine foliage, especially in the south-eastern US. Apple curculio beetle (*Otiorhyncus cribricollis*), thought to be a native of Europe, and vegetable weevil (*Listorderes costirostris*) also attack young vines in late spring and early summer, causing damage by eating vine leaves and/or young shoots. Beetles of importance in France are *Altica ampelophaga* and *Adoxus vitis*, which eat leaves, and *Otiorhyncus sulcatus*, which eats young shoots and buds. *Rhynchites betuleti* is called *cigarier* in French because it damages PETIOLES so the leaves roll up like cigars. Control of beetles, if necessary, is by application of the appropriate insecticide (see PESTICIDES) or an ORGANIC alternative. See also BORERS.

Galet, P., *General Viticulture* (2000).

Beira Interior. Close to the Spanish border in central Portugal, this large, diverse DOC has three subregions: Castel Rodrigo and Pinhel in the north and Cova de Beira to the south. Surrounded by mountains (most vineyards are on plateaus), the region's poor, shallow soils predominantly comprise GRANITE, with areas of SCHIST and veins of QUARTZ. Rising to over 750 m/2,461 ft ELEVATION, northern vineyards experience a harsh CONTINENTAL CLIMATE, producing racy whites from old-vine SÍRIA and Fonte Cal; newcomers Riesling and Chardonnay can be very good too. Due south in the

lower, warmer elevations of Cova de Beira, red varieties ripen more consistently. Between the mid 1990s and 2020, a sixfold rise in the number of private producers and restructuring of around one-third of the region's vines (some 5,000 ha/12,356 acres) has significantly increased quality and diversity. Today's TINTA RORIZ, TOURIGA NACIONAL, and TOURIGA FRANCA reds are a world apart from the indifferent RUFETE, MOURISCO, and MARUFO red wines of old. The VINHO REGIONAL designation is Terras da Beira. S.A.

Mayson, R. J., *The Wines of Portugal* (2020).

Beiras, once a VINHO REGIONAL covering most of central Portugal, embracing, from west to east, DOCs BAIRRADA on the Atlantic coast; the rugged, mountainous terrain of DÃO; and BEIRA INTERIOR, and including declassified wine from these areas. It was split into three separate regions in 2009: Beira Atlântico, Terras do Dão, and Terras da Beira.

Belgium , north European country which has traditionally been one of Bordeaux's and Burgundy's best customers but also produces an increasing amount of wine despite its northerly LATITUDE. While the wine industry of LUXEMBOURG to the south-east is older, Belgium has been home to grapevines since the 8th century, in the era of CHARLEMAGNE, when MONKS and noble families tended vines in central and southern Belgium. By the 16th century, viticulture had virtually disappeared due to CLIMATE CHANGE, military devastation, and the increasing influence of Burgundy, but by the 2000s the country's industry began growing quickly in quantity and quality, producing 18,500 hl/488,718 gal of wine in 2020, up from 5,500 hl in 2010.

The country's cool climate favours the production of white wines (about 35% of total production) as well as sparkling (45%).

More than 40 vine varieties are authorized, of which Chardonnay, Pinot Noir, and Pinot Blanc are the most planted. Auxerrois, Pinot Gris, and GERMAN CROSSES such as Regent, Kerner, Johanniter, and

Solaris are also common. Most of the country's wineries have less than 3 ha/7.4 acres of vines and produce wine exclusively for local sale although there are now several large wineries specializing in sparkling wine.

Belgium has five PDOs. The first was the Hageland, founded in 1997 in the Flemish Brabant region around Leuven; Haspengouw followed, its 25 ha/62 acres in East Limburg near the Dutch border. Heuvelland is on the other side of the country, in the hills near the French border. Côtes de Sambres-et-Meuse, created in 2004, was the first appellation in the southern, French-speaking part of the country; named for the two rivers that cross this southern appellation, it boasted more than 170 growers in 2020. Maasvallei Limburg, a 150-km/93-mile strip of sandy gravel that runs from Belgium into the NETHERLANDS, became the first cross-border appellation in Europe upon its approval in 2017.

In addition, there are three SPARKLING WINE appellations: Vlaamse Mousserende Kwaliteitswijn covers sparkling wine from the northern, Flemish side of the country; Crémant de Wallonie or Vin Mousseux de Qualité de Wallonie comes from the French-speaking south. All must be produced by the TRADITIONAL METHOD. For growers eschewing the confines of a CONTROLLED APPELLATION, there are two PGIs—one for Flanders (Vlaamse Landwijn) and one for Wallonia (Vin de Pays de Jardins de Wallonie). Subregions may be mentioned on the label of PDO and PGI wines. G.V.I.

beli, term meaning 'white' or 'light' in many Slavic languages. Beli Pinot is PINOT BLANC, for instance.

Bellet, historic, distinctive, but minute AOC in the far south-east of PROVENCE whose total vineyard area had by 2011 fallen to 50 ha/125 acres. It takes determination to find a bottle outside the Côte d'Azur and even greater determination to find the vineyards themselves, perched in the hills above Nice about 300 m/980 ft above the Mediterranean. Almost equal quantities of all three colours are

produced. The scented, full-bodied whites made from the local ROLLE grapes with some Chardonnay and occasionally BOURBOULENC are the appellation's most distinctive wines and reflect well the MESOCLIMATE, which is slightly cooler than much of the rest of Provence. Rosés may be made from BRAQUET while the intriguing FOLLE NOIRE (Fuella) is traditional for red wines, although it is often supplemented by Cinsaut and occasionally Grenache.

bench, a term used particularly in North America to describe a strip of level or gently inclined ground bordered on either side by land sloping in the same direction but with a different gradient. This can arise in a range of circumstances, but viticultural examples, sometimes called benchlands, include river terraces (e.g. California's Santa Maria Bench in Santa Barbara and the Russian River benches of Sonoma County), lake terraces (e.g. at Niagara and in the Okanagan Valley in Canada) and the ALLUVIAL FANS flanking California's Napa Valley (e.g. Oakville and Rutherford benches). A.J.M.

bench blending. See ASSEMBLAGE.

bench grafting, the viticultural operation of GRAFTING vines indoors rather than in the field. This procedure has become widespread since the 1980s, allowing more large-scale production of grafted vines using grafting tools in NURSERIES. It has almost totally replaced manual FIELD GRAFTING. Bench grafting leads to improved productivity and lower unit costs. However, there are claims of increased incidence of TRUNK DISEASE in bench-grafted plants. The procedure is widely used throughout the world and has become an important industry.

Dormant ROOTSTOCK and SCION cuttings (of the chosen variety and CLONE) are gathered from the field after LEAF FALL and stored in special cool stores. After soaking in FUNGICIDE solution, rootstock cuttings are disbudded and scion cuttings are cut into one-node pieces. Using

cuttings of similar diameter, a GRAFTING MACHINE cuts the bottom of the scion and the top of the rootstock into a similar shape, the most common being the omega. The scion and rootstock are matched, and the newly grafted cuttings are packed with a moistened, coarse-grained medium in boxes and stacked in humid, warm rooms (28–9 °C/82–4 °F) until the union has CALLUSED (in about two weeks). Once they have hardened, grafts are waxed to reduce water loss then planted out, usually in a field nursery. These plants are grown over the summer and then lifted from the nursery, the roots and shoots trimmed in the field, before delivery to the client in winter, typically in bundles of 50.

Such was the demand for grafted plants in the 1990s that in many countries nurseries sold young grafted plants in the spring and early summer of grafting for immediate planting in the field. Such young plants are called 'green grafts' (although this is not the same as GREEN GRAFTING) and may be about half the price of a dormant, grafted vine which the nursery would sell the following winter. However, good care is essential following spring/summer transplanting of green grafts, especially with regard to water supply and weed control.

In recent years grapevine nurseries have struggled with problems of fungal pathogens in young, grafted plants which can cause poor growth and even the death of the vine (see TRUNK DISEASES).

R.E.S.

Bendigo, historic (see GOLD RUSHES), temperate region in Australia's Central Victoria Zone notable for full-bodied, smooth reds. Lack of water for IRRIGATION (a potential problem in dry summers and periodic DROUGHT) limits expansion to fewer than 50 producers. See VICTORIA.

bentonite, FINING agent based on a montmorillonite clay found principally in the state of Wyoming in the western United States, as well as in many other areas of the world. Like most clays, bentonite is a hydrated compound of aluminium and silicon oxides, but it differs in

ways that are useful to winemakers. When mixed with water, it swells and assumes a form that has significant powers of adsorption.

Bentonite, so called because it was first discovered in the Fort Benton rock series, is widely used in the NEW WORLD to ensure PROTEIN stability, particularly to remove heat-unstable proteins from white wines, thus taking away the risk of deposits or hazes.

Bentonite fining is sometimes also used in white winemaking for the CLARIFICATION of juice before or during FERMENTATION to limit the instability of proteins post-fermentation and to facilitate rapid bottling. However, bentonite is usually used for fining after fermentation, which can hasten the settling of LEES and thereby reduce the time between RACKINGS. Bentonite is not generally used for red wines because their higher concentration of TANNINS can remove proteins naturally (but see BOTTLE DEPOSIT).

Many wine drinkers prefer a clear white to a hazy one, however strange the idea of a Wyoming clay treatment may seem. Too high a dosage of bentonite can cause loss of flavour resulting from adsorption of flavour molecules on the surface of the fining agent, which is why trials are usually carried out to ensure that the minimum amount is added. V.L. & M.J.T.

Béquignol, productive red-wine vine virtually extinct in its Bordeaux homeland but still grown on 512 ha/1,265 acres in Argentina in 2020, where it is mainly used to add colour. DNA PROFILING has suggested a possible parent–offspring relationship with SAVAGNIN.

Bereich, official term for a German winegrowing district. In some regions such as BADEN, the Bereich names corresponded largely with already familiar designations for well-defined subregions. In other instances, they represent (like the notorious GROSSLAGEN) legal inventions for marketing purposes. Prominent labelling with Bereich

names was common for cheaper German wines during the 1970s and 1980s but has since largely disappeared.

Bergerac, extensive AOC in SOUTH WEST FRANCE producing mainly red but also dry and sweet white and rosé wines in the image of BORDEAUX to the immediate west of the region, often at more appealing prices. The greater Bergerac region, named after the principal town at its centre on the River DORDOGNE, is the main appellation of the Dordogne *département* and can boast more beautiful and varied countryside than that of its vinously more glamorous neighbour. Lacking distinctions other than touristic (and gastronomic; Périgord is the home of *foie gras*), it has long been difficult for the wines of Bergerac to escape from the shadow of Bordeaux's more serious wine reputation, but thanks to pioneering producers such as Luc de Conti of Ch les Tour des Gendres and David Fourtout of Vignobles des Verdots, as well as a handful of sweet winemakers, some truly fine wine is being made, sometimes with sophisticated use of OAK.

The climate here is somewhere between MARITIME and CONTINENTAL, but overripeness is a rare characteristic of Bergerac grapes and wines. Soils vary from alluvial silt to CLAY and, on the higher terraces, LIMESTONE. Within the region are smaller districts, generally on higher sites with more obvious potential, which have their own appellations for specific wine types. MONBAZILLAC on the left bank of the river is the best known of these, recognized for the quality of its BOTRYTIZED wine. MONTRAVEL on the right bank makes lightish dry and sweet white wines, as well as a modern, oaked style of red. Both appellations were created in the late 1930s just after the creation of the Bergerac appellation. PÉCHARMANT won its own red-wine appellation in 1946, as did the tiny *moelleux*-wine appellation of ROSETTE. The SAUSSIGNAC sweet-white-wine appellation was created in 1982. To help with their marketing, many producers in these areas choose to sell their wines simply as Bergerac.

The vine was grown in the region in Roman times, but the wines were exported and appreciated in the Middle Ages, when viticulture thrived partly under the influence of MONKS AND MONASTERIES. The history of BORDEAUX outlines why the English were so fond of them and why they were discriminated against by the Bordeaux merchants. After the HUNDRED YEARS WAR, the DUTCH WINE TRADE dominated exports of Bergerac, developing the production of SWEET WINES here from the 16th century and, especially, after Protestant refugees left Périgord for northern Europe after the Revocation of the Edict of Nantes in 1685.

Bergerac was slow to recover from PHYLLOXERA, but the total area planted has grown from a low in the 1990s to 12,000 ha/30,000 acres by 2020. Vines grown are the classic Bordeaux varieties: Cabernets and Merlot for red wines (sometimes with supporting Cot (MALBEC), Mérille, or FER) and Sauvignon, Sémillon, and MUSCADELLE for whites (with occasional help from Chenin). Sémillon is still the most planted light-skinned variety, Merlot the most popular grape for the red wines, which constitute the majority of production.

Most Bergerac reds are very similar to red BORDEAUX AOC. An increasing proportion is sold as longer-lasting, often barrel-aged Côtes de Bergerac, for which ALCOHOLIC STRENGTH tends to be higher.

Some Bergerac Rosé is made, generally of Cabernet, but the second most common form of Bergerac is the dry white Bergerac Sec, increasingly well-made thanks to the application of some of the techniques employed for better dry white bordeaux. About one-quarter of all white wine is sweet, made mainly from Sémillon, and (beyond Monbazillac, Saussignac, and Montravel) is sold as Côtes de Bergerac Moelleux. P.S.

Bergeron , local name for ROUSSANNE in the Savoie appellation of Chignin.

Bergwein, a seldom-encountered official category in AUSTRIA for wine made on slopes steeper than 26% regardless of their region of

origin (thus most often applying to the otherwise disparate wines of STYRIA and the WACHAU).

Berlou. See ST-CHINIAN.

berry, botanical term defining a simple edible fruit, derived from a single flower, typically having seeds and a fleshy PULP. Common examples are grapes, currants, cranberries, blueberries, tomatoes, cucumbers, eggplants, and bananas. For more details, see GRAPE.

R.E.S.

berry cell death is a recently elucidated phenomenon associated with BERRY SHRIVEL. Cell death in the flesh of the GRAPE berry (mesocarp) occurs late in RIPENING but often before normal HARVEST in several varieties. There is a correlation between the onset of cell death in the mesocarp and the degree of late-season berry shrivel across several varieties, but it is most obvious in Shiraz. For this variety in Australia, for example, it usually begins around 90–100 days after FLOWERING. Elevated temperatures and WATER STRESS accelerate cell death and shrivel in Shiraz. Cell death in the mesocarp likely leads to an imbalance in water gradients that result in a net loss of water from the Shiraz berry, but this does not occur in Chardonnay berries. Cell death is highly correlated with anoxia (lack of oxygen) in the berry, which is thought to be caused by excessive respiratory demand (see RESPIRATION) at high temperatures and a restriction of oxygen diffusion into the berry via lenticels on the berry PEDICEL. The anoxia results in fermentation within the berry and the production of ETHANOL (0.1%, small in wine context but high in a cellular context) that may also be a prelude to cell death. This and the concentration that results from accompanying berry shrivel are likely to affect the flavour profile of wine made from these berries, for example giving a HERBACEOUS character.

berry rots. See BUNCH ROTS.

berry shrivel can be linked to SUNBURN, prolonged dehydration, and BUNCHSTEM NECROSIS. Late-season berry shrivel (LSBS) appears to be correlated with what is known as BERRY CELL DEATH. S.T.

Bondada, B., and Keller, M., 'Not all shrivels are created equal: morpho-anatomical and compositional characteristics differ among different shrivel types that develop during ripening of grape (*Vitis vinifera* L.) berries', *American Journal of Plant Sciences*, 3/7 (2012), 879–98.

berry size is considered by many to be a factor in wine quality. It is often said that smaller berries contribute to better wine quality, especially for red wines, since ANTHOCYANINS, PHENOLICS, and FLAVOUR COMPOUNDS are mostly contained in the skins. The higher surface-to-volume ratio of smaller berries potentially results in a higher concentration of these skin compounds in the MUST and hence in the wine. However, there are few scientific studies that confirm this, and berries that are too small, especially if they are the result of MILLERANDAGE or BERRY CELL DEATH, may have a negative effect on wine quality, such as loss of aroma.

Good-quality wine grape varieties typically have small berries, at least compared with both lower-quality varieties and TABLE GRAPES. The average weight of a premium wine grape at full ripeness is 1–2 g, whereas others weigh 3 g or more, up to 10 g/0.35 oz for some table grapes. These values doubtless represent the selection of VINE VARIETIES for their end use.

It is not the case, however, that any vineyard management practice which leads to smaller berries will necessarily improve wine quality. Certainly, WATER STRESS causes small berries, although some of the effects on wine quality may be the result of water stress on VINE PHYSIOLOGY rather than the direct result of small berries. The other simple means of reducing berry size is PRUNING to very many buds in winter, but this is contrary to the principles of BALANCED PRUNING. Such light pruning is associated with smaller berries but also with higher YIELDS and is therefore likely to reduce wine quality, since the vine may struggle to ripen grapes with insufficient leaf area.

Studies in California (with Cabernet Sauvignon) and Australia (with Shiraz and Pinot Noir) have shown that smaller berries do not necessarily make better wine. These studies concluded that it is the vineyard factors which make berries small—water stress in particular—that contribute directly to wine quality, not the smallness of the berries themselves. R.E.S.

Bhutan , Himalayan micro-kingdom with an extremely diverse range of MESOCLIMATES, soils, and ELEVATIONS up to 8,230 m/27,000 ft. In the late 2010s the Bhutan Wine Co. planted Bhutan's first VITIS VINIFERA vineyards, about 16 ha/40 acres in six vineyards at 762–

2,682 m/2,500?8,800 ft in elevation. Initial plantings included white varieties Sauvignon Blanc, Chardonnay, Petit Manseng, Chenin Blanc, and Riesling; and red varieties Merlot, Cabernet Sauvignon, Cabernet Franc, Malbec, Pinot Noir, Syrah, Sangiovese, and Tempranillo. The first vintage is slated for 2023, barring any issues with MILDEW, monsoon pressure, and the abundant hungry wildlife that count among local winegrowing challenges.

Biancame, one of the many synonyms of TREBBIANO TOSCANO, used in the Marche, also known as Bianchello. J.V.

bianco means 'white' in Italian, and the names of many Italian white wines therefore are Bianco d'/da/di/del Place name. For more details, see under the place name.

Note, however, that Bianco is also the name of a small town in CALABRIA where an ancient sweet white DRIED-GRAPE WINE, Greco di Bianco, is still produced today from grapes known locally as GRECO BIANCO.

Bianco d'Alessano, Italian white wine grape of PUGLIA which is frequently blended with VERDECA.

Biancolella, ISCHIAN white wine grape which survives on the island's steep terraces.

Biancu Gentile, rare but increasingly appreciated aromatic Corsican white wine grape planted on 59 ha/146 acres in 2018.

Bible. The subject of wine runs deep in the Bible. The vine is mentioned more often than any other plant, and there are nearly 1,000 references to wine and wine-related themes. Adam planted grains while Noah was the first to plant a vineyard, near Mount Ararat

in what is modern-day Türkiye (Gen. 9. 20). Some scholars see here a development of the theme of agriculture in the Bible from grain, a necessity for life, to wine, a culturally highly esteemed beverage. Lamech names his son Noah because he is to bring his people relief from their hard manual labour in a fallen world. This promise seems to have come to fruition when Noah became a winegrower and crafted his first vintage (Gen. 5. 29). From the time of Noah, vineyards, vines, and wine become regular features in the biblical narrative.

Wine as a gift and blessing

The Bible celebrates wine as a gift from God and upholds God as the Creator of all things. Ultimately it is God who causes all plants including the vine to flourish (Gen. 1; Ps. 104). The practice of agriculture and viticulture is therefore understood as a spiritual calling. An important purpose of wine is to gladden people's hearts and bring comfort in times of distress and worry (Ps. 104. 15; 4. 7; Prov. 31. 6–7; Eccles. 8. 15; 10. 19).

In the Song of Solomon, wine is celebrated as a gift from God and its enjoyment is compared with the pleasures of sexual intimacy. The lavish garden imagery harks back to the paradisiacal splendour of the Garden of Eden. It instils a longing in the reader for a restored paradise where people live in perfect harmony with their Creator, each other, and the natural world, enjoying and savouring the fruits of the vine.

Wine takes on a religious role when it becomes part of God's blessing. When Isaac blesses his son Jacob, this blessing includes fruitfulness of the land: '"May God give you of the dew of heaven, of the fatness of the earth, and plenty of grain and wine"' (Gen. 27. 28, 37). When Jacob blesses his son Judah, this blessing goes even further and evokes images of paradise, instilling a longing for flourishing vines and wine flowing in great abundance: '"The sceptre shall not depart from Judah…Binding his foal to the vine and his donkey's colt to the choice vine, he washes his garments in wine and his robe in the blood of grapes"' (Gen. 49. 10–12). Moses also affirmed wine as a blessing from God (Deut. 7. 13). When the Israelites arrived at the border of Canaan, Moses sent out spies to see how fertile the land was. The spies came upon 'the valley of grape clusters' (Hebrew *Eshkol*) during harvest season and brought back on a pole a single cluster of grapes, reporting to Moses that the land showed great abundance (Num. 13). It is this Biblical vision of vineyards and wine that inspired Christian monks and nuns throughout the Middle Ages to plants vineyards as part of their

mission, and their impact can still be felt today in many wine regions of the world (see MONKS AND MONASTERIES).

Wine as metaphor

Vineyards and vines were so prominent that they became a metaphor to describe God's relationship with his people. The Psalmist speaks of Israel as a vine that God brought out of Egypt and transplanted into fertile soil (Ps. 80. 8, 14), and God's people are compared to a vineyard (Is. 3. 13–15). God's judgement is compared to a winepress (Joel 3. 13, Lam. 1. 15, Rev. 14. 19–20, 19. 15), and his forgiveness and healing will make Israel 'blossom like the vine' (Hos. 14. 1, 7). In a climactic passage Jesus describes himself as 'the true vine', his Father as 'the vinegrower', and his disciples as his branches, emphasizing the profound union that believers can experience with God (John 15. 1–7).

Wine in cultic practices and celebrations

The Israelites offered up wine as a sacrifice to God. Different sacrifices served different purposes: to solicit God's blessing, to express gratitude, and to receive forgiveness of sin. Offering up the first fruits of their harvest reminded the Israelites that all life, including the fruit of the earth, is a gift from God (Lev. 23. 13; Num. 28. 14; Deut. 14. 22–3; 15. 14).

Wine was served during family and religious celebrations such as the grape harvest, the weaning of a child, marriage feasts, birthdays, the making of covenants, and the enthronement of a king (Gen. 21. 8; 29. 21–2; 40. 20; 2 Sam. 3. 20; 1 Chr. 12. 40).

Wine, drunkenness, and abstinence

Noah is the first person in the Bible to get drunk. The Old Testament portrays drunkenness and the abuse of wine in strictly negative terms and discourages and condemns it (Gen. 9. 20–6; 19. 30–8; Isa. 5. 11–12; Prov. 20. 1).

Some Israelites were to abstain from drinking wine due to their special callings, such as priests serving in the temple (Lev. 10. 9; Ezek. 44. 21) and the Nazirites as part of their special dedication to God (Num. 6. 3–4, 20; Judg. 13. 4, 7, 14). Proverbs discourages kings from drinking wine so they can rule with justice and mercy (Prov. 31. 4–9).

Wine in prophetic speech

When the prophets speak of God's judgement they speak of God withholding his blessings from his unfaithful people, and this includes wine. Israel is even compared to a vineyard from which God has withdrawn his protection because of their oppression of the poor (Isa. 5). To be without wine is a terrible curse and a sign of God's judgement (Deut. 28. 39; Isa. 24. 7; Hosea 9. 2; Amos 4. 9; Mic. 6. 15). When the prophets speak of God's future redemption, they speak of it in terms of vineyard planting, plentiful harvests, and lavish banquets with wine flowing in great abundance (Jer. 31. 5; Isa. 25. 6; Joel 2. 23–4). The prophet Hosea envisions God's redemption as a wedding banquet (Hos. 2. 18–23). The prophet Amos even speaks of a time when '"the mountains shall drip sweet wine, and all the hills shall flow with it"' (Amos 9. 13).

Wine in the New Testament

By the time of the 1st century, when Jesus began his ministry, Jews celebrated the Passover meal with four cups of wine, and wine had become a staple in Jewish culture. Palestinian hills were dotted with wine presses where wine literally flowed down the hills from one basin to another and each village crafted its own vintage. The people lived in expectant hope that God would send an anointed one (messiah) who would deliver them from Roman oppression. And as the prophets foretold, a sure sign of his coming would be joyous feasting and an abundance of choice wine.

The New Testament builds on the Hebrew scriptures and affirms wine as a gift and blessing from God: Jesus' first miracle is to turn water into fine wine at the wedding feast of Cana (John 2), and he offers his disciples a cup of wine in the celebration of the Last Supper (see EUCHARIST). The miracle at Cana is also the first sign given by Jesus that in him the promises of old have been fulfilled. He is the long-awaited messiah. Wine now becomes a symbol of the presence of the messiah who will bring God's deliverance.

Jesus' ministry often took the form of shared meals and the drinking of wine, especially with the marginalized of society—his own people accused him of being a glutton, a drunkard, and a friend of sinners (Matt. 11. 19; Luke 19. 7). The apostle Paul warns against drunkenness (1 Cor. 5. 11; 6. 10; Gal. 5. 21). The New Testament also speaks of the medicinal value of wine (1 Tim. 5. 23; Luke 10. 25–37), and Christians look forward to the second coming of Christ when they will drink wine with Christ in the Father's eternal Kingdom (Matt. 26. 29). G.K.

Kreglinger, G., 'Wine in the Bible', in *The Spirituality of Wine* (2016).

Becker, L., *Rebe, Rausch und Religion: eine kulturgeschichtliche Studie zum Wein in der Bible* (1999).

Bical, Portuguese white grape variety grown mainly in BAIRRADA, as well as in DÃO, where it is called Borrado das Moscas, meaning 'fly droppings'. The wines have good acidity and can be persuaded to display peachy aromas in still VARIETAL versions, although in Bairrada the grapes are often used in blends for sparkling wines. Some capacity for AGEING has been demonstrated, Bical developing an almost RIESLING-like bouquet after a decade in bottle. It was grown on 1,206 ha/2,980 acres in 2020.

Bienvenues-Bâtard-Montrachet, white GRAND CRU in Burgundy's CÔTE D'OR. For more details, see MONTRACHET.

Bierzo, fashionable DOP region in north-west Spain (see map under SPAIN) which administratively forms part of CASTILLA Y LEÓN. However, the River Sil, which bisects it, is a tributary of the Miño (Minho in Portugal), and the wines have more in common with those of GALICIA than those of the DOURO 140 km/88 miles to the south. Sheltered from the climatic excesses of the Atlantic and the central plateau, Bierzo shows promise as a wine region, with tiny plots on steep slopes climbing to 1,000 m/3,280 ft in ELEVATION. The MENCÍA grape is capable of producing balanced, fruity red wines in well-drained soils on the SLATE and GRANITE of this part of Spain. White wines made from GODELLO are also gaining reputation.

In the late 1990s, a group of small, mostly young growers reproduced in Bierzo the same 'miracle' which had happened in PRIORAT one decade earlier—they resurrected a moribund wine region. One of the protagonists, Álvaro PALACIOS, was indeed one of the Priorat pioneers as well. With his nephew Ricardo Pérez Palacios, he reclaimed old vineyards on slate slopes and produced wines with no resemblance to the light reds traditionally produced from fertile valley vineyards. In 2020 the region had 2,349 ha/5,805 acres planted.

In 2017, a new classification scheme was approved for Bierzo wines, allowing mention of smaller geographical units approved by the DOP regulatory board: Vino de Villa must come entirely from the named town or district, at yields 20% below that of the DOP Bierzo maximum; Vino de Paraje must come from a single recognized place at yields 25% below the DOP maximum. Vino de Viña Clasificada designates a wine from a single vineyard or adjacent vineyards at least five years old with yields 30% below the DOP maximum; Gran Vino de Viña Clasificada requires that the named vineyard be at least ten years old, with yields 35% below the maximum. R.J.M. & F.C.

Barquín, J., Guitiérrez, L., and de la Serna, V., *The Finest Wines of Rioja and Northwest Spain* (2011).

Biferno, one of only four DOCs in the Italian MOLISE region and arguably its most important.

Big Rivers Zone large catchment area in NEW SOUTH WALES, comprising the Murray Darling, Perricoota, Riverina, and Swan Hill regions.

Bikavér or, on export markets, Bull's Blood, is a Hungarian red wine style that may be made in the EGER or SZEKSZÁRD regions. At one time the blend depended heavily on KADARKA, but this demanding local variety was replaced by KÉKFRANKOS, supplemented by Cabernet, Merlot, Syrah, Portugieser, and sometimes Pinot Noir. Both regions are now making serious efforts to produce elegant, fruity Bikavér wines worth ageing that are neither heavy nor aggressively tannic. SINGLE-VINEYARD examples are increasingly found. G.M.

bin, traditional term for a collection of wine bottles, normally stacked horizontally on top of each other, or the process of so storing, or binning, them. Thus these bins needed BIN LABELS, and a bin end has come to signify a small quantity of wine bottles left over

from a larger lot. Some Australian wine companies, notably PENFOLDS, have a tradition of using the word 'bin' in BRAND names.

Binissalem, DOP with 570 ha/1,408 acres of vines on the Mediterranean island of MALLORCA in Spain producing red, white, sparkling, and rosé wines mostly destined for the Balearic holiday resorts. The red wines must contain at least 30% MANTO NEGRO, Binissalem's dominant grape, with up to 30% Gorgollassa; white wines must be at least 50% MOLL or MOSCATEL.

bin labels were necessitated by the practice of binning unlabelled bottles.

The most common form of bin label was made of pottery and was approximately the shape of a coat hanger some 7–13 cm/3–5 in wide. At the apex there was an additional lug, pierced so that it formed a suspension ring. As many were nailed to the cellar masonry, they have often been broken or cracked during removal.

Early English bin labels (dating to the mid 18th century) are delftware (tin-glazed earthenware) with blue or deep magenta calligraphy (upper case) on a white to pale blue ground. Almost all later ones have black lettering on white pottery, although coloured lettering is very rarely seen. European labels came in a variety of forms and often with polychrome decoration; the language of the writing usually provides an obvious clue to the country of origin.

By the 19th century, labels developed rounded shoulders, the earlier ones being angled. Many had a portion of the face left unglazed where more precise details of the bin contents might be written. Home-made labels were sometimes fashioned from wood or slate and would likewise have written information.

In very large cellars and in commercial ones where the bin contents changed frequently, it was established practice to use circular bin labels with numbers that would cross-refer to the cellar records. Many of these, and the coat-hanger variety, are marked with the manufacturer's name (Wedgwood, Copeland, etc.) or the vendor's

name (e.g. Farrow & Jackson), almost invariably impressed during manufacture. Bin labels are not much collected in the world of wine antiques, but the most sought-after are delftware examples, those with spelling mistakes, and rarities of name, colour, or form.

R.N.H.B.

Bío-Bío, cool, wet subregion of the Southern region of CHILE.

biochar is made by heating organic materials such as wood waste, crop residues, municipal green waste, biosolids or manure to 350–500 °C/660–930 °F in a limited-oxygen environment. This process renders the organic material very resistant to decomposition, which reduces the release of CARBON DIOXIDE from this material into the atmosphere. However, biochar's main contributions to a vineyard soil are to increase the CATION EXCHANGE CAPACITY and the water-holding capacity, especially in sandy soils (see SOIL WATER). It is also said to increase soil biological activity (see SOIL BIOTA), but, because it is an inert material, this effect usually requires the biochar to be co-composted with animal manure to 'activate' it. The Ithaka Institute in Switzerland has developed a European Biochar Certificate, but, because of the variation in commercially available products and their complex interaction with SOIL TYPE, CLIMATE, grape variety and COVER CROP, no firm recommendations can be made for biochar use in vineyards except in relation to carbon storage. Yield responses have been inconsistent. It is usually applied at 8 tonnes per ha or more, so it is an expensive soil amendment if brought in from outside. R.E.W.

Schmidt, H.-P., et al., 'Biochar and biochar-compost as soil amendments to a vineyard soil: Influences on plant growth, nutrient uptake, plant health and grape quality', *Agriculture Ecosystems and Environment* (2014).

biodiversity. See ECOSYSTEM.

biodynamic viticulture is, depending on your perspective, either an enhanced or an extreme form of ORGANIC VITICULTURE. This controversial practice has produced some impressive results but without the reassurance of conclusive scientific explanation.

Biodynamics is the oldest 'green' farming movement, predating organics by 20 years. It is based on theories described in 1924 by the Austrian philosopher Rudolf Steiner (1861–1925) for agriculture in general. All biodynamic vineyards practise organic viticulture, but biodynamics differs from organics in three ways. The vineyard should become a self-sustaining individual or 'farm organism' (see SUSTAINABLE VITICULTURE and ECOSYSTEM): it should be treated regularly with nine herb- and mineral-based biodynamic 'preparations'; and key tasks such as planting, PRUNING, TILLAGE, PICKING, and BOTTLING should be timed to harness beneficial 'formative forces' exerted by earthly and celestial—planetary, solar, stellar, and especially lunar—rhythms.

France's first biodynamic winegrower, François Bouchet (1932–2005), began using the technique on his 6-ha/15-acre Domaine de Château Gaillard in Touraine in 1962. But France's biodynamic wine movement remained almost non-existent until the late 1980s, when Bouchet began helping leading names such as Domaine Leflaive of PULIGNY-MONTRACHET, Domaine LEROY in Vosne-Romanée, CHAPOUTIER in Hermitage, Huet in Vouvray, and Kreydenweiss in Alsace to convert to biodynamics.

These producers shared a belief that only a less technologically driven form of viticulture would allow wine QUALITY to keep improving; they were emboldened by former INRA soil microbiologist Claude Bourguignon's 1988 declaration that Burgundy's vineyards contained 'less life than Sahara desert sand'. Bourguignon made no claim to understanding how biodynamics works, but his research showed that levels of microbial life in vineyard topsoils (see SOIL BIOTA) were significantly greater on organic and biodynamic plots than on those of conventionally farmed ones. In addition, Bourguignon found

significant increases of microbial life on biodynamic vine roots at depths of several metres compared with conventionally and even organically farmed vines; and that the roots were thickest, longest, and most able to penetrate the soil, and to assimilate trace elements (see VINE NUTRITION, MICROBES, and MYCORRHIZA), when grown biodynamically.

The particularity of biodynamics is the use of animal sense organs such as cow horns as sheaths when making six of the nine biodynamic preparations. It is believed that animal organs enable the medicinal properties of the substances encased within—cow manure, ground quartz, oak bark, and the flowers of yarrow, chamomile, and dandelion—to become fully effective throughout the farm, keeping it within what Steiner called 'the realm of the living'. The animal organ sheaths disintegrate naturally or are discarded before the preparation material within is applied. Nevertheless, it is this aspect that convinces non-believers that biodynamics is unscientific and irrational.

The two main biodynamic field sprays are horn manure and horn silica. Only a handful of the former or a few grams of the latter are required per hectare. They are prepared by burying the cow manure or the ground quartz (silica) in a cow horn for six months over winter or summer respectively. Horn manure is sprayed on the soil in the afternoon, in autumn and early spring, to stimulate microbial life in the soil, helping maintain SOIL STRUCTURE and levels of ORGANIC MATTER and encouraging deeper vine roots and TERROIR expression. Horn silica is sprayed over the vines, at sunrise, either side of FLOWERING to regulate plant metabolism and promote stronger, more upright vine growth, to LIGNIFY the wood, and to improve the nutritional and keeping qualities of the wine. One further field spray, the silica-rich common horsetail (*Equisetum arvense*), is sprayed as a fresh tea or fermented liquid manure to encourage fungal spores to remain in the soil rather than affecting the vine. It is a fundamental tenet that all three biodynamic spray preparations are 'dynamized' before application. This involves rhythmically stirring the material in water, first one way and then the other, to create a vortex. When the

direction of stirring is changed the water is thought to undergo chaos, allowing beneficial 'formative forces' within the preparation to be transferred to the water and thence to the vineyard when it is sprayed. Organic fertilizer in the form of COMPOST is used to nourish the soil, but biodynamic compost differs from other composts in that the remaining six biodynamic preparations made from yarrow, chamomile, stinging nettle, oak bark, dandelion, and valerian must be inserted into the compost pile, which should be manure-based. The compost preparations are said to infuse the manure with vitalizing living forces whose role is more important to vine growth and form than the actual composted manure. Where specific ingredients are not available, substitutes may be used. For example, *Casuarina stricta* is often substituted for common horsetail in Australia.

Late 20th century MECHANIZATION saw the almost complete disappearance of livestock from vineyards. Biodynamic growers are at the forefront of reversing this trend by acquiring livestock for manure (cows), traction (horses, mules), weed control (sheep), or pest control (chickens to eat cutworms). In this way, vine monocultures begin changing towards the biodynamic ideal of self-sustaining farm organisms, creating a natural equilibrium in which pests and diseases become potentially less potent.

Biodynamic growers see plants as comprising four 'organs'—ROOT, LEAF/SHOOT, FLOWER, and FRUIT—and these are respectively linked to the four elements of earth, water, air, and fire (solar heat). Each plant component is said to be favoured during particular points of the moon's sidereal cycle when the moon passes in front of one of the 12 constellations of the astronomical (rather than astrological) zodiac. Thus, for example, spraying horn manure on the soil for root growth is said to be most effective if the moon is in front of an earth/root constellation such as Bull, Virgin, or Goat. These windows occur every nine days or so but for two or three days only, so only the smallest vineyards, or those with abundant labour, can time all their agricultural work according to the biodynamic calendar. Biodynamicists claim that on conventional vineyards, where neither biodynamic compost nor the field spray preparations are used, the

effect of these earthly and celestial rhythms will not be felt, as the soil and the vines will not have been sensitized to them.

Cellar work is also said to benefit from the biodynamic calendar, with, it is claimed, bottling best under Lion if the wine is designed to age (the heat/fruit 'force' will be most concentrated in the wine at this point, so bottling then will capture or seal it).

Where VINE PESTS need to be controlled in biodynamic farming, a number of the pests are collected and burnt, their ashes scattered around the affected area to discourage future infestations.

Biodynamic viticulture alone will not a great wine make: good viticultural and winemaking practices such as CANOPY MANAGEMENT and cellar HYGIENE are also essential. Biodynamic winemaking standards are similar to those used for ORGANIC WINE but impose stricter guidelines regarding ENRICHMENT, NUTRIENT additions, the use of energy-intensive practices (e.g. PASTEURIZATION), MICRO-OXYGENATION, and recyclable PACKAGING.

Between 2013 and 2021, the global biodynamic vineyard doubled to more than 22,000 ha/54,363 acres, according to the American Association of Wine Economists (AAWE). Winegrowers obtain certified biodynamic status either from the German-based Demeter International organization (renamed Biodynamic Federation Demeter International in 2020), the body which de facto controls the Biodynamic (with a capital B) agricultural trademark, or from wine-only bodies such as the France-based Syndicat International des Vignerons en Culture Bio-dynamique (Biodyvin) or the Austria-based respekt-BIODYN. Australian Demeter Bio-Dynamic, privately created and trademarked by consultant Alex Podolinsky, is not a member of Demeter International.

Biodynamic vineyards range in size from a handful of hectares to 600 ha/1,480 acres at Emiliana in Chile, the world's biggest biodynamic wine estate. In 2021, France had the greatest area of certified biodynamic vineyards in the world (10,166 ha/25,121 acres), but as a proportion of total vineyard area Switzerland and Austria top the table with 2.78% and 2.73% respectively.

Waldin, M., *Biodynamic Wine* (2016).

biogenic amines are a diverse group of nitrogenous, low-molecular-weight compounds that are chiefly derived from the decarboxylation of certain AMINO ACIDS by specific microbes. The most commonly known biogenic amines, HISTAMINE, tyramine, and putrescine, all occur in wine and are significant for human health. Produced largely during the winemaking process by LACTIC ACID BACTERIA (LAB), particularly *Pediococcus* and *Lactobacillus* spp., both the amino-acid precursor and LAB are required for biogenic amines (BAs) to accumulate.

If ingested in excessive amounts, BAs can trigger toxicity reactions that mimic allergic response (see ALLERGIES AND INTOLERANCES), with symptoms such as nausea, headache, rhinoconjunctival symptoms, hyper- or hypotension, flushing, rashes, and heart palpitations. ETHANOL inhibits the enzymatic detoxification process, making BAs in alcoholic beverages such as wine and beer more significant. Managing winemaking conditions that control microbial growth, such as total SULFUR DIOXIDE level, PH, and, to a lesser extent, TEMPERATURE, is key to ensuring biogenic-amine concentrations are kept low.

Many countries have informal upper limits on histamine concentrations in wine (ranging from 2 to 10 mg/l), but legal regulation is still a matter of debate. S.P.-T.

biological ageing See FLOR and SHERRY.

biologicals, living or dormant organisms, or by-products of a natural product or process, for example tea made from raw COMPOST,

or fermented seaweed. They are used in plant protection through the control of pathogens or as a stimulant for plant and soil health. This is a growing field of research and understanding, with many new products coming on to the market. Theories about such products and processes and how they work have been around for generations, notably as part of BIODYNAMIC VITICULTURE. While many of the early formulations were seen as 'snake oil', there has been real scientific progress towards legitimizing some of them.

Plant protection can happen in three ways:

- by directly attacking the pathogen (typically a fungus, e.g. POWDERY MILDEW or BOTRYTIS)—common formulations use *Trichoderma* spp.
- by outcompeting a pathogen for space on the leaf or berry—common formulations use *Bacillus subtilis* or so-called effective microorganisms (EMs)
- by inducing systemic acquired resistance (SAR), whereby the grapevines' own immune system is activated by enzymes and elicitors that increase the accumulation of PHYTOALEXINS in the vine to protect it from a pathogen.

Biologicals are also used in the control of insect pests, commonly *Bacillus thuringiensis* for moth species. New research is being carried out on the control of MEALYBUGS.

In soil, these products are used to enhance the microbiome, either by adding more of a specific fungi or bacteria (e.g. compost teas, EM) or by feeding and stimulating the existing population (e.g. biodynamic preparations, humic acid, seaweeds, enzymes). This promotes a healthy living soil environment, leading to a healthy plant less susceptible to attack by a pathogen, better equipped to defend itself by SAR, and better equipped to cope with abiotic stresses such as drought/waterlogging and excessive heat/cold. N.S.

biological viticulture, a loose term since all viticulture involves biology, but for more details of the general philosophy implied see

ORGANIC VITICULTURE. In France, many ORGANIC WINES are sold as *vins biologiques*. See also BIOLOGICALS.

Biondi-Santi, family synonymous with BRUNELLO DI MONTALCINO and, in 1888, responsible for one of the first wines ever to be so labelled. Before that time Montalcino's fame was based solely on a sweet, often sparkling white based on the MOSCADELLO grape, until Ferruccio Biondi-Santi isolated a particular type of SANGIOVESE on his Il Greppo estate using MASS SELECTION with better resistance to OÏDIUM than Moscadello. It was subsequently called Sangiovese Grosso and officially registered as BBS 11. Ferruccio also increased VINE DENSITY and lowered YIELDS, while eliminating the white grapes that were routinely blended with Sangiovese then.

Tancredi, Ferruccio's son, is credited with founding the first Montalcino CO-OPERATIVE during the crisis years of the 1920s, while focusing on exporting the Bondi-Santi wines. He was soon joined by his son, Franco, who committed himself firmly to Il Greppo's traditional methods which, during the 1980s and 1990s, were challenged by a new generation of Brunello producers preferring to make a more concentrated, richer, and more internationally accessible style by harvesting ultra-ripe grapes, using shorter MACERATION time, and ageing the wines in French BARRIQUES. This modernist approach, which received glowing reviews from the then all-powerful Italian wine guides, was especially successful in the US but made the Biondi-Santi style look outdated and light. However, in 2008 during the scandal described in BRUNELLO DI MONTALCINO, Biondi-Santi rose as the natural defender of Brunello and was subsequently joined by a majority of the region's growers and wine producers who together prevented the proposed change in production rules to allow INTERNATIONAL VARIETIES into Brunello di Montalcino.

With the taste for rich, extracted wines on the wane and a growing international appetite for more locally authentic, TERROIR-driven wines, Biondi-Santi's future looked promising until Jacopo Biondi Santi, who had taken over the estate after the death of his

father Franco in 2013, sold the estate to the French EPI conglomerate in 2017. Widespread concerns that the archaic style of wines would be compromised by the new owners have so far proved unfounded. W.S.

Boldrini, M., et al., *This Is My Land: Franco Biondi Santi, Montalcino and Brunello* (2009).

O'Keefe, K., *Franco Biondi Santi: The Gentleman of Brunello* (2005).

biotechnology. See GENETIC MODIFICATION for some examples of viticultural biotechnology.

biotype, a group of CLONES that share similar morphological characteristics. See also PHYLLOXERA for a different use of the term 'biotype'.

birds can be a more serious modern vine pest than PHYLLOXERA in some areas because they are so difficult to control, particularly during grape RIPENING when they feed on grapes. Birds have eaten grapes for about 60 million years as they have co-evolved and in so doing have spread grape seeds in their excreta. This is one reason why grapes are thought to have developed small, black, sugary fruits which attract birds. (Subsequent human selection of MUTATIONS has given us light-skinned grapes.)

For small vineyards in isolated regions, and particularly for early-ripening vine varieties, birds may destroy an entire crop. Unfortunately, the birds begin their destruction as soon as the grapes begin to ripen at VERAISON, so early harvest is not a solution. As well as the potential crop loss, bird pecks provide entry points for BUNCH ROTS. The cost of control measures or damage to the fruit can make some vineyards uneconomic. Birds are often the greatest problem facing vineyards in new viticultural regions, especially if the vineyards

are isolated (as in ENGLAND and Long Island in NEW YORK, for example).

The species of birds which attack grapes vary from region to region. The ubiquitous starling is one of the most widespread problem species, but blackbirds, partridges, robins, sparrows, thrushes, and finches are also common. A starling, for example, can eat 60–80 g/2.8 oz of grapes a day. The planting of a vineyard and the consequent provision of an extra food source can actually lead to a population increase of birds. Many growers notice that bird damage depends on the availability of alternative food sources. In the MARGARET RIVER region of Western Australia, for example, silvereye birds do more damage to vineyards when nectar from local eucalyptus trees and saltbush berries is limited. Where vineyards are extensive and the varieties ripen together, damage to individual vineyards is lessened.

Many bird-protection devices are based on scaring birds by sight or sound. In time, birds become accustomed to new objects or noises in a vineyard so that, for example, the traditional immobile scarecrow can rapidly lose effectiveness. Other scaring devices include a wide range of auditory contraptions, guns, gas-powered cannon, tape across the vineyards, robotic solar-powered lasers, etc.

NETTING of vineyards is becoming increasingly common. The nets are made of woven string or perforated plastic and can often be reused, and tractor-mounted rollers assist installation and removal. Since the nets provide for virtually 100% effective control yet do not harm birds, they are acceptable to growers and environmentalists alike.

Some local bird populations are affected by eating insects or grapes which contain pesticides used in vineyards, which bird lovers view as an argument against the use of AGROCHEMICALS. R.E.S.

bird's eye rot, vine disease. See ANTHRACNOSE.

Biscoitos, DOC on the island of Terceira in the AZORES making small quantities of FORTIFIED WINE and, more recently, TABLE WINE from the VERDELHO grape. Biscoitos is so-called because VOLCANIC stones in the soil resemble biscuits. Between 2014 and 2020, the DOC area under vine increased from 15 to 24 ha/59 acres. S.A.

bisulfite. See SULFUR DIOXIDE.

bitterness, one of the primary tastes (see TASTING) which can be detected via taste buds mainly on the tongue in many wines, even if it is not as common as SWEETNESS and ACIDITY and is often confused with the quite different tactile sensation caused by ASTRINGENCY. Many Italian red wines are relatively bitter, as are some less successful examples of particularly aromatic grape varieties such as Gewürztraminer, typically because of an excess of PHENOLICS. Poorly seasoned OAK can also make a wine taste bitter.

bitter rot, a FUNGAL DISEASE of ripe grapes that is active in warm, humid conditions. It is found only on damaged and almost senescent tissues, but the bitter fruit flavour can be detected in the finished wine. The cause is the fungus *Greeneria uvicola*, and the disease is widespread in the eastern United States, Asia, Australia, and South Africa but not in France or Germany. It is easily controlled by most FUNGICIDES. R.E.S.

black dead arm. See BOTRYOSPHAERIA DIEBACK.

black foot, fungal disease found in young vines in both vineyards and NURSERIES which can lead to the premature decline and death of

young vines. Causal agents of this TRUNK DISEASE include more than 20 species of soil-borne fungi in the genera *Campylocarpon, 'Cylindrocarpon', Cylindrocladiella*, and *Ilyonectria. Ilyonectria liriodendra, I. macrodidyma*, and *I. torresensis* are known to be the most virulent and widespread. Symptoms include slow growth, poor vigour, chlorotic leaves, brownish-black discoloration of rootstock trunks, roots, graft unions (see GRAFTING), and a reduction in root biomass. Affected young vines usually die during the growing season or in the following winter. Control measures include field rotation, planting clean vines, and avoiding planting in heavy, wet, and poorly drained soils. The most common PHYLLOXERA-resistant ROOTSTOCKS used today are susceptible to black foot. L.T.M. & J.R.U.-T.

black goo, name coined in 1995 by American viticulturist Lucie Morton to describe the symptoms of black spots and tarry ooze in XYLEM vessels produced by *Phaeomoniella chlamydospora* and *Phaeoacremonium* species, fungi that cause premature decline in young vines or PETRI DISEASE in older vines suffering from ESCA. L.T.M.

Morton, L., 'Viticulture and grapevine declines: the lessons of black goo', *Phytopathologia Mediterranea*, 39/1 (2000), 59–67.

black knot, vine disease. See CROWN GALL.

black measles, vine disease. See ESCA.

black rot, FUNGAL DISEASE which is one of the most economically important diseases of vines in the eastern half of the United States and some wetter regions of Europe. The disease is native to North America and was probably introduced to other countries by contaminated cuttings. It was introduced to France, for example, on PHYLLOXERA-tolerant ROOTSTOCKS as early as 1885. The disease is caused by the fungus *Guignardia bidwelli*, which attacks young shoots, leaves, stems, and especially berries. The disease develops only in wet weather; although it occurs across a broad range of temperatures, it is especially problematic in warmer conditions (optimum 28 °C/82 °F). Crop losses can be up to 80%. Control of the disease is based on FUNGICIDES sprayed from spring to VERAISON (crucially during early berry development) and removing infected mummified berries. As might be expected from the origin of the disease, some native American species and their HYBRIDS are relatively tolerant. R.E.S. & W.W.

black spot, vine disease. See ANTHRACNOSE.

Blackwood Valley, relatively young, inland wine region of WESTERN AUSTRALIA.

black xylem decline, a more formal name for the condition BLACK GOO, which affects young GRAFTED VINES. It has been studied for more than 50 years in South Africa and has also caused concern in Europe, Australia, and New Zealand. It was a particular problem in California during the 1980s when unexpected lack of resistance to PHYLLOXERA in the AXR1 ROOTSTOCK forced rapid replanting.

More recently the condition has been associated with a group of fungal diseases known generically as grapevine TRUNK DISEASES, which are spreading globally at an alarming rate. R.E.S.

Blagny, small village in Burgundy's CÔTE D'OR. For more details, see both MEURSAULT and PULIGNY-MONTRACHET.

blanc, blanche, masculine and feminine French adjectives meaning 'white' and therefore a common suffix for white wines and light-berried grape variety names.

blanc de blancs, French for 'white of whites', may justifiably be used to describe white wines made from pale-skinned grapes, as the great majority of them are. The term has real significance, however, only when used for white SPARKLING WINES, in the production of which dark-skinned grapes tend to predominate. A blanc de blancs CHAMPAGNE, for example, is, unusually, made exclusively from CHARDONNAY grapes.

Blanc de Morgex, alpine white wine made from the PRIÉ grape, a speciality of the Valle d'AOSTA.

blanc de noirs, French for 'white of blacks', describes a white wine made from dark-skinned grapes by pressing them very gently and running the pale juice off the skins as early as possible. Many such still wines have a slightly pink tinge (see WHITE ZINFANDEL, for example). The term has a specific meaning in the Champagne region, where it is used to describe a CHAMPAGNE made exclusively from PINOT NOIR and PINOT MEUNIER grapes. See also VIN GRIS and BLUSH.

Blanc Fumé is a French synonym for SAUVIGNON BLANC, notably in Pouilly-sur-Loire, centre of the POUILLY-FUMÉ, or Blanc Fumé de Pouilly, appellation, many of whose aromatic dry whites do indeed have a smoky, if not exactly smoked, perfume. Thanks to one imaginative American, FUMÉ BLANC is today a much more widely known term (see MONDAVI).

blanco, Spanish for white, as in *vino blanco*, or white wine.

Blandy, a name that is synonymous with MADEIRA, both the island and the wine. The Blandy family has extensive interests on Madeira, including hotels, travel, and property. John Blandy of Dorset came to live on the island in 1808, having been introduced to the island and its wines while working for wine merchant Newton, Gordon, Murdoch. He founded the company in 1811 and his son Charles was astute enough to buy up considerable stocks of mature wine during the outbreak of POWDERY MILDEW in 1852, which contributed to the success of the madeira wine firm Blandy Brothers & Co. in the second half of the 19th century. In 1874, Charles's daughter married a Cossart, of the other important madeira wine firm Cossart Gordon. The tourist showpiece of the madeira wine industry, Blandy's Wine Lodge (the old São Francisco lodge) in Funchal, was once the Blandy family home and offices.

The difficult years of the early 20th century saw the formation of the Madeira Wine Association, which Blandy's joined in the 1920s, eventually acquiring a controlling interest. The group is now known as the Madeira Wine Company, includes all the British madeira firms (Cossart Gordon, Leacock, Rutherford & Miles), and is one of the largest producers on the island. Between 1988 and 2011 the SYMINGTON family had a controlling interest in the Madeira Wine Company, but it is now back in the hands of a Blandy, Chris Blandy, who is actively engaged in reviving the madeira category.

Binney, M., *The Blandys of Madeira (1811–2011)*, (2011).

blanketing, winemaking term for protecting grapes, juice, or wine, particularly from OXYGEN, by applying a gas, usually INERT GAS or sometimes CARBON DIOXIDE.

Blanquette de Limoux. See LIMOUX.

blau or blauer is the adjective meaning 'blue' in German, often used for darker-berried vine varieties. Blauburgunder and Blauer Burgunder are PINOT NOIR, for example, while Weissburgunder and Weisser Burgunder are PINOT BLANC.

Blauburger, Austrian red wine grape variety and, like the much more common ZWEIGELT, a cross made in the 1920s by Dr Zweigelt at KLOSTERNEUBURG, in this case of PORTUGIESER and BLAUFRÄNKISCH. Plantings had gone down to 460 ha/1,137 acres in 2022, the majority planted in Lower Austria, where it produces relatively undistinguished light reds although its deep colour makes it a useful ingredient in blends. Hungary has 433 ha, mostly around Eger. There is also a little in Germany.

Blauburgunder, sometimes Blauer Burgunder, common name for PINOT NOIR in Austria and Switzerland. In Germany, SPÄTBURGUNDER (occasionally Blauer Spätburgunder) is more common.

Blauer Wildbacher, ancient, dark-skinned, perfumed grape variety that is a speciality of WESTSTEIERMARK, where all of the 458 ha/1,132 acres grown in Austria are located. Schilcher wines, marketed as the principal distinction of the region's recently launched DAC, are typically tart, pink and fizzy; but red and sweet variants are becoming common. DNA PROFILING analysis suggests a parent–offspring relationship with GOUAIS BLANC.

Blaufränkisch is the Austrian name for the increasingly respected middle European black grape variety the Germans call LEMBERGER. From pre-medieval times it was common to divide grape varieties into the (superior) 'fränkisch', whose origins lay with the Franks, and the rest. It is today Austria's second most planted dark-berried variety after its progeny ZWEIGELT, producing wines of real character, if

notably high acidity, when carefully grown. Its good colour, tannin, and raciness encourage the most ambitious Austrian producers, led by Moric, to treat it like SINGLE-VINEYARD burgundy, and the lavish use of new oak for top bottlings is in decline. For many years it was thought to be the Beaujolais grape GAMAY. Bulgarians still call it Gamé, while Hungarians translate its Austrian name more directly as KÉKFRANKOS. DNA PROFILING has shown that it is a spontaneous GOUAIS BLANC × Blaue Zimmettraube CROSS. Gouais Blanc is known in Austria as Heunisch, and Blaue Zimmettraube is an old dark-skinned variety from lower Styria (today part of SLOVENIA), also called Sbulzìna in FRIULI. The crossing most likely took place in Lower Styria, putting the origin of Blaufränkisch not in Austria but in Slovenia, where 637 ha/1,574 acres of Modra Frankinja are planted.

Its Austrian home is BURGENLAND, where most of its 2,597 ha/6,417 acres are situated. It is grown particularly on the warm shores of the Neusiedlersee, in Mittelburgenland, and at Eisenberg in South Burgenland. As Kékfrankos it grows even more prolifically on the Hungarian side of the lake, notably in SOPRON, whose version has the distinction of having been singled out for mention by Napoleon. Today it is seen both at home and abroad as one of Austria's best local varieties. Blaufränkisch gives varied wine styles with red fruit flavours, firm acidity, and generally good weight, deep colour, and spicy character. The variety called Frankovka in CZECHIA and Serbia is one and the same and here can produce lively, fruity, vigorous wines for early consumption. In SLOVAKIA, as Frankovka or Frankovka Modrá, it is the most important dark-skinned grape, with plantings of 1,260 ha in 2021. In FRIULI in the far north-eastern corner of Italy, the variety is called Franconia and can yield wines with zip and fruit.

The vine buds early and ripens late and can therefore thrive only in a relatively warm climate. However, in the cooler sites of Washington State and on the US east coast, there's a small but growing number of producers who see a promising future for this exciting Austrian emigré.

Blaye, fortified town across the Gironde estuary from Margaux in the BORDEAUX region which has been exporting wine much longer than the famous MÉDOC. It gives its name to a region of scattered vineyards with soils that vary considerably (much more than in neighbouring Côtes de BOURG) but are mainly CLAY and LIMESTONE. At the beginning of the 20th century it produced mainly white wine for distillation into cognac, and even today some of its white wine is distilled. Early 21st century tinkering with nomenclature resulted in most of the wines being sold as Blaye Côtes de Bordeaux. Mainly robust, early-maturing, red BORDEAUX BLENDS were produced from 5,543 ha/13,691 acres of vines in 2020 planted predominantly with Merlot. A much smaller number of growers produce reds according to the stricter rules of Blaye *tout court*. Around 300 ha/740 acres of Sauvignon Blanc and Sémillon vines are responsible for some particularly successful, lively dry white Blaye Côtes de Bordeaux.

J.L.

bleeding. Vines are said to bleed when they lose fluid in spring from pruning cuts. This event can take place over several days and is generally seen following the first few days of warm spring weather. Individual vines can lose up to 5 l/1.3 gal of water. The liquid which drips from the pruning cuts is mostly water, with low concentrations of MINERALS, SUGARS, organic acids, and HORMONES. This is the first visible sign of the start of the new VINE GROWTH CYCLE and corresponds to renewed activity of the root system. Osmotic forces create root pressure, which forces water up through the plant. The term is also used occasionally in winemaking; see SAIGNÉE. R.E.S.

Galet, P., *General Viticulture* (2000).

blend, any product of BLENDING but specifically a wine deliberately made from more than one grape variety as opposed to a VARIETAL wine (which may contain only a small proportion of other varieties).

blending different batches of wine is a practice that was once more distrusted than understood. In fact almost all of the world's finest wines are made by blending the contents of different vats and different barrels (see ASSEMBLAGE); CHAMPAGNE, SHERRY, and PORT are examples of wines which are quintessentially blends. It is often the case, as has been proved by the most rigorous of experiments, that a wine blend is superior to any one of its component parts.

Blending earned its dubious reputation before the mid 20th century when wine laws were either non-existent or under-enforced, and 'stretching' a superior wine by blending it with inferior wines was commonplace (see ADULTERATION). Blending of different lots of the same wine as it is commonly practised today to ensure that quality is maximal and consistent was not possible before the days of large blending vats; before then wine was bottled from individual casks or vats, which is one explanation of the much higher degree of BOTTLE VARIATION in older vintages.

Modern blending, important in the production of both fine and everyday wines, may combine wines with different but complementary characteristics: heavily oak-influenced lots aged in new barrels may be muted by blending with less oaky lots of the same wine; wines that have undergone MALOLACTIC CONVERSION may be blended with crisper ones that have not. In the case of ordinary table wines, blending is an important ingredient in smoothing out the difference between one VINTAGE and its successor. Such practices are by no means unknown in the realm of fine-wine production, whether legally sanctioned or not. The wine regulations in many regions permit the addition of a certain proportion of another vintage to a vintage-dated wine or of a certain proportion, generally less than 15%, of wine from a region or even grape variety other than that specified on the label.

In today's competitive and quality-conscious wine market, motivation for blending is more often improvement than deception.

Perhaps the most enthusiastic blenders are the Australians, who regularly blend the produce of two or more different wine regions, possibly many hundreds of miles apart. The philosophical differences

between these blenders and the European authorities were resolved by an agreement reached in the mid 1990s allowing the importation of such wines into the EU.

For details of fractional blending, see SOLERA. For an alternative approach, in which grape varieties are mixed before fermentation, see CO-FERMENTATION.

blind tasting, form of wine TASTING in which the taster attempts to evaluate and/or identify wines without knowing their identity. Only by blind tasting can a true assessment of a wine's style and quality be made, so subjective is the wine-tasting process. Many professional tastings, those designed to make significant judgements about quality and possibly value, are therefore conducted blind. A comparative tasting, for example, comprises a group of wines of the same approximate age and provenance served blind together in order to evaluate them without prejudicial knowledge of their identity.

Blind tasting with the sole purpose of identification is a particularly masochistic but potentially rewarding exercise, conducted sometimes round the dining table, sometimes in the examination room (as part of a MASTER OF WINE exam, for example). The blind taster generally attempts to identify VINE VARIETY, geographical provenance, and VINTAGE. The first of these should generally be the easiest, but in some cases a wine's geographical provenance can be easier to detect than specific grape variety or blend of varieties. Red bordeaux and white Alsace, for example, tend to express place before grape.

In identifying vintage and general maturity, a wine's COLOUR can be particularly helpful, although, given the extent of vintage variation, a vintage several years from the actual one may well be a better guess than the vintage either side of it. Blind tasting does not usually involve blindfolding the taster (although if this is done, many tasters can even be confused as to whether a wine is red or white, particularly if the wines have similar weight and are made from vine varieties with similar genetic antecedents, as in red and white burgundy). Common practice is to disguise labels or even whole

bottles by swathing them in foil, paper, or fabric and identifying them simply by number. A tasting is said to be single blind if the tasters know what is being tasted but not which wine is which, whereas in a double blind tasting no clues are given.

The OPTIONS GAME was devised by Len EVANS as a way of combining the arcane process of blind tasting with general entertainment. Beginners often make the best blind tasters; experience can confuse.

Burton, N., *The Concise Guide to Wine and Blind Tasting* (3rd edn, 2019).

blockchain, a technology that verifies and records transactions between parties without the need for a central authority. Just as the advent of the internet allowed the transfer of information between multiple parties, blockchain similarly allows the transfer of value and the creation of immutable records of transactions.

Blockchain technology offers a powerful weapon against COUNTERFEIT WINE and ADULTERATION AND FRAUD. A Euromonitor 2018 global study on illicit alcohol suggests that as many as one in four bottles of alcohol may be fake, which can lead to health risks for the consumer and losses in revenue for governments estimated to be $3.6 billion each year.

Implementing the wine supply chain on a blockchain provides a system that can verify the AUTHENTICITY of each batch of wine from the grape-grower to the end consumer, so that at each stage of the supply chain the transaction is recorded as an immutable block in the chain and can be viewed by all participants. These transactions cannot be altered, as any attempt to defraud a transaction record becomes immediately apparent.

The possible applications to the wine supply chain are not limited to the fine-wine trade. The blocks in the chain could also be used to verify the ‘ingredients’ at each stage, for example any ADDITIVES used in the production process and the TEMPERATURE conditions under which wines are transported. What’s needed for this technology to become mainstream is hardware that allows measurement of the

critical data points at each stage of the supply chain and the inputting of this data into blockchain platforms.

But while fine-wine producers may be able to absorb or pass on the extra costs to the consumer, more commercial producers will need to find ways to implement it without dramatic price increases per bottle. M.K.

Euromonitor International, 'Size and shape of the global illicit alcohol market' (2018), 12.

bloom on a grape's skin is the whitish covering consisting of waxes and cutin which protects the berry against water loss and helps stop the penetration of spores. 'Blooming' is another term for FLOWERING.

blue fining, largely outmoded though still used winemaking process whereby excess COPPER and IRON are removed from wine by FINING with potassium ferrocyanide. The process works because soluble copper and iron form insoluble compounds with the ferrocyanide ion. A century ago, before STAINLESS STEEL was widely available, winery equipment was often made of iron, copper, or bronze, an alloy of copper and tin. They would be attacked by the ACIDS in wine. Wines containing more than 10 mg/l of iron or 0.25 mg/l of copper could easily form a haze, so blue fining was needed to remove the excess copper and iron dissolved from the equipment after prolonged contact with the metals.

The process was developed by the German chemist Möslinger at the beginning of the 20th century and is still legally used, under strict controls, in many countries. In contemporary winemaking, iron may be introduced from metal grape bins and from BENTONITE fining; vineyard sprays such as BORDEAUX MIXTURE are still a common source of copper. Because of fears that hydrogen cyanide could be formed from potassium ferrocyanide, the use of blue fining is a major regulatory issue for wine treatments internationally and is illegal in many countries. P.J.W.

Blue Nun, the most successful German wine BRAND, and for most of the 20th century a LIEBFRAUMILCH owned by H. Sichel Söhne of Mainz. It was launched with the 1921 vintage in 1923 as a more accessible product than the host of German bottles adorned with Gothic script and long, complicated names. The label initially featured several nuns in brown habits against a bright blue sky. The label, and subsequently the brand, became known as Blue Nun, featuring a single, alluring nun in a blue habit. Long before MATEUS Rosé, Blue Nun became a substantial commercial success as a result of heavy investment in advertising which preyed on the fears of what was then an unsophisticated wine-drinking public. Blue Nun was advertised as the wine you could drink 'right through the meal', thereby solving the awkward problem of FOOD-AND-WINE MATCHING. It began to grow rapidly, mainly in Britain and America, in the 1950s when German wines enjoyed greater prestige than they do today, and Blue Nun commanded about the same price as a second growth (see CLASSIFICATION) red bordeaux. At its zenith, in 1984/5, annual sales in the US alone were 1.25 million cases, with a further 750,000 cases sold elsewhere. Quality was reliably high, despite the quantities needed to satisfy world sales, and blending at the Mainz headquarters was conscientiously undertaken, but sales declined and H. Sichel Söhne and the Blue Nun brand were bought by F. W. Langguth Erben in 1995. An attempt at relaunching the brand, in all three colours, was made in 2014.

Sichel, M. F., *The Secrets of My Life* (2016).

blush wine is made, rather like France's VIN GRIS, by using black-skinned grapes as if to make white wine. The name is said to have been originally coined by Mill Creek winery in California, but the style was promulgated by Bob Trinchero of Sutter Home when he introduced his WHITE ZINFANDEL in 1972. Although that wine was originally dry, it was the slightly sweet version he produced in 1975 that sparked a rage for 'blush' wines in the US in the 1980s. Its success inspired a rash of VARIETALS labelled White Grenache and

Merlot Blanc, as well as GENERIC wines. The term is now used around the world, for beverages as diverse as wine, cider, and gin, though it has largely lost its cache and is used mainly for slightly sweet wines sold at the lower end of the market. See also SAIGNÉE.

Boal, often Anglicized to Bual, is the MADEIRA name for the MALVASIA Fina grape. Most of the Boal growing to a limited extent on Madeira today (14 ha/35 acres in 2018)—though not nearly as limited as the island's other three traditional varieties—is Boal Cachudo. Portugal's Instituto da Vinha e do Vinho (IVV) lists four other Boal Somethings: Boal Barreiro, Boal Branco, Boal Espinho, and Boal Ratinho, though only Cachudo and Branco have been shown by DNA PROFILING to be synonyms for Malvasia Fina.

Bobal, a very important Spanish dark-skinned grape variety which produces deep-coloured red wines and even GRAPE CONCENTRATE in south-east Spain, substantially but by no means exclusively for BULK WINE production. In 2019 its plantings totalled 56,184 ha/138,834 acres, making it Spain's third most planted red wine grape after Tempranillo and Garnacha. Its reputation has been growing as producers such as Mustiguillo have managed to fashion velvety reds from high-ELEVATION vineyards in UTIEL-REQUENA. It retains its acidity better than MONASTRELL (which tends to be grown in slightly warmer, more southerly parts of Spain) and is notably lower in alcohol. It is allowed in four DOP areas: Utiel-Requena, VALENCIA, MANCHUELA, and RIBERA DEL JÚCAR. Drought-resistant and always grown as unirrigated bush vines, Bobal is extremely sensitive to springtime cold spells. Young vines may ripen unevenly. Although more rustic than the internationally famous Garnacha and Monastrell, Bobal wines are fresher, with fine colour, a good dark berry component, and an ability to transmit TERROIR.

Bobal Blanco, also known as Tortosí, is still grown to a limited extent in Valencia but is Alcañón and not related to Bobal.

Boca, historically important red-wine DOC in the Novara Hills in northern PIEMONTE, comprising 16.5 ha/40 acres in 2020, up from 12 ha in 2010, divided among 12 producers. Nebbiolo grapes, called SPANNA here, should comprise 70–90% of these intriguing reds. Although marginal in size, Boca produces such good wines, notably Le Piane's, that they are attracting international attention.

Bocksbeutel, bottle in the shape of a flattened flask used in the German wine region of FRANKEN and four communes in the northern Ortenau area of BADEN. The name probably derived from the Low German *Bockesbeutel*, a pouch to carry prayer-books and the like, rather than from any ostensible resemblance to a goat's scrotum (the literal translation). From the early 18th century onwards, the original purpose of the special bottle was to guarantee the authenticity of Würzburger Steinwein. Only after the First World War did it become common throughout Franken. T.S. & D.De.

BOD, biological oxygen demand. See WINERY WASTE.

bodega, Spanish for a wine CELLAR, a WINERY, or a tavern or grocery store selling wine.

body, tasting term for the perceived 'weight'—the sensation of fullness, resulting from DENSITY or VISCOSITY—of a wine on the palate. Wines at either end of the scale are described as full-bodied and light-bodied.

Next to water, ALCOHOL is the major constituent of wines. It has a much higher viscosity than water and is the major component responsible for the sensation of fullness, or body, as a wine is rinsed around the mouth. ALCOHOLIC STRENGTH is therefore clearly an important factor: the more potent a wine the more full-bodied it is usually said to be.

Sweet wines are not necessarily full-bodied (ASTI, for example, is sweet but very light-bodied, thanks to its low alcohol content).

Contrary to popular conception, GLYCEROL makes only a very minor contribution to density, viscosity, and therefore to body (although it does have a slight effect on apparent sweetness).

Body is not related to wine quality, BALANCE and HARMONY being more important in a wine than whether it is full- or light-bodied.

Amerine, M. A., and Roessler, E. B., *Wines: Their Sensory Evaluation* (2nd edn, 1983).

Bohemia, in the north of CZECHIA, remains better known for the production of beer and GLASSES than for wine even though its winemaking history reaches back to the 9th century. By the 17th century the region boasted 3,500 ha/8,650 acres of vineyards. In 2021, that had dwindled to just 650 ha spread around the cities of Mělník, Litoměřice, and Prague. The production is small and mostly drunk straight from the wineries, save for the sparkling wines of Bohemia Sekt, a substantial business owned by Dr. Oetker. Cooler than MORAVIA and relatively dry, Bohemia specializes in Pinots Noir and Blanc as well as Svatovavřinecké (ST-LAURENT) and Ryzlink Rýnský (RIESLING). K.K.

bois noir. See GRAPEVINE YELLOWS.

Boisset, Burgundy's largest wine producer and one of the world's largest family-owned producers of good-quality wine currently called Boisset, La Famille des Grands Vins, and based in Nuits-St-Georges. It has wineries in Burgundy, the Jura, Beaujolais, the Rhône Valley, and the south of France, as well as in California's Napa Valley, Russian River Valley, Sonoma Valley, and Monterey. It also owns 800 ha/1,977 acres of vines in France and 200 ha in California. Quite a force! Although there's a constantly changing roster of acquisitions and sales of subsidiaries.

It was formed as recently as 1961 by Jean-Claude and Claudine Boisset when Jean-Claude was just 18. The early business was successful enough to acquire NÉGOCIANTS Charles Viénot and Thomas-Bassot in 1982. A portion of the company was floated on the stock market in 1985, and they took over Pierre Ponnelle, Morin Père et Fils, Jaffelin, and Bouchard Ainé & Fils during the next six years. In 1994 the company then diversified into sparkling-wine production via such acquisitions as Charles de Fère and Louis Bouillot Crémants de Bourgogne in 1997 while consolidating its Côte de Beaune holdings by buying Ropiteau Frères, followed in the late 1990s by Mommessin in Beaujolais, J. Moreau & Fils in Chablis, and the fruit liqueur business L'Héritier-Guyot (sold in 2008). Ch Pierreux with 100 ha of vines in Brouilly was acquired in 2002, and Antonin Rodet in Mercurey with its 80-ha domaine was snapped up in 2009.

The company is now styled *négociant-éleveur* with a commitment to ORGANIC and BIODYNAMIC VITICULTURE in its flagship 40-ha/99-acre vineyard holding Domaine de la Vougeraie. The term *viniculteur* was coined to stress Boisset's degree of control of quality in vineyards both owned and bought from.

Having abandoned its JOINT VENTURES in Canada and South America, the company has determinedly expanded into California, building a Franco-American identity from 1992 with the acquisition of Lyeth Estate in the Alexander Valley. This was followed in 2003 by DeLoach in the Russian River Valley, Raymond in the Napa Valley in 2009, and Sonoma's Buena Vista (California's first winery) and Monterey's Lockwood Vineyards in 2011, joining what has come to be known as the Boisset Collection. Also in 2011, Boisset bought négociant Skalli based in Sète in the LANGUEDOC.

In 2012 JCB by Jean-Charles Boisset became the first range of wines from both Burgundy (sparkling and still) and California. (Boisset lives in the Napa Valley with his wife Gina GALLO.) The acquisitions continue: Henri Maire, now Domaine Maire & Fils, and the biggest vineyard holding in the JURA (280 ha) in 2015; creation of the first 'lounge' in Burgundy, La Maison Vougeot in 2016; the substantial Rhône négociant Gabriel Meffre and its 80-ha Domaine de

Longue Toque in Gigondas and Vacqueyras in 2018; Alex Gambal in Beaune and the historic Oakville Grocery in Napa in 2019; and in 2021 Louis Bouillot in Burgundy and a winery in Beaucaire now called Les Chais du Sud and designed to ride the wave of Provençal rosé.

Bolgheri, small town in the Tuscan MAREMMA made famous by Marchese Mario Incisa della Rocchetta, who planted Cabernet Sauvignon vines for a house wine as early as the 1940s on his San Guido estate, labelling the resulting wine SASSICAIA. Bizarrely, the DOC created for Bolgheri in 1983 was only for whites and rosé, but it was amended in 1994 to include red wine, and the subzone Sassicaia was created. Prior to this Sassicaia had to be labelled as VINO DA TAVOLA, but due to its high quality it became known as a SUPERTUSCAN, spawning many copies throughout Tuscany. In 2013 Bogheri Sassicaia was created, becoming Italy's only single-estate DOC, evidence that it is this estate more than any other that gives credentials to an area where previously only cattle used to roam.

The success of Sassicaia, Grattamacco (first vintage 1982), and Ornellaia (1985) triggered an investment frenzy in the region, which expanded from 250 ha at the end of the 1990s to more than 1,190 ha/2,940 acres in 2020, with 60 producers.

The DOC's red-wine production is based on Cabernet Sauvignon and Merlot, which until 2011 were presented in blends only, before VARIETAL wines were allowed. Sangiovese and Syrah are also allowed but at no more than 50% of a blend. Most estates produce a classic BORDEAUX BLEND aged in BARRIQUES. The wines are generally of a high quality, but styles can differ due to soil composition and location of the vineyards as much as differences in winemaking. Although once hailed as one of Italy's future fine-wine regions, the lower ELEVATIONS have proved too warm to produce wines of sufficient elegance to mimic Bordeaux, which seems to be the objective of most producers here. However, VERMENTINO, a distinctly Mediterranean white variety, is experiencing an increase in interest. W.S.

Masnaghetti, A., *Bolgheri: Cellars and Vineyards* (e-book, 2009).

Bolivia in SOUTH AMERICA has a long history of vine-growing and a small but growing modern wine industry. Viticulture was brought to Bolivia from neighbouring PERU in the 16th century by Spanish settlers and Catholic MISSIONARIES. Though the whereabouts of the first vineyards in the country is debated, wines were being produced throughout the region in the late 1500s, sprouting in diverse places like Mizque in present-day Cochabamba, Sutó in present-day Santa Cruz, and Tomina, Pilaya, Paspalla, and Cinti in present-day Chuquisaca. Wine was also made in Tarija, where 71% of the country's vineyards are located today.

PHYLLOXERA and NEMATODES severely hampered Bolivian viticulture in much of the 20th century. Resistant ROOTSTOCKS and good-quality VITIS VINIFERA cuttings were imported in the 1970s in an effort to restore vineyard health. By 2021, the country had 5,000 ha/12,300 acres of vineyard, most of it planted to GRAFTED VINES trained in ESPALIER. IRRIGATION is widely practised throughout the country.

Over 90% of Bolivia's wines come from Tarija, in the far south of the country, close to the Argentine border. At ELEVATIONS of 1,600–2,700 m/5,200–8,800 ft, the climate here is mild CONTINENTAL, with significant DIURNAL TEMPERATURE RANGE and intense levels of ULTRAVIOLET RADIATION. HAIL can be an issue, and many producers have installed nets to protect the vines. RAINFALL can also be challenging, averaging 500 mm/19 in annually, most of it falling during the growing season, encouraging FUNGAL DISEASES. As in all of Bolivia, MUSCAT OF ALEXANDRIA is the most planted variety, as a significant portion of the harvest goes to the production of *singani*, a distillate akin to PISCO, and of which Tarija is the largest producer. However, many producers have converted their vineyards to TANNAT to make red wines, which make up most of Bolivia's production.

The Cinti Valley, about 400 km/249 miles north in the department of Chuquisaca, claims about 8% of Bolivia's land under vine. Most of it is planted to CRIOLLAS, including Negra Criolla (NEGRAMOLL) and Vischoqueña, a red grape unique to Bolivia which gives light-

coloured, floral-scented wines with medium tannin structure. The climate is similar to Tarija though Cinti sits at higher elevation (2,200–2,800 m/7,200–8,800 ft) and rainfall averages 300 mm/12 in. The valley is known for its strong *singani* tradition and for ARBOREAL VITICULTURE in which vines are trained around indigenous pink peppercorn (*Schinus molle*) and chañar (*Geoffroea decorticansis*) trees. Many of these vines are very old, and it is thought that this traditional system has helped the vines fend off diseases.

The second largest—and fastest-growing—wine regions are in the east of the country, in the Santa Cruz valleys (16% of total vineyard), near to Santa Cruz de la Sierra, Bolivia's largest city. Vines are planted at 1,600–2,100 m/5,200–6,800 ft) in elevation, and the climate is continental, with about 600 mm/23 in annual rainfall. SYRAH and Tannat are the most popular varieties in this region.

There are also some small vineyards in the La Paz, Potosí, and Cochabamba valleys. The country has a long tradition of *patero* wine, foot-trod and traditionally vinified in clay jars or, more commonly today, plastic vessels. M.J.G.

Goldstein, E., *South American Wines* (2014).

Bollinger, family-owned Champagne house producing a range of top-quality wines based on Pinot Noir grapes. Bollinger was formed from the de Villermont family's holdings in the village of Aÿ near Épernay, where the company is still based. In 1829, Jacques Joseph Placide Bollinger formed a partnership with Athanase-Louis-Emmanuel de Hennequin, Comte de Villermont, and Paul-Joseph Renaudin, resulting in the house of Champagne Renaudin Bollinger & Cie. In 1837, Jacques Bollinger married de Villermont's daughter Louise Charlotte and became a French citizen. In 1865, the house started to ship low-DOSAGE champagne to Britain, which was unusual for a period in which most champagne reaching the country was sweet. Champagne Bollinger received the Royal Warrant as Official Purveyor of Champagne to Queen Victoria in 1884.

Control of the house eventually passed to Jacques's grandson (also named Jacques), who died young in 1941, leaving his widow Elisabeth 'Lily' Bollinger (1899–1977) in charge. Madame Bollinger oversaw the family vineyards on foot and bicycle for three decades, enduring the 1944 German bombardment of Aÿ while sleeping in the Bollinger cellars. After the Second World War, she increased the house's vineyard holdings, which in 2021 stood at 179 ha/442 acres. By the time of her death, Madame Bollinger had seen sales double to a million bottles a year. She believed that nothing should change the traditional Bollinger style, and to this day the following five rules are obeyed: a majority of grapes from the house's own vineyards, 85% of which are GRAND CRU and PREMIER CRU; Pinot Noir dominance in the blend; BARREL FERMENTATION in over 4,000 old barrels to encourage MICRO-OXYGENATION; reserve wines aged in MAGNUMS; and bottle AGEING for two to four times longer than required even for the non-vintage Special Cuvée. Bollinger RD ('recently disgorged', with marked AUTOLYSIS as a result of being aged for a minimum of 14 years on LEES) was introduced by Madame Bollinger with the 1952 vintage. Rarest of all Bollinger champagnes is the Vieilles Vignes Françaises, a BLANC DE NOIRS produced exclusively from UNGRAFTED Pinot Noir vines that grow in two walled vineyards that were never affected by PHYLLOXERA.

The Bollinger family company, Société Jacques Bollinger, acquired Burgundy producer Chanson in 1999. It also owns a majority stake in the SAUMUR house Langlois-Chateau, as well as a minority stake in the cognac house Delamain. In 2005 the company bought their neighbouring house in Aÿ, Champagne Ayala, one of the original GRANDES MARQUES.

In 2021 Bollinger made its first acquisition outside France: Ponzi Vineyards in Oregon.

See also CHAMPAGNE.

Ray, C., *Bollinger: Tradition of a Champagne Family* (3rd edn, 1988).

Bolognesi, Colli, small DOC zone in the hills of EMILIA-ROMAGNA in north-central Italy. Colli Bolognesi PIGNOLETTO, both still and sparkling, has been elevated to DOCG. See EMILIA-ROMAGNA for more details.

Bolzano , or Bozen in German, the main town of ALTO ADIGE in northern Italy. Local light red wines with a minimum of 85% SCHIAVA (Vernatch) may carry the name Colli di Bolzano or Bozner Leiten as a suffix to the DOC Alto Adige/Südtirol.

Bombino Bianco was planted on 1,138 ha/2,812 acres of southern Italy, mainly in PUGLIA, in 2015. It is distinct from TREBBIANO d'Abruzzo, sometimes called Bombino Bianco di San Severo.

It ripens late and yields extremely high quantities of relatively neutral wine. Some of its synonyms, Pagedebit ('it pays the debts') and Straccia Cambiale ('tear up the invoices') in particular, allude to its profitability to the vine-grower. The dark-berried Puglian Bombino Nero, planted on 865 ha, is its natural offspring.

Bonarda, Italian red grape variety, or more accurately the name of three distinct Italian varieties: (1) the Bonarda of the OLTREPÒ PAVESE and Colli PIACENTINI (also planted in southern PUGLIA), which is, in fact, not Bonarda at all but rather the CROATINA grape; (2) the Bonarda Novarese, used to soften SPANNA in its range of DOC reds in the Novara and Vercelli hills, which again is not Bonarda but UVA RARA, a variety more widely employed in the Oltrepò Pavese; and (3) the so-called Bonarda Piemontese, an aromatic variety which has been virtually abandoned because of its small bunches and low productivity, although it covered 30% of the region's vineyard before the advent of PHYLLOXERA. There are scattered patches around Chieri, near Turin, and further west around Castelnuovo Don Bosco, as well as in Albugnano in Asti.

The only DOC wines in production which bear the name Bonarda are from the Oltrepò Pavese and are, confusingly, made from

Croatina.

Bonarda is also the name of the third most widely grown red wine grape variety, after Malbec and Cereza, in ARGENTINA, where total plantings had grown to 18,153 ha/44,857 acres by 2020, which means that Argentina has far more 'Bonarda' planted than Italy, although DNA PROFILING has shown that Argentine Bonarda is unrelated to any of the Italian Bonardas and is in fact identical to California's CHARBONO, which is the Douce Noire of Savoie. The variety makes particularly exuberant, fruity wines for relatively early consumption.

bonbonne, a large glass jar or carboy, also known as a demijohn, typically holding 25 l/6.6 gal, used as a neutral container to store wine, VIN DOUX NATUREL, or brandy, often after a period of wood ageing.

bonded warehouse, one in which no DUTY has been paid on the goods inside it. Prices for wines and, especially, spirits held in bond (IB) are therefore considerably lower than those quoted duty paid. It is sensible for any foreigner buying wine to store for possible shipment outside that country to buy it in bond. For that reason, many FINE WINE prices are quoted in bond.

Bondola, traditional VITIS VINIFERA grape of SWITZERLAND's Ticino, where it may be an ingredient in the local blend called Nostrano. Largely replaced by Merlot.

Bonnes Mares, red GRAND CRU in Burgundy's CÔTE D'OR. For more details, see CHAMBOLLE-MUSIGNY and MOREY-ST-DENIS.

Bonnezeaux, particularly well-favoured enclave for sweet, BOTRYTIZED white wine made solely from Chenin Blanc near Thouarcé

in the ANJOU part of the Loire within the Coteaux du LAYON area on the steep slopes of the right bank of the river. In this respect Bonnezeaux resembles QUARTS DE CHAUME to the north-west, but—perhaps because of its greater extent, 100 ha/247 acres spread across three south-facing hills (Montagne, Beauregard and Fesles) of SCHIST and QUARTZ, and its much more exposed situation—its required ripeness is lower, its acidity brighter while CHAPTALIZATION is allowed, leading to uneven quality and reputation. Yet when the grapes are naturally concentrated by NOBLE ROT, or sometimes by PASSERILLAGE, and picked by mandatory TRIES, Bonnezeaux can live up to its historic fame and turn into a world-class gold nectar able to age for decades. See also LOIRE, including map. P.Le.

books on wine. See LITERATURE OF WINE and WINE WRITING. For references to wine in some more obviously literary works, see ENGLISH LITERATURE, WINE IN.

Borba, DOC subregion in the northern part of the ALENTEJO in southern Portugal. Rising to around 450 m/1,476 ft, the area around Estremoz is home to a cluster of pioneers of modern classic reds based on ARAGONEZ, CASTELÃO, and TRINCADEIRA. S.A.

Bordeaux , important port on the GARONNE River leading to the GIRONDE estuary on the west coast of France. Bordeaux gives its name to a wine region that includes the vineyards of the Gironde *département* and, as such, the wine region that produces more top-quality wine than any other, from a total vineyard area that ballooned in the mid 2000s to about 124,000 ha/306,280 acres but was down to 110,000 ha/271,700 acres by 2020, divided among about 5,500 increasingly impoverished producers as the PRICE gap widened between the most famous wines and the rest. Bordeaux has a higher proportion of large estates than any other French wine region and produces more of the world's FINE wine and TROPHY WINES than

anywhere else. The most famous examples represent less than 5% of the region's total production, however, and Bordeaux's most pressing long-term problem has been selling the other 95% profitably. The best red bordeaux, known by the British as CLARET, are characterized by their subtlety and ability to evolve after years, sometimes decades, of BOTTLE AGEING. The worst can be thin and evanescent. The producers in between suffer because there are simply too many of them to make much impact.

The proportion of bordeaux that is white has fallen from about one-quarter in the 1990s to just over 10%, 1% of which is sweet, in the early 21st century. Small quantities of rosé, light red CLAIRET, and sparkling CRÉMANT are also made. The total quantity of wine produced each year varies considerably according to VINTAGE but currently averages about 4.9 million hl, which represents about one-quarter of France's total AOC wine production. See BORDEAUX AOC for bordeaux wine at its most basic, BORDEAUX, CÔTES DE for a group of right-bank appellations, BORDEAUX TRADE for an account of the workings of the wine trade in Bordeaux, and BORDEAUX, UNIVERSITY OF for details of its important contribution to wine ACADEME.

Wine-growing regions

History to medieval times

The Latin poet Ausonius (*c.*310–393/4 CE) is not only the first author to mention that wine was grown in his native Bordeaux; he was also the region's first known wine-grower. In his poem 'De herediolo' ('On his small inheritance'), dated 379, he tells us that he grows 100 *iugera* (a *iugerum* is approximately two-thirds of an acre or 0.25 ha) of vines. His estate was probably at Bazas, near the river Garonne (although some have suggested St-Émilion). In two of his other poems, 'Mosella' ('On the Moselle') and 'Ordo urbium nobilium' ('The list of distinguished cities'), he describes the banks of the Garonne overgrown with vines. Ch AUSONE is named after him.

Although Ausonius' descriptions indicate that viticulture was well established in Bordeaux in his lifetime, no definite earlier evidence exists. Given that members of the Allobroges tribe were growing wine around Vienne in the RHÔNE Valley in the 1st century CE, the Bituriges may have been doing the same in Bordeaux, but Strabo, author of the *Geography* (completed in 7 BCE), merely says that Bordeaux ('Burdigala' in Latin and in Strabo's Greek) was a place of commerce, and PLINY, writing *c.*77 CE, does not tell us clearly that the Bituriges grew wine (although he does refer to a Biturica vine, which may have been associated with either the Bituriges tribe of Bordeaux or the other to the west of Bourges), so the likelihood is that viticulture spread to Bordeaux after it had come to the Rhône.

We know little about Bordeaux in the centuries following the fall of the Roman Empire. The area was overrun by the Visigoths in the 5th century, and when Clovis defeated the Visigoths in 507 it became part of the Frankish kingdom. CHARLEMAGNE is said to have displayed a temporary interest in FRONSAC. With the economic expansion in Europe which started in the 11th century, demand for wine grew. Initially the new port of LA ROCHELLE, on the Atlantic coast north of Bordeaux, brought wealth to the region in the 12th century; consequently Bordeaux increased both its trade and its production. By 1200 wine was grown in BLAYE, BOURG, the lower DORDOGNE and the

Garonne Valley, and in the GRAVES. The Graves was the largest producer, with Ch Pape-Clément its oldest named vineyard. In 1305 Archbishop Bertrand de Goth, who was to become Pope Clement V, presented it to the see of Bordeaux. Throughout the Bordeaux region more red wine was grown than white, but SAUTERNES and CÉRONS probably had white wine, although these white wines cannot have been like the botrytis-affected wines of today, for the deliberate commercial use of NOBLE ROT in Sauternes and Cérons dates from after the Middle Ages. Until the late 17th century the MÉDOC was too marshy to produce much wine and was known mainly for its corn: there were just a few vineyards in what is now called the Bas-Médoc, north of ST-ESTÈPHE. ST-ÉMILION was already a winegrowing district, however. Some of the wine of Bordeaux was neither white nor red but a mixture of white and red grapes fermented together called 'clairet' in Old French, which is the origin of the modern English word CLARET.

Bordeaux's pre-eminence began because of the English connection. In 1152, Eleanor of Aquitaine married Henry Plantagenet, who in 1154 became king of England (and duke of Normandy) as well as acquiring Eleanor's territories, GASCONY and most of western France. To win the favour of the citizens of Bordeaux, King John (1199–1216) granted them numerous privileges. The most important of these was exemption from the Grand Coutume, the export tax imposed on ships sailing from Bordeaux. Also, Gascon merchants were given favoured treatment in London. All this made Gascon wine cheaper for the English than any other imported wine. In the 14th century, most French wine consumed in England was from Gascony, and one-quarter of Bordeaux's wine exports went to England. Against these protective measures La Rochelle could not compete, despite its superior position right on the coast while Bordeaux was 60 miles/100 km upriver. When La Rochelle fell to the French in 1224, it ceased to be a commercial threat to Bordeaux.

Not all the wines sold by the Gascon merchants were from the immediate Bordeaux area. In the HAUT PAYS (Gaillac, Quercy, Nérac, and Bergerac) the climate was more reliable, and its wines were

stronger than those of Bordeaux. The Haut Pays wines were more expensive because they were taxed in Bordeaux; and those from the parts of the Haut Pays which had fallen to the French were not allowed into Bordeaux until St Martin's Day, 11 November, or even until Christmas, so that Bordeaux wines dominated the wines available for the fleet which arrived each autumn to deliver the year's new wine to England, Scotland, Ireland, the Low Countries, and the Hanseatic ports.

In 1453, at the end of the HUNDRED YEARS WAR, Gascony reverted to French rule; yet its trade with England soon picked up again, even though it never regained its 14th-century volume. Bordeaux had been a major port before it became a wine-producing area to feed its wine trade. Its winemakers were not patient monks, as they had often been in Burgundy, but opportunistic laymen, whose aim was to cash in on the huge demand for Bordeaux's chief export product, and so they switched from grain to wine. The thin wines of Bordeaux, which before the advent of glass BOTTLES and CORKS did not last from one vintage to the next, cannot have been anything like modern bordeaux. H.M.W.

Modern history

Trade with Britain continued after the English were expelled, but the DUTCH WINE TRADE gradually became dominant, not so much in wines for their own consumption but in inexpensive white wines for the rest of northern Europe and the Hanseatic states. The Bordeaux merchants had to fight hard to maintain their position in northern Europe, for the Dutch also bought from the Mediterranean countries.

It was the Dutch who drained the marshy MÉDOC in the mid 17th century, thereby creating the basis for the fine wines that made Bordeaux's reputation throughout the world. Before this the best wines were to be found in the well-drained GRAVES near the city, notably Ch HAUT-BRION. Today's leading Médocain estates—Chx LAFITE, LATOUR, and MARGAUX—were probably planted in the last third of the 17th century and reached England, to be offered at auction in the coffee houses of London, only after consignments had been captured at sea in the Anglo-French wars at the beginning of the 18th century.

The simultaneous trade war between Britain and France led to ever-increasing duties on French wines and the Anglo-Portuguese Methuen Treaty of 1703. In return for a Portuguese promise to admit British woollen goods in perpetuity, the British government agreed that duty on French wines should never be less than 50% higher than on the wines of Portugal (and, in fact, Spain). Officially, British wine imports from Bordeaux declined sharply, but smuggling must have been rife, to judge from the prevalence of bordeaux in the household sales conducted by Christie's (see AUCTIONS) after their foundation in 1766. Conditions in both Bordeaux and Britain were ripe for the development of trade in fine CLARET: in the Gironde there was a new affluent bourgeoisie, members of the legal Bordeaux Parlement, with the means to plant and maintain expensive vineyards, while in Britain bordeaux's almost exclusive market was created by a wealthy, landowning aristocracy and, soon, the new industrial middle class.

The necessary link was a Bordeaux merchant class, sufficiently well established to be able to buy, cellar, and export these 'new French clarets'. These merchants came largely from the British Isles and from Germany, which had long been prominent in the inexpensive red bordeaux trade. BARTON & Guestier joined forces in 1725; William, later Nathaniel, Johnston began in 1734; and BROKERS Tastet & Lawton in 1740. These are some of the longer survivors of many more. The German firms of standing appear to have arrived later: Cruse from Danish Schleswig-Holstein, later incorporated into Germany, arrived in 1819; Eschenauer in 1821; and Kressmann in 1858. A substantial French merchant, with its roots in the RHÔNE Valley, was Calvet, which opened a Bordeaux office in 1870. It is also significant that the trade's 'bible' was the creation, in 1850, of an English teacher, Charles Cocks (see FÉRET).

Until well into the second half of the 20th century, most of these firms had their premises in the suburb of Les Chartrons, named after a medieval Carthusian monastery. The Quai des Chartrons, facing the River Garonne, and its side streets was the headquarters of the so-called *aristocratie du bouchon* (aristocracy of the cork).

In 1852, Bordeaux was struck by oidium, or POWDERY MILDEW, the first of a series of vine plagues which were to devastate many other wine regions too. First noted in the sweet wine areas near the Garonne, it spread through the Graves and then into the Médoc. Between 1854 and 1856, all the properties which were rated CLASSED GROWTHS in the 1855 CLASSIFICATION produced a total of only 3,400 TONNEAUX of wine, not much more than half the crop in a prolific year. By 1858 this fungal disease was conquered by spraying with SULFUR, a practice which continues to this day (see below).

Trade with Britain increased as a result of the Anglo-French Treaty of 1860, for in the following year Gladstone, then Chancellor of the Exchequer, reduced duty on French wines to twopence (less than 1p) a bottle. This was a particularly prosperous time for Bordeaux, which had also developed substantial markets in South America and Russia, as well as a small one in North America.

However, the severe onset of PHYLLOXERA in the late 1870s, followed by DOWNY MILDEW in the next decade, proved a serious setback to the trade in everyday GENERIC red and white bordeaux. For the first time ever an import BOND was established in Bordeaux, largely supplied with blending wine from the new vineyards of ALGERIA. On the other hand, excessive FERTILIZATION by important châteaux proprietors to compensate for losses by disease led to large crops of inferior quality and a fall in reputation and price. In 1910, nevertheless, two out of every three bottles of French wine imported into Britain came from the Gironde. They totalled 110,000 hl/2.9 million gal, approximately the same as for BELGIUM, although Germany imported almost twice as much. In 1911, the Gironde *département* was delimited, leading eventually to the establishment of Bordeaux's AOC system in 1936.

A serious slump followed soon after the First World War, with many châteaux changing hands, and this continued in the 1930s. After the First World War, the Russian market had disappeared, the South American one was much reduced, and the US market was closed by PROHIBITION between 1919 and 1933, with hardly time to recover before the Second World War.

At this time the market for fine wines was largely confined to the Médoc and the châteaux in the Graves near to Bordeaux. It was not until after the Second World War—during which Bordeaux, and many large châteaux, were occupied by the German army—that any ST-ÉMILION property other than Ch CHEVAL BLANC was widely known outside France, and the same was true of POMEROL, even Ch PETRUS, although there was a good market for inexpensive St-Émilions in Belgium.

It was not until the end of the 1950s that those châteaux with an international reputation made sufficient profits to begin serious replanting and the installation of modern equipment, notably FERMENTATION VESSELS made of STAINLESS STEEL, although this was an option which many châteaux, including Lafite, Margaux, and MOUTON-ROTHSCHILD, did not take. From the mid 1960s, the United States

market became increasingly important, especially for the classed growths. This was particularly marked with the successful 1970 vintage when large American purchases were made as futures, EN PRIMEUR, followed some years later in Britain. Previously, if a vintage was considered likely to be very fine, the BORDEAUX TRADE would sometimes buy SUR SOUCHE, but otherwise a vintage would not be marketed until shortly before or after BOTTLING, either by the château or by the Bordeaux merchants. In 1972, CHÂTEAU BOTTLING became compulsory for the classed growths and was generally applied to the more important properties in the Graves, St-Émilion, and Pomerol. The leading red and white Graves had first been classified in 1953, and the St-Émilions in 1955 (see CLASSIFICATIONS). The Pomerols remain unclassified.

These en primeur campaigns reflected the changed financial situation in Bordeaux (although the generic wines, accounting for up to half the annual crop, continued—and continue—to be sold chiefly within 12 months of the harvest). No longer could most châteaux afford to hold several vintages in stock; nor could the Bordeaux merchants or their customers in France or abroad. For the most part in the 1970s and 1980s, consumers had to bear the financial responsibility of AGEING young red bordeaux and some leading sweet wines.

The 'energy crisis' of 1973, in which Middle East oil producers greatly raised their prices, caused havoc in Bordeaux, where recent vintages had been sold en primeur at excessively high prices. This had applied at all quality levels, and one result was that, in order to meet contracts for generic red bordeaux, the distinguished house of Cruse bought wine from outside the region, involving altered Appellation Contrôlée documents. A sharp fall in prices occurred, as well as subsequent mass disposals of stock by both merchants and leading châteaux. Some of the traditional firms were saved from bankruptcy only by foreign ownership, and the old world of the Chartronnais disappeared forever. Later, classed growth châteaux passed into the financial control of such outsiders as insurance companies (see AXA for example) and multinational corporations.

The succession of fine vintages in the 1980s improved the situation of many châteaux, but competition was so keen on the Bordeaux market that the merchants were unable to build up the financial reserves to tide them over poor years, as they had done in the past. So when Bordeaux was hit first by the heavily FROST-DAMAGED 1991 vintage and then by the diluted 1992, the en primeur trade virtually ceased internationally, and considerable financial problems arose—although the chiefly domestic trade in generic and humble appellation wines continued much as usual.

From the 18th century until 1939, the Bordeaux trade normally called the price tune, and—with the exception of the *belle époque*, from 1858 to 1878—the château owners had to fall into line. For the 30 years from 1961, the leading proprietors then held the whip hand in allocating their new wines to more than 100 Bordeaux merchants. In the early 1990s, when Bordeaux had no great vintages to sell, power was transferred to the consumer. The number of potential purchasers of fine bordeaux grew substantially, however, in the mid 1990s when the exciting 1995 and 1996 vintages were available, in the United States and for the first time in Asia. This, coupled with a widespread economic boom, helped create an unprecedented price spiral in Bordeaux in the 2000s. It faltered temporarily as a result of the invasion of Iraq and financial turmoil in Asia, only to accelerate when the undoubted quality of the 2009 and 2010 vintages coincided with unprecedented, and short-term, interest from investors, many of them without any wine-trade experience, notably but not exclusively from CHINA, a market that had been courted assiduously by the Bordelais. Prices of these vintages subsequently stagnated or fell, and the Bordelais were faced with the combination of a succession of lacklustre vintages and a lack of interest in their wines among many consumers, particularly younger ones. The quality of vintages 2015–20 reignited some interest. E.P.-R., J.R. & J.L.

Geography

The wine districts of Bordeaux hug the Gironde estuary and the Rivers DORDOGNE and GARONNE which flow into it (see map). The largest and most important appellation is BORDEAUX AOC, but there are 65 appellations in all, though many are rarely seen outside the region. The notably flat Bordeaux vineyards are rarely at elevations of more than a few metres above sea level.

Conventionally, in terms of the all-important fine red wines at least, the whole region is split into 'left bank' and 'right bank', or MÉDOC and GRAVES on the west side of the Gironde and St-Émilion and POMEROL on the east side, leaving the vast ENTRE-DEUX-MERS ('between two seas') district in the middle. Within the Haut-Médoc, the superior, higher land closer to Bordeaux, are the world-famous communes, south to north MARGAUX, ST-JULIEN, PAUILLAC, and ST-ESTÈPHE, together with the slightly less illustrious and more inland appellations of LISTRAC and MOULIS. Most of the finest wines of the Graves, on the other hand, have come from an enclave awarded its own appellation in 1987, PESSAC-LÉOGNAN. Pomerol and St-Émilion have their 'satellite' appellations: LALANDE-DE-POMEROL; and Montagne-St-Émilion, Lussac-St-Émilion, St-Georges-St-Émilion, and Puisseguin-St-Émilion (for details of which see ST-ÉMILION). And just west of Pomerol are the historic appellations of FRONSAC and Canon-Fronsac. Other appellations on the right bank of the Gironde are BOURG and BLAYE, grouped as CÔTES de Bordeaux. The GRAVES DE VAYRES enclave near Libourne remains resolutely outside the fold. Although some white wine is made between the two rivers, most of Bordeaux's best white wines are made south of the river Garonne: dry wines from Graves and Pessac-Léognan, and sweet white wines which include some of the finest in the world from SAUTERNES and BARSAC. (See CLIMATE below for a more detailed explanation.) Other, lesser sweet-white appellations in the south-east of the region are CADILLAC, CÉRONS,

LOUPIAC, PREMIÈRES CÔTES DE BORDEAUX, STE-CROIX DU MONT, and STE-FOY CÔTES DE BORDEAUX which can also be red.

The most famous vineyards are on particularly well-drained soils, notably GRAVELS in the Médoc and Graves, and more CALCAREOUS terrain in parts of St-Émilion and Ste-Croix-du-Mont. For more details of local soils and conditions, see under these appellation names.

Climate

The mild climate of Bordeaux is tailor-made to produce mild wines, wines that are marked more by subtlety than power. (It is the vine varieties, described below, which endow the wines with longevity.) Unlike the much more CONTINENTAL climate of inland France or the more arid Mediterranean influence in the south of the country, the vineyards of Bordeaux are heavily influenced by their proximity to the Atlantic, here warmed by the Gulf Stream, and this gentle oceanic regulation of the climate extends well inland, thanks to the wide Gironde estuary. Most years the MARITIME CLIMATE protects the vines from WINTER FREEZE (although February 1956 was so cold that many vines were killed) and spring FROST (although April 1991 was so cold that much of that year's growth was frozen to extinction and the crop much reduced). However, CLIMATE CHANGE has led to greater extremes on all fronts (frost, hail, heat, rain).

Spring is generally mild and damp, providing ample supplies of water for the growing season. Bordeaux's climate is hardly marginal, in that most grapes are usually ripened, but the late-ripening Cabernet Sauvignon may not reach full ripeness everywhere every year, and the region's weather is sufficiently unpredictable that the period of the FLOWERING in June is critical, with unsettled weather, especially cold rain and strong winds, seriously prejudicing the quantity of the forthcoming crop. COULURE and MILLERANDAGE are perennial threats, especially to the Merlot crop, although average rainfall in June is markedly lower than in any other month.

Summers are usually warm, with occasional storms but rarely prolonged rainfall. The forests of the Landes to the south protect the wine districts from strong winds off the Atlantic and help to moderate temperatures, which reach an average maximum of 26 °C/79 °F in August, the hottest month. July is usually the driest and sunniest month. Annual average sunshine is well over 2,000 hours. Increasingly, however, during July and August it can be so hot and dry and the vines suffer such WATER STRESS that the ripening process

stops altogether. HEAT STRESS may be such that vines have to be picked in August. But generally Bordeaux's grapes ripen steadily, swollen by occasional rainfall, until a harvest between mid September and mid October. Rainfall can vary considerably from vintage to vintage and within the Bordeaux region itself, with the Médoc being wetter overall, with an average annual rainfall of 950 mm/37 in.

Excessive rain is the chief hazard at harvest. In the sweet wine areas, on the other hand, humidity is sought in autumn to encourage the spread of NOBLE ROT. It is no coincidence that Bordeaux's sweet white wine districts are clustered together on either side of the Garonne, about 20 miles upstream of the city, where the river Ciron flows into the Garonne. The waters of the Ciron, shaded for most of its length by the forests of the Landes, are invariably cooler than those of the Garonne and encourage the autumn morning mists which promote the BOTRYTIS fungus. In years when these are followed by warm, dry afternoons, the benevolent form of botrytis, noble rot, forms, and great sweet white wine may be made. In damp years the malevolent form, GREY ROT, simply rots the fruit.

Vine varieties

Bordeaux's most famous, and best travelled, grape variety is that on which the Médoc and Graves depend for their red wines, CABERNET SAUVIGNON. Bordeaux's most planted variety by far, however, is MERLOT, which in 2020 occupied 66% of all red vineyards, three times as much as the later-ripening Cabernet Sauvignon. Merlot predominates not just in the famous right-bank appellations of St-Émilion and Pomerol but more importantly also in the Entre-Deux-Mers (BORDEAUX AOC country) and throughout the right bank, in whose damper, cooler soils Cabernet Sauvignon can be difficult to ripen. CABERNET FRANC, also important on the right bank, where it is often called Bouchet, is the third most planted grape variety. PETIT VERDOT is the only other red grape variety of any importance, playing a minor, but in ripe vintages useful, role in the Médoc. Cot, Pressac, or MALBEC is an ingredient in some right-bank wines and, perhaps thanks to its popularity in ARGENTINA, is increasingly mentioned by producers, as is CARMENÈRE, a red grape variety of historical importance in Bordeaux (mentioned for reasons associated with CHILE).

In addition, in reaction to climatic warming trends, the INAO approved in 2021 four more red varieties for use in a limited and regulated basis for BORDEAUX AOC and Bordeaux Supérieur AOC wines: ARINARNOA, CASTETS, MARSELAN, and TOURIGA NACIONAL. Two white varieties, ALVARINHO and LILIORILA, have also been added to the roster.

In the early 1970s, Bordeaux's single most planted grape variety of either colour was SÉMILLON, but it is now much less important except for sweet wine production. SAUVIGNON BLANC is Sémillon's traditional minor blending partner in sweet white bordeaux but is used increasingly for dry white wines, often unblended, and by 2020 was almost as widely planted as Sémillon. SAUVIGNON GRIS is now also allowed in many dry white bordeaux. The only other white grape variety fully sanctioned by the appellation laws is the Bordeaux and Bergerac speciality MUSCADELLE, but small quantities of UGNI BLANC,

COLOMBARD, and Merlot Blanc are also planted and used in white Bordeaux AOC.

In stark contrast to France's other famous fine wine, BURGUNDY, red bordeaux is quintessentially a wine made from a blend of different vine varieties. This is only partly because Merlot and Cabernet are complementary, the flesh of the former filling in the frame of the latter. It is also an insurance policy on the part of growers in an unpredictable climate. Merlot grapes bud, flower, and ripen earlier than Cabernet Sauvignon and are much more susceptible to COULURE, which can seriously affect quantity. Cabernet Sauvignon, on the other hand, ripens so late that a cool, cloudy late summer can seriously affect its quality. Although the ENCÉPAGEMENT, the exact proportions of different vine varieties, varies from château to château, a typical Médoc recipe is 70% Cabernet Sauvignon, 10% Cabernet Franc, and 20% Merlot, while a typical St-Émilion recipe might be closer to 70% Merlot and 30% Cabernet Franc.

Among dry white wines, the recipe is less predictable, although some all-Sauvignon wines are produced. The classic blend for sweet white wines is 80% Sémillon to 20% Sauvignon Blanc. In the wake of the success of Pavillon Blanc de Ch Margaux, an increasing number of white wines have emerged from the red wine country of the Médoc.

Viticulture

With their neat, low rows of densely planted, GUYOT-trained, low-vigour vines, Bordeaux's vineyards are some of the world's most recognizable. Vine TRIMMING is a perennial activity, and VINE DENSITY in less glorious vineyards averages 5,000–6,000 vines per ha, although it is often as high as 10,000 vines per ha/4,000 per acre in the Médoc.

FUNGAL DISEASES thrive in Bordeaux's damp climate, and frequent SPRAYING is a fact of life here. (This may explain why Bordeaux was slow to embrace ORGANIC VITICULTURE, though it has latterly been making up for lost time). The incidence of EUTYPA DIEBACK became a serious preoccupation in the 1980s. BOTRYTIS BUNCH ROT is one of the most common hazards, although in sweet wine districts it is encouraged in its benevolent form as NOBLE ROT. Fertilizers (including manure from specially reared herds at some top properties) and pesticides have played their part in increasing YIELDS. CROP THINNING and selective LEAF REMOVAL during the growing season has been widely employed since the late 1980s—although vignerons are increasingly aware of the hazards of SUNBURN.

The flat, well-drained vineyards submit easily to MECHANIZATION, and, indeed, about 80% of Bordeaux is harvested by MECHANICAL HARVESTING (the top wines, though, are still harvested by hand).

Traditionally the Bordeaux harvest would begin 100 days after the flowering, but the 1990s saw a tendency to leave the grapes on the vine longer to achieve fully ripe PHENOLICS. It has not been uncommon therefore to start picking 110 days or more after the flowering, although a growing trend in the late 2010s was to pick earlier. Grapes for dry white wines and Merlot are in general picked before Cabernet Sauvignon and, especially, grapes for sweet white wines, which may not be picked until November in SAUTERNES.

Bordeaux must be the only region able to command prices high enough to justify hiring HELICOPTERS to agitate cold air during spring

FROSTS or to dry grapes during a wet vintage, as Chx MOUTON ROTHSCHILD and PETRUS have been known to do. Since the difficult vintages of the early 1990s, a high proportion of properties have invested in GRAPE SORTING equipment in order to maximize wine quality.

Winemaking

Winemaking techniques in Bordeaux's top estates are regarded as the paradigm by producers of Cabernet and Merlot wines, and of fine sweet white wines, throughout the world. Under the guidance of BORDEAUX University these techniques underwent considerable modernization in the 1970s and are continually being refined. Émile PEYNAUD in particular led the way towards much more approachable, more concentrated red wines, a trend intensified under the influence of consultant Michel ROLLAND. And the way in which dry white bordeaux is made was revolutionized in the 1980s, notably by Denis DUBOURDIEU.

Red wines Classic vinification of red bordeaux requires time and, because of the size of most top estates, considerable space in which to house the wine as it slowly makes itself (see RED WINEMAKING). The process begins in the vat hall or *cuvier*, then moves to a first-year CHAI in which a year's production is stored in barrel, continues in the second-year *chai*, and increasingly necessitates an area for bottle storage.

Grapes are almost invariably DESTEMMED before crushing and fermented in large FERMENTATION VESSELS, known as CUVES in Bordeaux, which may be made of concrete, stainless steel, or even wood, for between five and ten or more days. Some form of TEMPERATURE CONTROL was installed at most properties in the 1970s or early 1980s and is now widespread. Fermentation temperatures are generally slightly higher in Bordeaux than in the NEW WORLD, with 30 °C/86 °F a common maximum during fermentation, although this is trending lower for more gentle EXTRACTION. The concentration of PHENOLICS in ripe Bordeaux Cabernet Sauvignon grapes is such that the precise techniques of extraction are an extremely important aspect of vinification. Much modern research is concentrated on the relative merits of various PUMPING OVER regimes, usually several times a day. The post-fermentation MACERATION is therefore seen as crucial by most winemakers, who allow the newly made wine at least a week and sometimes much longer 'on the skins'.

Some degree of CHAPTALIZATION was long commonplace, and generally well judged, in Bordeaux, although there has been some experimentation with CONCENTRATION techniques, including both osmosis and reverse osmosis, since the early 1990s. Ambient YEASTS are common.

After fermentation and maceration, the FREE-RUN wine is racked off the solids into another large vessel, either by PUMP or, in the most meticulously or fortuitously designed properties, by gravity (see WINERY DESIGN). If the free-run wine is drained into a lower tank, the

volume of harsher PRESS WINE can be reduced from more than 15% to about 10%, and the wine tastes softer and riper.

After, and increasingly before, MALOLACTIC CONVERSION, the wine is racked into BARRELS made of French OAK, with the typical Bordeaux barrel being called a BARRIQUE. The luxury of new barrels was introduced only in the 1980s, and the proportion of new barrels used even at top estates tends to be lower than in the most lavish New World wineries: rarely more than 60%, and even lower in less ripe vintages. Traditionally, during the first year the wine is racked off its LEES into a fresh barrel every three months or so, as well as being clarified by egg-white FINING. Unless the property is unusually small, the wine is generally moved to a separate second-year *chai*, where it remains until the wine is blended immediately prior to BOTTLING, usually in early summer. The wine then undergoes the all-important period of AGEING in bottle, although this is likely, depending on the state of the market, to take place in the cellars of the BORDEAUX TRADE, the wine merchant, and, most typically, the consumer.

The ASSEMBLAGE is a crucial operation of selection, generally undertaken in the first few months after fermentation, during which it is decided which lots of wine will be blended to form the principal GRAND VIN for that year, which lots will form the SECOND WINE, and which may be sold off at an even lower level, either in BULK or in bottle. In less successful years, less than half of the wine produced on an estate might be selected for the *grand vin*. The actual blending may take place at any time up to bottling, according to the producer's preference. MICRO-OXYGENATION became increasingly popular in the 21st century, being especially useful for preparing early SAMPLES for the all-important annual tastings (see EN PRIMEUR) which determine the reputation of each vintage.

The procedure above is that followed by the CLASSED GROWTHS and those who aspire to that quality level. Most wine which qualifies merely as BORDEAUX AOC is more likely to be fairly ruthlessly filtered than fined and is not given any BARREL MATURATION but is bottled after

a few months in tank. Some PETITS CHÂTEAUX may well treat their wines to a stint in barrique, but such barrels are likely to be hand-me-downs from other properties.

For Bordeaux's exclusively red-wine appellations, see MÉDOC, HAUT-MÉDOC, ST-ESTÈPHE, PAUILLAC, ST-JULIEN, MARGAUX, LISTRAC, MOULIS, ST-ÉMILION, POMEROL, FRONSAC, and some of the Côtes de Bordeaux (see BORDEAUX, CÔTES DE).

Dry whites WHITE WINEMAKING is relatively unremarkable in Bordeaux, except that the region was one of the last in France to cling to high doses of SULFUR in finished dry wines (perhaps because of its long history of turning its white grapes into sweet wines, which do need more sulfur), and in the upper echelons of white Graves and Pessac-Léognan BARREL AGEING has one of the longest histories in the world. Bordeaux is also the home of cryomaceration, whereby additional flavour may be imbued by pre-fermentation SKIN CONTACT at low temperatures, known here as *macération pelliculaire*.

For Bordeaux's principal dry white wine appellations, see PESSAC-LÉOGNAN, GRAVES, ENTRE-DEUX-MERS, BLAYE, and BORDEAUX AOC.

Sweet whites Bordeaux's sweet white wine appellations are, in very approximate descending order of quality, SAUTERNES, BARSAC, STE-CROIX-DU-MONT, LOUPIAC, CÉRONS, CADILLAC, PREMIÈRES CÔTES DE BORDEAUX, GRAVES Supérieures, STE-FOY CÔTES DE BORDEAUX, Côtes de Bordeaux ST-MACAIRE, and Bordeaux Supérieur (for which see BORDEAUX AOC).

Basic sweet white bordeaux, often described as *moelleux*, is a simple, sugary wine for which demand is falling. It is typically made by stopping the alcoholic FERMENTATION once it has reached the level of sweetness required. (See RESIDUAL SUGAR.) This is generally achieved by a combination of techniques: chilling, SULFUR DIOXIDE addition, and sterile FILTRATION. Winemakers in Sauternes and Barsac, however, as well as their more ambitious counterparts elsewhere, aim to make very rich BOTRYTIZED wines from grapes at the full limit of ripeness, which may be described as LIQUOREUX. This involves a considerably more painstaking winemaking regime, even more dependent than any other on events in the vineyard, which is described in SAUTERNES. The wine's selling PRICE, which in the 20th century was depressed by the whims of FASHION, may also play a part in determining whether its maker is able or prepared to take the risks involved in trying to maximize ripeness of the grapes. Bordeaux, Côtes de, group of appellations on the right bank of the Garonne that brings together the (mainly red) wines of five smaller regions. The first Côtes de Bordeaux vintage was 2009, and by 2020 the vineyards involved totalled 10,556 ha/26,083 acres. The group comprises CADILLAC CÔTES DE BORDEAUX and CASTILLON Côtes de Bordeaux, which apply specifically to red wines; BLAYE Côtes de Bordeaux for both reds and dry whites; and FRANCS Côtes de Bordeaux and Ste-Foy Côtes de BORDEAUX for reds as well as dry and sweet whites. The appellation Côtes de Bordeaux *tout court* applies to any wine made from one or more of these geographically specific appellations, has slightly less strict requirements than them, and is generally used by merchants rather than individuals. These wines tend to have more personality than regular BORDEAUX AOC, the result perhaps of local pride, and can provide some of Bordeaux's better wine values.

Côtes de Bordeaux-ST-MACAIRE applies to white wines made in an enclave across the Garonne from the town of Langon. See also BOURG, GRAVES DE VAYRES, and STE-FOY CÔTES DE BORDEAUX.

J.R. & J.L.

Bordeaux, University of, university complex whose Faculté (formerly Institut) d'Oenologie is a centre of oenological ACADEME of world renown. Viticultural research is conducted under the auspices of the Institut National de la Recherche pour l'Agriculture, l'Alimentation et l'Environnement (see INRAE) and Bordeaux Sciences Agro, the agricultural university of Bordeaux.

The institute was founded in 1880 (the same year as the research institute that was to become the University of California at DAVIS) as a mere *station agronomique*, when Ulysse Gayon, the sole Professor of Chemistry at the associated University of Bordeaux, became its director.

Gayon had studied and worked with Louis PASTEUR, the founder of scientific OENOLOGY. He considered the *station*'s function to be the promulgation of sound methods of making and maturing wine. In

addition to his contributions to the ANALYSIS of wines, he worked with Alexis Millardet on the development of the copper-based vine treatment designed to combat FUNGAL DISEASES which was to be known as BORDEAUX MIXTURE.

During the 40 years Gayon directed the *station*, its tradition of identifying the practical applications which could be made from research results was established, as was the importance of transmitting information to winemakers in unscientific language.

From 1927 the most significant research in the world on wine and related subjects was carried out at the University of Bordeaux through a collaboration between Jean RIBÉREAU-GAYON, the grandson of Ulysse Gayon, and Émile PEYNAUD, who did not officially join the University until 1949. From 1949, when Jean Ribéreau-Gayon became director of the *station*, the results of basic and extensive research became apparent to winemaker and consumer alike. Chromatography provided legally convincing evidence of the use of HYBRIDS in any wine sample and encouraged their replacement by VITIS VINIFERA vine varieties in the vineyards of Bordeaux and other French winegrowing regions, thereby greatly improving the quality of BORDEAUX AOC and other French wines. At the same time, the understanding of the process of MALOLACTIC CONVERSION gave wine producers the knowledge they needed to control a fundamental step in winemaking and gave them much greater control over the style and quality of the wines they made. Research into the influence of TERROIR on wine style and quality has been conducted at Bordeaux since the early 1960s.

The importance of the education of OENOLOGISTS was officially recognized in 1956 with the creation of an École Supérieure d'Oenologie empowered to award a winemaker's diploma. This became the Institut d'Oenologie in 1963, which was transformed into the Faculté d'Oenologie in 1995. During this period oenology achieved full recognition as a new science, and in 1971 the institute formally became part of the university, its work and educational titles enjoying full academic status. From 1977 to 1997, the work of the

institute continued under the direction of Pascal Ribéreau-Gayon, the son of the previous director.

In 2009, the Faculté merged with Bordeaux Sciences Agro and part of INRA to form the ISVV, which encompasses a high level of research and academic training in both oenology and viticulture.

The Faculté is currently engaged in research on subjects which vary from explorations of the nature and effects of different YEASTS to investigations into TANNINS and the characteristics of different families of aroma compounds. The most significant result of research in the 1980s was arguably the dramatic improvement in aroma and subtlety of dry white bordeaux, in which field Denis DUBOURDIEU deserves much credit.

In addition to training oenologists who make wine throughout the world and belong to what is outside France referred to as the 'Bordeaux school' of winemaking, the Faculté supervises doctorates on vinous subjects and is one of only two French organizations to enjoy this privilege, along with SupAgro Montpellier (see INRAE). A prominent feature of the professional training at the Faculté is the importance attached to tasting wines and analysing their characteristics. Since 1949 the Faculté has also given tastings and lectures for growers and cellar workers without scientific training, particularly through the Diplôme Universitaire d'Aptitude à la Dégustation (DUAD), which is one of the world's most in-depth courses in wine TASTING. C.v.L.

Bordeaux AOC. The most important sort of wine produced in Bordeaux, quantitatively if not qualitatively, is that which qualifies for the simple appellation Bordeaux. About half of all the AOC wine produced in the region is on this lowest rung of the ladder of quality. Red Bordeaux AOC was produced from 51,399 ha/127,000 acres of vineyard in 2020. Such wine is typically produced outside the more specific commune or regional appellations, although a great deal of red Bordeaux AOC comes from the ENTRE-DEUX-MERS region, whose eponymous appellation applies only to white wine. (A counterpoint to

this is the fact that the appellations of the Médoc apply only to red wines, so that even the Médoc's smartest white wines, such as Pavillon Blanc du Ch MARGAUX, are not allowed any appellation grander than Bordeaux AOC. Similarly, dry white wines made from grapes usually grown for SAUTERNES qualify only for Bordeaux AOC.) The other area with the greatest concentration of vineyard dedicated to the production of Bordeaux and Bordeaux Supérieur is that north of Libourne, where Merlot grapes predominate.

The great majority of Bordeaux AOC produced is made, often by CO-OPERATIVES, to be sold for blending anonymously into humble GENERIC wines of very varying quality, but there are also some individual properties, so-called PETITS CHÂTEAUX, which lie outside any grander appellation but which express their own TERROIR and practise CHÂTEAU BOTTLING. Almost 90% of all Bordeaux AOC produced is red, and the white, if sweet, may be labelled Bordeaux Moelleux. Made from the same area, Bordeaux Supérieur is a generally more concentrated, ambitious wine than Bordeaux AOC with base yields 50 rather than 55 hl/ha that has been aged for at least 10 months. About three times as much Bordeaux AOC Rouge is made as Bordeaux Supérieur, or 'Bord Sup' as the BORDEAUX TRADE call it. Also included in the generic Bordeaux AOC appellation are the relatively rare Bordeaux Rosé and slightly deeper-coloured Bordeaux Clairet as well as the bottle-fermented sparkling wine CRÉMANT de Bordeaux. Bordeaux Haut-Benauge is the name given to the small amount of white wine, both dry and sweet, made in an enclave just across the Garonne from Langon (see also ENTRE-DEUX-MERS).

Most of these wines are designed to be drunk within a year of bottling if white, rosé, or CLAIRET and within two or three years if red. The better examples are unmistakably lighter versions of Bordeaux's grander wines, while the worst can taste like homeless PLONK. With the exception of the best Bordeaux Supérieur reds, few producers can afford to age these wines in OAK, and even fewer of the wines have the concentration to benefit from it, especially since expensive viticultural techniques such as CROP THINNING are hard to justify at this

price level, although exceptions are becoming more numerous. Most of the Bordeaux BRANDS are Bordeaux AOC, most notably MOUTON CADET, which started off life with the much grander and more specific appellation of PAUILLAC.

Bordeaux blend, usually a red wine made up of some or all of CABERNET SAUVIGNON, CABERNET FRANC, MERLOT, PETIT VERDOT, and possibly MALBEC and CARMENÈRE. Its white wine counterpart is made from SAUVIGNON BLANC, SÉMILLON, and possibly SAUVIGNON GRIS and MUSCADELLE. See also MERITAGE.

Bordeaux mixture, *bouillie bordelaise* in French, the much-used mixture of lime, copper sulfate, and water first recorded in 1885 by Alexis Millardet, Professor of Botany at BORDEAUX University, as an effective control of DOWNY MILDEW. Use of the mixture was a historic event since it was to become the most important chemical for the control of both FUNGAL DISEASES and BACTERIAL DISEASES for 50 years. There are now alternative FUNGICIDES, many of them containing copper, but it is still used today by very traditional growers in some regions, and it is one of the few preparations permitted in ORGANIC VITICULTURE and BIODYNAMIC VITICULTURE.

There is some debate as to how the treatment was discovered. It was common for Bordeaux vignerons to spray the outside vineyard rows with the blue-staining copper sulfate to deter thieves. No doubt it was noticed that this practice halted the devastation caused by downy mildew which had begun in 1883. Continued use of Bordeaux mixture can lead to accumulation of COPPER in the soil, which can reach toxic levels especially in acidic soils. Some vineyards affected by copper toxicity in the Bordeaux area and elsewhere are much reduced in vigour and production, but the problem can be overcome by adding LIME to the soil. Also, copper sprayed within 14 days of harvest can produce browning, turbidity, and SULFIDE characters in the wine and can result in incomplete FERMENTATIONS. R.E.S.

Bordeaux trade. The sheer quantity of wine produced in Bordeaux, the fact that so much requires AGEING, and the historical importance of Bordeaux as a port (see BORDEAUX, history), mean that its wine trade is more stratified than most—even if wine is no longer the city's economically most important commodity.

Bordeaux wines have always been produced by one category of people and sold by another. The wine producers of the region range from world-famous estates with 200 ha/500 acres under vine to owners of 2.5 ha or less, whose grapes are delivered to one of the region's wine CO-OPERATIVES.

The wine merchants, or NÉGOCIANTS, traditionally brought most of the wines they bought into their CHAIS in or around Bordeaux (notably its Quai des Chartrons) to be matured and shipped out to export customers, particularly in Britain and northern Europe, either in barrels or after bottling. They were joined in the early 20th century by merchants in LIBOURNE, who concentrated especially on France and Belgium (see POMEROL).

So great was the quantity of wine to be traded that numbers of middlemen were needed between producers and the merchants, of whom professional brokers, or *courtiers*, such as Tastet & Lawton have become an essential part of Bordeaux's vinous commercial structure. There were 77 of them in 2021. What the merchant supplied originally in addition to the mere buying and selling of wine was technical ability (the cellarmasters' teams were likely to be considerably better technicians than those of the producers) and financing for the grower.

This three-tier way of distributing a large quantity of wine to customers all over the world, known as La Place de Bordeaux,

changed considerably after 1945, when even some of the FIRST GROWTHS were still made available to the merchants in BULK, and most of the CLASSED GROWTHS have since 1959 been sold to the merchants on the condition that they are CHÂTEAU BOTTLED.

Since 1945, improvements in winemaking at all levels and, since the 1980s, PRICE increases and inflation levels which have made it impossible for even the biggest merchants to finance large quantities of wine have tended to transform the role of the merchant from principal to broker—certainly for the wines traded EN PRIMEUR. The balance of financial power between the 300 merchants and the 100 or so most significant proprietors, changing over time according to vintage quality and quantity and international demand, in the 21st century shifted in favour of the producers who increasingly became stockholders.

Things are very different at the bottom end of Bordeaux's highly stratified community of wine producers. A huge SURPLUS of AOC Bordeaux and uneconomic selling prices led to demands in 2022 for subsidies to encourage the GRUBBING UP of the region's less glamorous vineyards, even though the wine they produce has improved enormously, partly thanks to CLIMATE CHANGE. Some of this wine finds its way into BRANDS, typically developed by the bigger merchants.

The Bordeaux FINE WINE trade is increasingly involved in selling direct to and STORING WINE for the consumer, having constructed many substantial wine warehouses around the city's fringes. For examples of specific Bordeaux merchants, see BARTON and MOUEIX.

Bordo, occasional Romanian name for CABERNET FRANC and sometimes used in north-east Italy for CARMENÈRE.

bore, wine. For some reason, wine bores exist in public consciousness and, it has to be said, in reality in a more vividly pestilential way than art bores, music bores, or even sport bores. Perhaps this is because for most people wine is associated with sensual pleasure rather than analysis and verbal communication, and so their wine-related boredom threshold is low. So far, wine bores are usually men, although women wine bores may be an eventual consequence of greater female financial emancipation. One woman's wine bore can be another person's wine expert, however.

borers, usually BEETLES or their larvae, which bore into the woody parts of plants, sometimes killing them. The branch and twig borer, *Melalqus confertus*, occurs throughout California and parts of Oregon and damages grape CANES. Control is usually by cultural methods, by keeping vines healthy, and by PRUNING off all dying and dead parts and infested wood in winter. Beetle larvae causing problems to vineyards can be quite regionally specific. The fig longicorn (*Dihammus vastator*) beetle larvae causes vine damage only in the Hunter Valley region of Australia, for example. M.J.E.

boron, a MINERAL element required in minute quantities for healthy vine growth and thus called a micronutrient. Boron deficiencies in vines are commonly found in sandy soils where SOIL ACIDITY and RAINFALL are high. Boron is required for the movement of SUGARS and the synthesis of AUXINS in the plant. A major effect of boron deficiency is poor FRUIT SET and MILLERANDAGE caused by the effect of this deficiency on POLLEN tube growth affecting germination, which can result in substantial reductions in YIELD. Bunches on boron-deficient vines often have many small berries, which may lead to uneven ripening (see BERRY SIZE).

Boron toxicity is also possible, sometimes due to over-application of FERTILIZER. Excess boron can, coincidentally, also come from bore water used for IRRIGATION. R.E.S.

Borraçal, synonym for Galicia's CAIÑO Tinto in Portugal's Vinho Verde region, where it makes tart reds.

Borrado das Moscas, the DÃO region's name for the Portuguese variety BICAL.

Bosco, grown on just 42 ha/104 acres of LIGURIA, can make exciting sweet amber wine.

Bosnia and Herzegovina is an independent federal republic since 1992, previously part of YUGOSLAVIA. Located on the western Balkan peninsula with just 12 km/7.5 m of Adriatic coastline and high central mountains, it is divided into the Federation of Bosnia and Herzegovina (FBiH) and Republika Srpska (RP), plus the district of Brčko. Each has its own constitution, and no single administration oversees the wine industry. Viticulture zoning dates to 1984 and identifies six wine districts in two regions: Sjeverna Bosna (Kozaračko, Ukrinsko, Majevičko districts) and Herzegovina (Mostarsko, Lištičko, Jablaničko districts). 'Middle Neretva' is used on export labels to the EU and US for wines from the Mostar area.

Data from the Federal Institute for Statistics for FBiH indicate approximately 4,000 ha/9,884 acres of vineyards in FBiH, producing 42,357 tonnes of grapes in 2020 and 76 registered wine producers. The Ministry for Foreign Trade estimated a further 600 ha/1,483 acres in RP in 2018, producing 5,000 tonnes. Approximately 55% of production is white, led by INDIGENOUS VARIETIES in FBiH but international grapes in RP. Estimates suggest 1,000 growers but only 200 with more than 2 ha. The devastating war between 1992 and

1995 scarred the wine industry, but it is recovering strongly in terms of quality, if not quantity, helped by developing TOURISM.

Herzegovina is by far the most important wine region, especially around Mostar. The CALCAREOUS karst landscape is stony and dry, and summer temperatures can reach 40 °C/104 °F. Plantings are dominated by drought-tolerant indigenous varieties led by ŽILAVKA. It can produce high-quality, aromatic white wine with generous body and good acidity, and that can age well. Records for this variety go back 600 years to the time of Bosnian King Tvrtko. Other local white-wine grapes include Krkošija, Bena, and SMEDEREVKA. Red-wine varieties are dominated by local Blatina, a female variety that requires a cross-pollinator and is usually interplanted and blended with Kambuša (ALICANTE BOUSCHET), Trnjak, Merlot, or occasionally VRANAC. Several producers have revived Trnjak as a varietal wine as it has more depth and structure than Blatina. The cooler, northern Sjeverna Bosna vineyards usually grow INTERNATIONAL VARIETIES including Cabernet Sauvignon, Merlot, and Temjanika (MUSCAT BLANC À PETIT GRAINS). C.G.

www.wineroute.ba

botanical classification, a system of classifying plants—including vines, but also YEASTS and the organisms responsible for FUNGAL DISEASES of the vine—which shows their relationship one to the other and allows them to be uniquely described and identified. The basic unit of classification is the species; related species are sometimes grouped into genera (plural of genus); related genera into families; and related families into orders. In turn, species can be divided into subspecies, when different types have developed

naturally, and into varieties, or occasionally cultivars (a contraction of cultivated variety), when different types have been selected by human hands. VINE VARIETIES can be further divided into three PROLES, according to their geographical origins. Different CLONES of individual varieties have also been selected. The International Code of Nomenclature for algae, fungi, and plants (ICN) regulates the naming of plants and other organisms treated like plants.

Kingdom
Order
Family
Genus
Species
Variety
Prole
Clone

Recent DNA PROFILING has considerably modified the earlier classifications created by botanists; although there are still some controversies, current consensus according to the Angiosperm Phylogeny Group of international systematic botanists is that GRAPEVINES belong to the order Vitales, comprising the Leeaceae family, which consists mostly of shrubs, and the Vitaceae family, which consists of approximately 13–17 genera and about 900 species primarily distributed in tropical regions in Asia, Africa, Australia, the neotropics, and the Pacific islands, with a few genera in temperate regions (*Vitis*, *Parthenocissus*, and *Ampelopsis*).

Most of the plants are climbers and have tendrils opposite leaves on the shoots, the grapevine being representative. Wen et al., using PHYLOGENETIC analyses, list 16 genera in this family, including *Vitis*; the largest genus is *Cissus* with about 300 species, from succulent species such as cacti to the lianas of tropical jungles. *Ampelopsis* and *Parthenocissus* are two more genera closely related to each other and are observably similar to grapevines. Ornamental plants related to the

grapevine include the Virginia creeper in the US and Europe, the kangaroo vine in Australia, and Japanese ivy and Crimson Glory in Japan. (A complete list of genera and species and their distribution is given in Wen et al.)

The grapevine genus VITIS, created in 1700 by Tournefort, comprises about 60 species, including VITIS VINIFERA, first studied by Linnaeus in 1735. The full botanical binomial of the most common wine-producing vine species is therefore *Vitis vinifera* L., often abbreviated to *V. vinifera* or (botanically incorrectly) *vinifera* (the first person to describe the species often being listed, usually as initials, after the scientific name). Another convention is the use of Latin, often confected, and italics.

The genus *Vitis*

The *Vitis* genus has traditionally been divided into two distinct sections called *Vitis* (previously *Euvitis*) and MUSCADINIA, and this has been confirmed by DNA classification. The two sections may be differentiated not only on the basis of appearance but also by chromosome number. *Muscadinia* has 40 chromosomes while *Vitis* has only 38. (This is a frustration to VINE BREEDERS, who would welcome ready access to the many pest- and disease-resistant genes of *Muscadinia*.)

Most *Vitis* species are native to North America (see AMERICAN VINE SPECIES) and Asia. The common wine grape species *Vitis vinifera* is native to Europe and the Near East and is commonly divided into two subspecies, the wild *Vitis vinifera* subsp. *silvestris* and the cultivated *Vitis vinifera* subsp. *sativa*. The latter shows great diversity as a result of selection and cultivation by people, and three basic eco-geographic groups of varieties, or proles, were created by Russian ampelographer Negrul in 1938 (*occidentalis*, *pontica*, and *orientalis*), reflecting differences between origin and end use. Each prole contains numerous grape varieties (or cultivars), for example 'Cabernet Sauvignon', which are themselves subdivided into numerous clones. (Botanists put the names of varieties in inverted commas.) See VITIS and VITIS VINIFERA for more details. The full botanical classification of Cabernet Sauvignon might therefore be: order Vitales, family Vitaceae, genus *Vitis*, section *Vitis*, species *vinifera*, proles *occidentalis*, variety 'Cabernet Sauvignon', clone INRA BX 5197. Botryosphaeria dieback, FUNGAL DISEASE affecting the TRUNK and ARMS of the vine caused by a range of 22 species from different genera in the family Botryosphaeriaceae. It is the most widespread TRUNK DISEASE, causing loss of production in both newly planted and mature vineyards. Botryosphaeriaceae fungi primarily infect vines through pruning wounds but can also be found as latent pathogens in NURSERY-propagated material. Virulence depends on the species, but the most characteristic symptoms of the disease are perennial cankers in the wood (typically wedge-shaped) and lack of spring growth. Other symptoms include black or light-brown streaking of the XYLEM vessels, graft failure, cane bleaching, cane dieback, shoot NECROSIS, and bud necrosis. In some grape-growing regions, several Botryosphaeriaceae species are also thought to be involved in causing BUNCH ROTS. Management strategies primarily involve the protection of pruning wounds using either synthetic FUNGICIDES or BIOLOGICALS. More extreme management strategies include CURETTAGE and TRUNK RENEWAL. botryticine. See NOBLE ROT.

botrytis, without the capital B it botanically deserves, is commonly used as an abbreviation for BOTRYTIS BUNCH ROT, for the fungus that

causes it *Botrytis cinerea* Pers, for its benevolent form NOBLE ROT, and occasionally for its malevolent form GREY ROT. Grapes affected by noble rot and the wines produced from them are often called BOTRYTIZED, or botrytis-affected.

Elad, Y., et al. (eds.), *Botrytis: Biology, Pathology and Control* (2007).

botrytis bunch rot, vine disease which, of all FUNGAL DISEASES, has the greatest potential effect on wine quality. The disease can also have a disastrous effect on YIELD when the fungus affects almost-ripe grapes. This malevolent form is known as GREY ROT, the most common of the BUNCH ROTS. On the other hand, if it affects ripe, healthy, light-skinned grapes and if weather conditions are favourable, botrytis can develop in a benevolent form called NOBLE ROT, which is responsible for some of the world's finest sweet wines. If it affects red grapes, it always damages PIGMENTS, resulting in wines with a brownish tinge and, often, off-odours associated with rot.

Botrytis rot is a problem especially for vineyards in damp climates. Rainfall near harvest can result in severe disease and thus be a major factor affecting the yield and quality of a particular vintage (as regularly happens in both BURGUNDY and BORDEAUX, for example).

Botrytis spores germinate primarily on wet surfaces. Optimal infection temperatures are 15–25 °C/59–77 °F. The botrytis fungus is most prone to develop within highly succulent, injured, or senescing plant tissues (such as ripening grapes). Berries can become infected soon after their formation, when the fungus attacks withering flower parts and grows into the nascent fruitlet, but natural defences in the expanding green berry then stop any further fungal development. Most of these early infections remain latent and harmless through harvest, but a portion can become active and rot that berry as it becomes ripe, providing a source for rapid disease spread as berries ripen near harvest. An especially common source of initial pre-harvest

disease is infected blossom parts that are shed from developing healthy berries but become trapped within the enlarging bunches at BUNCH CLOSURE, providing a platform from which the fungus can later grow directly into the ripening berries at points of contact as they become susceptible near harvest. Initial infections also can develop post-VERAISON when fungal spores, carried by air currents or insects, germinate and infect through the broken berry skin following wounds caused by bird pecks, insect damage, mechanical abrasion, or bursting, when berries within tightly compressed clusters continue to swell with no room to expand, especially when vines takes up water rapidly after rainfall.

Disease spread from these initial sources can be explosive as the fungus grows from one berry to the next in tightly compressed clusters but is much less severe in looser clusters. If the weather turns dry, infected berries tend to dry out, and major changes to the fruit's chemistry can result in grapes suitable for classic BOTRYTIZED wines influenced by noble rot. In continuing wet weather, however, the fungus rapidly spreads as grey rot, and the grape crop can literally rot before the owner's eyes. This explains the urgency of harvest when rot begins to establish itself and weather conditions are conducive to its spread. If the grapes have to be harvested early, the wines are typically lower in alcohol and complexity. Although pre-harvest grey rot is by far the most destructive form of botrytis infection, during prolonged wet springs it can also blight young succulent shoots and emerging flower clusters, which fall off with obvious effects on yield.

Vine varieties, and indeed various CLONES of individual varieties, differ markedly in their susceptibility to botrytis, depending especially on how tightly packed the berries are in the bunch but also on the thickness of the skin and perhaps to some extent on varietal differences in natural defence responses. Varieties with compact bunches of high sugar content are the most susceptible, including Sémillon, Sauvignon Blanc, Muscadelle, Carignan, Pinot Noir, and Merlot. Chardonnay is moderately susceptible and Cabernet Sauvignon quite tolerant.

Modern control measures take two complementary forms: cultural practices and spraying. CANOPY MANAGEMENT practices that avoid excessive leafiness around the bunches, such as LEAF REMOVAL and certain trellis designs, are most useful, providing better exposure to sun and wind to dry the fruit after rain or dew. CROP THINNING can also help. Various practices to reduce FRUIT SET and thus cluster compaction, including pre-bloom leaf removal and applications of plant growth regulators, have been very effective in some situations but have drawbacks that limit widespread adoption. In New Zealand, MACHINE HARVESTERS are used just after fruit set to shake the vine and dislodge infected blossom 'trash' that could otherwise get trapped within bunches and start a pre-harvest epidemic; research shows that this simple practice often reduces disease severity by half.

Chemical control using a FUNGICIDE is the second route and widely practised where the disease is problematic. The number of spray applications required depends on the climate. In some wet regions, up to half a dozen or more may be needed, beginning at FLOWERING and ending before harvest. The last sprays cannot be applied too close to harvest as yeast activity during FERMENTATION may be inhibited by some chemical RESIDUES, quite apart from considerations of potential health risks. Warning systems based on temperature and/or relative humidity have been developed to predict epidemics and help determine the need and timing for sprays. While several categories of fungicides are now used for botrytis control, the fungus has developed resistance to some after only a few years of use, forcing growers to rely increasingly on non-chemical options.

Multiple BIOLOGICAL control products have been marketed recently, with new ones in development. These include specific fungi antagonistic to or competitive with the botrytis fungus; bacteria that produce antifungal compounds; and bacteria, plant extracts, and crushed crustacean shells that purportedly induce natural defence responses by the vine. However, biological controls are variable in their efficacy, and even the best ones must be used in concert with appropriate cultural practices to provide significant benefit.

Botrytis is also a problem for stored TABLE GRAPES and during GRAFTING operations in nurseries.

See GREY ROT and NOBLE ROT for more details of the two different forms of botrytis. For details of how nobly rotten grapes are transformed into wine, see BOTRYTIZED wines. R.E.S. & W.W.

botrytized, or botrytis-affected, wines are those made from white grapes affected by the benevolent form of BOTRYTIS BUNCH ROT, known in English as NOBLE ROT. Distinctively scented in youth, and with considerably more EXTRACT than most wines, they are the most complex and longest lived of all the sweet white table wines. The noble rot smell is often described as honeyed, but it can also have a complex range of aromas including bitter orange, apricot, almond paste, and a certain type of glue.

History

There is no firm evidence that botrytized wines were recognized in antiquity, although Olney points out that a particularly fine ancient Greek wine produced on Chios (see CHIAN) in the 5th century BCE is described as *saprian* by ATHENAEUS, and that the literal translation of this may be 'rotten, putrid'. Noble rot is much more likely to occur in more humid climates than in the MEDITERRANEAN CLIMATE of the Aegean Islands, however, and the extremely unpleasant appearance of grapes infected by noble rot, and the difficulty with which they ferment, must have deterred many early winemakers.

Three important centres of botrytized wine production have their own accounts of the discovery that this particular sort of mouldy grape could be transformed into exceptional wine.

That of the TOKAJ region of north-east Hungary dates from at least 1650 when the priest-cum-winemaker on a particular estate there delayed the HARVEST because of the threat of attack by the Turks. This allowed the development of noble rot; the grapes were vinified separately, as one would expect, and the resulting wine much admired. For diplomatic purposes it was introduced to the French court in the early 18th century, long before French vine-growers had recognized the existence of the noble fungus.

In Germany, the principle of picking selected bunches of grapes (AUSLESE) was understood in the 18th century, but that of the widespread picking of grapes affected by noble rot not until about 1820. In spite of popular beliefs to the contrary, precisely when and where vine-growers first realized the value of noble rot is not certain, although the discovery in Germany is thought to have been in the particularly suitable climate of the Rheingau, which became most famous for botrytized wines. SCHLOSS JOHANNISBERG has certainly promulgated its own claim that in 1775 the traditional harvest messenger—licensed, as usual, to deliver permission to pick from the owner, the distant prince-abbot of Fulda—was delayed, thereby

supposedly allowing a noble-rot infection to proceed and resulting in Germany's first botrytized SPÄTLESE.

The sweet wines of Bordeaux and the Loire were much treasured in the Middle Ages, particularly by the DUTCH, but without any specific mention of a special fungus or acknowledgement of any special attribute. The principal French legend concerning the 'discovery' of noble rot—and legend it is widely believed to be—dates from as recently as 1847, at Ch d'YQUEM (although the quality, style, and youthfulness of earlier vintages of Yquem, such as the 1811, suggest that noble rot must have played an important part in wine production there before that date).

The risks and costs involved in making naturally botrytized wine make it necessarily expensive. It has therefore been an economical proposition only when sweet wines are highly valued. Germany's botrytized wines have always been regarded as precious rarities for which a ready market can be found within Germany. France's output of botrytized wines is potentially much greater, but when sweet wines were out of FASHION in the 1960s and 1970s, enthusiasm for producing them inevitably waned, only to be rekindled in the 1980s. In the 21st century, botrytized wines suffer from the more widespread lack of demand for very sweet wines.

Geography and climate

Many conditions have to be met before botrytized wines can be produced. Not only is a MESOCLIMATE which favours misty mornings and warm afternoons in autumn needed, but producers must have the knowledge and the will to sacrifice quantity for nothing more certain than possible quality. Botrytized wines are very much a product of psyche as well as nature.

The district with the potential to produce the greatest quantity of top-quality botrytized wine is SAUTERNES (although it all depends, as everywhere, on the precise WEATHER of the year). The confluence of the Rivers Ciron and GARONNE provide an ideal mesoclimate for the satisfactory development of noble rot. Nearby sweet white wine districts CÉRONS, LOUPIAC, CADILLAC, and STE-CROIX-DU-MONT may also produce small quantities of botrytized wines, although the price fetched by these appellations rarely justifies the additional production costs.

Botrytized wine is also made by the most meticulous producers in MONBAZILLAC and SAUSSIGNAC. With viticultural commitment and skilful vinification, these districts can make botrytized wines to rival all but the very best Sauternes made similarly from Sémillon, Sauvignon, and particularly Muscadelle grapes. One or two fine examples of this style have also emerged from GAILLAC.

On the River Loire, appellations such as Coteaux de l'AUBANCE, Coteaux du LAYON, QUARTS DE CHAUME, BONNEZEAUX, MONTLOUIS, and VOUVRAY can produce botrytized wines in good years, and they are given even greater ageing potential for being made from the acidic Chenin Blanc grape.

Botrytized wines may also be made from such varied grapes as Mâconnais Chardonnays and Alsace Rieslings in exceptional years.

Germany is the other famous source of botrytized wines, usually labelled BEERENAUSLESE or TROCKENBEERENAUSLESE, although the quantities made vary enormously according to vintage. Riesling is the classic grape, although some of the GERMAN CROSSES can be

persuaded to rot nobly in an exceptionally suitable year. Noble-rot infections are much more reliable in the BURGENLAND district of Austria, where, thanks to the influence of the NEUSIEDLERSEE, considerable quantities of botrytized Beerenauslesen and Trockenbeerenauslesen are made most years. Over the border in Hungary, TOKAJ is still closely associated with botrytized winemaking, as various parts of ROMANIA, notably COTNARI, once were.

Botrytized winemaking is an embryonic art in Italy, Spain, and most of Portugal, where producers and consumers tend to favour either DRIED-GRAPE WINES or FORTIFIED WINES.

Beyond Europe, botrytized wines are made with increasing frequency. Nederburg Edelkeur was a South African prototype which enjoyed international acclaim in the 1970s. Griffith in NEW SOUTH WALES's Riverina was producing Australian botrytized Pedro Ximénez as early as the late 1950s and is now a centre for the production of relatively early maturing botrytized whites, particularly Semillon. In Australia, New Zealand, South Africa, and particularly California, a host of botrytized Rieslings has emerged.

In California in the late 1950s Myron and Alice Nightingale in the Livermore Valley managed to simulate noble rot by growing spores of the botrytis fungus in a laboratory and spraying them on picked, healthy, ripe grapes before subjecting them to alternately humid and warm conditions for a couple of weeks. The result, Premiere Semillon, was followed by a series of similar wines made at Beringer in the Napa Valley. However, Beringer's Nightingale is now made naturally thanks to a vineyard in Calistoga with a suitable mesoclimate for the development of noble rot. Dolce Winery has also been particularly successful with naturally botrytized wines.

As awareness of noble rot and botrytized wines grows, the number of winemakers anxious to experiment also increases, even if the market is not always rapturous, and they are usually at the mercy of the weather. Even ENGLAND has succeeded in producing botrytized wine.

Vine varieties

Any white grape variety may be infected benevolently by the botrytis fungus; red varieties simply lose their colour and usually develop off-odours. Certain varieties seem particularly sensitive to the fungus and well adapted to the production of botrytized wines, however: Sémillon, Sauvignon Blanc, Chenin Blanc, Riesling, Gewürztraminer, and Furmint are traditional.

Viticulture

The chief viticultural aspect of making botrytized wines is the number of passages or *tries* (see TRI) through the vineyard which may have to be made in order to pick grapes only at the optimum point of botrytis infection, because noble rot is so crucial to quality. See SAUTERNES for a description of the likely routine there. In a year as difficult as 1974 at Ch d'YQUEM (admittedly the most conscientious Sauternes estate), 11 *tries* were made over a ten-week period. In 1990, on the other hand, noble rot spread rapidly and uniformly, and the grapes were picked by early October. In some vintages the spread and quality of botrytis may be so patchy that some estates, for example Yquem, Rieussec, and Suduiraut in 2012, elect not make a GRAND VIN. Hand-picking of these varied but usually disgusting-looking grapes is essential, and the cost of LABOUR is one important element in the price of botrytized wines.

In wet vintages, some producers use modern freeze-concentration techniques known as CRYOEXTRACTION.

Winemaking

If picking botrytized grapes is painstaking, obtaining their juice and persuading it to ferment is at least as difficult because of its composition (see NOBLE ROT). PRESSING is a physically difficult operation, and, contrary to the usual practice, later pressings yield juice superior to the first pressing because it is richer in sugar and the chemical compounds produced by the botrytis fungus. The most dehydrated grapes in the press may not yield juice until they have been pressed twice or three times.

A variety of winemaking methods are used, including the classic method described in SAUTERNES. Fermentation is necessarily extremely slow. The juice seems almost designed to inhibit YEASTS, being so high in sugar and antibiotics such as botryticine. Botrytized musts tend to lack nutrients such as thiamine and ammonia, which is another reason for STUCK FERMENTATIONS. Fermentation may be allowed to stop itself, or SULFUR DIOXIDE addition may be used. Care must be taken that these wines, which often have a RESIDUAL SUGAR level equivalent to about 6% alcoholic strength, do not suffer a SECOND FERMENTATION, and bottling, whether after two winters in new BARRIQUES (as in the top Sauternes properties) or in the following spring (as in the Loire and many German cellars) has to be undertaken with care. Higher levels of sulfur dioxide are needed during vinification and at bottling because the enzyme LACCASE produced by botrytis increases the risk of OXIDATION and is tolerant of high levels of sulfur dioxide. In addition, the chemical composition of botrytized wines means they have significant power to bind sulfur dioxide. This is why EU regulations permit a higher level of total sulfur dioxide for these wines than for all others. The development of *Botrytis cinerea* also results in the production of two POLYSACCHARIDES. One has antifungal properties and inhibits fermentation. The other, a *β*-glucan, can make FILTRATION much more difficult, especially if crushing, pumping, and pressing are carried out harshly.

Some wines, notably those made from aromatic varieties such as Muscat, are marked by a loss of varietal aroma. This is mainly because botrytis metabolizes the MONOTERPENES such as linalool and geraniol that are responsible for the distinctive aromas of such varieties.

Botrytized wines are capable of extremely long AGEING, for many decades in some cases.

botte, Italian word for a large wooden cask, presumably from the same root as BUTT. The plural is botti.

bottle ageing, the process of deliberately maturing a wine after BOTTLING, whether for a few weeks as a conscious effort on the part of the bottler to allow the wine to recover from BOTTLE SHOCK or, in the case of very fine wines, for many years in order to allow the wine to mature.

For more details, see AGEING.

bottle deposit in red wines is a lacquer-like pigmented deposit adhering to the inner bottle surface; it is different from SEDIMENT. This deposition, which may begin in the first few months after bottling, may cover only a small area of the bottle shoulder or may eventually

cover the entire glass surface with which the wine is in contact. Wine quality is not affected by bottle deposit, which is unlikely to occur if the wine has been FINED. The deposit is an insoluble complex polymer of PIGMENTED TANNINS and PROTEIN. P.J.W.

bottle fermented, description of some SPARKLING WINES made either by the traditional method or by the transfer method. See SPARKLING WINEMAKING for full details.

bottles, still by far the most common CONTAINERS for finished wine. Glass bottles are inconveniently fragile and relatively heavy, with a CARBON FOOTPRINT higher than any other form of wine PACKAGING, but, importantly for long-term AGEING, they are inert. A standard bottle contains 75 cl/25 fl oz, although see also BOTTLE SIZES.

History

Today it may be taken for granted that wine bottles of different colours and shapes will hold a precise capacity. Nor is it questioned that a paper LABEL will be firmly fixed to the bottle to give a plethora of information, much of it required by law. These, however, are recent developments.

In classical antiquity wine was stored and transported in large, elongated jars called AMPHORAE. They varied considerably in size and quality, but it would certainly be difficult to pour a drinking quantity from such an awkward vessel without using some sort of intermediate container. After the Romans invented glass-blowing, large numbers of flasks and jugs were made, many almost certainly used to serve wine.

Pottery and stoneware jugs were used for centuries in Europe for serving wine, but glass took over as technology to make glass in commercial quantities spread in the 17th century, and by the end of it glass bottles were plentiful, although reserved for the upper classes.

Shape Records from the 11th and 12th centuries show bottles with globular bodies and long necks known as shaft and globe, used for drinking and serving wine. The form developed (see illustration), becoming lower and wider in Britain, while on mainland Europe the flask-shape with an oval cross-section was popular. From *c.*1690 to 1720, the outline of a bottle resembled that of an onion—a wide compressed globular body with a short neck. Larger bottles were made too, whose shape resembled an inflated balloon or bladder. It is thought that all these forms were stored in beds of sand. By the 1720s the 'onion' became taller and the sides flatter—known by collectors as a 'mallet'. Naturally occurring impurities in the constituent ingredients gave glass an olive green hue which varied from pale to almost black and was beneficial to the bottled wine as it excluded light. Most bottles before 1700 had an applied ring of glass just below the rim which gave an anchorage to the string used to hold in a variety of stoppers. These bottles were of substantial weight and thickness too.

Wine drinkers made an important discovery in the 1730s. While it was known that some vintages of wine were better than others even in prehistory, their keeping and consequent maturing qualities were not realized until the introduction of binning, the storing of wine in bottles laid on their sides (see BIN). The effectiveness of CORK as a CLOSURE was thereby enhanced because it was kept wet and expanded by the wine. All this was achieved by the abandoning of onion-, bladder-, and mallet-shaped bottles in favour of cylindrical ones which stack easily. Early cylindrical bottles have short wide bodies with tall necks, but as the century progressed the modern shape evolved. In 1821, Ricketts of Bristol patented a machine for moulding bottles of uniform size and shape, early examples of which are impressed 'patent' on the shoulder of the bottle and the legend 'H Ricketts & Co. Glassworks Bristol' on the base. Thus the modern wine bottle had evolved, all later shapes and colours being decided as a question of aesthetics rather than technical limitation.

Identification From 1636, at the time the English bottle began to appear, it was illegal to sell wine by the bottle. This consumer protection measure was on account of vintners' willingness to take advantage of the varying capacity of blown bottles. From that time and for the next 230 years, wine was sold by the measure and then bottled. Customers who bought regularly had their own bottles and had them marked in order to distinguish them from any others that might be at the vintner's premises waiting to be filled. The usual marking was the attachment at the end of the production process of a disc seal of the same glass as the bottle, upon which was impressed the owner's initials, name, or heraldic device, often accompanied by the date. Innkeepers and taverners had appropriately marked, or 'sealed', bottles too. The seals did not indicate the contents.

Sealed bottles are avidly collected today, the most prized being 17th-century ones, particularly those with dates incorporated in the seal. Named examples are preferred to ones with initials, and earlier ones to later.

Bottles with paper labels indicating the contents, first hand-written and later printed, emerged during the opening years of the 19th century, but in Britain the law prohibiting wine from being sold by the bottle was not relaxed until 1860. Bottles with paper labels printed with pre-1860 vintages are probably relabelled or were intended for non-British markets.

Size Free-blown bottles relied on the skills of the glass-blowers to gather the exact amount of hot glass needed and, with the help of calipers and measuring rods, to create similar size vessels repeatedly and quickly. From about the 1740s, the use of open wooden moulds to shape the glass began the process of standardizing bottle capacities. By 1821, a complete metal bottle mould was patented, and in 1901, in America, Michael J. Owens invented the automatic bottle-blowing machine, which guaranteed the capacity of every bottle.

For a long while a bottle was more or less 1¼ UK pints (70 cl or 25 fl oz) and a magnum was a quart (1.12 l or 40 fl oz). Until the 1970s, when legislation in the EU and elsewhere enforced standardization, bottles varied from about 65 to 85 cl, CHAMPAGNE and BURGUNDY tending to be larger than those for BORDEAUX, while SHERRY bottles were often smaller. R.N.H.B. & C.R.H.

Modern bottles

Choice of LABEL and FOIL are not the only ways in which a wine producer can make a visual statement to a potential customer. Wine bottles are now made in an almost bewildering array of shapes, weights, colours of glass, and design, quite apart from their capacity (see BOTTLE SIZES).

In some regions one specific bottle has been adopted by all but the most anarchic producers, and indeed adoption of a special local, regional, or appellational bottle became particularly fashionable in the 1980s. Examples of special bottles are the heavy, embossed CHÂTEAUNEUF-DU-PAPE bottle (which comes in several rival versions); the BOCKSBEUTEL of FRANKEN; the CHÂTEAU-GRILLET bottle peculiar to a single property; and the long-necked green bottle particular to MUSCADET, although it can sometimes seem that every French appellation has developed its own exclusive bottle.

In general, Italians, with their firm belief in the importance of design, offer the most dazzling range of wine bottles. Some of the particularly artful shapes used for grappa have been adopted by wine producers in Austria and further afield, especially for halves of sweet wine. The problem with some special bottle shapes, however, is that they may well be difficult to store, both on the shelf (many a special bottle is simply too tall for the average supermarket display) and, particularly, in a wine rack designed for standard bottles.

Weight and darkness of glass seem to have been particularly highly valued by Argentines and Italians, although it was once a general rule throughout the wine world that the heavier a bottle, the greater the aspirations of the producer of the wine for its longevity, or at least its price. The weight of a 75-cl bottle can vary between about 345 g and, in extreme cases, more than a kilo. Bottling wine in the lightest, cheapest glass is one way of saving costs, on the bottle itself and on TRANSPORT. Eschewing overweight bottles is one way of saving the planet that is being adopted by more and more enlightened producers around the world. See SUSTAINABILITY.

Bottles

Bottle shapes Special designs apart, there are certain standard bottle shapes associated most commonly with certain regions or, increasingly, the styles of wine associated with those regions. Ambitiously made Chardonnays the world over, for example, tend to be put into burgundy bottles. Since the geographical provenance of most wines should be clear from the label, understanding bottle shapes is most useful for the clues they provide as to the intended style of the wine inside them. Some RIOJA producers, for example, put their Garnacha-dominated richer blends into burgundy bottles, while their Tempranillo wines designed for longer ageing are put into bordeaux bottles.

Most champagne and sparkling wines are sold in much the same shape of bottle, moulded to be thick and strong enough to withstand the pressure of up to six atmospheres inside each bottle. Considerable energy and money is expended, however, on designing special bottles for PRESTIGE CUVÉES, Moët & Chandon's Dom PÉRIGNON bottle having set a formidable standard. The precise shape of the lip of a champagne bottle indicates whether the second fermentation took place under a crown cap or under a cork, as it does in some very rare cases.

Bottles vary in the extent to which they have a punt, or inverse indentation, in their base. Most champagne and sparkling wine bottles have a particularly deep indentation because it strengthens the glass, which is under considerable pressure, and, during disgorgement when bottles are inverted, makes it easy for bottles to be lifted by suction during SPARKLING WINEMAKING. Punts are less obviously useful for still wines—although they can make bottles look bigger and more impressive—and deep punts can provide useful purchase for the thumb when SERVING wine from a bottle.

The exact shape and design of the neck and lip of the bottle is determined by what is used to stopper it. Most CLOSURES other than cork need some sort of modification, and the widespread adoption of SCREWCAPS has entailed considerable redesign of bottles. The 1990s

saw a marked but mercifully brief FASHION for bottles with a flange but no CAPSULE around the top, which damaged many a CORKSCREW.

Bottle colour Wine keeps best in dark glass—as the Champenois, the most energetic researchers into the effects of bottle choice on wine, have found. ROEDERER Cristal, which has traditionally been sold in clear glass, is always swathed in an orange wrap designed to filter out ULTRAVIOLET RADIATION (see LIGHTSTRIKE for more on this phenomenon). On the other hand, dark glass prevents the consumer from being impressed by the colour of a wine. For this reason, most ROSÉS, not generally designed for AGEING, are sold in clear glass. It is less clear why SAUTERNES and other sweet white bordeaux is sold in clear glass; TRADITION is presumably the explanation. Most wine bottles are, for reasons of both tradition and the orientation of glass furnaces, some shade of green, from pale blueish green to a colour that to all intents and purposes is black. For traditional reasons again, brown glass is used for some Italian wines and for many fortified wines; it was also the traditional way of telling a HOCK or Rhine wine from a MOSEL in green glass. Some German producers use blue-green glass, however, in a nod to Victorian times when blue glass was often used. One of the most distinctive glass colours for wine bottles is the yellow-green used for white burgundy, called *feuille morte* in France and therefore 'dead leaf' in much of the New World. Wines are occasionally marketed in bright blue and bright red bottles.

More clues from the bottle

Most wine bottles are moulded with the mark of their manufacturers, sometimes with their capacity, and all wine sold within Europe from the 1990s should have a lot mark (see LABELLING INFORMATION), a small code stamped on the label, foil, or more usually the bottle, so that each bottle can be traced back to its precise BOTTLING and dispatch.

See also PAPER BOTTLES.

bottle shock, a temporary phenomenon caused by the inevitable agitation of a wine during FILTRATION, BOTTLING, or transportation,

resolved quite simply by allowing the wine to rest for a day or two. The term was taken as the title of a 2008 film based very loosely on the late Steven SPURRIER and his JUDGMENT OF PARIS tasting.

bottle sickness, colloquial term used to describe an increasingly rare phenomenon resulting from exposing a wine to too much OXYGEN during bottling, or too little, resulting in REDUCTION and the production of VOLATILE SULFUR COMPOUNDS. High levels of SULFUR DIOXIDE at bottling may also make a wine smell unpleasant. More common is BOTTLE SHOCK.

bottle sizes are standardized in most countries. A bottle containing 75 cl/25 fl oz is now accepted almost universally as the standard wine (but not spirits, which is more usually 70 cl) bottle, with the magnum being 1.5 l, exactly twice the capacity. The standard bottle is about the same size as the first bottles (see BOTTLES, history), whose size may have been determined by the size of container conveniently blown by a (glass-blower's) lungful of air. The bottle has in its time been variously described as a suitable ration of wine for one person at a sitting, one person per day, and two people at a sitting (see CONSUMPTION).

Half-bottles usually contain 37.5 cl and are believed to hasten wine AGEING, partly because they contain more OXYGEN per centilitre of wine since the bottleneck and ULLAGE are the same as for a full bottle. Most wine bottlers have viewed halves and other bottles smaller than the standard bottle as an unwelcome inconvenience, and BOTTLING technology has been focused on standard bottles, but there continues to be strong demand for half-bottles, particularly in restaurants. There have been various attempts to launch a 50-cl bottle, particularly common for SWEET WINES, and some champagne producers have had notable success with single-serve quarter-bottles.

With the exception of JURA's special 62-cl *clavelin*, the bottle capacities permitted within Europe for still wines are 10 cl, 25 cl, 37.5

cl, 50 cl, 75 cl, and 1, 1.5, 2, 3, 4, 5, 6, 8, 9, and 10 litres (and wine may be served in 18.7-cl bottles, sometimes referred to as 'splits', aboard trains, planes, and the like). Sparkling wine bottles come in 12.5-, 20-, 37.5- and 75-cl and 1.5-, 3-, 4.5-, 6- and 9-litre capacities. The larger-sized bottles, some of them no longer in production, have different names in different regions.

Capacity (l)	Bordeaux	Champagne/Burgundy
1.5 (2 bottles)	magnum	magnum
2.25 (3 bottles)	Marie-Jeanne	not found
3 (4 bottles)	double magnum	Jéroboam
5 (6 bottles)	Jéroboam*	Réhoboam
6 (8 bottles)	Impériale	Methuselah
9 (12 bottles)	not found	Salmanazar
12 (16 bottles)	not found	Balthazar
15 (20 bottles)	not found	Nebuchadnezzar

* 4.5 litres before 1978

Others including an 18-l Melchior, a 26-l Sovereign, and a 30-l Melchizedek (or Midas) are also known, in theory. Bordeaux collectors particularly treasure larger bottles (often known as 'large formats' or *grands formats*) up to Impériale size, as they favour slow but subtle AGEING. Giant champagne bottles, on the other hand, tend to favour publicity rather than wine quality (sizes larger than a magnum tend to be filled with wine made in smaller bottles).

bottle variation is one of the more tantalizing aspects of wine appreciation. 'There are no great wines, just great bottles', is a popular saying among connoisseurs. It is only to be expected with a product as sensitive to storage conditions as wine (see STORING WINE) that bottles of the same wine will differ—perhaps because one has been exposed to higher temperatures or greater humidity. There can easily be a perceptible difference in quality and character between bottles from the very same CASE. SUBJECTIVITY may play a part, as well

as a difference in FILL LEVELS, but it is also possible that the individual wines were subtly different before they went into bottle, or that they were bottled under different conditions or under CORKS of different quality and efficacy. It was not until the 1970s, for example, that it became commonplace for Bordeaux châteaux to ensure that a uniform blend was made before bottling; some of the world's most artisanal producers still bottle by hand from cask to cask. Similarly, wines bottled on two different occasions may find themselves packed in the same case (although modern lot number marking provides more clues in this respect; see LABELLING INFORMATION).

bottling, vital winemaking operation for all wines aside from those packaged in containers other than bottles (see ALTERNATIVE PACKAGING) and those few served straight from a cask or tank as BULK WINE.

Bottling techniques vary greatly according to the size, resources, technical ability, and modernity of the winery, although since the 1960s it has been customary almost everywhere to blend all casks or vats of a given lot of wine together before bottling and to bottle it all at once. (Prior to this there could be considerable BOTTLE VARIATION between different bottlings of even FIRST GROWTHS.)

In the past, bottling lines subjected the wine to considerable AERATION and agitation with a significant impact on wine quality. At one time, high-volume, low-margin wines containing RESIDUAL SUGAR might have been subjected to PASTEURIZATION to ensure microbiological stability, but such methods have been largely replaced by membrane FILTRATION, often in combination with DMDC or SORBIC ACID to further reduce the YEAST population and lessen the risk of refermentation in bottle.

Modern bottling lines use advanced technology to ensure that dissolved OXYGEN is kept to the lowest level possible by constant monitoring and the use of NITROGEN or CARBON DIOXIDE to flush the bottle and exclude oxygen from the HEAD SPACE (see TOTAL PACKAGE OXYGEN). The expensive, high-volume, super-fast bottling lines used

for everyday wines often provide the best results because problems with oxygen pick-up tend to be worse at slower speeds, at the start and end of the bottling run, or if there is a stoppage. Oxygen management is likely to be given higher priority in wines not intended for ageing. In this aspect of wine production, big may be beautiful. Nevertheless, last-minute adjustments to wine before bottling, such as FILTRATION or the addition of SULFUR DIOXIDE, may result in the temporary shutting down of the wine (see BOTTLE SHOCK).

Some smaller producers of high-quality wine have the funds to invest in their own high-tech bottling line, but many other small wineries, especially in France, where *mis en bouteille au domaine* has considerable cachet, depend on the services of outside mobile bottling lines, bottling equipment mounted in a truck or lorry which can be brought to the winery for a day or more. Others still follow the ancient tradition of bottling wine from casks or even individual barrels in the cellar, but in general this is a part of the production process that is most often outsourced to specialists.

The specific steps involved in bottling are the preparation of the wine itself (BLENDING, ANALYSIS, and possibly final filtration) together with the preparation of the bottling line (sterilization and the preparation of the filler, corker or capper, labeller, capsuler, and casing machines, as appropriate). High-quality wines suitable for AGEING may not be labelled as soon as they are bottled, because they are stored for some time before being released and the labels may deteriorate in cellar conditions.

Bottling may take place at any time from a few weeks after HARVEST (as with NOUVEAU wines) to when the wine is many years old (as in some of the most traditional Iberian BODEGAS). On smaller wine estates, bottling normally takes place at an otherwise quiet time for cellar staff such as in the spring or early summer.

Place of bottling may be many thousands of miles from where the grapes were originally grown and even from where the wine was made, since BULK TRANSPORT is so very much cheaper than transporting wine in bottle and more environmentally friendly. A 20-foot container will hold approximately 1,100 9-litre cases of bottled

wine, but a disposable tank that fits into the same container will hold 24,000 litres of wine. The cost of bottling and bottles being so relatively high in California, Chile, and Australia, for example, some wines destined for sale in the US and Europe are bottled close to the market. According to the OIV, the total volume of wine shipped around the world in bulk (in containers bigger than 10 litres) represented more than 34% of all exported wine in 2020. In Eastern Europe and the former SOVIET UNION in particular, bottling has traditionally taken place much closer to centres of population than to the vineyard. Producers of hand-crafted, top-quality wines, however, usually prefer to conduct the bottling operation themselves since they have greater control over the process and are able to reduce to a minimum the amount of treatment the wine needs prior to shipping. However, for high-volume wines with a limited shelf life in bottle of around 12 months, there is the advantage that the wine is likely to reach the retailers' shelves much sooner after bottling than wine bottled at source. See BOTTLING INFORMATION for the significance of various bottling claims on the label.

While improved technology and QUALITY CONTROL have significantly reduced the risks involved in this mechanical process, the bottled wine can still occasionally develop problems which were not previously apparent. These may be the result of high levels of dissolved oxygen (see TOTAL PACKAGE OXYGEN), incomplete STABILIZATION, the failure of filtration to remove all viable yeast or bacteria, causing post-bottling fermentation, or dilution if water is used to push wine around the winery to the bottling line. Other possible contaminants include those associated with CORK TAINT or SMOKE TAINT. Incorrectly applied labels are not uncommon.

See also BOTTLES. J.R., J.E.H. & B.D.

bottling information. All wine labels must include information about the person who is responsible for the wine in the bottle—usually either the bottler or the importer, sometimes both. Details of

the bottler can give useful information about the provenance of a wine.

Common phrases for 'bottled' are *mis en bouteille* in French, *imbottigliato* in Italian, *embotellado* in Spanish, and *engarrafado* in Portuguese. Wines bottled by their producer will state 'bottled by', whereas wines bottled under contract are labelled 'bottled for'.

The bottler's (or importer's) address will also appear on the label, but the presentation must not mislead as to the origin of the wine, for example by highlighting that the wine was bottled in a famous region when the grapes came from somewhere else. For this reason, in the EU the bottler's postcode may sometimes be used instead of the full address, making labels less informative to those not conversant with, for example, French *département* numbers. Italy's stipulation that the bottler's code appear on the CAPSULE, screwcap, or cork is even stricter but is being phased out.

In the EU, PDO or PGI wines may use the name of a 'holding' (e.g. château, domaine, Schloss, Weingut, castello, or casa) only if they are made exclusively from grapes harvested in vineyards exploited by that holding and vinified and bottled entirely at that holding. See CHÂTEAU BOTTLING, DOMAINE BOTTLING, and ERZEUGERABFÜLLUNG.

WINES WITHOUT GEOGRAPHICAL INDICATION may not be described as having been bottled at the domaine or château.

Similar rules apply in other parts of the world. In Chile, for example, *embotellado en origen*, estate-bottled, or its synonyms can be used only for CONTROLLED APPELLATION wines grown, vinified, and bottled on lands owned or held by the producing winery. For US terminology, see ESTATE BOTTLED. J.P.H.B.

Bouchalès is a dark-berried vine variety still grown to a limited extent in Bordeaux and in the Lot-et-Garonne *département*. It is not particularly easy to graft or grow, and total French plantings fell from over 4,000 ha/9,900 acres in 1968 to 68 ha/168 acres by 2018.

Bouchard Père et Fils, one of Beaune's large merchant houses (quite distinct from Bouchard Aîné), and also one of the most important vineyard owners of the CÔTE D'OR with 130 ha/321 acres of vines in more than 100 CLIMATS, three-quarters of them PREMIERS CRUS and GRANDS CRUS. Founded in 1731, it has been based since 1820 in the 15th-century Château de Beaune, a landmark in this medieval wine town with usefully extensive, well-stocked cellars for ageing their top wines, complemented by newer cellars just outside Beaune. The house was established by Michel Bouchard, a Dauphiné textile merchant, and acquired in 1995 by the Henriot family, who added the Chablis firm William Fèvre in 1998. In 2022 the Henriot wine holdings were merged with those of ARTÉMIS DOMAINES.

Bouchet, name for CABERNET FRANC commonly used in St-Émilion and elsewhere on the right bank of the GIRONDE, while Bouchy has been known in MADIRAN.

bouchon is French for CORK, and bouchonné describes a faulty, CORKED wine.

bouillie bordelaise. See BORDEAUX MIXTURE.

bouquet, oft-ridiculed tasting term for the smell of a wine, particularly that of a mature or maturing wine. Although its original French meaning was 'small wood' (from the same root as the Italian *bosco* and the English *bosky*), 'bouquet' is a French word for a bunch of flowers which has been used to describe the perfume of a wine since the first half of the 19th century. It is used loosely by many wine tasters to describe any pleasant wine smell or smells but, just as a bouquet (rather than a bunch) of flowers suggests a composition of several varied elements, many wine professionals distinguish between the simple AROMA of the grape and the bouquet of the more complex

compounds which evolve as a result of FERMENTATION, ÉLEVAGE, and AGEING. There is little consistency in usage, however, and many authorities differ about the point in a wine's life cycle at which a wine's smell stops being an aroma and becomes a bouquet. See also ESTER, FLAVOUR COMPOUNDS, and FLAVOUR PRECURSORS.

Bourboulenc is an ancient Provençal white grape variety. Ripening late but keeping its acidity well, it is allowed into a wide variety of Provençal and southern Rhône appellations (including CHÂTEAUNEUF-DU-PAPE) but is rarely encountered as a dominant variety other than in the distinctively marine whites of LA CLAPE and an increasing number of other Languedoc whites. France's total area of Bourboulenc was 520 ha/1,285 acres in 2019. Together with Maccabéo (MACABEO), it should constitute more than 50% of the blend for any white MINERVOIS, and it is one of the principal varieties in CORBIÈRES Blanc. Wine produced can be fine, crisp, and aromatic.

Bourg, small town in the BORDEAUX region on the right bank of the River DORDOGNE, just upriver of its confluence with the Garonne, which is surrounded by the Côtes de Bourg appellation, also known as Bourg and Bourgeais. The 3,412 ha/8,428 acres of vineyard that produced Côtes de Bourg in 2020 have a characterful base of CLAY and LIMESTONE with sandy GRAVEL deposits and some MARLS. They are planted substantially with Merlot, and the best reds can be more concentrated and ageworthy than those from the larger BLAYE area to the immediate north; vineyards on the edge of the Gironde estuary are particularly well protected from FROST DAMAGE, thanks to the MARITIME influence. The star of the appellation is Ch Roc de Combes, related to St-Émilion's Ch Tertre-Roteboeuf, on a particularly well-favoured site on the Gironde itself. A little dry white wine is also made.

bourgeon is French for BUD, and *ébourgeonnage* is the viticultural practice of thinning surplus developing buds before FLOWERING, a form of early-season CROP THINNING.

Bourgogne, the French name for both the region of BURGUNDY (La Bourgogne) and burgundy, the wines thereof (*le bourgogne*), which are red, white, and very occasionally rosé. In particular, Bourgogne refers to the most basic, generic category of AOC in Burgundy.

For white wines the generic appellations are BOURGOGNE ALIGOTÉ, Bourgogne Blanc (made from Chardonnay grapes), and Coteaux BOURGUIGNONS. For red wines the generic appellations are BOURGOGNE PASSETOUTGRAINS, Coteaux Bourguignons, and Bourgogne Rouge. The last is usually pure Pinot Noir, although it may technically include the CÉSAR grown in the Yonne *département* and may be made from GAMAY grapes if grown in one of the BEAUJOLAIS crus. A small amount of pink wine is sold as Bourgogne Rosé, or Bourgogne Clairet. In practice this may be the result of a SAIGNÉE of a red wine from a major vineyard in order to concentrate it.

Bourgogne of whatever colour may be followed by a geographical suffix, either denoting a region (Hautes-Côtes de Nuits, Hautes-Côtes de Beaune, Côte d'Or, Côte Chalonnaise, Côtes d'AUXERRE, Côtes du COUCHOIS); a commune or group of communes (Chitry, Coulanges-la-Vineuse, Épineuil, Tonnerre); or in certain cases a vineyard (Côte St-Jacques at Joigny or La Chapelle Notre-Dame in the Côte d'Or).

Thus it is evident that the scope of 'Bourgogne', be it white, red, or pink, encompasses wide variations in provenance, quality, and style of wine which may not be clear from the label. A Bourgogne Rouge or Bourgogne Blanc made by a grower in one of the major villages of the Côte d'Or (such as MEURSAULT for whites and VOLNAY or CHAMBOLLE-MUSIGNY for reds) is likely to be reliably fashioned in the image of classic CÔTE D'OR burgundy, however, and may well represent excellent value, being generally ready to drink sooner.

There is every chance that the wine will be made from vines only just outside the village appellation yet will be sold at half the price.

CRÉMANT de Bourgogne is the generic appellation for sparkling Burgundy, either white or rosé, while the now-rare red version is classified as Bourgogne Mousseux.

See also BOURGOGNE ALIGOTÉ, BOURGOGNE PASSETOUTGRAINS, and Coteaux BOURGUIGNONS. J.T.C.M.

Bourgogne, Université de. See DIJON.

Bourgogne Aligoté, a generic appellation in Burgundy for white wines made from the ALIGOTÉ grape, whose production remains stable, despite a recent and sustainable boom in popularity, at around 1,600 ha/3,950 acres. Formerly either refreshingly crisp or disagreeably tart, the latter characteristic providing the basis for *vin blanc cassis*, or KIR, Aligoté has blossomed in recent warmer vintages. Traditionally flourishing in locations such as Chitry in the Yonne, Pernand-Vergelesses in the Côte de Beaune, and BOUZERON (which has its own appellation for Aligoté), Aligoté is now found in ageworthy SINGLE-VINEYARD variations by more enterprising producers. The golden Aligoté Doré is a old selection of the grape, typically found in Bouzeron. J.T.C.M.

Bourgogne Passetoutgrains, red thirst-quencher from Burgundy made from at least 30% Pinot Noir in a blend with Gamay grapes. Often deep in colour and rather savagely animal when young, Passetoutgrains with age can attain greater refinement as the Pinot Noir flavours start to dominate. The best examples come from vineyards in the CÔTE D'OR lying in the plain beyond the main D974 road which divides the finer vineyards from the generic. Only a little more than 200 ha/494 acres remain dedicated to this appellation. J.T.C.M.

Bourgueil, notable red wines made on the north bank of the Loire in the west of the TOURAINE district. Historically related to ANJOU, with which it shares its milder climate, its 1,400 ha/3,400 acres of vineyard experience more oceanic influence than CHINON. Two distinct terroirs shape Bourgueil wines: the lighter, earlier maturing and dominant style comes from the south-facing, alluvial terraces of GRAVEL and SAND in the area closest to the river, while the structured, long-lived bottlings are grown on the TUFFEAU slopes especially in Restigné, Benais, and Bourgueil.

Cabernet Sauvignon is permitted, but CABERNET FRANC is the primary grape. Lean wines are still produced (especially BULK WINES), but quality Bourgueil from the gravel (often made using SEMI-CARBONIC MACERATION) can be explosively juicy with raspberry flavour, while earthier, silkier BARREL-AGED bottlings from the chalk hills can compete with the best CHINON and SAUMUR. In the west, St-Nicolas-de-Bourgueil, whose mayor fought in 1937 for it to have its own appellation, generally produces a lighter style, as most of its 1,100 ha/2,700 acres of vines grow on deep, gravelly sand.

A little dry rosé Bourgueil is also made, but the appellation does not, unlike Chinon, encompass white wines. See LOIRE, including map.

P. Le.

Bourguignons, Coteaux. This 2013 appellation replaced Bourgogne Grande Ordinaire, applying to minor Burgundy vineyards, growing ALIGOTÉ, Chardonnay, MELON de Bourgogne, Pinot Blanc, and/or Pinot Gris for whites, and Gamay, Pinot Noir, and CÉSAR (in the Yonne) for reds. The key to this is the inclusion of the Gamay grape because the rules for BEAUJOLAIS allow de- or re-classification as Coteaux Bourguignons.

J.T.C.M

Bouschet is, like Müller, Scheu, and Seibel, a vine-breeder's surname that lives on in the name of his creations, although in this case there were two Bouschets, a 19th-century father and son whose work, perhaps unfortunately, made the spread of ARAMON possible. In

1824 Louis Bouschet de Bernard combined the productivity of Aramon with the colour expected of a red wine by crossing Aramon with TEINTURIER du Cher and modestly calling the result Petit Bouschet. This expedient CROSS was popular in France throughout the second half of the 19th century and is still, just, to be found in Portugal. Louis's son Henri carried on where his father left off, producing more durably ALICANTE BOUSCHET and GRAND NOIR DE LA CALMETTE as well as a Carignan Bouschet.

Boutenac, subappellation in the north-east of CORBIÈRES.

Bouvier, minor, low-acid white grape variety grown mainly in the Burgenland region of AUSTRIA, where it is particularly used for FEDERWEISSER, as well as for early-bottled wines. It can also be found in Slovenia, Slovakia, and Hungary.

Bouzeron, village in the Côte CHALONNAISE dedicated to the ALIGOTÉ grape. Production is increasing, with 161 ha/393 acres declared in 2018, up from 52 ha in 2012. J.T.C.M.

Bovale, dark-skinned grapes on SARDINIA distinguished as Bovale Sardo, a synonym for GRACIANO, and the more common Bovale Grande, a synonym for CARIGNAN. Both are used mainly for blending.

boxes, wine. In the late 1960s, an entirely new way of PACKAGING wine was developed in Australia, expressly to provide a significant volume of wine in a package that is not as breakable or heavy as a glass bottle. Subsequent improvements have resulted in a convenient container that is able to preserve wine for up to four to six weeks after opening.

It comprises a collapsible multilayer bag inside a strong cardboard carton (hence bag-in-box, or BIB). Wine is drawn out of a tap

designed to minimize the ingress of potentially harmful OXYGEN. Minimizing the oxygen ingress of the bag itself is also critical to the success of the format. There are two main types of bag: in the silver-coloured ones, the oxygen barrier is created by a thin layer of aluminium, usually provided by an aluminium-coated polyester sandwiched between layers of polyethylene via a lamination process; in the clear bags, the barrier is provided by ethylene vinyl alcohol copolymer (EVOH) co-extruded between layers of polyethylene. The main disadvantage of the former is 'flex cracking', which tends to occur during transportation and weakens the oxygen barrier. Both types have significantly reduced OXYGEN TRANSMISSION RATES compared with earlier versions.

This package, known flatteringly as 'cask wine' in Australia (less flatteringly as 'goon bags'), most commonly holds 2.25 or 3 litres of wine. It has grown in popularity in recent years: Sweden, Norway, and Australia all consume 50% or more of their wine from a box. This growth is in part because the improvements to the bags and taps have encouraged winemakers and importers to use this format for higher-quality wine, but also because of its low CARBON FOOTPRINT. A series of life-cycle assessments have identified the BIB format as having the lowest carbon footprint associated with any commonly used wine packaging (more than seven times lower than even lightweight glass bottles). Despite these improvements, bag-in-box wine has a shorter lifespan prior to opening than traditional bottles, typically 9–12 months from filling, although some wines will last longer. For this reason, wines packed in this format are normally those that are considered ready to drink.

Gaia Consulting, 'Update of wine packaging LCA: final report Alko Oy' (2021).

Brachetto, distinctively aromatic light red grape variety found principally and most successfully round Asti, Roero, and Alessandria in the PIEMONTE region of Italy, although it is also found in Emilia-Romagna. It produces wines, notably Brachetto d'Acqui promoted to

DOCG status in 1996, that are fizzy, are light in alcohol (usually under 6%), and have both the colour and flavour of roses or strawberries—the light red equivalent of MOSCATO D'ASTI. Occasional dry versions are made in Piemonte. Total Italian plantings in 2015 were 1,692 ha/4,181 acres. Some is planted in Victoria, Australia.

Bragato, Romeo , Dalmatian-born graduate of Italian viticulture studies and employee of the Victorian government in Australia, invited in 1895 to investigate the prospects for viticulture and winemaking in New Zealand. His report was very favourable and became an important document encouraging the development of the industry.

Bragato identified PHYLLOXERA in New Zealand in 1895 and suggested the use of resistant ROOTSTOCKS, but his advice was initially ignored. Offered the position of government viticulturist in 1902, he immediately began importing and distributing these rootstocks (which were to be used again to fight phylloxera outbreaks of the 1980s). He established a research station at Te Kauwhata with experimental vineyards and a training winery, and he also published a handbook, *Viticulture in New Zealand*. Bragato and the fledgling wine industry were, however, not supported by his masters in the Department of Agriculture. In 1908 he lost control of the Te Kauwhata Research Station and in 1909 migrated to Canada in disgust. R.E.S.

Bramaterra, tiny DOC in Italy's Alto PIEMONTE enjoying a renaissance, going from 28 ha in 2014 to 41.5 ha/102 acres in 2020. Wines should contain 50–80% Nebbiolo with CROATINA, UVA RARA, and VESPOLINA. See SPANNA for more detail.

Brancellao, Galician name for the ALVARELHÃO of the Douro.

branco, Portuguese for 'white'. *Vinho branco* is therefore white wine.

brands, interpreted strictly as individual products marketed on the basis of their name and image rather than on their inherent qualities, have a much less dominant position in the market for wine than for drinks such as beer or cola, for instance; thanks to GLOBALIZATION, however, they are growing in importance. The leading industry resource IMPACT Databank calculated that the global market share of the top 25 wine brands in the world, while having grown significantly since the mid 1990s, was still less than 10% by 2020, with three of the top five brands—Franzia (including sangria), Barefoot from GALLO, and all the Robert MONDAVI lines—from California. It is perhaps significant that IMPACT is based in the United States, where distribution is tightly controlled (see THREE-TIER SYSTEM, for example) and where brands account for more than half of all wine sales.

Most sectors of the wine market are relatively fragmented (although the FORTIFIED WINE business is not and has been built on brands), so that brand promotion is difficult to make cost-effective and can leave branded wines looking poor value. By far the most common promotion in the 21st century has been based on PRICE and close relationships with the decreasing number of multiple retailers, many of which have been turning away from third-party brands to their own exclusive labels.

Wine brands offer a familiar lifeline to new wine consumers baffled by a multiplicity of unfamiliar, often foreign, proper names. But as wine drinkers become more sophisticated, they learn to decode what initially seems the arcane language of wine names, usually by identifying the major VARIETALS, some of the more important place names, and/or favourite producers. Thus, brands are most sought after in embryonic and fast-growing markets, such as northern Europe and the rest of the English-speaking world between the 1950s and the 1980s, or in Africa and some Asian countries today.

It may be difficult to market branded wines in a competitive market, but it can be even more difficult to maintain consistency of a product as variable as wine. Supplies are strictly limited to an annual batch production process. Wine cannot be manufactured to suit demand, and different vintages impose their own characteristics on

the product regardless of consumer taste. A high proportion of all wine drinkers were introduced to wine through brands, and it is to the credit of those brand owners most dedicated to maintaining quality standards whenever the introduction was a happy one.

Notably successful international individual wine brands are relatively few, and they have perforce to be based on wine of which there is no shortage of supply. BLUE NUN, MATEUS rosé, and MOUTON CADET are all examples of brands which in the 20th century achieved annual sales measured in millions of cases. YELLOW TAIL was the miracle brand of the early 21st century.

There are those who argue that the grape varieties CHARDONNAY and PINOT GRIGIO, for example, like the extraordinarily popular PROSECCO, have become brands in their own right, so strong is consumer recognition of the name. Others claim that in certain markets buyers' own brands have become so important, and so cleverly marketed, that, for example, some retailers' names have established themselves as brands. The definition of a wine brand is certainly a loose one. In some respects, the New French CLARETS, named for the estate which produced them, were the first wine brands, emerging in the late 17th century; today, though, the French wine industry blames some of its difficulty in selling everything it produces on its failure to build brands, in conspicuous contrast to the bigger companies in Australia and the US. Certainly any definition which incorporates the notion of relatively elastic supply and some studied promotion would allow that the most successful wine brands of all are the so-called *grande marque* (which translates directly as 'big brand') CHAMPAGNES. In his book, Graham Harding argues that the British created many of these brands in the 19th century.

Harding, G., *Champagne in Britain, 1800–1914* (2021).

Braquet, also called Brachet, historic light red grape variety of PROVENCE which is still a valued, if minor, ingredient in the red and pink wines of BELLET near Nice. Yields are low and the vine is

relatively delicate, but the wine is truly distinctive. This variety is not related to the much more aromatic Italian BRACHETTO.

Brazil , is the third most important wine producer in South America after Argentina and Chile, although most of its 81,000 ha/200,155 acres of vineyards in 2021 remain planted with non-VITIS VINIFERA varieties. In 2020 there were an estimated 1,200 wineries in Brazil, mostly small family businesses. The country produces a vast variety of wines, with a particular strength in sparkling wines.

History

The first vines were introduced by Portuguese explorers in the state of São Paulo in 1532, but the vines withered in the region's excessive heat and humidity. European settlers followed, planting vines in different areas, eventually finding success in Rio Grande do Sul, in the extreme south, where Brazil shares its border with Argentina and Uruguay.

By the mid 1800s, the industry had turned to high-yielding AMERICAN HYBRIDS such as CONCORD, Isabel (ISABELLA), and NIAGARA to cope with climatic conditions. Hybrids, in fact, still make up most of production: Vinho Fino ('fine wine'), defined as wine produced with *vinifera*, corresponds roughly to 10% of production, and Isabel, brought to Brazil in 1840, is the country's most widely planted variety. Italian immigrants arriving in the late 1870s brought, among other things, grape varieties such as BARBERA, BONARDA, MOSCATO, and TREBBIANO, with mixed results.

The industry entered a new phase in the 1970s when international companies such as Martini & Rossi, MOËT & CHANDON, and Seagram started investing in Brazilian vineyards, bringing new cuttings of *vinifera* varieties including Cabernet Sauvignon, Cabernet Franc, Merlot, Chardonnay, Sémillon, Welschriesling, and Gewürztraminer. These companies also introduced modern winemaking equipment such as automatic TEMPERATURE CONTROL, STAINLESS STEEL, and BARRIQUES.

Competition stepped up in the 1990s, when the Brazilian government reduced import barriers. The increased competition for market share, especially from neighbouring countries CHILE and ARGENTINA, inspired a new round of investments in technology and infrastructure of the wine sector, with lasting effects on wine quality.

Geography and climate

Brazil is a large country, the distance between its north and south equivalent to the distance between London and Baghdad. Grapes are grown in most of its 26 states; however, the most southerly, Rio Grande do Sul (which includes the subregions of Serra Gaúcha, Serra do Sudeste, Campanha, and Campos de Cima da Serra), is responsible for around 90% of total still-wine production and 85% of SPARKLING WINE production.

Colonized mainly by Italian settlers, Serra Gaúcha is responsible for the largest proportion of the country's production, most of it made from American and hybrid varieties grown by farmers with average holdings of just 2.5 ha/6 acres. It is here that international companies invested with the objective of capturing a share of the domestic market. This area includes Vale dos Vinhedos, Brazil's first DO, created in 2009 and located immediately east of the town of Bento Gonçalves, considered Brazil's wine capital. It also includes Garibaldi, heavily influenced by Italian descendants and traditionally renowned for its sparkling wine. Styles vary from light, off-dry wines made using the TANK METHOD to serious, dry TRADITIONAL METHOD versions.

The undulating topography of Serra Gaúcha permits vineyards to be planted at ELEVATIONS of 300–850 m/984–2,789 ft. Soil is predominantly CLAY over BASALT, and annual average RAINFALL is around 1,700 mm/67 in, of which at least 700 mm falls during the growing season of September to February; hence vineyards were traditionally established using the PERGOLA system to mitigate excess humidity. Modern vineyards are planted using VSP (see VERTICAL TRELLIS). The main red varieties are Merlot, Cabernet Sauvignon, Pinot Noir, Tannat, and Cabernet Franc. Chardonnay, Riesling Itálico (WELSCHRIESLING), many varieties of Moscato, and GLERA are the principal white varieties.

Serra do Sudeste, in the south of the state, is drier and more TEMPERATE, noted for cold winters, dry springs, and warm summers.

Its gentle slopes, at 200–500 m/656–1,640 ft in elevation, and granitic soil have demonstrated great potential with many varieties including ALICANTE BOUSCHET, Barbera, Cabernet Franc, Cabernet Sauvignon, Merlot, and Pinot Noir for red wines and Gewürztraminer, Riesling, Moscato, MALVASIA de Cândia, and especially Chardonnay for whites.

Campanha, at LATITUDES 29–31° S, shares a long border with URUGUAY. Unlike in most of the country, seasons here are well defined, with hot summers and winter temperatures dipping to −10 °C/50 °F. Gently undulating plains at 100–300 m/328–984 ft in elevation with sandy soils are suitable for many red varieties such as Cabernet Sauvignon, Cabernet Franc, Merlot, TANNAT, TEROLDEGO, Pinot Noir, MARSELAN, Touriga Nacional, and Tempranillo. White varieties are also cultivated, especially Chardonnay, Sauvignon Blanc, Viognier, Pinot Gris, and Gewürztraminer. Wines tends to be ripe and round, with balanced acidity.

Campos de Cima da Serra is in the north of Rio Grande do Sul, bordering the state of Santa Catarina. Situated on a high plateau at 900–1,100 m/2,953?3,609 ft, the region enjoys a cool climate, with continuous breezes to help protect against FUNGAL DISEASES. The ripening season is long, lasting into early April, whereas harvest in Campanha is typically finished by March. The DIURNAL TEMPERATURE RANGE can be 15 °C/27 °F, ensuring fresh acidity and well-structured wines. Since 2000 there have been several investments, and interesting wines are emerging from varieties such as Cabernet Sauvignon, Cabernet Franc, Merlot, Pinot Noir, Tannat, ANCELLOTA, and Petit Verdot as well as white varieties such as Chardonnay, Sauvignon Blanc, Moscato, Viognier, Glera, and Gewürztraminer.

In the state of Santa Catarina, Planalto Catarinense is renowned for being the coldest place in Brazil. Its icy weather has enabled production of the country's first naturally made ICE WINE. Elevations can reach 1,400 m/4,593 ft, hence an association has been created by a group of producers centred at São Joaquim Plateau to promote Vinhos de Altura (High-Altitude Wines). Conditions are especially

suited to Sauvignon Blanc and Pinot Noir, while long growing cycles also ensure adequate phenolic ripeness (see PHYSIOLOGICAL RIPENESS) for Cabernet Sauvignon, Merlot, Malbec, Cabernet Franc, Tannat, Syrah, Sangiovese, Nebbiolo, Montepulciano, and Tempranillo.

Vale do Rio São Francisco is the second largest wine-producing area after Rio Grande do Sul (RS). In the north of the country, between the states of Pernambuco and Bahia, it is defined by the São Francisco River, which provides the water for the IRRIGATION that is essential in this semi-arid climate. There is no winter at this latitude; the average temperature is 26 °C/79 °F and the sun shines 300 days a year. Less than 300 mm/12 in of rain falls annually. To encourage vine DORMANCY, producers withhold water. Once the plant is pruned and irrigation re-established, a new growing cycle begins (see TROPICAL VITICULTURE). With such techniques it is possible to harvest individual plots twice each year, which makes grape-growing commercially attractive. Unlike in RS, where most of production is done by smallholders, this region is dominated by a handful of large producers. Red varieties planted include Syrah, Cabernet Sauvignon, Tempranillo, Touriga Nacional, and Alicante Bouschet. White varieties include Moscato, Chardonnay, and Chenin Blanc.

Emerging areas The state of São Paulo, originally dismissed for being too hot and humid for winegrowing, is today responsible for some of the country's best wines. At its northern end, 200 km/124 miles from São Paulo city, Sauvignon Blanc, Chardonnay, and Viognier have shown potential, and Syrah and Cabernet Franc grown at elevations of 800–1,300 m can be exceptional. To overcome the adverse weather, growers prune twice, forcing the crop to ripen during winter months when conditions are cooler and drier. Over the border, in the state of Minas Gerais, renowned for its coffee plantations, a number of developments have shown serious potential, particularly for Sauvignon Blanc, Chardonnay, Tempranillo, and Syrah. There are also significant projects expanding throughout the states of Paraná, Espirito Santo, Goiás, and Bahia.

As wine quality has improved in the last three decades, Brazilian consumers' interest in wine has followed suit. In 2020, per capita consumption stood at around 2 l/0.5 gal, with the highest consumption in major cities and in the south, where wine is part of the culture due to historical links with Europe. Overall, more than 80% of the still wine consumed in Brazil is imported; by contrast, local producers supply over 80% of sparkling wine sold. Collective work by producers aligned with a clear, consistent message would help Brazilian wines gain more awareness in international markets.

D.V.J.

breathing, an operation, believed beneficial by some consumers, involving pulling the cork and letting the open bottle stand for a few hours before it is poured. In fact, in such circumstances the wine can take only the most minimal of 'breaths', and any change is bound to be imperceptible (except possibly in the case of BOTTLE SHOCK). The surface area of wine exposed to the air is so small that the effects of any AERATION as a result of this operation are negligible. See DECANTING for details of effective aeration.

Breede River Valley, important wine region in SOUTH AFRICA.

breeding. See VINE BREEDING.

Breganze, DOC in the VENETO region in north-east Italy, mainly for INTERNATIONAL VARIETIES. Wines of real interest are produced from Bordeaux varieties, but TAI BIANCO, the red MARZEMINO, and the rare Gruaja, probably related to Valpolicella's NEGRARA Veronese, add distinction to the DOC. The local VESPAIOLA, used for the BOTRYTIZED or DRIED-GRAPE sweet white speciality Torcolato, is increasingly produced in a complex dry version called Vespaiolo. There is also a growing number of TRADITIONAL METHOD sparkling wines, which must be made of Pinot Noir only. Maculan put Breganze on the map in the 1980s by focusing on quality instead of quantity: lowering yields, introducing modern winemaking equipment, and using BARRIQUES. Several estates followed his example, but the region receives little attention from the international market. W.S.

Breton, name sometimes used in the middle Loire for the CABERNET FRANC grape. The reference is not to Brittany but to Abbot Breton, who is reputed to have disseminated the vine in the 17th century.

Brettanomyces, sometimes called brett, one of the YEAST genera found rarely on grapes but more often in wines, especially those that have undergone BARREL AGEING or CASK AGEING. *Brettanomyces* in its perfect or sporulating form was known as **Dekkera**, but changes to the rules for naming fungi suggest *Brettanomyces* should be used for both sporulating and non-sporulating forms. It is widely considered a spoilage yeast due to the production of off-flavours in wine. There are producers who suggest that at low levels some of the flavours produced by *Brettanomyces* can improve red-wine complexity, but it may not be possible to keep them at this low level. (In some beers, for example Belgium's spontaneously fermented lambic and gueuze beers, *Brettanomyces* and its effects are considered key stylistic attributes.)

The first isolation of *Brettanomyces*, originally designated *Mycotorula intermedia*, in wine was in the 1930s by Krumbholz and Tauschanoff. Although the number of *Brettanomyces* species has expanded and contracted due to changes in methods of identification, of the five species currently recognized, *Brettanomyces bruxellensis* is the only one that has been unequivocally associated with wines worldwide (although there is mounting evidence of hybrids being isolated from wine). This species can grow in both red and white wine, although it is more often associated with red.

A resourceful microbe, *Brettanomyces* can grow either anaerobically or aerobically and utilize a variety of substrates at low levels and under restrictive conditions. The range and quantity of by-products produced by *Brettanomyces* depend on various factors, including levels of substrates, available precursors, and the size of the *Brettanomyces* population in the wine. The most important substrate is RESIDUAL SUGAR, although some OXYGEN is needed to maximize growth.

There are four key by-products of *Brettanomyces* growth which can affect the flavour and aroma of a wine: esterases, volatile fatty acids, tetrahydropyridines, and, arguably the most important, volatile phenols. Two critical volatile phenol compounds have been isolated from *Brettanomyces* activity: 4-ethylphenol (4-EP) and 4-ethylguaiacol (4-EG). 4-EP is often described as introducing an 'animal', 'medicinal', and 'sweaty saddle' flavour to wine. Its presence is an almost certain indicator of a *Brettanomyces* infection, and this is what most diagnostic laboratories test for to verify the presence of *Brettanomyces*. 4-EG in wine has a more appealing smoky, spicy, clove-like aroma. Formation of tetrahydropyridines, which are responsible for MOUSY off-flavour, seems to result from a large population of *Brettanomyces* which is stimulated by exposure of wine to oxygen, for example when the wine is on ULLAGE.

Brettanomyces can create significant levels of volatile phenols in a short period of time and is difficult to manage in the cellar. However, the tools for monitoring *Brettanomyces* have never been more advanced, and winemakers can use microbiological techniques such

as selective growth media containing cycloheximide (to inhibit the growth of *Saccharomyces*) and odourless hydroxyphenolic acid precursors (to allow for the production of volatile phenols), DNA-based identification methods, and/or analytical techniques such as gas chromatography–mass spectrometry to monitor volatile-phenol production in high-risk wines.

Brettanomyces strains display variable sensitivity to SULFUR DIOXIDE. Recent research suggests that winery populations are adapting to it but that these more resistant strains can be controlled by maintaining at least 0.625 mg/l molecular sulfur dioxide. Wines are at greatest risk of spoilage if fermentation is sluggish, if the onset of MALOLACTIC CONVERSION is delayed, or if there is insufficient molecular sulfur dioxide present during maturation. HYGIENE is an important factor in controlling the spread of *Brettanomyces* in the cellar. Areas that provide suitable niches for *Brettanomyces* are must lines, dirty crush equipment, barrels, or any tank or transfer line that is not cleaned effectively. There have also been suggestions that the fruit fly (see DROSOPHILA) can carry *Brettanomyces*. Once it is embedded in COOPERAGE, it can be difficult to eliminate from the cellar, and barrels may need to be discarded to significantly reduce the populations. As with other microbes, the cleaner the winery the more control one has over *Brettanomyces*. There are currently only two methods that virtually eliminate *Brettanomyces* at bottling: sterile FILTRATION and dimethyl dicarbonate (see DMDC). A.B.

bricco, or *bric* in the dialect of the north-west Italian region of PIEMONTE, indicates the highest part of an elevation in the landscape or, in particular, a vineyard with a steep gradient at the top of a hill. The term was first used on a wine label by Luciano de Giacomi in 1969 for his Bricco del Drago, a blend of DOLCETTO and NEBBIOLO grapes from Alba, and has been extensively used for the other wines of Piemonte ever since.

Brindisi, Adriatic port and DOC in PUGLIA for robust red wine made mainly from NEGROAMARO grapes and Chardonnay-based whites shipped mainly in BULK.

Britain , or Great Britain, has long been one of the most important markets for wine. It regularly imports more wine than any country other than Germany and has shown unusually healthy growth in wine CONSUMPTION since the late 20th century. Its long wine-MERCHANT tradition has made it one of the most discerning, yet open-minded, wine-consuming nations, and London has been an important centre for wine AUCTIONS and FINE WINE trading. Domestic vine-growing in England and Wales has now grown to a scale where most supermarkets and independent wine merchants stock English and Welsh wines, and they can be found on wine lists in many hotels and restaurants. A certain amount of wine is also made from imported

GRAPE CONCENTRATE (see MADE-WINE). Historically, Britain's commercial influence helped shape the very existence of such wines as claret, madeira, marsala, port, and sherry (see BRITISH INFLUENCE ON THE WINE TRADE).

See also ENGLAND (especially for history and modern viticulture), SCOTLAND, and WALES.

British Columbia is CANADA's second largest wine region, with 4,478 ha/11,065 acres of vines in the west of the country. European vines are well suited to the various growing areas once believed too cold for VITIS VINIFERA. The province is divided into nine GEOGRAPHICAL INDICATIONS (GIs) with five official sub-GIs. The Fraser Valley (40.5 ha/100 acres) near Vancouver and the coastal appellations Gulf Islands (46.5 ha) and Vancouver Island (112 ha, which includes the Cowichan Valley sub-GI) have a cool MARITIME CLIMATE and are largely planted to early-ripening varieties (Pinot Gris, Pinot Noir, Bacchus). Many wineries here buy additional grapes from the dominant appellation Okanagan Valley (3,892 ha/9,617 acres) and nearby Similkameen Valley (256 ha/633 acres). These latter appellations, comprising 92.5% of British Columbia's vineyards, are 400 km/249 miles east of Vancouver, in the rain shadow of the Coastal Mountain Range. The short growing season is hot and arid, which makes it suited to ORGANIC VITICULTURE. Hot, dry summers have also led to increased risk of WILDFIRES. With the lowest precipitation in southern Canada, IRRIGATION is essential.

Four more GIs were announced in 2018: Thompson Valley (36 ha/90 acres), Shuswap (40.5 ha), Lillooet (20 ha), and the Kootenays (34 ha) are small inland regions where vineyards and orchards have grown for decades.

The Okanagan Valley, a superbly scenic glacial trench extending from the 49th parallel north for about 160 km/100 miles, is defined by the vast Okanagan Lake, the largest of the valley's chain of lakes, which tempers the summer heat (see LAKE EFFECT). The southern part of the Okanagan is desert-like and very hot and dry during the

growing season. Vineyards throughout the Okanagan are planted on CLAY, GRAVEL, SAND, or LOAM with soil drainage properties depending on site.

The first vines in the Okanagan were planted in 1859 by a French Oblate priest, Charles Pandosy. The earliest attempt at commercial grape-growing was near Salmon Arm in 1907 (in the present-day Shuswap GI) and in 1927 horticulturalist J. W. Hughes planted VITIS LABRUSCA vines in Kelowna and sold grapes to the province's first two wineries.

Plantings of *labrusca* continued over the next 30 years with winter-hardy French and American HYBRIDS introduced in the 1960s. There were also a few experimental plantings with *vinifera*. In 1961 Quail's Gate Winery planted Chasselas, which was mistakenly included in its order of hybrid vines, and in the late 1960s Chenin Blanc and Trebbiano were planted in the south Okanagan Valley. In 1977 the British Columbia government established the Becker Project, hiring Helmut Becker of Germany's GEISENHEIM Grape Breeding Institute to undertake planting trials of Riesling, Pinot Blanc, EHRENFELSER, SCHEUREBE, and GEWÜRZTRAMINER, with many early plantings overseen by Osoyoos Indian Band at their Inkameep Vineyards in the south Okanagan. The positive results spurred more *vinifera* plantings. In the 1970s and 1980s on Vancouver Island there were also government-funded planting trials of almost 100 varieties, including the now widely grown ORTEGA, Pinot Noir, and Pinot Gris.

The 1988 free-trade agreement between Canada and the United States was also a catalyst for quality as it removed the subsidies and protections domestic wines had enjoyed against competing imports. Through federal government assistance, more than two-thirds of *labrusca* and French hybrid vineyards in the Okanagan were pulled out and replaced with *vinifera*.

As the number of wineries grew, the industry formed the British Columbia Wine Institute in 1990 (now known as Wine Growers British Columbia) and adapted the ONTARIO-developed Vintners Quality

Alliance (VQA) regulations, which imposed the region's first significant standards of wine quality.

By 2021 British Columbia boasted 288 wineries working with more than 90 grape varieties, with Merlot, Pinot Noir, and Cabernet Sauvignon leading the reds and Pinot Gris, Chardonnay, and Gewürztraminer dominating whites. The appellation rules allow for a wide variety of styles, from sparkling wine to ICEWINE. J.D.

British influence on the wine trade. For centuries, wine consumption in Britain has had significant ramifications in many of the world's most important wine regions. A cool, wet climate has limited the production of wine in ENGLAND, so that British wine drinkers historically had no choice but to look overseas for their supplies. Since they owe no permanent allegiance to any one wine region or wine-producing country, they have traditionally had a broad range from which to choose, although that choice has been dictated by convenience, FASHION, ECONOMICS, and POLITICS as often as by taste.

British influence on the wine trade resulted from more complex circumstances than a simple lack of native wines, however. (Otherwise, British influence on the wine trade would be no greater than, for example, Swedish or Danish—although see DUTCH WINE TRADE.) Britain enjoyed a unique combination of factors: relative prosperity and political power, a worldwide commercial empire supported by a strong navy, and a steadily increasing middle class. These circumstances not only helped to foster an interest in imported wines but also provided the economic clout to acquire them. And at certain times in history, in specific wine regions, the British market

was so influential that wine styles evolved, or completely new wines were invented, to satisfy its demands.

The first region fully to devote itself to British needs was SOUTH WEST FRANCE, when it belonged to the English Crown. Indeed it could be argued that for 300 years, from 1152, Britain did have its own extensive vineyards. During this period BORDEAUX was transformed into the most important wine centre in France. Vineyards were planted or extended around the city and far up the rivers Garonne and Dordogne to quench the English thirst. The loss of Bordeaux to the French in 1453 saw a decline in exports to England, but this part of France was by now well established as a commercial wine region.

During the Middle Ages, wine was relatively cheap and plentiful in Britain. Wines from Germany, Portugal, Spain, Italy, Greece, the Mediterranean islands, and the Holy Land could all be found in London taverns, as well as those from France. It was not until the 16th century, however, that British merchants found, in southern Spain, a wine region to compensate for the loss of Bordeaux. Known collectively as SACK, the wines of Andalucía became immensely fashionable in Tudor times despite wars with Spain. Thousands of BUTTS of wine were sent back to England by British merchants settled in Sanlúcar and MÁLAGA. British taste and investment laid the foundations of what was to become the SHERRY industry.

The 17th century brought many problems for wine. The introduction of exotic new beverages such as coffee, chocolate, and teas, as well as the growing popularity of 'hopped' beer, threatened the wine trade. The situation was not eased by the fact that the cost of wine had steadily grown to such a point that only the middle and upper classes could afford it. Crippling customs duties exacerbated the crisis. If the wine trade was to survive in Britain, some drastic changes were needed.

Medieval CLAIRET and Tudor sack had been staple beverages enjoyed by many English. British influence at the end of the 17th century was felt by a different sort of wine producer and encouraged the development of sophisticated superior-quality wines which only a

limited clientele could afford. This select English market had particular influence in two areas of France: Bordeaux and CHAMPAGNE.

After the Restoration of Charles II in 1660, all things French were extremely fashionable in London. At this time individual producers in both Champagne and Bordeaux were making efforts to improve the quality of their wines. Champagne was promoted in London by French exiles (although it was English aristocrats who developed the taste for sparkling wine while French connoisseurs decried it as an aberration). Meanwhile a wealthy landowner from Bordeaux, Arnaud de Pontac, succeeded in creating a stir when he opened a restaurant in London, Pontack's Head in Abchurch Street, to sell the wines of his Graves estate of HAUT-BRION.

The English aristocracy were delighted by these new styles of French wines, CLARET, and paid through the nose for them. Thus London became the chief market for fine wine and in turn influenced the quality of the wines themselves, for in the wine trade it is export that makes reputations, raises standards, and, above all, provides the driving force for investment. New vineyards were planted in Champagne and in the MÉDOC to exploit these refined English palates and purses.

The next great instance of a British-inspired wine was PORT. The exorbitant cost of champagne and good-quality claret, combined with the supply difficulties that resulted from war with France, caused British merchants to look elsewhere. Political rapprochement with Portugal signalled the possibility of a new, and cheap, source of wine. The British moved into OPORTO, prospected the DOURO Valley for wine and vine-growing potential, and started a boom. Huge quantities of port were sent to Britain from the early 1700s, and as the century progressed the nature of the wine evolved to suit. Originally a rough red table wine, port was soon discovered to be improved by the addition of brandy, which made it even more palatable to the English and considerably more stable for the sea voyage required. A whole new industry was created, and the steep sides of the Douro Valley terraced and planted to victual the English shires.

Similarly, Sicily's MARSALA wine industry was developed by the British when, in the early years of the 19th century, Napoleon set up his Continental System in the hopes that, by depriving his enemies of French wine (among other things), he could cause British morale to collapse.

In 1860, William Gladstone stated that an Englishman's taste in wine 'is not an immutable, but a mutable thing'. He meant that British palates were capable of adapting to whatever was most available or pleasing at any particular period. A host of factors influenced taste, and in turn demand influenced supply. Of all wine-drinking societies, Britain showed these developments most strikingly. Top-quality claret, sparkling champagne, and distinguished vintage port are today sought after all over the world. But ties of tradition and affection remain strong with the British market, a reminder of the fundamental part it played in the evolution of these and many other wines and the wine trade in general.

From the early 1980s, Great Britain was targeted by many of the world's wine producers as one of the few substantial wine markets in which per capita wine consumption was growing. In 2021, according to OIV statistics, only Germany and the US imported more wine than Great Britain, but 56% of German imports were of BULK WINE compared with 32% and 35% for the US and the UK respectively.

The revival of selling wine at AUCTION and the resultant nucleus of FINE WINE traders made London the focus of the fine-wine market until the US and HONG KONG took over. But Britain retains its influence as the chief production centre for the LITERATURE OF WINE and for wine EDUCATION.

Johnson, H., *The Story of Wine: From Noah to Now* (2020).

Simon, A. L., *The History of the Wine Trade in England* (1906–9).

British wine, a curious alcoholic drink made in the image of WINE from dried grapes, MUST, or GRAPE CONCENTRATE, typically imported into Great Britain. It is known as MADE-WINE, and a decidedly manufactured product it is. It may also contain other fruits or vegetables, honey, sugar, and more. MEAD and ginger wine are also types of British wine.

Most commonly, grape concentrate is imported in bulk throughout the year from wherever happens to be able to supply the best value (Spain is a notable source). The must is reconstituted by adding water and is fermented using selected YEAST strains. Until the 1980s, almost all British wine produced was FORTIFIED, made to resemble sherry or port, or flavoured with ginger or other spices or fruits. Since the early 1980s, British wines of normal TABLE WINE strength have also been made, much to the dismay of the producers of English wine (see ENGLAND), with whose products made from freshly picked grapes there is possible confusion.

Producers of British wine, few and relatively industrial, claim as initial historical precedent a Francis Chamberleyne, who was granted a charter by Charles I in 1635 to make wine from imported raisins. The real catalyst for the establishment of an economically viable British wine trade came when a technique for the concentration of GRAPE JUICE was perfected by Emmanuel Roche of Toulouse, south-west France, who promptly shared it with two Greek brothers Mitzotakis, members of his wife's family, to help them sell a surplus stock of Greek grapes and grape juice in London in 1900. Their Crown Grape Wine Company (worryingly, on the site of a previous VINEGAR plant) eventually became Vine Products, whose premises outside the capital in Kingston-upon-Thames were described in the 1960s as 'the biggest BODEGA in Europe'. This highly profitable concern continued under various owners until 1989.

WSTA, *The Code of Practice of the British Wine Producers' Committee of the Wine and Spirit Trade Association* (2021).

Brittany, or Bretagne in French and Breizh in Breton, may be more known for its apple-based beverages, but winegrowing is increasing in popularity in the 21st century. The peninsula, which juts out into the Atlantic at France's north-western edge, has grown grapes since at least the 5th century but effectively disappeared from wine maps in the 20th century due in part to PHYLLOXERA and then to a Second World War-era prohibition against commercial wine production in the province which lasted until 1 January 2016. Since 2006, the ARVB (Association pour la reconnaissance des vins Breton) has encouraged winegrowing in Brittany; in 2021 a professional group, the ABV (Association des vignerons breton), was launched. By 2022 there were about 40 ha/99 acres of vines in commercial production, with many more in development. The most popularly grown grape varieties in this MARITIME CLIMATE include CHENIN BLANC, CHARDONNAY, PINOT GRIS, and SAVAGNIN, as well as the red grapes GAMAY and PINOT NOIR; there is also experimentation with disease-resistant HYBRIDS and varieties such as ALBARIÑO.

www.vigneronsbretons.bzh

Brix, scale of measuring total dissolved compounds in grape juice and therefore its approximate concentration of grape sugars. It is used in the United States; like other scales used elsewhere (see BAUMÉ and OECHSLE), it can be measured with either a REFRACTOMETER or HYDROMETER. Degrees Brix indicate the percentage of solutes (of which about 90% are sugars in ripe grapes) by weight in the liquid, at a temperature specified for the instrument used. One degree Brix corresponds approximately to 10 g/l sugar.

The Balling scale is similar although the specified temperature may differ. For more details, see MUST WEIGHT. B.G.C.

Broadbent, J. Michael (1927–2020), wine taster, writer, and auctioneer known particularly for his experience of fine, old wines.

Broadbent trained initially as an architect in London and then joined the late Tommy Layton as a wine-trade trainee in 1952. Three years later he joined Harveys of Bristol, then in its heyday, where he worked for Harry WAUGH and eventually became UK sales director. In 1966, partly as a result of his own personal enterprise in corresponding with the chairman, Broadbent was taken on by Christie's to revive their, and the London, wine AUCTION business. From then until 1992 he ran Christie's wine department and in that capacity traded in and tasted a greater number of fine and rare wines than anyone else in the world.

Naturally didactic, he lectured on wine from the late 1950s and conducted wine tastings all over the world, always emphatically insisting on correct tasting conditions. Never inhibited about airing his elegant wine vocabulary in public, he painstakingly recorded his disciplined impressions of every wine tasted, nearly 120,000 of them in more than 150 notebooks.

It is these notebooks, retyped by his equally hard-working late wife Daphne, which formed the basis for Broadbent's *Great Vintage Wine Book* and the more discursive *Vintage Wine*, unique records of wine-tasting history which stretch back to wines of the early 18th century. Unlike PARKER, his most obvious rival as publisher of personal TASTING NOTES, Broadbent eschewed scoring wines with numbers, preferring to award up to five stars to each wine.

Broadbent's life was marked by competition, particularly with Sotheby's, and ambition. While at Christie's he not only wrote his own classic on the subject of *Wine Tasting*, first published in 1968 and much republished since, but instituted and directed Christie's Wine Publications, which issued many invaluable books—including the *Christie's Wine Review* anthologies—during the 1970s and 1980s. He also wrote a highly personal monthly column for the British magazine *Decanter* from its inception in 1977 until 2013.

Incurably active and apparently indefatigable, he became a MASTER OF WINE in 1960, a freeman of the City of London in 1964, chairman of the Institute of Masters of Wine in 1970, international president of the INTERNATIONAL WINE & FOOD SOCIETY in 1986, master of the City of

London's Distillers' Company in 1990, and council chairman of the Wine & Spirit Trades Benevolent Society in 1991; he even stood, unsuccessfully, for sheriff of the City of London in 1993. He was made a Chevalier de l'Ordre du Mérite National in 1979, before he was implicated in the sale of the so-called Jefferson bottles, subsequently shown to be counterfeit. His second marriage, in 2019, was to Valerie Smallwood, the widow of a fellow MW, owner of another fine cellar. His son Bartholomew could be said to have helped establish the United States as the prime market for vintage PORT in the 1990s and continues as a wine importer there.

Broadbent, M., *Wine Tasting* (various editions 1968–2022).

Brock University is CANADA's leading university for vine- and wine-related ACADEME; it offers North America's only undergraduate and graduate degrees in the study of COOL-CLIMATE VITICULTURE and winemaking. It is home to the Cool Climate Oenology and Viticulture Institute (CCOVI), established in 1996. Students can participate in exchange programmes with Okanagan University College in British Columbia, neighbouring Niagara College, Acadia University in Nova Scotia, and LINCOLN UNIVERSITY in New Zealand. CCOVI graduates make wine in all regions of Canada, as well as in California, Australia, and Germany. The Institute conducts research on grapevine winter injury (see WINTER FREEZE), quality crop improvement through PRECISION VITICULTURE, disease and pest control, particularly SOUR ROT and the Multicoloured Asian Lady Beetle (see LADYBUG TAINT), ICEWINE production and authentication, sparkling wine production, and sensory and consumer perceptions of Ontario wine. CCOVI has created a Grape Preharvest Monitoring Program for berry SAMPLING and analysis, as well as VineAlert, a comparative grapevine-bud cold-hardiness database. Niagara College offers a Winery & Viticulture course as well as a graduate course in Wine Business Management.

brokers, important members of any trade and increasingly important when it comes to wine. Known charmingly as *courtiers* in French, brokers can play a vital role as intermediaries between vine-growers and merchants, or NÉGOCIANTS, discussing, collecting, and exhibiting hundreds of samples, or *échantillons*, and taking a small percentage of any eventual sale.

Another class of brokers, further along the distribution chain, guide those who sell wine through the maze of those who produce it, some of them nursing 'stables' of producers rather in the manner of a literary agent representing a rollcall of authors.

And then, just one or two links away from those who actually pull the cork, there are the FINE WINE brokers, those who sell from a list of glamorous properties and vintages which may, but often do not, belong to them. This last group, many of whom are based in Britain, represents one of the very few sectors of the wine trade that has been highly profitable. Several London firms did extremely well in the 1990s, and especially with the 2009 and 2010 Bordeaux EN PRIMEUR, as the number of wine collectors and investors around the world increased exponentially and ASIA woke up to the delights of fine wine. The sort of wine of interest to fine-wine brokers and traders typically sits in an unbroken CASE in a BONDED WAREHOUSE in Britain while being traded so profitably around the world. The profitability of this business was so obviously attractive to traditional MERCHANTS more used to trading and delivering individual bottles and cases of much less valuable wine that in the early and mid 1990s many of them set up their own broking divisions. Much of these brokers' trade is between their own established customers, a convenient internal market. Towards the turn of the century most of these fine-wine brokers established outposts, often extremely profitable, in HONG KONG.

Brouilly, largest of the BEAUJOLAIS crus, with 1,200 ha/3,000 acres of vineyards producing some of the region's most velvety wines. Vineyards flank the VOLCANIC Mont Brouilly, although Côte de Brouilly is an entirely separate appellation including just 315 ha/778 acres on the top portion of the hill. Its wines tend to be more concentrated and longer lived than those of Brouilly. J.F.B.

brown marmorated stink bug is, as the name suggests, an insect winegrowers would not want to crush along with their grapes. This insect (*Halyomorpha halys*) was an accidental introduction from Asia to Pennsylvania in the mid 1990s and is now found in more than 40 states, as well as in Canada, Germany, France, and Italy. The beetle releases two TAINT compounds, tridecane and E-2-decenal, that can affect wine quality. Despite widespread early concern in many parts of the world, the pest has not so far caused substantial problems for wine producers, probably because grapevines are not the insects' preferred food source. R.E.S.

Brulhois, AOC in SOUTH WEST FRANCE encompassing 206 ha/510 vineyard acres in the rolling farmland near Agen on both sides of the Garonne. From medieval times Brulhois wines were blended with those of BORDEAUX, but the ravages of PHYLLOXERA in the late 19th century were followed by widespread planting of HYBRIDS. The district's wines made from recently replanted VITIS VINIFERA vines were given VIN DE PAYS status initially before elevation to VDQS in 1984 and to AOC in 2011. The majority are red and must be a blend of at least 70% Cabernet Franc, Merlot, and TANNAT (which must constitute 15–40% of the blend); they can include small amounts of FER, MALBEC, and ABOURIOU. The wines are often described as 'black' and

are at their best after five years. Some rosé is also made. There are a handful of independent growers, but most wine is made by one of the two CO-OPERATIVES and consumed locally. P.S.

Brunello, Montalcino name for SANGIOVESE planted there.

Brunello di Montalcino, one of Italy's most prestigious red wines, having been invented as a wine by Ferruccio BIONDI-SANTI, the first to bottle it and give it a distinctive name, in 1865. Conventional descriptions of the birth of the wine stress Biondi-Santi's successful isolation of a superior CLONE of SANGIOVESE, the Sangiovese Grosso or Brunello, an investigation begun by his father Clemente Santi. The 1865 vintage of a wine Clemente had labelled 'brunello' had been a prize-winning entry in the agricultural fair of Montepulciano in 1869, indicating that genetically superior material was available in the zone at an earlier date. (Some records show the wines of Montalcino referred to as Brunello as early as the 14th century; see TUSCANY, history.) Only four vintages—1888, 1891, 1925, and 1945—were declared in the first 57 years of production, contributing an aura of rarity to the wine that translated into high prices and, in Italy at least, incomparable prestige. The Biondi-Santi were the only commercial producers until after the Second World War, and a government report of 1932 named Brunello as an exclusive product of the family, estimating its total annual production at just 200 hl/5,280 gal.

Until the 1960s the region was almost exclusively known for sweet and often sparkling MOSCADELLO. With the arrival of the American company Banfi at the end of the 1970s, Brunello's fortunes took a sharp turn. Banfi's owners, the Italo-American Mariani brothers, who had had huge commercial success with LAMBRUSCO, bought up whole swathes of land in the hotter, southern part of the zone which until then had never been vineyards, planting them with Moscadello for the production of a fizzy sweet white. The plan failed spectacularly, after which the vines were grafted over to Sangiovese and INTERNATIONAL VARIETIES. Banfi started to produce Brunello in great

quantity and had such commercial success that soon Brunello turned into an internationally recognized brand with a distinct style. The region, which in the 1960s consisted of 11 producers on a mere 63.5 ha/157 acres, swelled to 2,100 ha/5,189 acres (plus 510 ha/1,260 acres for Rosso di Montalcino) shared by 260 producers by 2020. This dramatic increase was made possible by including land new to viticulture. In 1996 the DOC, Sant'Antimo, was added to the production regulations to allow for the international varieties that inevitably turned up in the wake of the success of SUPERTUSCANS.

The question of Brunello's true identity culminated in a blending scandal in 2008 when Italy's financial police sequestered batches of wines from several producers that were not the mandatory 100% Brunello but rather illegal blends containing international varieties. The scandal, known as Brunellogate (Brunellopoli in Italy), led to a controversial proposal, eventually rejected, to allow the addition of other varieties, highlighting the uncomfortable fact that the official Brunello zone may well include land unsuitable for Brunello vines.

Brunellogate proved a stylistic turning point, as opaque, dark, highly concentrated, oaked wines began to disappear in favour of wines that showed increased transparency and greater stylistic diversity.

MESOCLIMATE, ELEVATION, and clones all play a part in these stylistic differences. The town of Montalcino, 112 km/70 miles south of Florence, enjoys a warmer, drier climate than CHIANTI. Indeed, it is the most arid of all Tuscan DOCG zones, with an annual rainfall of about 700 mm/28 in (compared with over 900 mm in central Chianti Classico). In addition, cool MARITIME breezes from the south-west ensure both excellent ventilation and cool evenings and nights. Sangiovese can reach its maximum ripeness here, giving fuller, more structured wines than anywhere else in Tuscany.

The zone can be split roughly in two: the north, with vineyards at ELEVATIONS up to 500 m on GALESTRO soils; and the warmer south, where there is more CLAY in the soil and where the wines tend to be fuller than the more aromatic wines from the north. Many producers have vineyards in both north and south to give balance to their wines

as well as to offset the effects of CLIMATE CHANGE. While winemaking practices may differ from estate to estate, terroir differences put a far greater stylistic stamp on the wines, of which the finest examples manage the tricky balancing act of combining layers of red fruit, bold structure, and elegance.

The DOC regulations of 1960, largely written by Biondi-Santi on the basis of the family's oenological practices, include five to six years' CASK AGEING for the RISERVA and established a model of Brunello as a full-bodied, intense, long-lasting wine, which was confirmed in 1980 by the DOCG rules. The minimum cask-ageing period was lowered to 36 months in 1990 and then to two years in 1998. The once-popular practice of BARRIQUE ageing has been widely supplanted by a return to large oak casks, and a growing number of producers are using CONCRETE, AMPHORAE, and oval casks of Austrian oak.

More attention is being paid to SINGLE-VINEYARD WINES, which are sold at a premium. This growing interest in a hugely profitable aspect of Montalcino's terroir has not broken the region's defiant resistance to producing a detailed map of its vineyards.

The qualitatively heterogeneous Rosso di Montalcino, the 100% Sangiovese DOC wine from either declassified Brunello wine or vineyards unclassified for Brunello production, can be marketed after one year. W.S.

O'Keefe, K., *Brunello di Montalcino: Understanding and Appreciating One of Italy's Greatest Wines* (2012).

SEE WEB LINKS

www.consorziobrunellodimontalcino.it

brush, the flesh remaining attached to the end of the berry stalk, or stem, after a grape is pulled from the bunch, as occurs during MECHANICAL HARVESTING or DESTEMMING, for example. The brush's size varies between vine varieties, from a barely discernible bit of flesh to a 'tongue' up to 5 mm/0.2 in long. The brush is caused by strong adhesion between the berry and stem, causing tearing of the skin,

combined with particular characteristics of the zone of the flesh at the top of the berry. The cells of the brush are rich in TANNINS. The French term is *pinceau*.

The word 'brush' is also used in the US for the total cane growth evident after LEAF FALL. B.G.C.

brut, French word meaning 'crude' or 'raw', adapted by the CHAMPAGNE industry for wines made without (much) added sweetening or DOSAGE. It has come to be used widely for any SPARKLING WINE to indicate one that tastes bone dry. The upper limit for the RESIDUAL SUGAR of a brut champagne has been reduced from 15 to 12 g/l. A wine labelled extra brut should contain less than 6 g/l residual sugar. Particularly dry wines may be labelled brut nature, with less than 3 g/l residual sugar, and are made without dosage. The word bruto may be used in Portugal.

Brynšt, Czech synonym for TRAMINER.

Bual, Anglicized form of BOAL most often used for a style of MADEIRA, richer than SERCIAL and VERDELHO yet not as sweet as that called MALMSEY.

Bucelas, tiny white wine DOC just north of Lisbon, Portugal's capital city (see map under PORTUGAL) and formerly spelt Bucellas. At one time it was FORTIFIED, and it is thought to be Shakespeare's Charneco, mentioned in *The Second Part of King Henry IV* and named after one of the local villages. The Duke of Wellington popularized the wine in Britain following the Peninsular Wars, and for a time Bucelas was widely sold and appreciated in Victorian Britain as Portuguese HOCK. Representing at least 75% of DOC wines, ARINTO can make zesty, fruity dry whites in this sub-MEDITERRANEAN CLIMATE thanks to the tempering Atlantic breezes, which funnel up the river Trancão. Oaked,

sparkling, and late-harvest styles are produced, too. Nonetheless, as at 2020, there were only 138 ha/341 acres under vine. The acquisition of the region's largest estate by SOGRAPE in 2019 bodes well for future investment. S.A.

bud, a small part of the vine shoot which rests between the leaf stalk or PETIOLE and the shoot stem. In the summer it is covered by green scales, which turn brown in winter. The bud contains three miniature, compressed (primordial) shoots. Normally the best developed of these shoots (from the 'primary' central bud) bursts at BUDBREAK. Grapevine buds are classified as compound and fruitful; their development is complex. B.G.C. & R.E.S.

Budai Zöld, Hungarian white grape grown around Lake Balaton making deeply coloured, full-bodied wine for local consumption.

budbreak, or budburst, a stage of annual vine development during which small shoots emerge from vine BUDS. This process begins in the spring of the new growing season and signals the end of DORMANCY, the period of winter sleep. The first sign that dormancy is ending and budbreak imminent is BLEEDING, when the vines begin to drip water from PRUNING cuts. The buds left at winter pruning begin to swell in the few weeks prior to budbreak, and budbreak itself is marked by the first signs of green in the vineyard, as the first young leaves unfold and push through the bud scales.

Budbreak takes place in early spring in cool climates, when the average air temperature is about 10 °C/50 °F. For many northern-hemisphere regions, budbreak occurs in March, and for the southern hemisphere in September. Budbreak is more uniform when winters are cold but not subject to WINTER FREEZE. In warm to hot regions, budbreak is earlier, and in cooler regions it is delayed. In fact in TROPICAL VITICULTURE the vines never achieve proper dormancy, and budbreak can be induced by pruning at any time of the year.

Not all varieties show budbreak at the same temperature. For example, French studies indicate that for the early TABLE GRAPE Pearl of Csaba budbreak occurs at 5.6 °C, MERLOT at 9.4 °C, and UGNI BLANC at 11 °C. Late pruning in winter delays budbreak, and this can be used to reduce the risk of winter FROST and also to delay HARVEST when growth cycles are compressed by CLIMATE CHANGE (see HARVEST COMPRESSION). See also DOUBLE PRUNING.

In temperate regions with warm winters, a few warm days, even in midwinter, can be enough to induce bud swelling, which can lead to budbreak if the warmth persists. One of the very few places around the world to show this problem is the MARGARET RIVER region in Western Australia. Because of the nearby moderating effects of the Indian Ocean, the midwinter (July) mean temperature is a warm 13 °C/55 °F. CHARDONNAY vines are particularly prone to this premature budbreak, with only a few buds breaking on the vine in midwinter and the rest somewhat more erratically later in spring.

For vines which are properly pruned (see BALANCED PRUNING) most of the buds left at winter pruning will burst, and budbreak is near 100%. Budbreak is, however, normally lower for buds in the middle of long CANES. (When vines are left unpruned, as in MINIMAL PRUNING, it is the buds near the ends of canes and higher up the canes which burst preferentially; see APICAL DOMINANCE.) The two buds on either side of the cane just below the pruning cut typically burst. This is because of the flow of HORMONES in the plant and is the reason for pruning to two-bud SPURS. The biggest problem for many vineyards at this time of the year is spring frost, to which the young shoot growth is particularly sensitive. R.E.S.

Iland, P., et al., 'Grapevine growth', in *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

budding, the viticultural operation of GRAFTING where only a single bud is inserted into the rootstock. The term is also used in the context of BUDBREAK.

budwood, name given to vine CUTTINGS when they are destined for GRAFTING. Depending on the cutting length and bud spacing, four to 12 buds may be taken from each cutting. The budwood is typically put into cold storage to await grafting in the spring.

buffering capacity, the measure of resistance to change in PH by the addition of either acids or bases.

Bugey, Vins du, collective name for the wines of the Ain *département* in the southern Jura Mountains just west of SAVOIE in eastern France, increasingly called just Bugey. Vines have been present here since Roman times, and its chequered history has seen it under the rule of the Dukes of Burgundy and the House of Savoy. Under the medieval influence of MONKS AND MONASTERIES the area was considered an important wine producer. The wines were elevated to AOC from VDQS in 2009. In 2020, the region covered roughly 470 ha/1,161 acres in three chief vineyard zones of Cerdon, Belley, and MONTAGNIEU.

In the northern sector, hillside vineyards lie at 400–500 m/1,312–1,640 ft in elevation and produce almost exclusively the sparkling pink Bugey-Cerdon. Delicate, medium-sweet, with around 7.5% alcohol, Cerdon is made by the MÉTHODE ANCESTRALE from the Gamay grape and some POULSARD. It accounts for nearly half of Bugey's annual four-million-bottle production. In the southern sector on rolling hills close to the Rhône river other white and pink TRADITIONAL METHOD sparkling wines are important, usually labelled *mousseux* or *pétillant*. The still wines are mainly VARIETAL: Chardonnay dominates whites and traditional-method sparkling wines, and Savoie's ALTESSE

performs well as Roussette du Bugey; tiny quantities of ALIGOTÉ and Pinot Gris as well as JACQUÈRE, MONDEUSE BLANCHE, and MOLETTE are also grown. Among reds, Gamay and Pinot Noir are joined by the interesting MONDEUSE NOIRE of Savoie. These were the wines with which the notable gastronome Anthelme Brillat-Savarin grew up, and today attention is being given to the increasing numbers of young, ORGANICALLY run estates. W.L.

Lorch, W., *Wines of the French Alps: Savoie, Bugey and Beyond* (2019).

Bukettraube, or Buketrebe, white grape variety, a GERMAN CROSS of SILVANER and TROLLINGER. It is grown almost exclusively but to a limited extent in South Africa (44 ha/109 acres in 2020) for sweet and occasionally BOTRYTIZED dessert wines, with a slightly grapey aroma.

Bulgaria , Eastern European country that has undergone a winemaking revolution from volume production to small, quality-focused estates.

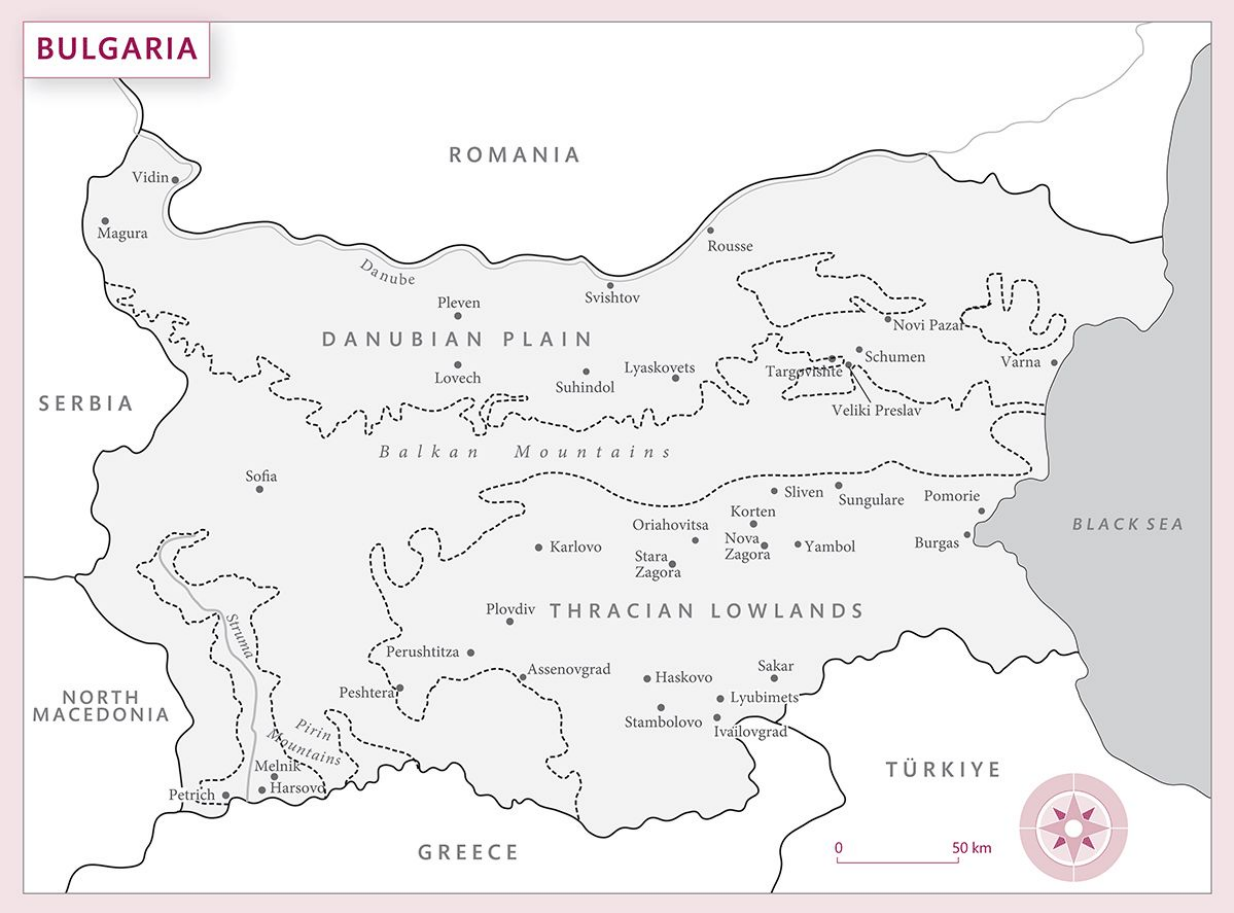
History

The country has a long vinous heritage, with traces of grape-growing found on Neolithic sites and the first written records of wine, plus ornate drinking vessels, linked to ancient Thrace (a territory that includes modern-day Bulgaria). Numerous archaeological finds depict wine consumption, including discoveries at the Thracian temple complex near Starosel dated to the end of the 5th century BCE. PLINY the Elder stated that the first European wine grower was a Thracian named Evmolp. Wine drinking continued with stories linked to Khan Krum, then the country's conversion to Christianity from 864 CE brought new impetus to wine consumption (see EUCHARIST). Ottoman rule from the 15th to the 19th centuries (see ISLAM) suppressed but failed to destroy viticulture, as winemaking survived as a symbol of the Christian community. By liberation in 1878, the country had around 50,000 ha/123,553 acres under vine, and the first law enacted as an independent state was a statute for excise duty on drinks. Unfortunately, PHYLLOXERA arrived soon after, prompting the establishment of Europe's fourth research institute, at Pleven, in 1902.

At the beginning of the 20th century, the first Bulgarian wine CO-OPERATIVES were founded to overcome the problem of fragmented land holdings. After the Second World War, the new communist government, established in 1947, nationalized wine production and quickly set about collectivizing the vineyards. In 1949, the state wine and spirits monopoly Vinprom was set up to control all commercial production and trade.

In 1952, decree number 1058 was enacted, officially promoting viticulture and winegrowing in Bulgaria. Bulgaria had a major role as wine supplier in the Soviet Bloc's planned economy (Comecon), so the industry underwent significant modernization to meet these requirements. Until the early 1960s, INDIGENOUS VARIETIES dominated, especially DIMYAT, PAMID, and MAVRUD, but Comecon demands saw extensive single-variety plots of INTERNATIONAL VARIETIES such as

Cabernet Sauvignon, Merlot, and Chardonnay as well as RKATSITELI, MUSCAT OTTONEL, and ALIGOTÉ, often on flatter sites and using higher TRAINING SYSTEMS designed to avoid frost and increase YIELDS. By the 1970s Bulgaria had around 150,000 ha/370,658 acres of wine grapes, chiefly for the SOVIET UNION and Comecon countries. Vinprom controlled 80% of winemaking facilities, with three smaller state-owned 'vine and wine complexes' producing the remainder. All exports went through the state monopoly Vinimpex.



Western expertise came with PepsiCo, the giant American cola manufacturers. In the 1970s they were eager to barter their soft-drink concentrate in Eastern Europe for a saleable product (wine in Bulgaria's case). They established links with California's wine faculty at DAVIS, with Professor Maynard AMERINE, and provided travelling winemakers. This influenced the style of winemaking, for instance

vinifying Chardonnay with American oak and full MALOLACTIC CONVERSION. The year 1978 saw the Ordinance of Wines with Controlled Origin; following detailed research, 23 controlled-origin wines were approved between 1982 and 1986. This marked a shift from production of quantity towards quality, and at its peak Bulgaria was the world's fourth largest exporter of bottled wine. It also set the scene for exports of inexpensive but competently made VARIETALS to the west, especially to Britain. This proved to be fortunate timing as demand from the vast Soviet market started to decline, accelerated by GORBACHEV's arrival as Soviet premier. His campaign to curb alcohol consumption in the mid 1980s involved uprooting huge tracts of Bulgarian vineyard. Grape prices were then fixed every year, irrespective of quality, which encouraged the co-operatives to turn their attention away from vines to other crops.

By 1990 the total crop was just 1.8 million hl/40 million gal, and this at a time when exports to the West were at record levels.

Post-communism

In 1990, the wine sector was suddenly liberalized as part of the free-market reforms introduced in the wake of the fall of communism in 1989. Throughout the 1990s, the Bulgarian wine industry was in disarray as attempts were made to return land to its pre-1947 owners, though records were often poor and families divided. This process of restitution continued until 2000, with the result that land was handed back in small, fragmented holdings, often to uninterested owners. There was little investment in viticulture due to uncertainties over land ownership. Winemaking also remained separated from grape-growing, and even as recently as the mid 2000s few wineries actually owned vineyards. Yields, already low, declined further, and by the end of the 1990s the Bulgarian wine industry was suffering from a serious fruit shortage. The ensuing fierce competition for grapes encouraged early picking, which in turn led to lean, underripe wines at a time when western consumers expected ripe, fruity wine styles. Bulgaria rapidly lost market share and many wineries found themselves in trading difficulties.

Bulgaria joined the EU in 2007. Undoubtedly, pre-accession EU funding programmes helped to revitalize wine. Subsidies of up to 50% for both winery and vineyard investments brought in substantial foreign capital and enabled some small, individual projects and wine estates—a novelty in Bulgaria at that time. Many wineries took on the huge bureaucratic burden of consolidating landholdings. Today most wineries of any significance own vineyards or source under long-term contracts.

By 2020 there were 282 registered wineries, all privately owned, most by Bulgarians with a handful of foreign investors, and increasingly focused on quality wine. Today Bulgaria has switched from being an exporter to drinking most of its wine at home. By 2019 exports had fallen to 250,212 hl/6,609,902 gal, with the majority (202,915 hl) going to the EU led by Poland, Sweden, and Czechia.

Geography and climate

Bulgaria is a small country just 450 km/280 miles from the western border to the Black Sea and 300 km/200 miles from Romania to the north and Greece and Türkiye to the south. With the exception of the Stara Planina (Balkan mountain range), which runs east to west, and the environs of the capital Sofia, vines are planted all over the country. Vineyards lie mainly at 100–300 m/330–990 ft in ELEVATION, although some north-western vineyards are as high as 600 m/1,967 ft.

The climate is largely CONTINENTAL, moderated by the Black Sea in the east and the Aegean in the south-west. Summers in the south tend to be hot, with temperatures up to 40 °C/104 °F, while the temperature can fall to −25 °C/−13 °F in winter.

The most common climatological hazards are FUNGAL DISEASES caused by humidity. Typical annual rainfall is 470–650 mm/18–26 in, and in non-DROUGHT years rainfall and high temperatures combine to promote rot and both POWDERY MILDEW and DOWNY MILDEW. Increasingly, new vineyards are being planted with IRRIGATION.

Vineyards

As part of EU membership negotiations, Bulgaria negotiated a vineyard area of 153,000 ha/378,071 acres, and indeed official data for 2006 showed an area under vine of 135,760 ha, but this seems never to have been a realistic reflection of what was planted or likely to be planted. By 2020 there were officially 60,162 ha, but less than half was harvested for commercial wine production, producing 735,359 hl/19,426,130 gal of wine. It appears that many small vineyards have simply been abandoned at the same time as wineries have invested in consolidated plots and professional viticulture. There is also still some unofficial grey-market wine and home-distilled grape spirits called *rakia*.

Winemaking

External investment and ongoing EU programmes have been used to fund winery renovations and the installation of STAINLESS STEEL, TEMPERATURE CONTROL, and modern technology across the industry. OAK use is widespread in premium wines, with leading producers usually opting for French oak, although some local oak is appearing now COOPERAGE standards are better. Oak use has also become more subtle, so today's wines are more harmonious. The late 2010s saw considerable dynamism in winemaking, with efforts going into reviving and improving native grape varieties and a diversity of styles appearing, including PET-NAT and ORANGE WINES. Most wineries now have locally trained winemakers who have gained international experience, and Bulgaria has an unusually high proportion of women winemakers, estimated to be close to 50%.

Vine varieties

Bulgaria's commercial plantings are split between 15,791 ha/39,020 acres of red wine grapes and 13,317 ha of white varieties, as of 2020, though the harvest is close to 50:50 as white varieties give higher yields. Red grapes dominate in all regions except the north-east. Bulgaria may have been famous for its Cabernet Sauvignon in the 1980s, but by 2020 Merlot had overtaken it to become the most planted variety at 5,071 ha, followed by Cabernet Sauvignon and PAMID, a local variety fallen out of favour as its light body, low acidity, and low EXTRACT means that it produces only basic wines for early consumption. The most interesting of the red INDIGENOUS VARIETIES is MAVRUD (855 ha), now planted in most southern zones and capable of high quality and ageability. Gamza (KADARKA, 218 ha) is gaining interest in the north. Shiroka Melnishka Loza or broad-leaved MELNIK, which covered 1,580 ha/3,904 acres in 2013, had fallen to 197 ha by 2020. It is very late ripening and can be austere as a red, but its high acidity is proving good for TRADITIONAL METHOD sparkling wines. Confusingly its offspring, the earlier ripening and softer Early Melnik or Melnik 55, is often labelled simply Melnik. The other important local red is RUBIN, a 1944 local cross of Syrah and Nebbiolo that some believe to have potentially higher quality than Mavrud.

In INTERNATIONAL VARIETIES, Syrah has grown strongly to reach 1,032 ha as it suits Bulgarian growing conditions. Cabernet Franc (668 ha) is increasingly impressive as a varietal wine or in blends, while Pinot Noir (516 ha) can produce very good results in cooler spots.

Bulgarian researchers have been enthusiastic developers of crosses, including Buket or Bouquet (Mavrud × Pinot Noir), Evmolpia (Mavrud × Merlot), Melnik 1300 (Saperavi × Shiroka Melnishka Loza), and Ruen (Cabernet × Melnik), as well as a number of lower-quality varieties developed primarily for disease resistance such as dark-skinned Storgozia, a cross of the local Buket with VILLARD Blanc.

White varieties in Bulgaria are led by Muscat Ottonel (3,103 ha), followed by Chardonnay (2,553 ha), which can produce very high-quality wines in Bulgarian conditions. Sauvignon Blanc (1,307 ha) can produce fresh, aromatically true wines in the cool north. The most important local white-wine variety is the FROST-resistant, pink-skinned MISKET Cherven, or Red Misket (1,170 ha). Grown mainly in the Valley of the Roses area, it produces distinctly grapey, short-lived white wines. (Confusingly there are several grapes named Misket—Sandanski, Vrachanski, Varnenski, Kailashki—which are unrelated to each other but which all produce grapey, simple wines.) RKATSITELI once accounted for 40% of Bulgaria's white vines but had fallen to 950 ha by 2020. DIMYAT (791 ha), also known as Smederevka, typically makes ordinary whites, though some more promising oaked and orange versions are starting to appear. Other important whites include Traminer, Ugni Blanc (often used for distillation), Tamianka (MUSCAT BLANC À PETIT GRAINS), Riesling, Viognier, Pinot Gris, and Vermentino. There are a few attempts as well to revive old varieties such as the low-acid Keratsuda in the south-west and Kokorko (Bercebel) in the north.

Regions and quality designations

Winemaking practices were brought into line with EU standards before Bulgaria's accession in 2007. At that point, it established two PGIs that split the country into the northern region of the Danubian or Danube Plain and, in the south, the Thracian Lowlands (sometimes written Thracian Valley). These remain controversial, believed to be the result of lobbying by larger wineries rather than reflecting growing conditions. For instance, it's not hard to see distinct differences between the hot, dry Struma Valley in the south-west and the Black Sea-influenced east coast, though both are officially Thracian Lowlands. PGI wines accounted for over 40% of production in 2019, and in practice these very broad regions allow winemakers considerable freedom to plant a range of varieties and experiment with unusual blends. Increasingly, as producers own or control where they source their fruit, the concept of TERROIR is coming to the fore, in contrast to the historical approach of sourcing grapes all over the country.

The previous era of wine legislation (in the late 1970s) divided the country into five regions: Struma Valley, Black Sea Coast, Danubian Plain, Thracian Valley, and the Sub-Balkan region or Valley of the Roses, based on real science according to sources who worked on it then. And it seems the current authorities agree, with tentative identification of five regions similar to the historic regions in the national wine strategy up to 2025. In 2022 the process of amending legislation appeared to have stalled, but the industry often refers to these five regions.

The current status of PDOs is unhelpful to the industry: 52 are listed and accepted by EU, though most are not used, and they account for less than 1% of production. The rules are strict and bureaucratic, making them almost impossible to use in practice. Two regions, Struma Valley and South Sakar, were in the process of defining new PDOs and seeking EU approval as of 2021. C.G.

bulk method, alternative name for the TANK METHOD of SPARKLING WINEMAKING.

bulk storage of wine is important in the production and BLENDING of everyday, low-margin commercial wines valued for their affordability and consistency. Large temperature-controlled storage tanks are usually made of stainless steel and may hold as much as 800,000 l/176,000 gal. OXIDATION is always a risk and, if the tank is not completely filled with wine, the HEAD SPACE must be filled with an INERT GAS. Many commercial blends are bottled throughout the year from such tanks, which need to be kept at 12–18 °C/54–64 °F. Extremes of heat or cold are likely to have a negative effect on quality. B.D.

bulk transport of wine is the movement of large quantities of wine within a single winery or from one place to another, typically from where it was held in BULK STORAGE to the BOTTLING location, which may not even be in the same hemisphere.

Bulk transport over long distances has increased considerably over the last 20 years in an effort to reduce both financial and environmental costs. Twice as much wine can be transported in the same space in bulk than in bottle, PACKAGING waste is reduced, and locally recycled glass may be used (although bottlers in the producing country suffer the consequences). According to the OIV, 34% of exported wine was moved in bulk in 2020, compared with 30% in 2000. In the same year, 51% of Australia's wine exports were in bulk and 63% of US wine was exported in this way. Other benefits include

the better thermal protection offered by a large volume of wine and longer shelf life for wine sold in BOXES. However, local regulations, particularly in Europe, may insist that wine is bottled in the place of production.

Wine is most commonly transported in bulk from one installation to another by road tanker and/or ocean-going tank ships, although rail and barge are not unknown. The two main options used on ships are an ISO tank (a stainless-steel pill-shaped container within a standard ISO frame that can carry up to 26,000 litres/6,870 gal) or a Flexitank (a hermetically sealed, collapsible, and flexible single or multilayer polyethylene/polyester bag or bladder, which is fitted into a container and typically holds 24,000 litres). Pipelines are occasionally used to transport wine over short distances, for example between winery sites or to a neighbouring bottling facility.

Whenever wine is moved in bulk, the key considerations are wine quality, wine losses, cost, availability of suitable tanks, environmental impact, the risk to consumers from cross-contamination (especially allergens) unless the tanks are single use, and the safety of winery operators during loading and off-loading.

In terms of wine quality, it is important to guard against OXIDATION and against thermal stress resulting from temperature variation in transit, during layovers, or on the dock. Studies have shown that temperature fluctuations are more likely to occur when wine is transported overland. Flexitanks, because of their flexibility, offer more effective management of ULLAGE levels, a critical factor in controlling the level of dissolved oxygen. Because of this, and because of their global availability and low risk of cross-contamination, they have become the most popular method of shipping a wine in bulk. However, the more solid construction of ISO tanks may offer better thermal protection. Shipping a wine in bulk has placed new demands on the modern winemaker, who must prepare a wine for the rigours of a journey of up to two months, often crossing the equator. Critical factors include the levels of dissolved oxygen and dissolved CARBON DIOXIDE, the latter a good protection in transit and adding freshness to certain wine styles.

Ideally the winemaker at the destination should have to make minimal adjustments prior to bottling. B.D.

Tchouakeu Betnga, P. F., et al., 'Effects of transport conditions on the stability and sensory quality of wines', *OENO One* 55/2 (2021).

bulk wine, or wine *en vrac*, as the French call it, is wine that is ready to drink but has not been put into smaller CONTAINERS such as BOTTLES. This may be because it is about to be packaged, because it will be sold to another producer, or because it will be packaged in the country in which it is to be sold. Most of the wine that is sold in bulk is marketed at less than US$10 per bottle and is not meant for long-term ageing. BULK TRANSPORT is by far the cheapest way of moving wine, and it is common for wine to move in bulk between producer and blender or bottler, possibly even between continents and hemispheres.

When SURPLUS PRODUCTION became an increasingly geographically widespread phenomenon in the early 21st century, the bulk-wine market became an important feature of international wine trade, helped considerably by online trading. Today concerns about the cost, both financial and environmental, of transporting wine in bottles has encouraged many large retailers to ship in bulk. (See CARBON FOOTPRINT and SUSTAINABILITY.)

Spain is by far the biggest exporter of bulk wine, at more than one billion litres in 2018, with France its biggest market by far. Way behind Spain at second place was Australia, with just 386 million litres. Italy's main customer for bulk wine is Germany, which imports more than any other country, though in value terms it was overtaken in 2019 by the UK, where the wine is destined for both brands and private labels. China has emerged as a significant buyer of bulk wine, sourced wherever it is cheapest but especially from France and Italy. The country's imposition of punitive trade tariffs on Australia in 2020 put an end to the significant volumes of bulk (and bottled) wine shipped across the Pacific.

Brokers of bulk wine have become increasingly important, and their business is strongly influenced by factors such as the weather during FLOWERING where large quantities of wine are grown, extreme weather events such as HAIL or FROST that can drastically reduce volumes in a particular vintage, currency movements, and FASHIONS in grape varieties (see SIDEWAYS, for example). They follow the bulk markets daily and provide information to their client base.

On a smaller scale, bulk wine may even be sold in measured quantities drawn off from some form of BULK STORAGE. In southern Europe it is still commonplace to take a container, perhaps a BONBONNE or large plastic container, to be filled with bulk wine, which is sold by the litre.

Bullas, DOP of 1,811 ha/4,475 acres just south of JUMILLA in the autonomous region of Murcia in Spain. The region is generally dry and hot, with an annual rainfall of 300 mm/12 in, although the MESOCLIMATE is cooler in the higher ELEVATIONS of the north-west, where vineyards reach 900 m/2,953 ft. Red wines and rosés predominate, primarily from the MONASTRELL grape. F.C.

Bull's Blood, once a wine BRAND named after a historic style of red wine made in HUNGARY, known as BIKAVÉR in Hungarian.

bunch, or cluster, the viticultural term for that part of the grapevine comprising STEM and BERRIES: *grappe* in French, *Traube* in German, *racimo* in Spanish, and *grappolo* in Italian. Before the berries SET, each berry position is occupied by a flower; a bunch develops from the INFLORESCENCE of the vine once the berries have set. In the grapevine the inflorescence grows at the node on the side of the stem opposite to a leaf, an unusual position within the plant kingdom. It is closely related to a TENDRIL, both deriving from the same

embryonic organ, the anlage. Depending on the time of development, anlagen produce bunches, tendrils, or SECOND CROP.

Like a tendril, a grape bunch has two arms, called outer and inner. The inner arm develops the bulk of the bunch, while the outer arm may vary in form from a large, well-set 'wing' (as in UGNI BLANC) to a small tendril arm without berries, or it may even abort. Berries on wings sometimes ripen differently from those on the main crop.

Bunches vary hugely in size depending on that year's FRUIT SET and VINE VARIETY, from a few grams to many kilograms. They also vary in shape and tightness depending on the lengthening and flexibility of the STEM and branches and, of course, on setting and BERRY SIZE. B.G.C.

bunch closure, stage in the VINE GROWTH CYCLE between BUDBREAK and VERAISON when the berries begin to touch and the bunch hangs down. It is an indistinct phenological stage but significant for vineyard SPRAYING as it affects penetration of the bunch and hence BOTRYTIS protection. R.E.S.

bunch rots, or berry rots, occur in vines all over the world and can be caused by many species of fungi including YEASTS and by BACTERIA. Yield losses can be as high as 80%, and wine made from rotten fruit often smells and tastes tainted, typically mouldy, with a perceptible loss of fruit flavour. Vineyards badly infected with bunch rots themselves have a distinctive and unpleasant smell. Wet weather at HARVEST causes the worst cases of bunch rot, especially if grape skins are broken. The best-known of the bunch rots is BOTRYTIS BUNCH ROT.

Some fungi, such as *Botrytis, Alternaria*, and *Cladosporium*, can infect healthy berries, and these are called 'primary invaders'. 'Secondary invaders' such as *Aspergillus*, *Rhizopus*, and *Penicillium* gain access to berries split by rain, bird, or insect attack, or diseases such as DOWNY MILDEW and POWDERY MILDEW, ESCA, or WHITE ROT. So-called SOUR ROT is due to a mix of fungi, yeasts, acetic acid bacteria,

and fruit fly larvae. Control measures can include SPRAYING, bunch thinning, increasing fruit exposure to wind and sun (see CANOPY MANAGEMENT), and avoiding other pests and diseases which can break berry skins (see also FUNGAL DISEASES). However, once the rot is well established, the grapes are unusable and likely to be left for the birds. R.E.S.

bunchstem. See STEM.

bunchstem necrosis, or BSN, physiological condition which causes grape stems to shrivel and die during RIPENING. This condition is also known as waterberry in California, shanking in New Zealand, *Stiellähme* in Germany, and *dessèchement de la rafle* in France. Affected berries do not ripen properly and shrivel on the bunch, although it is rare for all berries to be affected. CABERNET SAUVIGNON vines are particularly prone to this disorder. Affected berries have lower SUGARS, ANTHOCYANINS, and fatty acids but higher ACIDITY. The cause is unknown, but factors associated with the condition are vigorous SHOOT growth, the weather at FLOWERING, and levels of MAGNESIUM, CALCIUM, and ammonium in the plant tissue. Yield can be severely reduced, especially with MECHANICAL HARVESTING, as affected berries fall off. Wines can taste bitter and are poorly coloured. There is no widely accepted control, although magnesium sprays at VERAISON have sometimes reduced the problem. A similar disorder affects INFLORESCENCES at flowering and has been termed early bunchstem necrosis, or inflorescence necrosis. R.E.S.

Bondada, B., and Keller, M., 'Not all shrivels are created equal: morpho-anatomical and compositional characteristics differ among different shrivel types that develop during ripening of grape (*Vitis vinifera* L.) berries', *American Journal of Plant Sciences*, 3/7 (2012), 879–98.

bung. A bung, made of glass, plastic, rubber, earthenware, silicone, or wood, is a barrel's stopper, analogous to the cork of a bottle. It is inserted in a bung-hole. If a barrel is stored so that the bung is at its highest point (bung up), the bung may be left so that gas can escape from the bung-hole. Some bungs incorporate a device that encourages this. If a barrel is stored with the bung at either two or ten o'clock, the position is called bung over.

Since OXYGEN tends to enter a barrel around the bung-hole, silicone bungs are sometimes used to keep a particularly tight fit. These also have the advantage of being gentler on the stave in which the bung-hole is drilled, which is weakened and sometimes cracked by the hammering needed on wooden bungs every time the barrel is TOPPED UP.

So-called aseptic bungs, made of plastic or glass, incorporate a container filled with liquid SULFUR DIOXIDE to keep bacteria out of the barrel or cask. Electronic bungs have recently been designed that automatically measure temperature, pressure, oxygen content, and liquid level at regular intervals, helping the winemaker to monitor the barrel without opening it.

Traditionally in Bordeaux and Burgundy, barrels were filled and topped up through the top bung but racked via a RACKING bung on the head of the barrel, but this is now relatively rare. A.P.

Burgenland, topographically heterogeneous Austrian state, home in 2021 to 27% of that country's vine hectarage, best known as its pre-eminent source for red wines (especially from BLAUFRÄNKISCH and ZWEIGELT) as well as for nobly sweet ones (from diverse white and even red grape varieties), and incorporating the DACs of EISENBERG,

LEITHABERG, MITTELBURGENLAND, NEUSIEDLERSEE, ROSALIA, and RUSTER AUSBRUCH. (QUALITÄTSWEIN not qualifying or not submitted for DAC labelling will identify Burgenland as its place of origin.) Extending some 160 km/100 miles along the eastern edge of Austria from the outskirts of Bratislava, SLOVAKIA, to a sliver of Austria's border with SLOVENIA, Burgenland was created in 1921 out of the former German West Hungary. (Croatian is the state's second language; see AUSTRIA, history.) D.S.

Burger, white grape variety that was once very important in CALIFORNIA, where it was the state's most planted VITIS VINIFERA variety, having been promoted by one pioneer as greatly superior to the MISSION grape. The total had fallen to 442 ha/1,093 acres by 2020, mainly in the hot SAN JOAQUIN VALLEY, many of the vines planted in the early 1980s.

It is the almost extinct southern French variety Monbadon, probably a natural cross of FOLLE BLANCHE and UGNI BLANC, that was cultivated to a limited extent in the Languedoc until the 1980s. It produces sizeable quantities of neutral wine.

Burgunder, common suffix in German, meaning literally 'of Burgundy', for such grape varieties as SPÄTBURGUNDER, Blauburgunder, Blauer Spätburgunder, or Blauer Burgunder (PINOT NOIR); WEISSBURGUNDER or Weisser Burgunder (Pinot Blanc); and GRAUBURGUNDER or Grauer Burgunder (drier styles of PINOT GRIS).

Burgund Mare means 'big Burgundian' in ROMANIA and is the local name for BLAUFRÄNKISCH.

Burgundy, known as BOURGOGNE in French, province of eastern France famous for its great red and white wines produced mostly from PINOT NOIR and CHARDONNAY grapes respectively. The province

includes the viticultural regions of the Côte de Nuits and Côte de Beaune in the *département* of the CÔTE D'OR, the Côte CHALONNAISE and the MÂCONNAIS in the Saône-et-Loire *département*, and CHABLIS and the wines of AUXERRE in the Yonne *département*. In 2018, the total area of Burgundy vineyard was 30,052 ha/74,260 acres, giving an average crop of 1.45 mhl/38.3 million gal of which 60% is white, 29% red, and 11% sparkling.

BEAUJOLAIS in the Rhône *département*, while sometimes being considered part of greater Burgundy, is a distinct region viticulturally, if not administratively, and is treated separately.

Ancient history

When the Romans (see ROME, CLASSICAL) conquered Gaul in 51 BCE, they probably found the CELTS inhabiting what is now Burgundy already growing wine, if not yet in substantial quantities. In the early 21st century the remains of a small vineyard dating back to the 1st century CE, apparently for the use of those living in a Roman villa close to Gibriacum (GEVREY-CHAMBERTIN), was unearthed. A tombstone in the village church of Corgoloin depicts what appears to be a Celtic god with a vine in his right hand; other gravestones have carvings of grapes. Also, archaeologists have found no Italian AMPHORAE of the mid 2nd century or later in Burgundy, which may indicate that from then on the region was producing enough wine of its own. From at least the 3rd century onwards, however, wine was transported from Italy in wooden BARRELS instead of amphorae, and wood is far more perishable than pottery.

The earliest literary evidence dates from 312 CE. In a panegyric addressed to Emperor Constantine the Great on the occasion of his visit to Autun (Augustodeunum), the citizens plead poverty. Part of the grim picture their orator paints is abandoned vineyards, the roots of the old vines so thickly intertwined that it would be impossible for a farmer to dig ditches. However old the vines were—and a mere human lifetime's worth of neglect would account for their tangled state—commercial viticulture had clearly been well established by the early 4th century.

As the Roman Empire disintegrated, Burgundy came once more under BARBARIAN rule, by the Franks, the Alamans, and the Vandals. The Burgundians, Scandinavians by origin, founded a kingdom in the RHÔNE Valley, later including Lyons and Dijon, in 456; they were defeated by the Franks under Clovis's sons in 534. The first recorded words in praise of Burgundian wine date from the Merovingian period. Gregory of Tours, who finished his History of the Franks in 591, says that the hills to the west of Dijon produce a noble wine that is like FALERNIAN—the highest praise possible from a Dark Age Latinist. That wine, and the clear water flowing from the springs around the city, are sufficient reasons why in his opinion Dijon should become an episcopal see. In 587 King Guntramn, grandson of Clovis and son of Clotaire, gave a vineyard to the Abbey of St Benignus at Dijon, and in 630 the duke of Lower Burgundy donated vineyards at Gevrey, Vosne, and Beaune to the Abbey of Bèze, near Gevrey. The beginnings of monastic viticulture in Burgundy were in these Merovingian times.

Monastic influence

Nobles, peasants, and monks cultivated the vine under CHARLEMAGNE, when political stability brought prosperity. Medieval Burgundy owes its reputation as a producer of excellent wines largely to the MONKS AND MONASTERIES. The monks had several advantages over lay growers: they had cellars and store rooms in which to mature their wine; and, most importantly, they kept records and had the time and the degree of organization necessary to engage in systematic improvement. The Benedictines of Cluny were the first group of monks to acquire vineyards in Burgundy on a large scale. The foundation in 910 of the Abbey at Cluny in the Mâconnais was the beginning of the Benedictine reform movement. Through benefactions from pious laymen, Cluny came to own all the vineyards around Gevrey by 1273, and in 1232 the duchess of Burgundy granted the Abbey of St-Vivant the vineyards now known as Romanée-Conti, La Romanée, La Tâche, Richebourg, and Romanée-St-Vivant (see also DOMAINE DE LA ROMANÉE-CONTI). It also owned Pommard and vineyards at Auxey and Santenay.

The other group of monks to have a lasting effect on Burgundian viticulture were the Cistercians, an order founded in 1098 which took its name from the site of its first monastery, Cîteaux, east of modern Nuits-St-Georges. Although austerity and asceticism were the aims of the order, in contrast to the luxury and ostentation of the Benedictines, the Cistercians, often through donations, became rich and important landowners.

The Cistercians' first vineyard was given to them by the duke of Burgundy in 1098, not long after their foundation. Soon they were buying vineyards as well: in 1118 the Cistercians of Pontigny on the River Serein purchased, after much haggling, vineyards from the Benedictine monks of St-Martin at Tours from which they produced a white wine, the first CHABLIS. In 1110 the monks of Cîteaux were given land at Vougeot and went on to acquire more land there: it took them until 1336 to acquire enough to form one large vineyard, which they surrounded with a wall, the CLOS DE VOUGEOT. They bought

or were given more vineyards all over the CÔTE D'OR and trained their lay brothers to work them: Beaune, Chambolle, Fixin, Pommard, and many more.

Aided by their skilled workforce, the monks had the time, the experience, and the learning necessary to experiment, record, and compare. By observing how different plots of vines produced different wines, the Cistercians discovered the importance of TERROIR and began to acknowledge different CRUS.

In the 12th and 13th centuries, white wine was preferred to red. In an age of murky drinking water, carefully made white wine was valued for its clarity. The wines that were most highly reputed, however, were not those of Burgundy but those of the Île-de-France centred on PARIS, which could easily be transported by RIVERS. Burgundy, on the other hand, was cut off, and its wines, which could only be transported north with much expense and difficulty along bumpy roads, were as yet little known. In medieval French texts, 'vin de Bourgogne' was from Auxerre, whose wines could easily reach Paris along the River Yonne: transport by boat was cheaper, easier, and less harmful to the wine than being carried by horse-drawn cart along bumpy roads. Until the 15th century what we call burgundy was known as 'Beaune'.

Upon his election in 1305 Clement V moved the papal court to Avignon. During this 'Babylonian captivity', which lasted until 1377, the court of the Avignonese popes was famous for its extravagance as well as its corruption, and demand for the wines of Burgundy to the north surged. The wines of 'Beaune' came generally to be regarded as second to none. Urban V (1362–70) went to Rome for three years in 1367 but, exasperated by the political infighting there, returned to Avignon. In a letter, Petrarch made a vain attempt to persuade him to go back to Rome but had to admit that the best burgundy was not to be had south of the Alps. The Babylonian captivity ended with Urban's successor Gregory XI, but the wines of Burgundy retained their high reputation.

The dukes of Burgundy

From a byword for largesse in Avignon, Burgundian wine became a status symbol with the Valois dukes, four generations of whom governed Burgundy from 1363 to 1477. The first duke, Philip the Bold, son of King John of France, took a keen interest in the wine of the region, its most important export. In 1395, he issued a decree declaring the GAMAY grape variety to be harmful to human beings and its planting contrary to Burgundian practice. The first mention of the PINOT NOIR grape, named Noirien, dates only from the 1370s, but in all probability the grape had been in use longer. Modern Gamay has a far higher yield than Pinot Noir, and documentary evidence suggests that the same was true in the 14th century. In the same decree, Philip inveighs against the use of organic FERTILIZERS, presumably because it also increased YIELDS. Philip was trying to maintain quality, while many growers thought that manure and Gamay would make for easy profits. Although Philip the Bold wanted every single Gamay plant uprooted by the next Easter, we find his grandson Philip the Good (1429–67) later still thundering against the inferior vine, which he called a threat to both the wines and the dukes of Burgundy. Fearing for his immortal soul, Philip the Good's rapacious Chancellor Nicolas Rolin built the famous HOSPICES DE BEAUNE in 1443.

But what were these famous wines really like? The white wines of Burgundy were probably made from the grape that also produced the highly reputed white wines of north-eastern France, Fromenteau, which had pale-red berries and white juice and could well be the ancestor of our PINOT GRIS. (The CHARDONNAY of modern white burgundy did not appear in the region until after the Middle Ages.) In the Middle Ages wines were drunk in the year following the vintage, so properly matured burgundy would then have been unknown.

Modern burgundy

The duchy of Burgundy was once so proud of having the finest wines and finest court in Christendom that it developed into a state and very nearly a kingdom in its own right. The defeat and death of the over-ambitious Charles the Rash, however, led to its being reincorporated into the kingdom of France. As the monarchy became stronger, the power of the Church declined slowly, so that during the 17th century many of the famous vineyards donated to the Church during the Middle Ages were sold to the increasingly important bourgeoisie in Dijon.

Although transport difficulties (see RIVERS) still hindered burgundy's fame abroad, the famous Pierre Brosse managed to interest Louis XIV in his Mâcon, and the Sun King's physician, Fagon, prescribed old burgundy instead of champagne as the most suitable wine for his monarch's health. Roads began to improve in the 18th century, and the trials and tribulations inherent in road travel diminished, encouraging the start of commercial traffic in Burgundy. The first NÉGOCIANT houses were founded in the 1720s and 1730s, including Champy (1720) and BOUCHARD PÈRE ET FILS (1731), names which have survived to this day.

The earliest major work on the wines of Burgundy, Claude Arnoux's *Dissertation on the Situation of Burgundy*…was published in 1728. It demonstrates the fame of the red wines of the Côte de Nuits and the special reputation of the Œil-de-Perdrix (partridge-eye) pink wines of Volnay, while the existence of white wine in the Côte de Beaune earns only a brief mention.

Most vineyards remained in the hands of Church or nobility until the French Revolution. From 1791 the vineyards were sold off, often divided among several owners. Since then they have further fragmented as a result of the law of equal inheritance among children laid down in the Napoleonic Code. This process has caused much of the difficulty in understanding burgundy: consumers must familiarize themselves not only with a plethora of village and vineyard names

but also with the relative merits of possibly dozens of producers of each one.

Burgundy prospered in the early 19th century, although wine PRICES were low even for the fine vineyards. In addition, there was widespread planting of the inferior GAMAY grape to provide wine that was plentiful and cheap, albeit mediocre. Transport conditions continued to improve with the opening of a canal system in Burgundy and, in 1851, the Paris–Dijon railway.

Easy prosperity, however, was first checked by the spread of POWDERY MILDEW in the 1850s and then destroyed by the arrival of PHYLLOXERA in the 1870s. This calamity was finally admitted in the Côte d'Or in 1878 when an infested vineyard in Meursault was surrounded by soldiers. The Burgundians did not find it easy to come to terms with the problem: there were riots in Bouze-lès-Beaune between factions in favour of treating vineyards and those against; a posse of growers in Chenôve actually attacked a team sent in to spray the vines; and American ROOTSTOCKS, the eventual saviours of French vineyards, were banned from the region between 1874 and 1887. Eventually, however, common sense prevailed, and by the 1890s post-phylloxera wines were again on the market. Only the best vineyards were worth replanting after the predations of phylloxera—a silver lining to the disaster.

The Burgundians were well aware of the considerable variation in quality of the wines produced by different plots of land, or *climats*, as they are known in Burgundy. In 1855 Dr Lavalle published his influential *History and Statistics of the Côte d'Or*, which included an informal CLASSIFICATION of the best vineyards. This was formalized in 1861 by the Beaune Committee of Agriculture, which, with Lavalle's assistance, devised three classes. Most of the first class were in due course enfranchised as GRANDS CRUS when the AOC system was introduced in the 1930s.

Most burgundy was sold through the flourishing NÉGOCIANT houses until the years of hardship after the First World War. The economic depression of the 1920s and early 1930s threatened to ruin many

small growers. One solution was the CO-OPERATIVE, particularly useful in the Mâconnais, where prices were lower. Another was for proprietors to bottle their own produce, a move which met with opposition from the merchants when growers such as the Marquis d'Angerville, Henri Gouges, and Armand Rousseau pioneered the concept of DOMAINE BOTTLING in the 1930s. Whereas in 1962 wines produced and bottled by growers accounted for only 15% of production, by 1990 nearly half of all Côte d'Or wines were domaine bottled.

Geography and climate

The vineyards of Burgundy are based on LIMESTONE originating in the Jurassic period. This takes the form of undulating CHALK hills in Chablis; a long narrow escarpment running south and a touch west from Dijon to Chagny, the CÔTE D'OR; more isolated limestone outcrops in the Côte Chalonnaise and the Mâconnais; and the vineyards of POUILLY-FUISSÉ beneath the imposing crags of Solutré and Vergisson in the extreme south.

The climate in Burgundy is broadly CONTINENTAL. In contrast to BORDEAUX, Burgundy is a little cooler during the summer, noticeably colder in the winter, and similar in temperature in the spring. Although winters are usually dry, Burgundy tends to suffer from particularly heavy rainfall in May and June and again in October, which may or may not fall after the HARVEST. Spring FROST can be a problem (especially in CHABLIS), while HAIL causes local damage almost every year. Indeed the incidence of hail seems to be on the increase, particularly in the Côte de Beaune, and is perhaps a by-product of CLIMATE CHANGE.

Overall, Burgundy has a shorter and more variable summer than Bordeaux (which is why only early-ripening grape varieties can be grown there), though there are significant climatic differences north to south: among Chardonnay wines, the wines of Chablis, reflecting their northern origin, are tinted green in colour and comparatively austere in flavour; further south, those of the Mâconnais enjoy enough sun to become (relatively) fat and ripe. The temperamental PINOT NOIR vine is less regularly successful. In Auxerrois, historically at the limit of successful ripening, the red wines rarely achieved much depth or body, but they continue to improve in today's climate. Burgundy's greatest reds are produced on the escarpment of the Côte d'Or, especially in the Côte de Nuits.

For more details of Burgundy's special aptitude for wine production, see CLIMATE AND WINE QUALITY.

Viticulture and winemaking

For details, see CÔTE D'OR, CHALONNAISE, and MÂCONNAIS.

Vine varieties

Burgundy has one of the world's least varied ranges of vine varieties. Almost all of the region's best red and white wines are made from Pinot Noir and Chardonnay respectively. According to official 2021 statistics, Chardonnay is grown on 51% of the region's total vineyard area (a proportion swollen by the substantially white wine production of Chablis and the Mâconnais), followed by Pinot Noir (39.5%) and Aligoté (6%), with Gamay, Sauvignon Blanc, and others such as MELON, SACY, and CÉSAR combined comprising 3.5%.

Organization of Burgundian vineyards

The vineyards of Burgundy, especially those of the Côte d'Or, are the most minutely parcellated in the world. This is mainly because the land has been continuously managed and owned by individual smallholders—there was no influx of outside capital with which to establish great estates as in BORDEAUX. But the combination of the Napoleonic Code, with its insistence on equal inheritance for every family member, and the fact that the land has proved so valuable has meant that small family holdings have been divided and subdivided over generations. One vineyard, or *climat*, as it is known here, may therefore be owned by scores of different individual owners, each of them cultivating sometimes just a row or two of vines (see CLOS DE VOUGEOT, for example).

The CLASSIFICATION of the vineyards is according to the potential of the site rather than the fame of the producer. The lowest rung is generic BOURGOGNE in various forms, usually on lower-lying land, then village wines named for the commune they come from. Within most village appellations the better vineyards, with favourable exposure at mid slope, have been designated as PREMIER CRU, while in some locations the very finest vineyards, with characters which transcend the TYPICALITY of their village, have been designated GRAND CRU with appellations of their own.

Organization of trade

Unlike the BORDEAUX TRADE, with its large volume of single appellations and many stratifications of those who sell it, the Burgundian wine trade became polarized between growers and merchants. Because the laws of equal inheritance have been strictly applied in a region of such valuable vineyards, individual growers may for example produce just one barrel of a particular appellation, enough to fill just 25 cases. The market for burgundy was originally built by the merchants, who would buy grapes and wine from many growers before blending and selling the results. Increasingly, individual growers with leading vineyards have been bottling their own wines. Since the early 1990s, the distinctions between growers and merchants have become increasingly blurred, with many widely admired growers also producing another range of wines made from grapes they did not grow themselves, while most merchants have been increasing their vineyard holdings. For more details, see NÉGOCIANTS.

Burgundy grands crus (from north to south)	
Commune	**Grand cru**
Côte de Nuits (all for red wine unless otherwise stated)	
Gevrey-Chambertin	Mazis-Chambertin
	Ruchottes-Chambertin
	Chambertin Clos-de-Bèze
	Griotte-Chambertin
	Charmes-Chambertin
	Le Chambertin
	Latricières-Chambertin
	Mazoyères-Chambertin
	Chapelle-Chambertin
Morey-St-Denis	Clos de la Roche
	Clos St-Denis
	Clos des Lambrays
	Clos de Tart
	Bonnes Mares (some)
Chambolle-Musigny	Bonnes Mares (most)
	Le Musigny (some white wine too)
Vougeot	Clos de Vougeot
Flagey-Échezeaux	Grands Échezeaux
	Échezeaux
Vosne-Romanée	Richebourg
	Romanée-St-Vivant
	Romanée-Conti
	La Romanée
	La Grande Rue
	La Tâche
Côte de Beaune (all for white wine unless otherwise stated)	
Ladoix-Serrigny	Corton (almost all red)
	Corton-Charlemagne
Aloxe-Corton	Corton (almost all red)
	Corton-Charlemagne
	Charlemagne (scarcely used)

Commune	Grand cru
Pernand-Vergelesses	Corton-Charlemagne
	Charlemagne (scarcely used)
Puligny-Montrachet	Chevalier-Montrachet
	Bienvenues-Bâtard-Montrachet
with Chassagne-Montrachet	Le Montrachet
	Bâtard-Montrachet
Chassagne-Montrachet	Criots-Bâtard-Montrachet

Busby, James (1801–71), the so-called father of Australia's wine industry, was born in Edinburgh in 1801 and arrived in Sydney with his family in 1824. Prior to his departure, James Busby had travelled to Bordeaux in 1822 to investigate viticulture. During the five-month voyage to New South Wales, he wrote *A Treatise on the Culture of the Vine and the Art of Making Wine*, which was published in 1825. It was the first homegrown manual on winemaking for Australian settlers. While it is now considered one of Australia's most important early books, much of the text is a translation of CHAPTAL's *l'Art de faire le vin* (1807 and 1819). Little of it had any relevance for Australian conditions, and it was not well received.

James Busby took up a government position (aged 23) at the Male Orphan School near Liverpool where he was entrusted to develop and manage the extensive 12,300-acre/4,978-ha estate and to teach viticulture at £100 a year. But the farm closed in 1826, and he then worked as a tax collector. His *A Manual of Plain Directions for Planting and Cultivating Vineyards and for Making Wine in New South Wales*, published in 1830, was much better received. Soon afterwards he 'distributed 20,000 vines to fifty intending growers'. George Wyndham planted 600 cuttings at Dalwood in early September 1830.

Frustrated with the slow grind of the New South Wales colonial government, James Busby returned to Europe, where he embarked on a four-month tour of France and Spain in 1831. His tour was partly sponsored by James and William MACARTHUR, whose Camden Nurseries and Vineyard south of Sydney would become an important source of grapevine and other plant material for the colony. It was during this fateful journey that James Busby assembled the greatest collection of grape varieties to be imported into Australia.

Busby collected 437 varieties from the Montpellier Botanical Gardens and 133 varieties from the French National Collection in the Luxembourg Gardens in Paris. He also sourced 44 cuttings from Syon

House near Kew outside London. Those collected in Jerez and Malaga perished on the voyage. The collections were planted in the Sydney Botanical Garden, the Busby family's property Kirkton in the Hunter Valley, and Camden Vineyards.

Busby was praised by the colonial press for donating to Sydney's Botanic Gardens 'vines which have hitherto proved the best adapted for making wine'. Of the Sydney collection, however, the NSW Government Gazette (no. 106) reported in 1834, there were '543 varieties in the whole and only 334 are at present alive'. Lack of funding and poor management led to their demise, and when Busby returned to Sydney in 1840 the collection was non-existent. Although cuttings were distributed to local winegrowers by his brother-in-law William Kelman of Kirkton, James Busby's legacy was secured by Sir William Macarthur, whose thriving plant nursery distributed vines throughout the Australian colonies. Genetic material from the Busby collections survives through Australian vineyards established in the 19th century with, notably, clonal selections of Shiraz and Pinot Noir said to have come from HERMITAGE and CLOS DE VOUGEOT respectively.

Busby's life had entered a new dimension in 1833 with his appointment as the first British Resident at the Bay of Islands in New Zealand. He possessed only nominal power but is commonly credited as an architect of the Treaty of Waitangi proclaimed in 1840. This resulted in New Zealand becoming a formal British possession, thwarting French colonial ambitions in the South Pacific. It also led to James Busby's government position becoming redundant, but he remained in New Zealand and had brought vine cuttings with him in 1833. He planted a small plot of vines at his residence at Waitangi Bay, producing a wine described by French explorer Dumont d'Urville in 1840 as 'a light, white wine, very sparkling and delicious to taste'. In all likelihood it was made primarily from Sweetwater (CHASSELAS) and was the first record of winemaking in New Zealand. A.C.

bush vines, an alternative term used mainly in Australia and South Africa to describe GOBELET or HEAD-TRAINED, SPUR-PRUNED vines. The comparison with a bush is apt: the vines are trained to a short trunk, normally free-standing (without a TRELLIS SYSTEM), and are pruned to a few SPURS commonly arranged in a ring on short arms from the trunk. Many of these old, and typically low-vigour, vineyards have been replaced by more productive vines with a trellis system, although those OLD VINES that have survived are increasingly valued.

butt, BARREL TYPE associated particularly with SHERRY production. It is usually made from American oak and has a capacity of 600–650 l/160–170 gal. A *bota chica* or shipping butt holds 500 l and is sometimes used as a unit of measurement. New butts are an inconvenience in the sherry-making process and have to be seasoned by being used for the FERMENTATION of lower-quality wines.

Buzet, Gascon AOC in SOUTH WEST FRANCE up the Garonne river from BORDEAUX. The recent history of the appellation, created in 1973, is inextricably intertwined with the dynamism of the local CO-OPERATIVE, which makes all but a tiny proportion of Buzet. Resistance to a monopoly is led by a handful of independents, among whom the BIODYNAMIC Domaine du Pech stands out.

The region, which extends along the left bank of the Garonne between Agen and Marmande, has known viticulture since Roman times. The fortunes of the district's wines suffered during the HUNDRED YEARS WAR, when the district supported the English crown. Trade was further hampered by the restrictions imposed by the

Bordelais on all HAUT-PAYS, or 'high country', wines. PHYLLOXERA seriously affected viticulture in the late 19th century, and a ruling in the early 20th century that the name 'Bordeaux' was restricted to wines produced within the GIRONDE *département* was a further blow to this district in the Lot-et-Garonne, which had habitually supplied BLENDING wines to the Bordeaux merchants.

Buzet's vineyards cover more than 1,900 ha/4,695 acres. The GRAVELS and CLAYS of these inland hills are planted with classic red Bordeaux vine varieties Cabernet Sauvignon, Cabernet Franc, and, especially, Merlot; Cot (MALBEC), ABOURIOU, and Petit Verdot are also allowed. Whites rely on MUSCADELLE, Sauvignon, and Sémillon. Long a leader in SUSTAINABLE VITICULTURE, the co-operative also began planting grape varieties such as Tempranillo and Syrah and the recent HYBRIDS Artaban and Vidoc in 2019 in response to CLIMATE CHANGE concerns. P.S.

Byblos, ancient town in LEBANON 40 km/25 miles north of modern Beirut. It had the reputation of being the oldest town in the world and was a PHOENICIAN centre of trading. Its wines were famous in classical times.

BYO stands for 'Bring Your Own (Wine)' and is a type of restaurant most common in Australia and New Zealand, where the term was coined. The term is associated with maximum wine-drinking pleasure at minimum cost to the restaurant-goer (in tandem with reduced profit to the restaurateur). New Zealanders claim that the BYO name and concept was born in 1976 when the New Zealand authorities, still notably cautious about the distribution of alcoholic drinks, devised the Bring Your Own licence for restaurants at which diners would be allowed to take their own wine. Australians in the state of Victoria, also famously restrictive in its legislative attitude to alcoholic drinks, maintain that Melbourne had BYO establishments in the 1960s. Wherever its origins, this arrangement has become common for a wide range of restaurants in Australia, New Zealand, and elsewhere,

the wine often being bought in a nearby retail establishment. CORKAGE is sometimes but not always charged. The expression in North America is BYOB, as in ‘Bring Your Own Bottle’, most commonly encouraged here and elsewhere either in restaurants too new to have a liquor licence and during quiet periods such as Mondays or when regular customers are on holiday.

C

Cabardès, LANGUEDOC appellation (since 1999) to the north of Carcassonne which produces red and some rosé wines that testify to its location on the cusp of Atlantic and Mediterranean influences. The grape varieties planted in its 460 ha/1,137 acres of vineyard also represent a Bordeaux/Languedoc cocktail of Cabernet Sauvignon, Cabernet Franc, Merlot, Cot (MALBEC), and some FER Servadou, spiced and fleshed out with the more meridional Syrah, Grenache, and CINSAUT (mainly for rosé). The Bordelais varieties tend to prosper on the western, wetter, deeper soils, while wines produced from the hotter, shallower soils of the eastern Cabardès are more likely to have a high proportion of Mediterranean varieties. Winds almost constantly buffet the small hills punctuated by pines and GARRIGUE and minimize the local wine producers' dependence on AGROCHEMICALS. In contrast to MALEPÈRE, a somewhat similar AOC to the south of Carcassonne, production here is mainly in the hands of a small but committed band of individuals constrained by low financial returns. Winemaking equipment and methods are not always the most sophisticated, but the wines boast an originality and potential for longevity that is unusual for this part of France.

Cabernet is loosely used as an abbreviation for either or both of the black grape varieties CABERNET FRANC and CABERNET SAUVIGNON. In north-east Italy in particular there has been a certain lack of precision about the identity of the Cabernet grown and allowed into the many Cabernet-permitting DOCs, although Cabernet Franc has tended to predominate. Elsewhere, Cabernet is more likely to be an abbreviation for Cabernet Sauvignon. Cabernet is also a popular prefix for recent German and Swiss hybrids such as Cabernet Blanc,

Cabernet Carbon, Cabernet Carol, Cabernet Colonjes, Cabernet Cortis, Cabernet Dorio, Cabernet Dorsa (the most popular), Cabernet Jura, and Cabernet Mitos.

Cabernet Blanc, Swiss hybrid bred by Valentin Blattner in 1991 for its DISEASE RESISTANCE. One parent is Cabernet Sauvignon, while the second remains undisclosed but is said to include Riesling and Sylvaner in its genealogy.

Cabernet Franc, fine French black grape variety, much blended with and overshadowed by its progeny the more widely planted CABERNET SAUVIGNON. Only in Anjou-Saumur and Touraine in the Loire Valley, on the right bank of the Gironde in Bordeaux, and in parts of north-east Italy is it quantitatively more important than Cabernet Sauvignon, but Cabernet Franc is sufficiently widely grown to be one of the world's 20 most planted cultivars for wine.

In the vineyard it can be distinguished from Cabernet Sauvignon by its less dramatically indented leaves, but the two share so many characteristics that they had long been thought to be related. In 1997, thanks to DNA PROFILING, it was established that Cabernet Franc was, with the Bordeaux white vine variety SAUVIGNON BLANC, a parent of the noble Cabernet Sauvignon (see CABERNET SAUVIGNON for more details).

There is some evidence that the variety's origins lie in Spanish Basque country, but by the end of the 18th century Cabernet Franc was already documented as producing high-quality wine in the Libournais vineyards of St-Émilion, Pomerol, and Fronsac, where it is often called Bouchet today. Long before this, however, according to Odart, it had already been selected by Cardinal Richelieu, as a well-respected vine of south-west France, to be planted at the Abbaye de St-Nicolas-de-Bourgueil in the Loire by an abbot called Breton, whose name persists as the Loire synonym for Cabernet Franc to this day.

Cabernet Franc is particularly well suited to cool, inland climates such as the middle Loire and the Libournais. It buds and matures

more than a week earlier than Cabernet Sauvignon, which makes it more susceptible to COULURE, but it is easier to ripen fully and is much less susceptible to poor weather during harvest. In the Médoc and Graves districts of Bordeaux, where Cabernet Franc constitutes about 10% of a typical vineyard and is always blended with other varieties, it is regarded as a form of insurance against the weather's predations on Cabernet Sauvignon and Merlot grapes. Most Libournais bet on Cabernet Franc in preference to the later, and therefore more difficult to ripen, Cabernet Sauvignon to provide a framework for Merlot, Bordeaux's most-planted variety.

In Bordeaux, plantings of Cabernet Franc and Cabernet Sauvignon were almost equal, at about 10,000 ha/25,000 acres, in the late 1960s, but Cabernet Sauvignon was so often chosen in preference to Cabernet Franc by those replacing unprofitable white-wine vineyards that by 2020 Cabernet Sauvignon covered two-and-a-half times Cabernet Franc's total area in the Gironde of 9,276 ha/22,921 acres.

As a wine, Cabernet Franc tends to be rather lighter in colour and tannins, and therefore earlier maturing, than Cabernet Sauvignon, although CHEVAL BLANC, the world's grandest Cabernet Franc-dominated wine, proves that majestic durability is also possible. Cabernet Franc is, typically, light- to medium-bodied with more immediate fruit than Cabernet Sauvignon and has a marked fragrance, including sometimes some of the HERBACEOUS aromas evident in unripe Cabernet Sauvignon.

Cabernet Franc is still planted all over south-west France, although, in appellations such as BERGERAC and MADIRAN (where Cabernet Franc is known as Bouchy), Cabernet Sauvignon has been gaining ground.

Cabernet Franc was France's sixth most planted black grape variety throughout the 20th century and has now risen to fifth place, with about 35% of its 2019 total of 32,282 ha in the south-west and nearly 30% in the greater Loire Valley. Steadily increasing appreciation (largely within France) of relatively light, early-maturing reds such as SAUMUR-CHAMPIGNY, BOURGUEIL, CHINON, and ANJOU-VILLAGES fuelled demand for Cabernet Franc in the Loire at the

expense of Rosé d'Anjou and Chenin Blanc whites. Here Cabernet Franc tends to be the dominant variety in perfumed, fresh red wines that can smell of raspberries and/or pencil shavings.

Cabernet Franc is also well established in Italy, particularly in the north-east (see FRIULI and VENETO in particular), where it has sometimes been encouraged to yield such quantity that wines can be over-herbaceous and where some vines previously thought to be Cabernet Franc have been identified as CARMENÈRE. Some Tuscan and central-Italian producers of Cabernet Sauvignon grow the variety for blending purposes, but in BOLGHERI and the rest of the Maremma it can yield wines of real interest and complexity, as it does at Tenuta di Trinoro in southern Tuscany. In 2015, Italy recorded 5,590 ha/13,813 acres of Cabernet Franc compared with the Cabernet Sauvignon total of 14,220 ha. Elsewhere in Europe, only HUNGARY takes Cabernet Franc particularly seriously—especially in Villány.

Elsewhere, with a few notable exceptions such as Viader in the Napa Valley, Cabernet Franc has generally been grown for the express purpose of blending with Cabernet Sauvignon, following the Bordeaux recipe. California's total plantings of the variety, 3,350 acres/1,356 ha in 2020 concentrated in Napa, Sonoma, and San Luis Obispo, have remained stable for years. The variety has been responsible for some well-balanced, fruity wines in WASHINGTON State, where Cabernet Franc is more resistant to WINTER FREEZE than Merlot, but it has been losing ground to the more fashionable Syrah and the hugely dominant Cabernet Sauvignon, so that there were only 674 acres/273 ha by 2017.

In the cooler northern and eastern wine regions of North America (especially VIRGINIA, the Niagara Peninsula of CANADA, where ICEWINE has been made from it, Pennsylvania, and Long Island in NEW YORK State), Cabernet Franc has emerged as the red VITIS VINIFERA variety of choice, ripening much more reliably than Cabernet Sauvignon and providing much more EXTRACT than do most HYBRIDS.

ARGENTINA's plantings of Cabernet Franc have more than doubled in ten years, reaching 1,352 ha/3,341 acres in 2019, while Chile has

1,685 ha/4,164 acres, some of the best being old vines in MAULE.

In Australia, Cabernet Franc plays a very minor, generally lacklustre, part while most of the best of New Zealand's 91 ha/225 acres (down from 161 ha in 2011) contribute to HAWKE'S BAY blends. Although the likes of Rijk's and Warwick make fine varietal versions, Cabernet Franc is planted on less than 1% of South Africa's vineyards.

As the pendulum swings back from super-concentrated, high-alcohol reds, Cabernet Franc is likely to benefit.

Bowers, J. E., and Meredith, C. P., 'The parentage of a classic wine grape, Cabernet Sauvignon', *Nature Genetics*, 16/1 (1997), 84–7.

Odart, A.-P., *Ampélographie universelle* (1845).

Cabernet Gernischt, Chinese name for CARMENÈRE, probably a misspelling of Cabernet Gemischt ('mixed Cabernet').

Cabernet Sauvignon, the world's most renowned, but relatively recent, red wine grape, now the world's most planted grape variety, total plantings having more than doubled between 1990 (when it was the world's eighth most planted variety) and 2016 to nearly 310,671 ha/767,685 acres. From its power base in Bordeaux, where it is almost invariably blended with other grapes, it was taken up in other French wine regions and in much of Europe and beyond, included in BORDEAUX BLENDS or blends with INDIGENOUS VARIETIES, and often used to produce VARIETAL wines, especially in warmer climates. Cabernet Sauvignon is now more widely planted beyond Europe than within it.

Perhaps the most extraordinary aspect of Cabernet Sauvignon is its ability to produce a wine that is so recognizably Cabernet, even if remarkably few wine regions, considering its ubiquity, have so far proved reliable sources of seriously top-quality expressions of this potentially top-quality grape: MÉDOC, PESSAC-LÉOGNAN, NAPA, SONOMA, SANTA CRUZ MOUNTAINS, WASHINGTON State, BOLGHERI, COONAWARRA, MARGARET RIVER, STELLENBOSCH, and part of PENEDÈS spring most readily

to mind. What makes Cabernet Sauvignon remarkable to taste is not primarily its exact fruit flavour—which is sometimes likened to blackcurrants or cigar boxes—but its structure and its ability to provide the perfect vehicle for individual vintage characteristics, winemaking and ÉLEVAGE techniques, and, especially, local physical attributes, or TERROIR. Unlike CHARDONNAY, which is almost as widely disseminated, late-ripening Cabernet Sauvignon must be grown in relatively warm climates and can in some years fail to reach full RIPENESS even somewhere as mild as the Médoc.

It is Cabernet Sauvignon's remarkable concentration of PHENOLICS that really sets it apart from most other widely grown vine varieties. It is therefore capable of producing deeply coloured wines worthy of long MACERATION and long-term AGEING. Over the centuries, it has demonstrated a special but by no means exclusive affinity for French OAK. The particular appeal of Cabernet Sauvignon lies much less in primary fruit aromas (with which other varieties such as Gamay and Pinot Noir are more obviously associated) than in the much more subtle flavour compounds that evolve from complex interaction between compounds derived from fruit, fermentation, alcohol, and oak over years in bottle. It is also true, however, that so distinctive is Cabernet Sauvignon that part of the reason it is so widely planted is that, even when irrigated to greedily high yields and hastily vinified without even a glimpse of wood, it can produce a wine with some recognizable relationship to the great Bordeaux growths of the Médoc and Graves on which its reputation has been built.

Cabernet Sauvignon's origins long remained shrouded in mystery, but DNA PROFILING revealed all in 1997. Bowers and Meredith of the University of California at DAVIS showed beyond all reasonable doubt that Cabernet Sauvignon's parents are none other than CABERNET FRANC and the Bordeaux white wine grape SAUVIGNON BLANC, a CROSS that is thought to have happened spontaneously in one of the many vineyards planted with a mixture of different vines in the old days. This neatly explains why Cabernet Sauvignon can smell like either or

both of its parents, as well as why Cabernet Franc is mentioned in the literature long before Cabernet Sauvignon.

There are no early references to Cabernet Sauvignon in the LITERATURE OF WINE, and the variety did not start to make any significant impact on the vineyards of Bordeaux until the end of the 18th century, when the great estates were built up and wine with real longevity emerged (see BORDEAUX, history). Baron Hector de Brane, once owner of Ch Mouton, together with his neighbour Armand d'Armailhacq, is credited with its promulgation, if not introduction, in the Médoc.

The distinguishing marks of the Cabernet Sauvignon berry are its small size, its high ratio of pip to pulp (1:12, according to Peynaud, as opposed to 1:25 for Sémillon), and the thickness of its skins, so distinctively blue as opposed to red or even purple. The pips are a major factor in Cabernet Sauvignon's high TANNIN level, while its thick skins account for the depth of colour that is the tell-tale sign of a Cabernet Sauvignon in so many BLIND TASTINGS—as well as the variety's relatively good resistance to ROT.

The vine is susceptible, however, to POWDERY MILDEW, which can be treated quite easily, unlike vine TRUNK DISEASES such as EUTYPA DIEBACK and PHOMOPSIS, which cannot. It is extremely vigorous and should ideally be grafted on to a weak ROOTSTOCK to keep its VIGOUR in check. It both buds and ripens late, one to two weeks after Merlot and Cabernet Franc, the two varieties with which it is typically planted and blended in Bordeaux. Cabernet Sauvignon ripens slowly, which has the advantage that picking dates are less crucial than with other varieties (Syrah, for example); but this has the disadvantage that Cabernet Sauvignon simply cannot be relied upon to ripen in the coolest wine regions, especially when its energy can so easily be diverted into producing dangerously shady leaves, such as in Tasmania or New Zealand, unless CANOPY MANAGEMENT is employed. Cabernet Sauvignon that fails to reach full ripeness can taste eerily like Cabernet Franc (just as unripe Sémillon, coincidentally, resembles Sauvignon Blanc).

Even in the temperate climate of Bordeaux, the flowering of the vine can be dogged by cold weather and the ripening by rain, so that Bordeaux's vine-growers have traditionally hedged their bets by planting a mix of early and late local varieties, typically 75% Cabernet Sauvignon plus a mixture of Merlot, Cabernet Franc, and sometimes a little Petit Verdot in the Médoc and Graves districts. (See CABERNET FRANC for the reasons the Cabernet in St-Émilion and Pomerol is much less likely to be Cabernet Sauvignon.)

A practice that had its origins in judicious fruit farming has proved itself in the blending vat. The plump, fruity, earlier-maturing Merlot is a natural blending partner for the more rigorous Cabernet Sauvignon, while Petit Verdot can add extra spice (if only in the sunniest years) and Cabernet Franc can perfume the blend to a certain extent. Except in warmer wine regions, wines made solely from Cabernet Sauvignon can lack charm and stuffing; the framework is sensational, but tannin and colour alone make poor nourishment. As demonstrated by the increasing popularity of Merlot and Cabernet Franc and even Petit Verdot cuttings, some producers follow the Bordeaux example of blending their Cabernet Sauvignon with other varieties in newer wine regions, even those warm enough to ripen Cabernet fully. In Tuscany, it is sometimes blended with Sangiovese. In Australia and in Provence it is blended with SHIRAZ/SYRAH, with very different results.

Cabernet Sauvignon, with its sophisticated whiff of French glamour, was extraordinarily popular in the NEW WORLD in the last two decades of the 20th century. Indeed, it could fairly be said that one of the first signs of 'modernization' of a wine region was its importation of and experimentation with Cabernet Sauvignon cuttings. Only those regions disbarred for reasons of climate, such as England, Germany, and Luxembourg, have found it difficult to join this particular club.

France

French plantings of Cabernet Sauvignon increased enormously in the 1980s and 1990s but have fallen this century so that in 2019 there were 46,971 ha/116,068 acres, of which about half were in the Bordeaux *département* the Gironde (although within the Gironde Merlot is almost three times as popular). The vine's stronghold is the left bank of the River Gironde, most notably the famously well-drained gravels of the Médoc and Graves CRUS classés, whose selling price can well justify the efficacious luxury of ageing their wine in small, often new, oak barrels. Most of the FIRST GROWTHS are famous for their high proportion of Cabernet Sauvignon. Their wines, although differing in character, are known for their firm structure and longevity.

The vine is also planted over much of SOUTH WEST FRANCE, often as an optional ingredient in its red, and occasionally rosé, wines, although only in BERGERAC and BUZET does it play a substantial part. In more internationally styled wines, however, it may add structure to the Négrette of GAILLAC and FRONTON and to the Tannat of BÉARN, IROULÉGUY, and MADIRAN. It is also used to add substance to the red ST-MONT.

Plantings in the Languedoc and Roussillon have increased substantially since the 1980s, so that the total was 14,810 ha/36,596 acres by 2019, but Syrah and Merlot have proved much more successful, and Grenache and Carignan are also much more widely planted. The most obviously successful southern French Cabernet Sauvignons are those used as ingredients in low-yield blends with Syrah and other Rhône varieties, such as Mas de Daumas Gassac in the Hérault or, further east in Provence, Domaine de Trévallon and Ch Vignelaure. Provence had 2,609 ha of Cabernet Sauvignon in 2019.

Cabernet Sauvignon's only other French territory is the Loire, but Cabernet Franc is more than seven times as widely grown, not least because it is so much easier to ripen.

Outside France

Cabernet Sauvignon is by far the dominant variety for the world's fastest growing wine-producing county CHINA, where, according to the OIV, total plantings have reached 60,000 ha/148,263 acres, far exceeding those of Bordeaux. The variety, incidentally, was also very widely planted in the old Soviet Union, where, according to the most accurate estimates available, there were approximately 30,000 ha/75,000 acres of Cabernet Sauvignon before it was broken up. The variety is still widely planted in RUSSIA, UKRAINE, and MOLDOVA—although in the many wine regions susceptible to WINTER FREEZE, the cold-hardy hybrid CABERNET SEVERNY is popular. Cabernet Sauvignon is also grown in GEORGIA, AZERBAIJAN, KAZAKHSTAN, TAJIKISTAN, and KYRGYZSTAN.

Another country with an extremely important area planted with the world's noblest black grape variety is CHILE, whose grand total of (generally UNGRAFTED) Cabernet Sauvignon grew from about 16,000 ha/39,500 acres to about 42,409 ha between 1997 and 2015, making it the country's most important vine variety even if the total has remained fairly stable while Chile experiments with new varieties. Here the fruit is exceptionally healthy and the wine almost rudely exuberant. Not surprisingly, Cabernet Sauvignon also flourishes in the rest of South America's vineyards: in ARGENTINA, where in terms of quantity it is dwarfed by Malbec, and in BRAZIL, URUGUAY, MEXICO, and BOLIVIA.

Cabernet Sauvignon, even less surprisingly, has been the bedrock of CALIFORNIA CULT wines. Such has been the quality of some of these wines that northern California could fairly be said to have proved itself Cabernet Sauvignon's second home, growing far more in total—38,429 ha/94,960 acres—than its first. Although the dramatic growth in Cabernet plantings has stopped, it is California's most important variety by far, though only just ahead of Chardonnay. In the better, and often extremely carefully tended, sites of northern California, Cabernet Sauvignon can ripen quite well enough to need no grower's

insurance or winemaker's additional complexity in terms of other grape varieties, and 100% Cabernet Sauvignon can be a hugely successful recipe. For more detail on the Golden State's Cabernet achievements, see CALIFORNIA.

Cabernet Sauvignon is also one of WASHINGTON State's two major black grape varieties. It definitively overtook Merlot in 2006, and by 2017 plantings totalled 7,530 ha/18,608 acres, double the area devoted to Merlot. Cabernet Sauvignon's vigour and late ripening make it unattractive to growers in damp, cool Oregon, but it has been most successful in other American states including Arizona and TEXAS (where it was by far the most planted variety in 2020). In CANADA, the warmer climate of the Okanagan Valley makes BRITISH COLUMBIA much more suitable than ONTARIO for Cabernet Sauvignon.

If Californians decided early on that the Napa Valley was their Cabernet Sauvignon hotspot, Australians did the same about COONAWARRA and, subsequently, MARGARET RIVER. They, however, have for decades employed a much less reverential policy towards blending their Cabernet. Cabernet–Shiraz blends (a recipe recommended in Provence as long ago as 1865 by Dr GUYOT) have been popular items in the Australian marketplace since the 1960s. The richness and softness of Australian Shiraz is such that it fills in the gaps left by Cabernet Sauvignon even more effectively than can the French Syrah recommended by Dr Guyot. Cabernet Sauvignon and Chardonnay vie for second most planted vine variety, but both lag a long way behind Shiraz. In 2022 there were more than 26,000 ha of Cabernet Sauvignon, mainly in South Australia, particularly Coonawarra.

Cabernet Sauvignon was once important in New Zealand, but by 2022 there were barely more than 200 ha/494 acres, most of them in HAWKE'S BAY. It needs careful CANOPY MANAGEMENT to ripen fully, and Pinot Noir is now firmly the country's signature red.

Cabernet Sauvignon was equally revered in SOUTH AFRICA in the late 20th century, but Shiraz had become far more important by 2020 when total Cabernet Sauvignon vineyards had fallen to 9,916

ha/24,503 acres. Many vines are still plagued by LEAFROLL VIRUS, which can prejudice full ripening.

Cabernet Sauvignon has been an increasingly popular choice for internationally minded wine producers in Spain, where it was planted by the Marqués de Riscal at his Rioja estate in the mid 19th century and could also be found in the vineyards of VEGA SICILIA. It was otherwise virtually unknown on the Iberian peninsula until the 1960s, when it was imported into Penedès by Miguel Torres Jr (see FAMILIA TORRES) and Jean León. It broadened its base in Spain, particularly Cataluña, in the late 20th century—not just for wines dominated by it but for blending, notably with Tempranillo. By 2020 there were 18,651 ha/46,088 acres of Cabernet Sauvignon in Spain, making it the sixth most planted red wine vine, yielding some successful reds and some boring basic varietals, from Penedès to Ronda. In Portugal it is much rarer, planted on 1,626 ha/4,018 acres of vineyard in 2020, mainly around Lisbon and in the Alentejo.

Italy, where Cabernet Sauvignon was introduced, via Piemonte, in the 1820s, now has a very substantial area of Cabernet Sauvignon, 14,240 ha/35,188 acres by 2015, almost triple the total recorded for Cabernet Franc. TUSCANY, SICILY, and the VENETO are the most important regions quantitively. Cabernet Sauvignon played a considerable role in the emergence of SUPERTUSCANS and has been popular as a seasoning in an increasing proportion of not just CHIANTI but a wide range of reds throughout the country. In the early 21st century there was a tendency, arguably regrettable, to amend DOC regulations to allow in a small proportion of INTERNATIONAL VARIETIES, notably Cabernet Sauvignon, even though by this time the demand for INDIGENOUS VARIETIES was growing. Cabernet Sauvignon was long a major ingredient in such Tuscan wines as Solaia, Sassicaia, Venegazzù, and Castello di Rampolla's Sammarco, and it even invaded the NEBBIOLO territory of Piemonte in such bottlings as Darmagi from GAJA.

East of Italy there are many thousands of hectares of Cabernet Sauvignon, which plays a particularly important part in the wine

industries of BULGARIA, where its 4,773 ha/11,794 acres in 2020 constituted just over 16% of the country's vines. Russia has even more, with 8,528 ha in 2015, and Ukraine 4,935 ha, but it is also very significant in MOLDOVA, where 4,644 ha were planted, making it the most important dark-skinned variety. ROMANIA had 5,496 ha. The variety can ripen reliably in the warm summers of eastern Europe and, as Bulgaria proved in the 1980s, can provide excellent value if grown and made carefully. Smaller amounts of Cabernet Sauvignon are grown in HUNGARY, AUSTRIA, and GREECE, where it was first planted (in modern times at least) at Domaine Carras.

Perhaps the most tenacious Cabernet Sauvignon grower has been Serge Hochar of Ch Musar in LEBANON, where in the last 20 years it has become, along with Cinsaut, the country's most planted wine grape with around 1,000 ha in 2015. It is also by far the most popular variety in ISRAEL's revitalized wine industry and can make fair, if often expensive, copies of California Cabernet there. There are other, rather less war-torn, pockets of Cabernet Sauvignon vines all over the eastern Mediterranean, notably in TÜRKIYE and CYPRUS, as well as in North Africa. In ASIA, Cabernet Sauvignon is planted by virtually all nascent wine industries and is well established already in JAPAN, where its strong links with the famous châteaux of Bordeaux are particularly prized.

Wherever there are any vine-growers with any grounding in the wines of the world, and where late-ripening grapes are economically viable, they are almost certain to try Cabernet Sauvignon—unless they inhabit one of Bordeaux's great rival regions, Burgundy and the Rhône.

Bowers, J. E., and Meredith, C. P., 'The parentage of a classic wine grape, Cabernet Sauvignon', *Nature Genetics*, 16/1 (1997), 84–7.

Lewin, B., *Claret and Cabs: The Story of Cabernet Sauvignon* (2013).

Cabernet Severny, red wine grape variety specially bred for cold climates at the All-Russia Potapenko Institute in the Rostov region of RUSSIA. It was created by pollination of a HYBRID of DIMYAT (known here as Galan) × VITIS AMURENSIS with a pollen mixture of other hybrid forms involving both the European vine species VITIS VINIFERA and the famously cold-hardy Mongolian vine species *amurensis*. It is grown in Russia and colder parts of Canada.

Cabinet, term of approbation applied to German wines from the 18th century until 1971, when its use was outlawed. A wine labelled Auslese Cabinet, for instance, signified an AUSLESE especially prized by its producer. The term was also used for precious works of art, implying a piece worthy of enshrining in the proprietor's cabinet. It was occasionally spelled with a K. *Kabinettstück* is still used in German in the sense of *pièce de résistance*, and its cachet was borrowed by the 1971 German wine law for the technically defined PRÄDIKAT known as KABINETT. D.S.

Cabrières, village and DÉNOMINATION GÉOGRAPHIQUE COMPLÉMENTAIRE for reds and rosés within the LANGUEDOC AOC inside the CLAIRETTE DU LANGUEDOC zone. The CO-OPERATIVE dominates production, but the launch of Gérard Bertrand's Clos du Temple in 2018, the world's most expensive rosé when it was released, has raised the profile of this obscure region.

Cachapoal, part of the Rapel subregion of the Central Valley in CHILE.

Cadillac, 62-ha/153-acre sweet-white-wine appellation created in 1967 to house the top-quality vineyards of 22 selected villages along the north bank of the GARONNE river, inside the broader PREMIÈRES CÔTES DE BORDEAUX appellation. Strict INAO rules insist on, among

other things, the use of only botrytized or raisined grapes (primarily Sémillon and Sauvignon), a minimum pre-fermentation sweetness of one-third more than for the Premières Côtes, and CHÂTEAU BOTTLING. A dozen growers are almost totally dedicated to producing these very sweet wines, nearly but not quite (because of their higher permitted yield of 40 hl/ha) in the generous style of SAUTERNES. Many of the large ENTRE-DEUX-MERS estates who major on dry wine (white and red) also like to try their hand at small cuvées of sweet Cadillac to widen their range. The region takes its name from its principal 13th-century fortified riverside town built during the 100 Years War. In 1801, Lord Lamothe-Cadillac became governor of Louisiana and founded the city of Detroit, whence the automobile brand name. Not to be confused with the red-wine appellation CADILLAC CÔTES DE BORDEAUX. W.J.B.

Cadillac Côtes de Bordeaux, part of the Côtes de BORDEAUX appellation, officially recognized in 2011, for the ambitious reds made on the south-facing slopes along the right bank of the Garonne between Bordeaux and Langon. Merlot with Cabernet Sauvignon and Cabernet Franc are planted on about 1,000 ha/5,000 acres of vineyard dedicated to the production of these often good-value reds. The soils here are very varied, with the *coteaux* rising from the riverbank offering the most valuably gravelly or CALCAREOUS terrain. CLAY predominates on the plateau between the *coteaux* and the ENTRE-DEUX-MERS boundary. The relatively small quantity of sweet white wines produced on this strip of land are called PREMIÈRES CÔTES DE BORDEAUX. There is a recognizable band of seriously ambitious producers here, especially of quite concentrated red wines which may lack the ageing potential of Bordeaux's more famous examples but can offer good value for drinking at three to five years old.

J.R & J.L.

Caecuban wine was ranked by the connoisseurs of ancient ROME among the finest wines of Italy for the last century BCE and the first half of the 1st century CE. Caecuban wine was produced on a small

vineyard in the low-lying marshy region, south of Terracina, on the west coast of central Italy, between the sea and the Lago di Fondi. The vines were trained up poplars (see ARBOREAL VITICULTURE). Caecuban was a white wine which, following standard Roman practice, was aged for a number of years, during which it deepened to a 'flame' colour. It was described as 'sinewy' and 'packing a punch' by the medical writer Galen. The vineyard was largely destroyed in the middle of the 1st century CE by the ambitious, though abortive, scheme of Emperor Nero to dig a canal to link the bay of Naples with the Tiber. Caecuban never recovered, and the name became simply a generic term for wine with the characteristic colour of the true wine. Small quantities of red wine called Cécubo are produced in the district today. J.J.P.

Pliny the Elder, *Natural History*, 14. 6, translated by H. Rackham (1945).

Cagnina, synonym for TERAN (or Terrano) in Italy's Romagna region.

Cahors, AOC wine region in the Quercy district of SOUTH WEST FRANCE producing exclusively red wine, uniquely in France dependent on the MALBEC or Cot grape (traditionally called here Auxerrois). Cahors is influenced by the Mediterranean as well as by the Atlantic, and, although winters are rather colder than in Bordeaux, the wines tend to be more concentrated. The region's reputation for wines rich in colour and BODY dates from at least the early Middle Ages. The River Lot provided an ideal trade route to the markets of northern Europe via the GARONNE and Bordeaux, and there are records of Cahors being sold in London in the early 13th century.

The wines were appreciated as blending material with the lighter wines of Bordeaux, and in the early 19th century they were famed as the 'black wines of Cahors'. (Such was Cahors's international renown in the 19th century that imitation 'Cahors' was made by at least one

of the Russian model wineries in the CRIMEA.) A method to make the wines even blacker had been adopted whereby a portion of the grape juice was boiled to concentrate its colour and fermentable sugars. The produce of this technique was designed specifically for blending rather than drinking.

At this time there were almost 40,000 ha/100,000 acres of vineyards in the greater Cahors region, but PHYLLOXERA reduced it to less than one-tenth of this, resulting in considerable replanting with HYBRIDS. The arrival of the RAILWAYS also gave the populous north ready access to the cheap and plentiful wines of the LANGUEDOC. Cahors fell into decline.

The Caves d'Olt CO-OPERATIVE, established at Parnac in 1947, encouraged a new era of quality winegrowing, increasing the proportion of noble grape varieties and the incidence of good winemaking equipment and technology. The notorious WINTER FREEZE of 1956 all but destroyed the Cahors vignoble and provided an opportunity for almost total reconstruction. An overwhelming majority of the vineyards were replanted with Malbec, a traditional Cahors variety which is nowhere else associated with particularly long-living wines.

In 1971 full AOC status was granted for the region's red wines, the rules stipulating at least 70% Malbec, supplemented by the tannic TANNAT and/or the supple MERLOT. Cahors is exceptional among south-west French appellations in that neither Cabernet vine is allowed in the AOC.

Production in 2020 amounted to 150,000 hl/3,962,581 gal from approximately 3,323 ha/8,211 acres of vines. Within south-west France only BERGERAC makes more wine. Vines may be planted either on the notably thin topsoil of the arid, LIMESTONE plateau, the *causses*, or on the SAND and GRAVEL terraces between the plateau and the river, the *terrasses*. Others come from the *coteaux*, the narrow corridors leading from the one to the other. Modern winemaking skills and techniques tend to blur the distinction between wines from these three sources.

Since its renaissance, Cahors has developed several distinct styles of wine, from fruity and quaffable to velvety, concentrated, and oaked, while a handful of growers continue the old-fashioned traditions (e.g. Clos de Gamot, Clos Triguedina). Wine-making techniques therefore vary accordingly, with variable approaches to MACERATION and BARREL MATURATION, some growers seeking to escape from the success of Malbec in ARGENTINA, others to emulate it.

Cahors is limited to wines made in the Lot *département*. Just over the western boundary in Lot-et-Garonne can be found the IGP Thezac-Péricard, whose wines are similar to but lighter than the Cahors style. Cahors growers seeking escape from AOC rules can produce IGP wines from the Lot, including whites and rosés. P.S.

Caíño Blanco is grown to a very limited extent in north-western Iberia, notably in GALICIA, while Caíño Tinto is the Galician name for the rather more common BORRAÇAL.

Cairanne, southern RHÔNE cru, promoted from Côtes du Rhône-Villages to AOC Cairanne in 2015. Only 5% of the wines produced from its 877 ha/2,167 acres of vineyards in 2020 were white; the rest are red, a blend of 40% Grenache plus Syrah or Mourvèdre (or both), possibly with small amounts of a further 16 varieties. Whites must contain at least two of the following: Clairette, Grenache Blanc, or Roussanne (and at least 20% of any that are used). They may also contain Bourboulenc, Marsanne, Piquepoul Blanc, or Viognier. The appellation is spread over the generally south-facing slope of the western flank of a large hill of MARL and pebbles situated between the Aigues and Ouvèze rivers, reaching 350 m/1,148 ft in ELEVATION. (The south-facing slope of the eastern flank is occupied by RASTEAU, an AOC with which Cairanne shares a border.) There is also some flat land at the foot of the hill and a further growing area on the other side of the Aigues. The reds have the characteristic generosity of southern Rhône wines but tend to be less bold and potent than those

produced in Rasteau. Whites are typically well balanced, with less body and oak influence than those of CHÂTEAUNEUF-DU-PAPE. M.C.W.

Calabrese, meaning 'of Calabria', is a common synonym for NERO D'AVOLA, while the rare, unrelated Calabrese di Montenuovo has been identified as a parent of SANGIOVESE.

Calabria, rugged, mountainous region in southern Italy, is one of the world's oldest wine regions. There were already vines trained on stakes when the first Greek settlers arrived around 400 BCE. This may be why they called this part of Italy Enotria or 'land of the vines': *oinotron* refers to the stake to which the BUSH VINES were tied. Still used in Calabria, they are now officially called *alberello enotrio con palo secco*.

With the arrival of the Romans in Calabria in 300 CE, large-scale agricultural holdings (the so-called *latifundi* worked by slaves) were introduced to the region. Food and wine production became more sophisticated and refined. The system continued for centuries, with slaves replaced by sharecroppers, until in the 1950s it was abolished, replaced by small family farms founded through land donations. A disastrous phase began with the emergence of the *cantine sociale*, CO-OPERATIVES, which encouraged high yields at the cost of quality. Soon more profitable crops such as citrus and kiwi replaced vineyards, which were decimated further by the 2008 EU VINE-PULL SCHEME. In 2019 the total surface was estimated at 10,706 ha/26,455 acres.

By the 2010s a renaissance had begun, spurred on by an interest in Calabria's many INDIGENOUS VARIETIES. Librandi, which conquered the international market in the 1990s with a BARRIQUE-aged blend called Gravello, has been the motor, making up for the absence of any regional academic viticultural department or station with its own extensive clonal research into local varieties such as GAGLIOPPO, the principal red grape of the region and the basis of the Cirò DOC. The

Cirò Revolution, a group of producers practising ORGANIC and BIOYDNAMIC VITICULTURE and long MACERATION times, has also been fundamental in forging change. In the tiny neighbouring Melissa DOC, newcomers produce small quantities of boundary-pushing wines fermented in QVEVRI.

Each of Calabria's nine DOCs boasts a host of high-quality, indigenous varieties. In Terre di Cosenza, a very large DOC bordering BASILICATA to the north, the white GRECO BIANCO (unrelated to Campanian Greco), Mantonico, and the red MAGLIOCCO Canino and Dolce take the lead, sometimes in blends with INTERNATIONAL VARIETIES but more and more on their own. Lamezia, on the west coast, shares NERELLO MASCALESE and NERELLO CAPPUCCINO with Sicily's Etna across the Strait of Messina, suggesting an ancient historic link, as does NERO D'AVOLA, here called Calabrese. Around the town of Bianco, the coppery-hued GRECO BIANCO could be a direct descendant of what Greek settlers first found here.

Promising developments come from Vibo Valentia, a Magliocco hotbed without a denomination where seven producers under the banner of Viticoltori Vibonesi are petitioning for a new IGT. Where state subsidies and intervention have failed for decades, private initiative now propels Calabria forwards. W.S.

Librandi, P. (ed.), *Calabria: Valorizzare con Metodi Moderni un'Antica Vocazione Vinicola* (2014).

Gagliardi, G., and Convertini, G., *Il Vino nelle Terre di Cosenza* (2013).

Caladoc, reliable dark-skinned cross of GRENACHE and Cot (MALBEC) created in 1958 by French AMPELOGRAPHER Paul Truel to produce a Grenache-like variety less prone to COULURE. It is a permitted ingredient in Côtes du Rhône and also used to add TANNINS and aroma to some southern French reds. France grew a total of 5,959 ha/14,725 acres by 2019, and there were 2,533 ha in Portugal,

mainly in Lisboa, by 2020. It is also grown in Spain, Lebanon, Morocco, and Argentina.

Calatayud, DOP with 3,293 ha/8,137 acres of vines in ARAGÓN in north-east Spain, in arid country on either side of the river Jalón, a tributary of the Ebro (see map under SPAIN). As in much of central Spain, YIELDS rarely rise above 20 hl/ha. Vineyards are planted at 550–1,040 m/1,804–3,412 ft in elevation, where the DIURNAL TEMPERATURE RANGE helps moderate the hot summers; the cierzo, a dry, cold north wind, helps minimize FUNGAL DISEASE pressure. Red grapes make up 92% of plantings, especially GARNACHA, which makes heady, potent red wine, although TEMPRANILLO and SYRAH are also planted. Some crisp white wines are made from VIURA. Most grapes are sold to one of six CO-OPERATIVES, although impressive results come from independent producers such as Escocés Volante, Langa, and Breca. F.C.

calcaire. See LIMESTONE.

calcareous refers to geological materials that are 'limy' (i.e. composed significantly of calcium carbonate, as the mineral calcite), in contrast to siliceous rocks such as GRANITE and SANDSTONE (see GEOLOGY). Calcareous materials include MARL, LIMESTONE (and its subvarieties CHALK and dolomite), and their associated soils.

Calcareous soils abound in the Eastern Mediterranean–Caspian Sea region in which VITIS VINIFERA originated, as well as in the southern European areas through which the vine eventually spread. Consequently they are associated with a number of classic European wines such as CHAMPAGNE, BURGUNDY, BAROLO, and SHERRY.

Most natural caves, some now utilized for wine maturation and storage, are formed in limestone. This is because much natural water contains carbon dioxide dissolved from the air, creating a weak acid

that reacts with calcareous materials to form calcium hydrogen carbonate (bicarbonate), which is soluble. This also explains distinctive landscapes such as that of the French *causses*. Similarly, calcareous bedrock is commonly fissured, allowing any deep vine roots to seek water that may be stored there.

Calcareous soils have a higher PH than siliceous soils, typically between 6 and 7, because free hydrogen is removed from water when it is integrated into bicarbonate. This is the pH range in which many nutrients are at their optimum availability (see SOIL ACIDITY, SOIL ALKALINITY). However, above pH 7 many elements become unavailable, so soils excessively high in calcium carbonate are not ideal for viticulture and can cause lime-induced CHLOROSIS. There is a common belief that the raised pH of calcareous soils leads to enhanced acidity in the finished wine, but there is no consistent relationship. A.J.M.

calcium is an essential mineral nutrient (see VINE NUTRITION) and is important in vineyard soils. In the vine, it participates in hormone signalling networks, for example in communicating WATER STRESS; it enhances the structure of cell walls and membranes; and it promotes resistance to microbial attack, such as from GREY ROT and DOWNY MILDEW. Calcium is taken up in soil water by the roots, principally during the period of rapid growth preceding VERAISON. Because it is easily precipitated and can partially block the PHLOEM, after veraison transmission to the fruit declines.

Most rocks yield soils with sufficient calcium for vines. It usually originates from clay minerals or plagioclase feldspar (see GEOLOGY) or from the calcium carbonate that defines the calcareous rocks. Calcium readily displaces sodium from clay surfaces, which increases soil friability, microbial activity, and drainage. (See SOIL TEXTURE and SOIL AND WINE QUALITY.) The drainage encouraged by calcium partly accounts for the suitability of soils in damp northerly European wine regions such as Burgundy and Champagne.

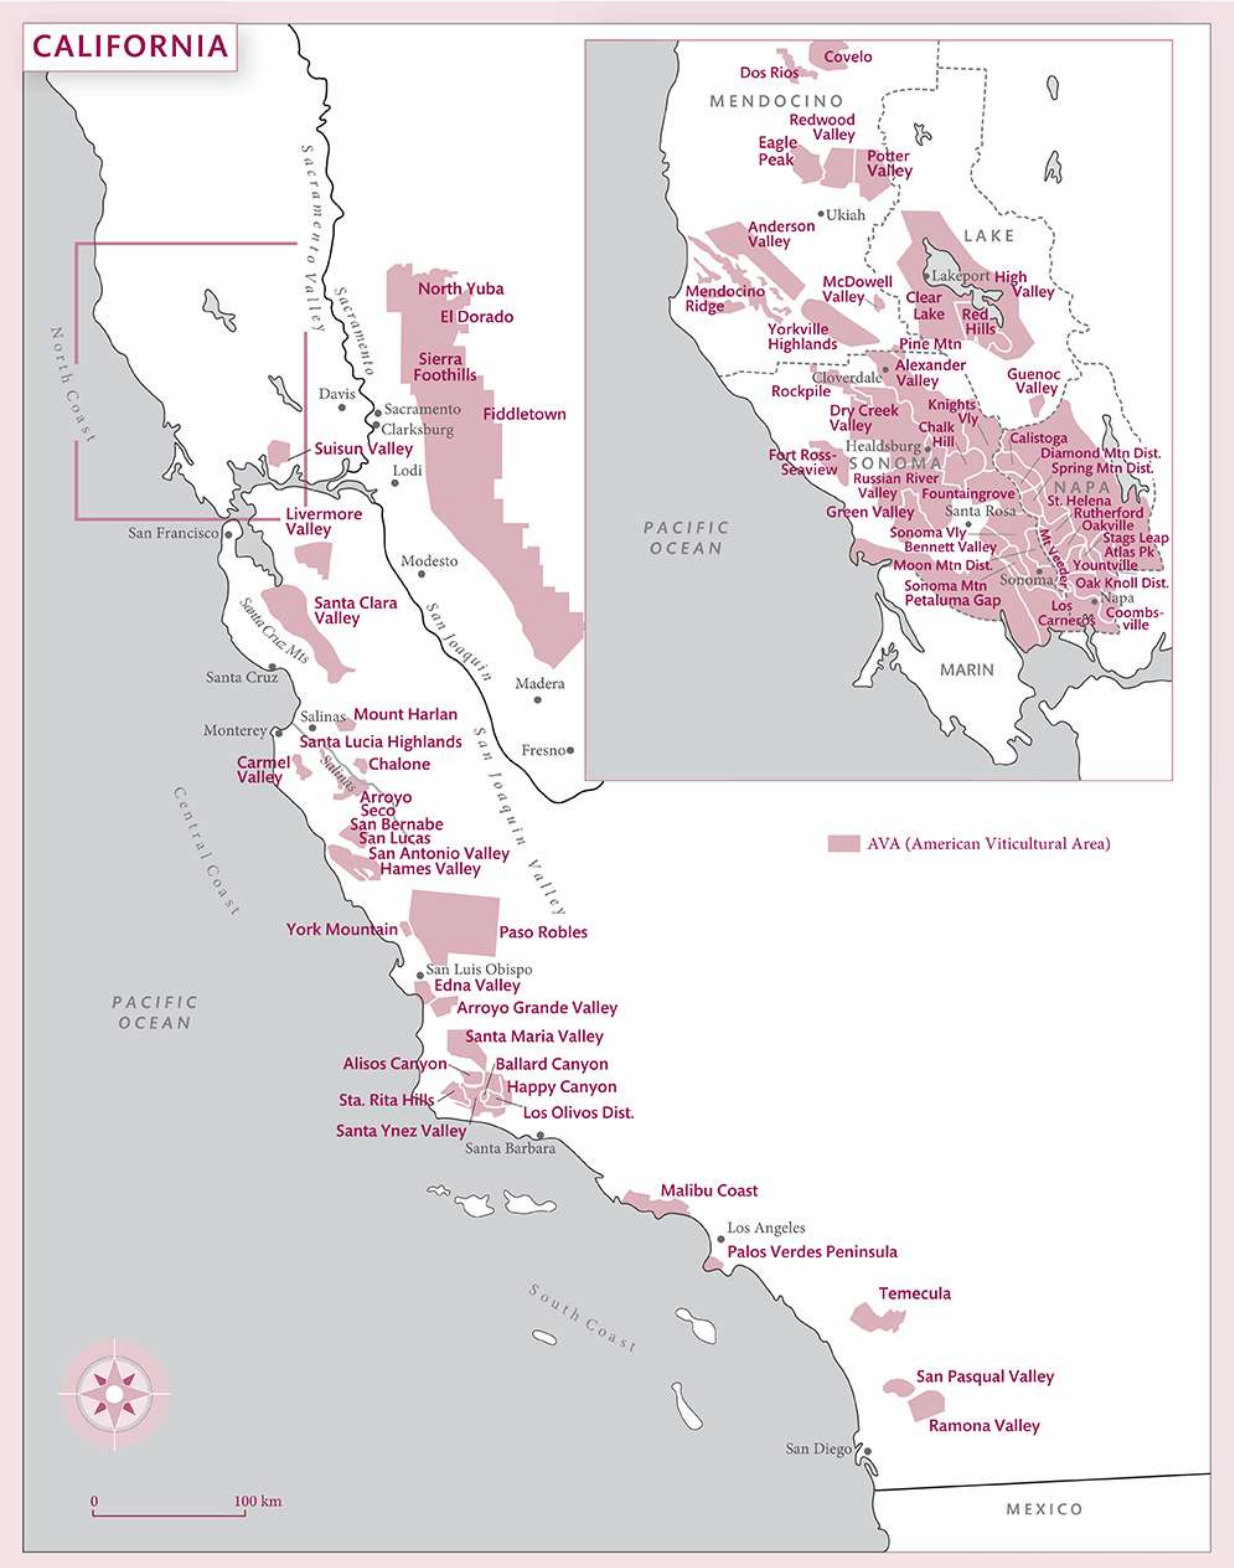
Calcium salts have important effects on soil PH and CATION EXCHANGE CAPACITY. The availability of elements as plant nutrients is broadly correlated with soil pH. Calcium in soils is usually accompanied by a pH of 6–7, at which point many plant nutrients and trace elements are at their most available (see SOIL ACIDITY, SOIL ALKALINITY). The presence of calcium in soils often correlates with the optimum pH for vine growth, which is why liming soils not only tends to improve soil texture but can also increase the availability of nutrients. However, above pH 7, many elements become unavailable, so soils extremely high in calcium carbonate are not ideal for viticulture and cause lime-induced CHLOROSIS. A.J.M.

Caldaro, or Kaltern in German, township in ALTO ADIGE, northern Italy. It gives its name to Lago di Caldaro or Kalterersee, a large DOC zone unreasonably extended into neighbouring TRENTINO for red wines produced from SCHIAVA Grossa, Schiava Gentile, and/or Schiava Grigia. The wines' general lightness owed much to high yields of 14 tons/ha, but a new generation of producers are proving that high quality is possible.

California , highly successful 'wine state' of the United States producing 81% of all US-grown wine, in some years more than 735 million gal/27 million hl in total, and three out of every five bottles sold in the US for a total of $40 billion in 2020, making the state effectively the world's fourth biggest producer of wine. California was also for many years the only source of VITIS VINIFERA wine in the US. California wine, has, since its true commercial beginnings in 1822, experienced several cycles of boom and bust, emerging in the modern era as a powerhouse in the global wine industry, with superior-quality wines anointed by critics as among the best in the world.

History

Franciscan MISSIONARIES planted the first *vinifera* vines with the help of converted, coerced, or conscripted Native Americans in California around 1779 (the native *Vitis californica* and *Vitis girdiana* being unfit for wine). For the next 70 years the Franciscans' MISSION grape remained the basis of California winegrowing, passing from the missions to small growers as the mission lands were secularized under the newly independent Mexican government beginning in 1834. In 1838, George Yount planted the first vines near the town that now bears his name in Napa. After the US annexation of Alta California in 1847 and the discovery of gold in 1848, winegrowing spread throughout the state. California's fame as a new wine region spread even as far as North Caucasus (see RUSSIA).



Following the GOLD RUSH of 1849, both population and vineyards expanded rapidly in the districts around San Francisco Bay and in

Gold Country as demand for many things, alcohol especially, drove a frenzied boom of commercialism. SONOMA Valley had been a centre of winemaking activity since the 1820s thanks to Mariano Vallejo, the Mexicans' military commandant for Alta California, whose wines were good enough to inspire Agoston HARASZTHY to purchase 560 acres in 1857 and begin what would become Buena Vista Winery.

By 1891, Sonoma had 9,180 ha/22,683 acres under vine compared with the NAPA Valley's 18,000 acres, the vast majority of both having been planted by Chinese labourers lately arrived from their work on the transcontinental railroad. The Chinese Exclusion Act of 1882 and the heavy persecution that followed would eventually drive most to leave the region entirely. Accelerated in no small measure by the devastation of Europe's vineyards by PHYLLOXERA, the 1870s and 1880s saw an extraordinary burst of investment in vineyards and wineries, benefiting not just these NORTH COAST counties but also LIVERMORE VALLEY, SANTA CLARA VALLEY, and LODI.

By the end of the 19th century, nearly every region currently producing wine in California had been tried, and production was over 1.1 million hl/30 million gal, largely from the northern part of the state, especially Sonoma, Napa, and Santa Clara counties. The vast central SAN JOAQUIN VALLEY began to be developed for the large-scale production of inexpensive wines in the 1870s, especially in Fresno and Madera counties. The state had officially encouraged winegrowing from the earliest years, recognizing it as one of California's most distinctive contributions to the US economy. A board of State Viticultural Commissioners did useful work from 1880 to 1895, and the wine research and education of the University of California (first at Berkeley and subsequently in DAVIS) began in 1880 and continues today.

Aggressive research and education by E. W. Hilgard and Frederic T. Bioletti at the university produced immediate and significant impacts. By 1881, scholars and growers alike saw clearly that the coastal counties were for finer TABLE WINES, the San Joaquin for everyday table wines. Already California grew more than 300 *vinifera* varieties,

with CHASSELAS, ZINFANDEL, BURGER, and of course Mission predominating, even if most of the nearly 800 wineries producing at California's 19th-century peak (about the same number as a century later) sold their wines anonymously in BULK to a handful of blender/bottlers who offered broad ranges of wine types to the trade.

Over-planting, however, and attempts by a few powerful merchants to corner the wine market caused prices of grapes and wine to crash in the 1890s, dropping below production costs. This and the first signs of phylloxera in California caused the first major setbacks for this burgeoning industry, devastating the state's wine production. PROHIBITION, legally in force from 1920 to 1933, challenged the remaining market. It was many decades before some areas recovered their pre-Prohibition status as wine regions, although Napa, Sonoma, and the Central Valley survived by producing and selling SACRAMENTAL and 'medicinal' wines and by shipping grapes and concentrate throughout the country for legal HOME WINEMAKING purposes.

Immediately after the Repeal of Prohibition, the market demanded mostly sweet wines. Relatively few producers attempted to make high-quality table wines from superior varieties. By the end of the Second World War, there were only about 120 producing wineries, most of them bottling their own production. A trade far more familiar with whiskey than wine encouraged the survivors to produce 'full lines', echoing not the old blender/bottlers but importers who were now bringing in broad arrays of wines from Europe sold under GENERIC names. In the THREE-TIER SYSTEM of distribution it may have been the retailers who were most to blame for wanting to keep their domestic orders as simple as their import invoices, reinforced by the general ignorance of the American drinking public. California thus produced wines sold under such generic names as Burgundy and Chablis.

During this time, however, researchers A. J. WINKLER and Maynard AMERINE at Davis were establishing the blueprints for the state's modern understanding of its wine industry, namely by answering the questions of what should be grown where and how to make

commercially viable wine at scale. Their work, including Winkler's famous CLIMATE CLASSIFICATION scale, set the stage for California's eventual rise as a global player in wine.

After a period of struggle that lingered beyond the Great Depression and the Second World War, a second grand burst of investment was evident between 1970 and 1985, most obviously in Napa but also in Sonoma. In 1976, the year of the famed JUDGMENT OF PARIS tasting, there were 45 wineries operating in Napa and 47 in Sonoma, and America's annual wine consumption was growing by double digits. That triumph of California wines over their French counterparts in Paris proved to be a watershed moment for the state, putting California wine on the map and sparking significant activity in the domestic market, amplifying America's already growing interest in wine to still greater heights.

New wineries proliferated, production rose, more suitable varieties were extensively planted, higher standards were aimed at, and market demand was swiftly answered, mostly with VARIETAL wines closely tied to their region of origin, a distinct step up from the generic wines that had dominated the state's production since Prohibition.

Although a new strain of phylloxera in the late 1980s slowed things down, growing populations around San Francisco pushed vineyard planting south into MONTEREY, SAN LUIS OBISPO, and SANTA BARBARA counties. Then in the late 1990s a third wave of expansion, in no small part fuelled by the overnight successes of internet and multimedia entrepreneurs in northern California, pushed experimental planting into lesser-known regions as land in the Central Coast, Napa, and Sonoma became increasingly expensive. (See Climate and geography, below, and AVA.) By 2005 the number of wine companies in the state had shot past the late 1980s record of 800 to nearly 1,700, and by 2020 the number of bonded wineries in the state numbered 4,200.

The first wave of commercial California wineries in the 19th century were founded by European immigrants who brought their (primarily) German and French sensibilities and experiences to the

industry. These pioneers were followed by a larger population of Anglo-Americans who arrived with the Gold Rush. A later wave of Italian immigrants kept things going during and after Prohibition. In the second half of the 20th century, traditional farming families were joined by an eclectic population of engineers, painters, physicians, pilots, retired industrialists, reformed hippies, and other second careerists who somehow found a calling in wine.

The most ambitious and well-funded of these new players were responsible for the next wave of prestige winery creation in the late 1980s and early 1990s, which found its apotheosis in the so-called CALIFORNIA CULT wines and set the stage for a dramatic and sustained rise in prices for land, grapes, and finished wines. These wineries and their wines also paved the way for a rise in both alcohol levels and extraction (see Winemaking below) as Robert PARKER and other American critics rewarded ripeness and opulence with higher and higher scores. The American palate and pocketbook followed.

The advent of CUSTOM-CRUSH FACILITIES and their associated services, combined with an increasingly flexible market for grape contracts in the early part of the 21st century, dramatically lowered the capital requirements for starting a premium wine label, most importantly eliminating the need to own a vineyard in order to make wine of the highest quality. A significant portion of the new wine companies created since 2010 own no property and make wine in shared facilities. The use of experienced consulting winemakers in conjunction with this estateless approach to production has made it possible for anyone with enough money and determination to launch a wine brand with vineyard-designated wines from well-known sites, made at remarkable levels of quality. So perfected has this model become that it is now impossible to distinguish between fine wines made in this manner and those hailing from landed estates with decades of history.

The market for wine in the United States grows at 1–2% annually, and California continues to supply three-fifths of all domestic requirements, shipping a high of 286 million cases in the generous 2018 vintage. Meanwhile US wine exports, which were negligible

after the Second World War, have grown steadily since the mid 1980s, with California supplying 95% of that volume. In 1986, the US exported only 7.3 million gallons/0.275 million hl with a value to the wineries of US$35 million. In 2020, those figures had risen to 100 million gallons/3.7 million hl with a value to the wineries of US$1.36 billion generated from 142 countries. Canada was the biggest importer, followed in order by the UK, EU member countries, Japan, Hong Kong, South Korea, and China.

The considerable costs and legal requirements associated with export and global distribution mean that the majority of California's finest wines never find their way abroad, leaving export sales largely the domain of only the largest or the most persistently dedicated wine brands. Climate and geography

Those unfamiliar with California assign it a two-season MEDITERRANEAN CLIMATE. This is but a partial truth that cannot accurately characterize a region with the topographic diversity of America's third largest state. Offshore ocean currents cause an intermittent fog-bank along California's 1,350-km/850-mile-long coast, creating extensive stretches with insufficient sunshine to ripen most grapes. These fogs do not penetrate far inland, because of the 1,000-m/3,300-ft high coastal range, leaving the San Joaquin Valley generally too warm and sunny to grow fine table wines. However, in the sharply convoluted in-between of the Coast Ranges, the jumbled terrain, variable fog, and marine breezes create pockets with growing seasons that echo those of Castellina-in-CHIANTI, ST-ESTÈPHE, BEAUNE, and even Hattenheim in the RHEINGAU. There is no linear pattern. Westerly parts of Santa Barbara County are cooler and foggier than any part of Napa which is some 500 km/300 miles north, while much of Mendocino, nearly 80 miles north of Napa, has hotter summers. Openings to the Pacific Ocean in the Coast Ranges indicate the cool spots, while mountain barriers locate the warmer ones.

While once relatively predictable, precipitation patterns and levels have shown volatility in the wake of widespread CLIMATE CHANGE, with sometimes localized extremes. Frequent DROUGHT effects notwithstanding, total annual RAINFALL north of San Francisco is 615–1,150 mm/24–45 in, while from San Francisco southwards non-drought totals range from 20 inches to the low teens/500 mm to around 330 mm. Occurring in 10- to 20-year cycles during the 19th and early 20th centuries, DROUGHTS are now more frequent and more extreme in California. The state experienced droughts in 1976–7, 1986–92, 2007–9, 2011–19, and again beginning in 2020, which proved to be the driest year since 1924.

Winters in California's grape-growing regions are mild to outright balmy. Damaging WINTER FREEZES are virtually unheard of.

Spring FROSTS, once common, are now less of a factor, though few growers are willing to scrap their costly investments in mitigation, which include SPRINKLERS and WIND MACHINES, huge fans that keep cold air moving in the vineyards. Spring rains sometimes interfere with flowering and fruit set, but rarely disastrously. The near total lack of summer rainfall (between mid June and September) usually makes for a relatively bucolic growing season and easy harvest.

California has been increasingly subject to WILDFIRES near harvest time, whose localized impacts have affected wine grapes to a greater or lesser extent in the 2007, 2008, 2017, 2018, 2020, and 2021 vintages.

It proves difficult to typify soil types in California's vineyards because so much of the state's landforms have been emplaced on the North American tectonic plate and then crumpled together by the Pacific tectonic plate sliding beneath it. Most vineyards have intrusions of several soil types, hence identification and separate vinification of different blocks within vineyards (see PRECISION VITICULTURE) became increasingly valuable tools in the early 21st century for California's most quality-conscious winemakers. As a result, single-vineyard, single-block, and/or single-clone bottlings have proliferated.

The US federal government began holding hearings in 1983 to approve AVA (American Viticultural Area) names for use on labels. That process is ongoing, but it has been widely criticized for outcomes which often seem more marketing-driven or politically expedient than useful to consumers. Before 1983, California's geographical appellations were by and large its counties. Those county names, still much used in practice on wine labels, have been, in descending order of popularity, NAPA, SONOMA, SANTA BARBARA, MENDOCINO, MONTEREY, AMADOR, EL DORADO, LAKE, and SAN LUIS OBISPO. Up to 25% of a wine labelled with the county name may come from elsewhere.

AVAs are purely geographical, imposing no restrictions on varieties planted, vineyard practices, or winemaking protocols. By 2022, California had 144 (out of a national total of 262), with subregions of

Napa, Sonoma, and Santa Barbara being the most recognized among wine lovers. More than 20 of the state's AVAs have been added since 2015, with many still so little known that county names often remain more effective at communicating vineyard location. The use of an AVA designation on a wine label requires 85% of its grapes to be grown in the stated AVA.

Individual California AVAs are detailed in this book under the name of the county or larger geographical unit in which they fall, except for CARNEROS, LIVERMORE VALLEY, PASO ROBLES, SAN FRANCISCO BAY, SANTA CLARA VALLEY, SANTA CRUZ MOUNTAINS, and TEMECULA.

Kramer, M., *Making Sense of California Wine* (1992).

Robinson, J., and Murphy, L., *American Wine* (2013).

See www.ttb.gov/wine/american-viticultural-area-ava for more information on AVAs.

Viticulture

After its early reliance on the Chinese, California has historically benefited from particularly adept Mexican LABOUR, but ongoing 21st-century federal crackdowns on illegal immigration and restrictive work-permit policies have made life more difficult for both employers and workers. As demand for skilled vineyard workers has increased, so too have wages, leading many estate wineries, as well as the increasingly popular VINEYARD MANAGEMENT COMPANIES, to move from seasonal to year-round employment. Despite this improvement, many vineyard workers still cannot afford to live in the increasingly expensive regions where they work. Worker safety issues continue to be a topic of concern in the face of summer heat and wildfire smoke.

MECHANICAL HARVESTING has long been common in the CENTRAL VALLEY and in much of MONTEREY, but in light of labour costs NORTH COAST growers at even the highest levels of quality continue to investigate harvesting machines and MECHANICAL PRUNING too.

With the exception of some remaining plots of ancient vines (see HISTORIC VINEYARD SOCIETY), all of California's vineyards have been replanted since the repeal of Prohibition. In the years following that date, California viticultural practices were relatively uniform: head-trained, SPUR PRUNED vines spaced about 8 ft apart in rows about 10 ft/3 m apart. Dry farming was the rule in the North Coast, while flood IRRIGATION was the universal practice in the San Joaquin Valley.

During the 1960s, vine TRAINING began to move on to wires, with cane PRUNING for lighter-bearing vine varieties and CORDON for heavier yielders. Overhead sprinkler systems for irrigation became more common, especially in the emerging Central Coast. AXR1 became the ROOTSTOCK of choice because of its vigour and near-universal adaptability, and heavy, dense canopies were the norm. Vine spacing remained at or near 8 ft × 10 ft, or 400–600 vines per acre (1,000–1,500 vines per ha).

Towards the mid 1980s, all of the old rules went by the way, impelled partly by a new mutation of phylloxera, the so-called biotype

B; partly by a recurrence of PIERCE'S DISEASE; and, more significantly, by closer observation of the variables caused by California's turbulent geology. It was not uncommon in the early 1990s to see single properties on the North Coast with three or four different vine spacings, ranging between 800 and 2,000 vines per acre, and as many different systems of CANOPY MANAGEMENT. The aim was to take advantage of variations in soil structures and exposures as well as vine varieties.

Since AXR1's resistance to phylloxera had proved disastrously low, rootstock selection was becoming a new art. The 1990s saw a major replanting programme, particularly in Napa and Sonoma, as a direct result of phylloxera and vine disease. The traditional alternative to AXR1 was Rupestris St George, but around 30 rootstocks were being trialled in the mid to late 1990s, with drought-tolerant variations emerging as those favoured by growers throughout the state.

This replanting also took full advantage of the well-developed catalogue of plant material overseen by the UC Davis Foundation Plant Materials Service. Established in 1958 with the goal of distributing virus-free plant material to the state's farmers, FOUNDATION PLANT SERVICES, as it is now known, has developed a catalogue of distinct CLONAL SELECTIONS for most of California's most popular grape varieties, from which nearly all the state's NURSERY stock descends. Most growers in the state choose to replant and propagate these CLONES, though some prefer to source their own cuttings of heritage material from known vineyard sites using MASS SELECTION, believing that genetic diversity trumps being virus-free.

As replanting proceeded, drip IRRIGATION became the norm for many coastal vineyards, with many growers opting for REGULATED DEFICIT IRRIGATION for its ability to both control ripeness and conserve water. DRY FARMING has seen renewed interest in the face of ongoing droughts as has the high-tech-enabled practice of PRECISION VITICULTURE. Growers in the SAN JOAQUIN VALLEY and in other river watersheds such as the RUSSIAN RIVER VALLEY depend upon diversions of water for their irrigation, while most others have wells and/or

ponds that fill with winter rains. Those dependent upon river flows or surface catchments can suffer greatly in the midst of drought.

The term SUSTAINABILITY has become nearly ubiquitous in the 21st century, pervading consumer consciousness and purchase decisions. Most major regional marketing bodies and grower associations in California have green initiatives, with many developing certification programmes for their members to drive adoption of sustainable practices across areas such as environmental impact, water conservation, social equity, worker health, and business stewardship. Critics of these programmes suggest they grant certification too easily and need stricter requirements in order to truly make a difference, citing unwillingness to ban chemical FERTILIZERS, soil fumigants, and HERBICIDES such as glyphosate.

ORGANIC VITICULTURE has grown from a cottage industry in the mid 1980s to a full-blown movement. In 2020 an estimated 61,776 ha/25,000 acres of California's vineyards were certified organic or in conversion, roughly 4.2% of the state's bearing vineyard acreage, up from 2.1% in 2016. As in many other parts of the world, some growers choose not to seek organic certification, either to avoid the fees required or merely because they wish to leave their options open. BIODYNAMIC VITICULTURE has continued to gain ground as well, with 933 ha certified by Demeter in 2020.

When the focus of winemakers' attention moved from flavour to TEXTURE in the 1990s, grapes tended to be picked at ever-higher BRIX. Since 2000 it became common to see Cabernet Sauvignon destined for higher-priced bottles left on the vine until 27 °Brix and PH levels above 3.7 were achieved. This technique, referred to as extended HANG TIME, was unpopular with growers since desiccation of the berries (see BERRY SHRIVEL) results in reduced tonnage and less income. Ripeness levels in Pinot Noir, Chardonnay, and most other grape varieties also crept upwards from the late 1990s onwards. As with many such trends, a backlash of sorts resulted, with some producers now picking for lower POTENTIAL ALCOHOL levels and higher acidity.

Rising temperatures and increasing drought have driven recent changes in CANOPY MANAGEMENT away from vertical trellising, which some now think provides too much sun exposure, and back to a more traditional CALIFORNIA SPRAWL or even GOBELET in an attempt to provide more shade and slower ripening for fruit.

Winemaking

Without long tradition as either guide or limitation, most California winemakers have consistently looked to achieve the kind of reproducible results their university training exalts. Understanding a process and then controlling it are, thus, the first two goals of the state's typical OENOLOGIST. Of all the steps in winemaking, FERMENTATION has received the most vigorous attention.

Temperature-controlled fermentation began in California in the 1940s. With the advent of STAINLESS STEEL tanks and more integral cooling systems in the 1960s, there came 'designed' fermentation curves for each major grape variety. Ultra-hygienic, precisely controllable stainless-steel tanks and sterile FILTRATION allowed MALOLACTIC CONVERSIONS to be brought under control at the same time. Today it is not at all unusual to have malolactic fermentation induced in one low-PH batch of Chardonnay and deliberately inhibited in another (higher pH) batch, then to blend these components for additional complexity in the resulting wine.

Throughout the modern era, ACIDIFICATION has been the norm across the state, but it is becoming slightly less commonplace as grapes are increasingly sourced from more MARGINAL CLIMATES, where they often have higher natural acidity. DEACIDIFICATION is rarely practised or necessary. CHAPTALIZATION is not permitted, nor ever needed when wines and GRAPE CONCENTRATE from warm inland areas are consistently available for blending.

OAK barrels from French forests came into play as ageing vessels at the beginning of the 1960s; within a decade, BARREL FERMENTATION of white wines was the height of fashion. Chardonnay was and remains foremost among the varieties so fermented. COOPERAGE activity in California surged in the 1990s after studies suggested that treatment and technique were more important than whether the oak was French or American. OAK CHIPS and INNER STAVES are commonly available but used primarily for inexpensive, mass-market wines.

With the exception of some who use oak fermenters, most producers ferment their red wines in tank (see CONTAINERS), almost always in stainless steel, frequently in open-topped vessels which allow manual or mechanical PUNCHING DOWN. The use of CONCRETE vats for fermentation, both rectangular and egg-shaped, has become popular in the 2010s; some are even experimenting with fermentation in buried AMPHORAE. After years of separating MUST from CAP just as the fermentation approached dryness, the vogue of the 1980s was extended MACERATION for as long as 25 days after the end of fermentation. Today a wide variety of maceration techniques, along with MICRO-OXYGENATION, are employed in a quest called TANNIN MANAGEMENT, targeting a soft MOUTHFEEL achieved through a high degree of EXTRACT and ripe tannins.

YEASTS are also much studied. For years, pure strains of specially cultured yeast ruled in California. Towards the end of the 1980s, however, winemakers were increasingly prepared to experiment with AMBIENT YEASTS, and by the turn of the century even large commercial wineries were fermenting as much as one-quarter of their production with naturally occurring ambient yeasts.

Organic winemaking has been defined by the US government for labelling purposes since 2001. However, unlike European regulations, the US does not allow any addition of SULFITES, which would raise the free sulfur dioxide level over 10 parts per million. The production of certified 'organic wine' in California is therefore limited to a small, and somewhat eccentric, segment of the industry. Many more wines go to market with a label claiming 'Certified Organic Grapes' but this number is far fewer than would be expected from the number of vineyards growing grapes without AGROCHEMICALS, in part due to a perceived lack of consumer confidence in wines labelled as organic.

Wine types

In 2020 the state had nearly 344,000 ha/850,000 acres of vines of grape-bearing age. Only 256,975 ha of these produced specifically wine grapes, however, with a significant proportion of grapes being varieties such as THOMPSON SEEDLESS (Sultana), making California one of the world's most important producers of RAISINS.

The majority of California's wine production, largely from the Central Valley and mostly in the hands of a few very large wine companies, is inexpensive table wine sold in supermarkets and liquor stores across the US. California's fine wines make up a relatively small percentage of the state's enormous annual production (Napa and Sonoma combined represent only 10% of the state's annual output) even as their reputation and pricing continue to push into the uppermost echelons of the wine world.

Known for having firmly established the dominance of, and preference for, VARIETAL wines in the American market, California now produces an impressively wide array of wine types and styles, driven primarily by the state's dynamic population of many small, independent wine producers who embrace a spirit of innovation and experimentation. These small wine brands, who increasingly sell their wares directly to consumers online, have enthusiastically expanded their offerings beyond the traditional to include (or sometimes focus entirely on) NATURAL WINE, PET-NAT, SKIN CONTACT and SKIN-FERMENTED white wines, PIQUETTE, VERMOUTH, and even ANGELICA for an increasingly curious and dedicated segment of the wine-drinking public.

After several decades of dominance by a few established domestic pioneers and some European wine companies who began setting up shop in the 1970s (including Louis ROEDERER, Taittinger, Mumm, and HENKELL FREIXENET, among others), the state's traditional sparkling wine category has dramatically expanded, helped in part by the availability of custom-crush facilities capable of handling both TRADITIONAL METHOD and TANK METHOD winemaking as well as new

packaging innovations such as aluminium CANS. The 2005 EU–US wine agreement, much to the dismay of the Champenoise, permitted continued use of the designation 'California champagne' for a handful of producers with a previous history of using the term. Apart from these mass-market, very inexpensive bottlings, the vast majority of the state's bubbly wines are labelled as California sparkling wine, with increasing numbers of AVA or even vineyard-specific designations.

In 2000, winemaker Dave Phinney blended a STUCK FERMENTATION of Zinfandel with some Cabernet to produce a faintly sweet blend he called The Prisoner, which quickly rose to be one of the most popular California wines of all time. Following Phinney's lead, wine companies such as GALLO and Trinchero Family Estates developed inexpensive red blends such as Apothic and Ménage à Trois, driving a resurgence of mainstream interest in blended red table wines after many years of VARIETAL dominance, even as the number of individual grape names appearing on California fine-wine labels has skyrocketed.

Vine varieties

California's annual official census of grape varieties tracks more than 110 varieties. According to 2020 data, among red varieties Cabernet Sauvignon is dominant with 32% of working acreage, followed by Pinot Noir at 16%, Zinfandel at 13%, Merlot at 12%, Syrah at 5%, and Petite Sirah at 4%, the last being a key component for many inexpensive red blends.

Among white varieties, Chardonnay reigns supreme at 53%, followed by French Colombard at 10%, Pinot Gris at 10%, Sauvignon Blanc at 9%, Chenin Blanc at 3%, and Riesling and Viognier with roughly 2% of bearing acres apiece.

For decades French Colombard has been a workhorse grape for producers churning out high-volume white and blush wines, thanks to its rather neutral character and tendency towards retaining acidity. Among the red grapes, a similar statement could historically be made about Zinfandel.

More than any other, Zinfandel can lay claim to being California's signature grape variety, not only because of its relative popularity as a wine but because of the crucial role it has played (more than once) in the state's wine history. Conclusively shown in 2003 by Dr Carole Meredith of DAVIS to have originated in CROATIA, the grape arrived in California during the 1850s and flourished in the dry California climate, with key plantings still surviving and producing in Sonoma's Dry Creek Valley, the Russian River Valley, Paso Robles, and Amador County (along with its neighbouring AVAs) in the Sierra Foothills. Its relative hardiness and productivity led it to quickly become among the most popular varieties during the planting boom of the 1880s.

Perhaps the highest concentration of remaining old-vine Zinfandel, including some dating to 1889, can still be found in the expansive LODI AVA, which has long supplied a significant portion of the grapes used in California's most inexpensive wines. This was especially true during Prohibition, when the relatively thick-skinned grape proved suitable for shipping across the country to supply a sudden interest in HOME WINEMAKING. Later, when a stuck fermentation left the 1975

vintage of Sutter Home Winery's rosé a little sweet, the explosive success of the wine they called White Zinfandel spawned many imitators and drove demand for the grape high enough to justify retaining many old plantings.

Even as consumer interests transitioned to drier, more Provençal styles of rosé in the early 2000s, a small number of producers drove a renaissance of premium red Zinfandel wines led by the expensive and hard-to-obtain single-vineyard bottlings of Turley Wine Cellars and the more populist wines of Carlisle or Ravenswood, whose wines were marketed by founder Joel Peterson under the slogan 'No Wimpy Wines'. Interest in Zinfandel among consumers peaked in the early 2000s when the annual ZAP (Zinfandel Advocates and Producers) tastings in San Francisco would draw nearly 10,000 wine lovers eager to taste the work of hundreds of small producers. Peterson and others, including more recently Turley's winemaker Tegan Passalacqua, can be credited with preserving many of the state's oldest vineyards through dedicated demand for dry-farmed, old-vine fruit, as well as through organized efforts at conservation such as the HISTORIC VINEYARD SOCIETY.

Along with the state's justifiably famous Cabernet Sauvignons and Bordeaux-style blends (decreasingly referred to as MERITAGE blends), Chardonnay has also become synonymous with California. In particular, the state has become known for a FRUIT-DRIVEN style characterized by the effects of BARREL FERMENTATION, LEES CONTACT, OAK AGEING, and MALOLACTIC CONVERSION. Popularized by wines such as the best-selling KENDALL-JACKSON's Vintners Reserve, this style of Chardonnay, with its tropical and butterscotch flavours and an occasional dollop of RESIDUAL SUGAR, has become at once the most popular style of wine in America as well as one of the most reviled, spawning the meme ABC—Anything But Chardonnay. Despite this, California winemakers continue to produce a dizzying array of Chardonnay bottlings from an ever-widening range of vineyard sites and MESOCLIMATES, in styles ranging from opulent to austere.

SYRAH, which occupied a mere 5,436 ha/2,200 acres in 1995, grew to more than 46,950 ha by 2013 largely through the success of the state's RHÔNE RANGERS, a group of winemakers championing any and all Rhône varieties. Syrah plantings had by 2020 dropped to 37,066 ha, as winemakers have found it a frustratingly difficult sell to consumers.

Perhaps the single largest trend in California's wine production since the late 1990s has been the rise of PINOT NOIR, which numbered 56,834 ha/23,000 acres in 2004 when the movie SIDEWAYS debuted, and have subsequently grown to 113,668 ha in 2020. The grape's history in California has been tumultuous, going from quite popular after Prohibition to all but dismissed in the 1960s, as winemakers wrestled with both where it should be grown and how it should be made. Other than some commendable work done by producers such as Hanzell, Calera, and Joseph Swan, Pinot Noir would not begin its ascendance until the late 1980s, when the tiny and all but unknown producer Williams Selyem bested all comers at the 1987 California State Fair with their 1985 Rochioli Vineyard bottling from the Russian River Valley.

Interest in the grape was rekindled. In 1991 the average price for a ton of Pinot Noir grapes was $804, but by 2001 the same ton was fetching $1,849. While there were only a few dozen producers of Pinot Noir in 1990, by 2000 there were hundreds. But if American appreciation of Pinot Noir can be said to have been sparked in the 1980s, its obsession most certainly arrived following Hollywood's celebration of the variety in *Sideways*. Since then, sustained demand has been answered with the methodical exploration and planting of cooler, coastal vineyard sites from Santa Barbara to Mendocino, resulting in a dramatic increase in high-quality offerings at many price points. In 2019 the average price per ton of Sonoma Pinot Noir was $3,949. The best California Pinot Noirs now receive ratings from prominent critics commensurate with many of the top examples from Burgundy and hail from multiple regions up and down the coast, suggesting the grape's eminent potential to be among the state's greatest success stories. California cult wines, a phrase coined in the 1990s to encompass wines made in CALIFORNIA—typically but not exclusively NAPA Valley Cabernets—for which collectors pay PRICES higher than those of some of Bordeaux's FIRST GROWTHS. They include such names as Araujo, Bryant Family, Colgin, Abreu, Dalla Valle, Grace Family, Harlan Estate, Scarecrow, Schrader, Screaming Eagle, and Sine Qua Non. Their common characteristics include being made in extremely limited quantities by talented consultant OENOLOGISTS currently favoured by FASHION and earning high, often 100-point scores from Robert PARKER's *Wine Advocate*.

California sprawl, term commonly used to describe the CANOPY of a vine trained on a simple TRELLIS SYSTEM, although such systems are not restricted to California. It generally refers to a trellis with a single fruiting wire plus one foliage wire above this, though there are some variations. This results in a sprawling vine without rigorous SHOOT POSITIONING. This inexpensive form of training can lead to a shaded canopy with poor bud FRUITFULNESS and increased vegetative growth. Such vine forms are more typically seen in vineyards in hotter parts of California's CENTRAL VALLEY and are also common in the inland irrigation regions of Australia. See also CANOPY MANAGEMENT.

Calistoga, CALIFORNIA wine region and AVA in northern NAPA Valley.

Callet, MALLORCAN grape of unclear origin, often planted as a FIELD BLEND with its natural parent FOGONEU, the other parent being the obscure Callet Cas Concos. Spanish statistics for 2020 recorded a total of 214 ha/529 acres planted. Callet tends to produce small quantities of light-coloured wine with relatively little alcohol. It is used mainly for rosés and in red blends but is occasionally responsible for elegant, red-fruited varietal wines.

callus, the white, formless tissue that grows from CAMBIUM tissue at cut and wounded surfaces of the grapevine on stems and roots. It is critical for vine GRAFTING since it signifies that the conditions for cell division are favourable and that the underlying graft or bud has united. High humidity, sufficient oxygen supply, and warm temperatures are the major requirements for rapid callus development. In the field, these conditions may be achieved by waxing or by wrapping the tissues tightly with plastic grafting tape. After BENCH GRAFTING, the cuttings are packed with moist material and held in a warm, humid room. (See also TISSUE CULTURE and illustration under GRAFTING.) Callus formation can be inhibited by the presence of TRUNK DISEASES, especially in the ROOTSTOCK cutting. B.G.C.

Hartmann, H. T., et al., *Plant Propagation: Principles and Practices* (8th edn, 2010).

Caluso, town in northern, pre-alpine PIEMONTE famous for a DRIED-GRAPE WINE made of ERBALUCE grapes. Today dry and TRADITIONAL METHOD sparkling versions, often from named vineyards, have triggered a new and much-needed dynamic.

calyptra, or flower cap, of the vine flower consists of the five petals joined together in the form of an inverted cup. The cap separates as a unit and falls from the grape flower at FLOWERING and exposes the STAMENS, which produce pollen, and the stigma, which receives pollen. The rate of capfall is slowed by cold and rain; the duration of capfall in one vine can stretch from a normal 7–10 days to as long as 15–20 days. FRUIT SET is impaired if the caps are retained, and so this very small part of the grapevine can affect YIELD, especially for varieties such as MERLOT. See also FLOWERS, VINE.

B.G.C.

Câmara de Lobos , or Cama de Lobos, occasionally found on bottles of ancient MADEIRA, is a wine district on the south coast of the island.

Camaralet, obscure, low-yielding vine allowed but hardly grown in BÉARN and JURANÇON in south-west France that can make strongly flavoured white wine.

Camarate, a natural Portuguese ALFROCHEIRO × CAYETANA BLANCA cross making soft, early-drinking reds in BAIRRADA. It is known as MORTÁGUA in ARRUDA.

cambium, a zone of dividing cells in plants such as the grapevine; the inner cells develop into XYLEM and later differentiate into wood, while the outer cells develop into PHLOEM and, later, bark. The matching of cambial zones is important to the success of BUDDING and GRAFTING.

The cork cambium cuts off non-living suberized cells yielding bark, as during vine CANE RIPENING. The cork most readily associated with wine is the CORK derived from the secondary cambium of QUERCUS *suber* and used as CLOSURES. B.G.C.

Cambodia has a single winery, Prasat Phnom Banan, 10 km/6.2 miles from its second largest city, Battambang, in the north-west of the country. It began with vines imported from THAILAND and made its first wine in 2004. The winery produces several thousand bottles of wine, brandy, and grape juice each year, from 10 ha/24 acres of mostly Black Queen and Shiraz vines. D.G.

Campania, region of south-west Italy of which Naples is the capital. In the ancient world, Campania was the home of some of the most renowned wines of Italy, if not of the whole Mediterranean basin: SURRENTINE, MASSIC, and, most famous of all, FALERNIAN.

Despite its southern location, Campania is known for its white wines, as daytime temperatures are largely mitigated by ELEVATION in the mountainous inland (Campania boasts its own ski resorts). Its INDIGENOUS VARIETIES, showcased in Campania's many DOCs and DOCGs, can retain freshness and acidity in a warm climate. On the basis of its soil types the region can be broadly grouped into three parts. The VOLCANIC, sandy soils of DOC Vesuvio and DOC Campi Flegrei (the 'fire fields' named by the Romans, who built thermal baths on the slopes of these extinct volcanoes) are almost in the suburbs of Naples, where the white FALANGHINA and red PIEDIROSSO are planted on their own ROOTSTOCKS as PHYLLOXERA cannot survive there. Once considered workhorse varieties, Falanghina and

Piedirosso now receive serious attention, including higher-density vineyards and lower yields. The DOC Vesuvio is based predominantly on Caprettone, Falanghina, and Piedirosso, often from old vines, resulting in white and red Lacryma Christi and now experiencing a qualitative revival.

The second soil type, ALLUVIUM, prevails in the DOC Sannio on the Piana Campania Plain between Naples and Benevento. In the early 2010s, the much smaller DOCs Guardia Sanframondi, Sant'Agata dei Goti (with its own CLONE of the Falanghina as produced by Mustilli), Solopaca, Solopaca Classico, and Taburno (its speciality being AGLIANICO) were all demoted to subzones of Sannio, while a new DOCG, Aglianico del Taburno, was created.

The third soil type is the porous LIMESTONE which typifies the hills of the DOC Irpinia. It was called tufo by the Romans (hence GRECO di Tufo), though incorrectly, as it is not of volcanic origin. Within Irpinia lie the superior DOCGs TAURASI, FIANO di Avellino, and Greco di Tufo, the last two producing Campania's most famous and long-lived whites, typified by peaches and flint, with smoky notes in aged versions. Taurasi is arguably Aglianico's finest and longest-lived expression.

Much of Campania consists of hills and mountains with myriad EXPOSURES and elevations. The higher the elevation, the cooler it is—so cool in fact that the grapes of Fiano di Avellino and Greco di Tufo are not picked before the beginning of October, and the late-ripening Aglianico may be picked even later in Taurasi. With the exception of Mastroberardino, a general focus on quality and ESTATE BOTTLING has been recent (see TAURASI for more details).

The third large Campania DOC, Cilento, lies 50 km/31 miles south of Naples, its coastline dominated by Paestum, one of the largest Greek temple complexes in the world, while its rugged mountainous hinterland is planted with olive trees and vines. Despite its extent, Cilento produces much less wine than Sannio, but its small quantities of Fiano and Aglianico are worth seeking out, especially from such overachievers as Conciliis and Casebianche. North of Cilento the tiny

DOC Costa d'Amalfi has low-yielding, PERGOLA-trained vineyards clinging to any available ridge on this stony coast. Whites based on Falanghina and Biancolella and reds based on Piedirosso and Sciasinoso are produced here, while its subzone Tramonti is renowned for its many centenarian vineyards. Aglianico and Piedirosso also feature in the DOC Falerno del Massico to the north, its wines said to have already been appreciated by the Romans (see FALERNIAN). Curiously, a 100% PRIMITIVO is also allowed here. While the demands of TOURISM have replaced the once-renowned viticulture of the island of Capri, Ischia has managed to retain enough vineyards to produce small quantities of complex whites based on the local FORASTERA and BIANCOLELLA and minuscule quantities of red wine based on Guarnaccia (MAGLIOCCO Dolce) and Piedirosso. See ISCHIA for more detail. W.S.

Campo de Borja, DOP in the warm, sunny, undulating plains around the town of Borja (after which the Borgia family was named) in Spain's ARAGÓN region (see map under SPAIN). Vineyard ELEVATIONS range from 350 m/1,148 ft in the north-east, along the River Ebro, to 700 m/2,297 ft in the south-west, in the foothills of the Moncayo Mountains. The vast majority of the region's 6,810 ha/16,828 acres of vines are planted to GARNACHA vines, which produce intensely sweet, dark grapes that make heady red wines. The Borsao Borja CO-OPERATIVE has revolutionized the region with its young, intensely fruity reds that have won a large following on export markets. F.C.

Canaan, or the Levant, comprises the coastal and inland areas of the eastern Mediterranean which played an important part in spreading VINICULTURE. The pharaohs of ancient EGYPT were struggling to maintain their control of this area during the 14th century BCE, as we can read in the Amarna letters, an extensive correspondence between the pharaohs and the local puppet rulers and officials of Canaan. 'See that much food and wine—everything in great quantities—is made available for the archers of the king', writes one Egyptian monarch. In the Egyptian *Story of Sinuhe*, Canaan was described as having 'more wine than water'.

Records on cuneiform tablets from the kingdom centre on the city-state of Ugarit (*c.*1500–1200 BCE; modern Ras Shamra near Latakia about 160 km/100 miles north of the vineyards of modern Lebanon) indicate extensive viticulture. A standard formulation in describing properties for real-estate transactions at this date mentions 'a house, together with its [watch-]tower, its olive grove and its vineyard'. However, life was as difficult in this area then as it was in the 1980s, since a complaint addressed by the prefect of Ugarit to a local great king, who was acting as mediator, stated that the people of Siyannu, a neighbouring city, 'have cut down our vines'. The people of Ugarit were obliged to swear not to cut down the vines of Siyannu and, moreover, to swear that they knew nothing of the identity of the perpetrators of such acts in the past. A similar dispute was adjudicated on the same occasion, this time concerning an allegation that wine from Ugarit had been stolen and sold unofficially to dealers at Beirut down the coast.

The southern Levantine wine industry, beginning *c.*4000 BCE, had matured to such a degree that by the time of Scorpion I (*c.*3150 BCE), one of the first rulers of a united Egypt, his tomb at Abydos was stocked with some 4,500 litres of wine imported from southern Canaan. From around 3000 BCE, the Egyptian pharaohs financed the establishment of a royal wine industry in the Nile Delta under the tutelage of Canaanite viniculturists. With the Egyptian winemaking success behind them, the Canaanites on their sea-going 'Byblos ships', made of Cedar of Lebanon, ventured further and further out

into the Mediterranean. They and their successors, the Phoenicians, applied a similar formula wherever they went: import wine and other luxury goods, entice the rulers with wine culture by presenting them with speciality wine sets, and then wait until they were asked to help in establishing native industries, including viniculture, by transplanting the domesticated Eurasian VITIS VINIFERA grapevine.

Canada , has a thriving wine industry, with 12,808 ha/31,650 acres of vineyards in 2021 spread throughout four winegrowing provinces: ONTARIO, BRITISH COLUMBIA, QUEBEC, and NOVA SCOTIA. Given the exigencies of the Canadian climate, grapes are usually grown near large bodies of water that moderate the effects of cold winters and decrease the risk of damaging WINTER FREEZE and spring FROSTS (see LAKE EFFECT). Until the 1970s, the industry depended on winter-hardy North American VITIS LABRUSCA varieties such as CONCORD and NIAGARA, followed by plantings of early-ripening, winter-resistant FRENCH HYBRIDS such as VIDAL BLANC, SEYVAL BLANC, BACO NOIR, and MARÉCHAL FOCH. Since the late 1980s, however, growers have put greater emphasis on VITIS VINIFERA varieties, whose wines enjoy increasing success both at home and abroad.

The Canadian climate is particularly suited to the production of SPARKLING WINES, but it first established a reputation for ICEWINE, of which it is the world's largest producer—not surprising, since sustained temperatures of −8 °C/17.6 °F can be relied upon in most regions each winter.

History

The Canadian wine industry dates from the early 19th century (although see also VÍNLAND). In 1811, a retired German corporal, Johann Schiller, domesticated the *labrusca* vines he found growing along the Credit River west of Toronto and planted a 8-ha/20-acre vineyard. In 1866, the country's first major winery, Vin Villa, was established in Canada's most southerly reaches, on Lake Erie's Pelee Island, by three gentlemen farmers from Kentucky who planted 8 ha of ISABELLA vines. By 1890 there were 41 commercial wineries across the country, 35 in Ontario. As in other wine regions, it was the Church that encouraged the planting of vineyards and fostered the art of winemaking.

PROHIBITION slowed the pace of development as Canadian provinces passed varying laws to limit alcohol sales and consumption between 1916 and 1919. However, Ontario permitted alcohol production for export. As a result, by the time the Ontario Temperance Act was repealed in 1927, 57 wineries were operating in the province.

Most other Canadian provinces ended Prohibition by the late 1920s and created provincially owned retail systems or government MONOPOLIES which control the sale and distribution of beverage alcohol and collect billions of dollars in government revenues. Today, most wine is sold by provincial monopolies such as the Liquor Control Board of Ontario (LCBO), though many smaller wineries rely on CELLAR DOOR sales. Alberta is an exception, with a privatized system since the mid 1990s. British Columbia, Nova Scotia, Manitoba, and Saskatchewan also allow privately owned wine stores to operate alongside government monopoly stores.

This shift in plantings from *labrusca* and hybrids to *vinifera* began after Prohibition, with Brights Winery producing the first Ontario Chardonnay in 1956 and Quail's Gate Winery in the Okanagan Valley planting some Chasselas vines in 1961. The pace picked up in the 1970s and 1980s, with the opening of wineries dedicated to the proposition that *vinifera* vines could be grown on appropriate sites

despite the harsh winters and unpredictable springs. This coincided with a shift in public taste towards drier, less alcoholic TABLE WINE, as, until the mid 1970s, most Canadian wines were sweet, highly alcoholic products made from *labrusca* varieties and labelled Sherry or Port, depending on colour. The 1988 free-trade agreement between Canada, the United States, and Mexico was a further catalyst as it removed the protections domestic wines had enjoyed against competing imports and inspired more wineries to focus on *vinifera* varieties.

Since the late 1990s, the number of estate wineries has grown exponentially. Canada is also home to the Cool Climate Oenology and Viticulture Institute (CCOVI) at BROCK UNIVERSITY in the Niagara Peninsula.

Climate

Geographically, the majority of Canadian vineyards are on the same latitude as the LANGUEDOC and CHIANTI, but lower winter temperatures, the freeze–thaw–freeze cycle of early spring, and unpredictable weather at HARVEST mean Canada is ranked as a COOL-CLIMATE wine region.

While some of Canada's wine regions enjoy hotter summers than either Bordeaux or Burgundy, the growing season tends to be shorter. Average sunshine hours during the growing season are 1,485 in the Niagara Peninsula, Ontario; 1,616 in the south of British Columbia's Okanagan Valley; and 1,257 in the Gaspereau Valley in Nova Scotia. Grapes may require CHAPTALIZATION in some years. DROUGHT can be a problem in parts of southern British Columbia, and many producers have installed irrigation systems. Many wineries in Ontario have invested in wind machines to counter cold winter temperatures and spring frosts. Some wineries use GEOTEXTILES for winter protection.

Wine laws

Wine laws are provincially regulated, although wine labelling is governed by the federal Food and Drug Act (1985) and the Safe Food for Canadians Act (2012).

In 1988, Ontario introduced the Vintners Quality Alliance (VQA), a CONTROLLED APPELLATION system similar to but separate from the system introduced in British Columbia in 1990. Each specifies production areas, permitted grape varieties, minimum MUST WEIGHTS, and limits to CHAPTALIZATION, among other details. Varietal wines must be made from at least 85% the stated variety and 95–100% for subappellation wines.

The Nova Scotia Wine Standards Regulations is the legal framework in Nova Scotia, while Quebec has a Protected Geographical Indication (PGI) Vin du Québec governing still and sparkling wine production and another for Quebec ice wine (Vin de glace du Québec).

Any wines that contain imported BULK WINE are not entitled to either a VQA designation or the more general Product of Canada label. These wines, common in Canadian liquor stores, must be labelled as 'International Domestic Blends'.

For more detail on individual regions, see BRITISH COLUMBIA, NOVA SCOTIA, ONTARIO, and QUEBEC. J.D.

Phillips, R., *The Wines of Canada* (2017).

www.winesofcanada.ca

Canaiolo, or Canaiolo Nero, red grape variety grown all over central Italy and, perhaps most famously, a permitted ingredient in the controversial recipe for CHIANTI, in which it played a more important part than SANGIOVESE in the 18th century. Plantings declined

considerably in the wake of PHYLLOXERA because it was relatively difficult to graft and suffered from poor CLONAL SELECTION, with just over 1,031 ha/2,548 acres remaining in 2015. The decline in popularity of the GOVERNO winemaking trick also hastened its decline, since soft, full-bodied Canaiolo, without either the structure of Sangiovese or the scent of MAMMOLO, was most prized for its resistance to ROT while being dried for *governo* use. However, in the last few years it has become rather fashionable, and Tuscan producers such as Bibi Graetz, Vallone di Cecione, and Le Torre ale Tolfe are making good-quality varietal Canaiolo. Canaiolo is also grown, to an even more limited extent, in LAZIO, LIGURIA, and UMBRIA.

A light-berried Canaiolo Bianco is also grown in Umbria, where, in ORVIETO, it is known as DRUPEGGIO, but it has also been declining in popularity.

Canary Islands , or *Islas Canarias* in Spanish, are Spanish islands in the Atlantic Ocean off the coast of Morocco which were famous in Shakespearian England, as witness Sir Toby Belch's call for 'a cup of canary' in *Twelfth Night*. Once known for mediocre wines mainly aimed at tourists, the islands, helped by government subsidies, have developed a reputation for distinctive wines borne from a subtropical climate and VOLCANIC geology quite different from the rest of Spain. The grape varieties grown also set the islands apart, including red varieties NEGRAMOLL and the indigenous LISTÁN NEGRO and white varieties Listán Blanco (PALOMINO FINO), MALVASÍA, VIJARIEJO, MARMAJUELO, and Gual (which is the same as Madeira's Boal/BUAL). VINE AGE is high. Although construction is encroaching on vineyards, the number of DOPs has ballooned, by the mid 2000s including one for each of the islands of LA PALMA, EL HIERRO, LANZAROTE, and GRAN CANARIA and five for the island of Tenerife (ABONA, TACORONTE-ACENTEJO, VALLE DE GÜÍMAR, VALLE DE LA OROTAVA, and YCODEN-DAUTE-ISORA). Islas Canarias VINO DE CALIDAD was created in 2012 as an umbrella appellation for all the Canary Islands (including

Fuerteventura, an island with no DOPs. Its use is voluntary, and it can coexist simultaneously with a more specific DOP.

V. de la S. & F.C.

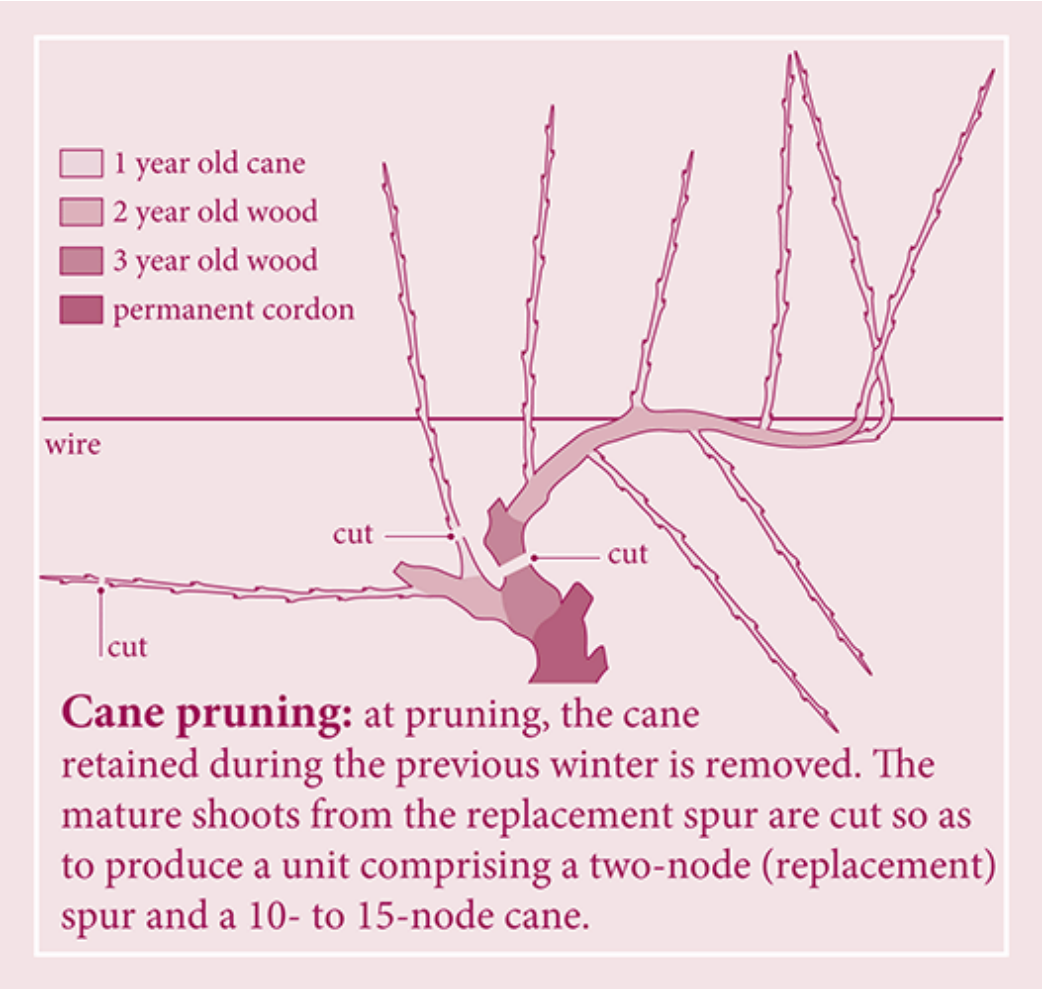
Canberra District , hilly wine region surrounding Canberra, the capital of AUSTRALIA, encompassing around 450 ha/1,112 acres of vineyards in 2020 in the Australian Capital Territory and NEW SOUTH WALES. The climate is largely CONTINENTAL, with warm summers, cold winters, and dramatic DIURNAL TEMPERATURE RANGE, but there is considerable MESOCLIMATE diversity due to variations in ELEVATION, from 300 to 800 m/984–2,625 ft. Most known for Shiraz, the region is also known for Riesling made in a variety of styles and Rhône white varieties including Viognier, Marsanne, and Roussanne. Experimentation is on the rise with small plantings of Grüner Veltliner, Sangiovese, Tempranillo, Graciano, and Malbec. A.R.P.

cane, the stem of a mature grapevine SHOOT after the bark becomes woody (lignified) and tan-coloured, beginning at VERAISON, and starts its overwintering form (see CANE RIPENING and CAMBIUM). After leaves have fallen, the canes of a vine display the total vegetative growth it made during the previous season (called the 'brush' in the US). The number of canes and their weight and average size are important guides to decisions about BALANCED PRUNING and CANOPY MANAGEMENT tactics. The canes are cut at winter PRUNING to reduce the number of buds and to select their position. The cutting may be to SPURS or canes. B.G.C.

cane pruning, a form of winter vine PRUNING in which the BUDS are retained on longer BEARERS called CANES, typically including 6–15 buds. This pruning system usually takes longer to perform by hand than the alternative SPUR PRUNING. Cane pruning is typically used for vines which have fewer FRUITFUL buds at the base of canes, which is the case especially in COOL-CLIMATE wine regions. The tendency in warmer

NEW WORLD wine regions is to use spur pruning, which can be equally productive, requires less LABOUR, and can be MECHANIZED. For more details, see GUYOT. See also MECHANICAL PRUNING.

R.E.S.



Cane pruning: at pruning, the cane retained during the previous winter is removed. The mature shoots from the replacement spur are cut so as to produce a unit comprising a two-node (replacement) spur and a 10- to 15-node cane.

cane ripening, or lignification, is a viticultural term used to describe a stage in the development of the SHOOT when the stem matures and changes colour from green to yellow and thence to brown. The change involves the formation of corky tissue known as periderm and cellular changes including the accumulation of CARBOHYDRATE reserves, which collectively prepare the stem to withstand the cold of winter. The process begins at the base of the shoot and progresses up towards the tip, as does the dormancy status of its buds. Careful observation shows that the first vineyards

to reach this stage, and where it proceeds rapidly, are those which produce the finest wine. This is because early and rapid cane ripening indicates a modicum of WATER STRESS, as well as generous plant levels of carbohydrates, both of which contribute to rapid fruit RIPENING. Cane ripening has therefore been incorporated into vineyard SCORING systems used to predict wine quality.

VERAISON, the change in colour of the grapes, usually occurs at about the same time. R.E.S.

Cangas, a VINO DE CALIDAD and sole appellation in the Asturias autonomous region of north-west Spain. While it extends only 32 ha/79 acres, the potential of the steep slopes, at 400–700 m/1,312–2,297 ft of ELEVATION, is promising, especially for the recovery of the local Albarín Blanco and red grapes Verdejo Tinto, Albarín Tinto, and Carrasquín. F.C.

Cannonau, sometimes spelt Cannonao, the Sardinian name for the widely planted red grape variety known in Spain as GARNACHA and in France as GRENACHE (see SARDINIA). A high proportion of the grapes are grown on the east of the island to produce a varietal Cannonau di Sardegna, which comes in several forms but most commonly as a full-throttle dryish red. Although the variety has lost ground since the mid 1990s, partly because as a BUSH VINE it is low-yielding and expensive to cultivate, 5,537 ha/13,682 acres of Cannonau were recorded in 2015. Wines from bush vines high up in the province of Nuoro have shown what can be achieved from the island's old Cannonau vines, often more than 80 years old.

Canon-Fronsac, underrated Bordeaux red-wine appellation, the heartland of FRONSAC.

canopy, that part of the vine above the ground, formed by the leaf and shoot system. It includes the trunk, cordon or canes, shoots,

leaves, and fruit. It is a term borrowed from forestry, first used for grapevines by Professor Nelson SHAULIS of CORNELL UNIVERSITY. See CANOPY MANAGEMENT.

canopy management, a portfolio of vineyard management techniques used to improve vineyard YIELD and GRAPE COMPOSITION AND WINE QUALITY, as well as to help control some foliar and fruit-affecting VINE DISEASES, especially where vines are of high VIGOUR. Canopy management techniques aim to produce a desirable CANOPY MICROCLIMATE essentially by improving the exposure of leaves and fruit to SUNLIGHT and airflow. The phrase became popular in many parts of the NEW WORLD in the 1980s and early 1990s as part of a growing awareness of the way in which canopy microclimate affects vineyards, but this awareness was not restricted to the New World. Considerable experimental work was also conducted in Europe, and the effects of canopy microclimate are now recognized as partly responsible for the ability of distinguished vineyards to produce great wines (see TERROIR and VITICULTURE).

Some of the underlying principles of canopy management can be traced to early Roman writings. For example, 'BACCHUS loves hills' is partly explained by the fact that low-vigour vines growing on shallower soils on HILLSIDES have open canopies with good fruit and leaf exposure. In modern times, the principles were best formulated by the experimental work of Professor Nelson SHAULIS of Cornell University in New York State. During the 1960s, he showed that increased fruit and leaf exposure to sunlight improved both YIELD and fruit composition. These early studies were also much involved with introducing MECHANICAL HARVESTERS and MECHANICAL PRUNING. Shaulis's work on CONCORD vines influenced researchers from other countries, who extended this work to VITIS VINIFERA vine varieties and also considered effects on wine quality. Studies in Bordeaux by Dr Alain Carbonneau demonstrated wine quality benefits of canopy manipulation in the mid 1970s. Other notable early pioneering studies

were by Intrieri in Italy, Kliewer in California, Reynolds in Canada, and Smart in Australia and New Zealand.

Canopy management techniques are essentially aimed at producing an 'open' canopy microclimate, which is characterized by good leaf and fruit exposure to the sun and airflow and therefore not much shade. The benefits of such a microclimate include improvements to wine quality and yield as well as a significant reduction in diseases such as POWDERY MILDEW and BOTRYTIS BUNCH ROT. The ULTRAVIOLET portion of the solar spectrum has been shown to increase PHENOLICS and colour in grapes and wine and also to suppress these diseases. Interest in overcoming the common problems of excessively vigorous vines caused canopy-management techniques to become popular. This was particularly marked in the New World, where a lack of experience to guide site selection and management practices resulted in some vineyards where vines were so leafy and the fruit so shaded that it affected ripeness and wine quality. These problems were exacerbated by the widespread adoption of AGROCHEMICALS developed after the Second World War to control pests, diseases, and weeds, which, along with practices such as FERTILIZATION and especially IRRIGATION, stimulated shoot growth, often excessively. Canopy-management techniques, especially a change in TRELLIS SYSTEM, can offset the negative effects of vines with excess VIGOUR but are not always necessary for low-vigour vineyards such as those found in most of the classic fine-wine regions of Europe.

A common feature of vineyards with a reputation for producing high-quality wines is that they are of moderate to low vigour and have an open canopy. Canopy management techniques can emulate this microclimate. For example, by altering the trellis, it is possible to remove the fruit from the deep shade associated with the depths of the canopy to the outside of the canopy in the sun. Canopy management can also increase yield. In particular, BUDBREAK and FRUITFULNESS are reduced by shade, no doubt an example of adaptive physiology which allowed WILD VINES to fruit only when they had

climbed to the top of forest canopies. With increasing global concern about the use of agrochemicals, there is a swing towards using canopy management to help control FUNGAL DISEASES and reduce reliance on sprays (see INTEGRATED PEST MANAGEMENT). Not only is it difficult and wasteful to force sprays to penetrate to the centre of dense canopies, but shaded conditions also encourage diseases such as botrytis bunch rot and powdery mildew.

There is a range of canopy management techniques, the applicability of which varies from vineyard to vineyard. The simplest of these are TRIMMING, which cuts off excessive shoot growth in the summer; SHOOT THINNING, which removes unwanted shoots early in the season; LEAF REMOVAL in the fruit zone, which allows more fruit exposure to sun and wind; and SHOOT POSITIONING, which makes trimming and leaf removal easy and effective. These canopy-management techniques are quite traditional in many parts of the OLD WORLD, and good examples may be seen in the neatly trimmed vineyards in many French regions. PRUNING also affects canopy density, as well as vine BALANCE. These practices may be termed 'Band-Aid viticulture' in the sense that they overcome the problem only in the season during which they are applied and hence need to be reapplied each year.

More permanent solutions require changes to the trellis system, which affects the canopy shape, size, and density. The changes to the trellis usually involve increasing the canopy surface area and decreasing shading. For example, dense canopies in vineyards where rows are as much as 3.5 m/11.5 ft apart can be converted to a trellis system such as GENEVA DOUBLE CURTAIN (GDC), which effectively results in a canopy twice as long as the row. This is achieved by dividing a dense canopy into two less dense canopies, or 'curtains', thereby roughly doubling the canopy surface area. Other popular trellis systems such as the LYRE, SCOTT HENRY, and SMART-DYSON rely on the same principle of increasing the exposed canopy area.

There was initial resistance to the ideas of canopy management, both commercially and among academics, even within the US where

the technique was effectively born, although it was eventually taken up there some 20 years behind other regions and seen to be imported from France, Italy, Australia, or New Zealand. This resistance stemmed partly from the fact that Shaulis's initial studies were made with the American grape Concord—even though it was proven quickly enough that VITIS VINIFERA varieties responded in the same way.

There is less scope in the Old World for canopy management, since ROW SPACING is traditionally narrower and trimming and leaf removal are routine. Centuries of trial and error have demonstrated the benefits of open canopies to improve wine quality and reduce vine diseases even if the benefits of canopy management were not always recognized by traditional viticulturists. By the early 1990s, however, there were commercial examples of new trellis systems applied to some more vigorous Old World vineyards in France, Spain, and Italy, and in 2021 Champagne growers voted to change the regulations on VINE DENSITY to allow for bigger vines (*vignes semi-larges* or VSL). Today far more attention is paid to every aspect of the canopy, including height and density.

Contemporary thinking about canopy management suggests the optimal degree of leaf and fruit exposure might vary according to variety and region. There have been instances where excessive fruit exposure has had negative effects on quality. For example, in association with high temperatures it can lead to loss of colour, an effect sometimes called 'berry pinking'; and berries may shrivel if they are exposed to too much heat. See BERRY SHRIVEL and SUNBURN.

canopy microclimate, the climate within and immediately around the grapevine CANOPY. This is the third level of climate definition (see also MACROCLIMATE, MESOCLIMATE) and in many ways the one of most relevance to contemporary viticulture because it can be so effectively manipulated, by CANOPY MANAGEMENT, to improve wine quality and YIELD and to reduce VINE DISEASES.

The canopy microclimate at the outside of the canopy is obviously affected by the macroclimate and mesoclimate, but that within the canopy depends on the way the canopy itself alters the climate. For example, if bright SUNLIGHT falls on a dense canopy with few gaps, a leaf facing the sun at midday receives, say, 100 relative units of sunlight. The second leaf in the canopy will receive less than ten units, and the third will receive less than one. So the second leaf in the canopy has a light climate like that of a high-LATITUDE vineyard on an overcast day, while the third layer is just very shaded. In other words, the number of layers of leaves in the canopy has even more effect than vineyard location on canopy microclimate. This drastic reduction in sunlight levels in the canopy is caused by the vine leaves absorbing and reflecting more than 90% of light falling on the upper surface; less than 10% penetrates through to the lower surface.

This simple example illustrates the importance of canopy microclimate and indeed how its effects can override those of regional CLIMATE, CLONE, ROOTSTOCK, and so on. (See VITICULTURE.) A feature of reputable vineyards is that they are typically of low to moderate VIGOUR, and as a result the canopies are not dense and shaded. In many older vineyards (see VINE AGE), leaves and fruit are well exposed to the sun. For vigorous and typically high-yielding vineyards, on the other hand, the canopy interior is a dark, humid, and cool place by day. Not only are the processes of fruit RIPENING slowed, but FUNGAL DISEASES such as BOTRYTIS BUNCH ROT and POWDERY MILDEW are encouraged. Canopy-management techniques can be

used to provide high-vigour vineyards with the same canopy microclimate as that of low-vigour vineyards.

Of the various climatological elements such as SUNLIGHT, HUMIDITY, TEMPERATURE, RAINFALL, EVAPORATION, and WIND, the canopy has greatest effect on sunlight, wind, and evaporation. For sunlight, the values in the centre of a dense canopy can be less than one-tenth of those outside the canopy, while temperature and humidity values are more similar to those outside. Air temperature values are typically slightly cooler in dense canopy interiors, and humidity slightly higher. It is the leaves of the vine canopy that are responsible for creating the distinctive canopy microclimate. They strongly absorb sunlight, lose water as vapour (TRANSPIRATION), and absorb the energy (strictly speaking, momentum) of the wind so that velocity behind just one leaf is very different from that behind one above it. Since evaporation and hence transpiration depend on sunlight, humidity, and wind, it is easy to appreciate that these values will also be reduced below the first leaf layer.

The amount and arrangement of vine leaf area therefore has a significant effect on canopy microclimate. If most leaves and fruit are exposed, the canopy microclimate values will not be too different from those above the canopy. If, on the other hand, the canopy is dense and the majority of leaves and bunches are not visible (and so are shaded), the microclimate values will be very different. A considerable body of research confirms that both wine quality and YIELD are reduced by such shading. A visual impression of the canopy can be definitive in terms of the vineyard's ability to produce good-quality wines and can be the basis of a system of vineyard SCORING used to assess vineyard potential to produce quality wine.

Exposed fruit can produce better wine quality, even in warm to hot climates where HEAT STRESS is anticipated. However, grape bunches exposed to sunlight can reach temperatures 5–10 °C higher than what might already be high air temperatures. Research in Washington State by Spayd and others has carefully separated light and temperature effects. They found a positive benefit of sunlight exposure on the fruit, but this could be negated by high grape

temperatures. Exposure to the ULTRAVIOLET part of sunlight improves GRAPE COMPOSITION AND WINE QUALITY. They suggest exposing fruit to the morning rather than afternoon sun, to avoid the problems associated with high temperature such as depression of ANTHOCYANINS. This result reflects the practice common in Bordeaux, for example, of leaf removal on the eastern side of the canopy in the hottest part of the season and then on the western side only later in the season. Extreme exposure to sunlight can also cause SUNBURN.

cans are an increasingly popular form of wine PACKAGING, ideal for smaller formats (e.g. 250, 330, or 350 ml), which has no harmful effect on wine destined for early consumption. The advantages are that cans are lighter and less fragile than BOTTLES, can be infinitely recycled, and have a lower CARBON FOOTPRINT once in use, although their initial manufacture is energy intensive. They also have a lower OXYGEN TRANSMISSION RATE than PLASTIC BOTTLES or POUCHES. However, the material from which they are made is not, unlike GLASS, inert. Cans are lacquered on the inside to give chemical resistance to the acid in the wine. However, if there is the slightest pinhole in the lacquer, the SULFUR DIOXIDE (SO2) in the wine reacts with the aluminium, producing foul-smelling HYDROGEN SULFIDE. It has also been suggested that free SO2 may be able to diffuse through the liner, with similar unwanted consequences. Aluminium bottles are now also being used for wine although their performance has not so far been independently trialled.

Allison, R., et al., 'The chemistry of canned wines', Appellation Cornell Research Focus (2020).

Canterbury (Waitaha in Māori), around Christchurch on the central east coast of NEW ZEALAND's South Island, represents a collection of small, diverse subregions. Waipara, by far the largest subregion, is a 45-minute drive north of Christchurch and includes both CLAY- and LIMESTONE-based Omihi and GRAVELLY Glasnevin soils. The surrounding hills provide a warmer climate than the rest of Canterbury. Inland from Waipara lies the limestone-rich Waikari subregion.

The VOLCANIC Banks Peninsula and stony Canterbury Plains subregions to the east and west of the city respectively have just a few producers each but are home to the region's first vineyard plantings. New Zealand's first and only university wine school, LINCOLN UNIVERSITY, is based here.

Spring and autumn FROSTS are a constant viticultural challenge, particularly for early-budding Pinot Noir, the region's most planted variety. Sauvignon Blanc takes the number two spot, while Pinot Gris, Riesling, and Chardonnay follow. S.P.T.

cantina, Italian for a cellar, a wine shop (although the word ENOTECA is much more common), and a winery. A *cantina sociale* is a CO-OPERATIVE winery.

cap, the layer of grape solids that floats on the liquid surface during red-wine fermentation and requires careful management. The cap usefully limits the amount of OXYGEN available to the YEAST, thereby encouraging the formation of alcohol, but has to be broken up and SUBMERGED in order to encourage the extraction of the desirable PHENOLICS which add colour, flavour, and longevity to a wine. See MACERATION, PUMPING OVER, RACK AND RETURN, and PUNCHING DOWN.

CAP stands for Common Agricultural Policy, a plank of EU policy which has had long-term effects on world wine production.

Cape, a synecdoche used for SOUTH AFRICA, particularly during the apartheid era.

Cape Agulhas, district in SOUTH AFRICA close to the southernmost tip of the continent.

Cape blend, South African term generally used to describe a red wine in which PINOTAGE is one of the blending components.

Cape Riesling, the old, misleading South African name for CROUCHEN Blanc. From 2010, wine produced from Crouchen Blanc had to be sold as such, or as Cape Riesling, and could no longer be labelled Riesling alone.

Cape Verde, or Cabo Verde, is an archipelago of ten VOLCANIC islands about 600 km/373 miles off the coast of West Africa. There is virtually no rainfall, but, on the island of Fogo, condensation from the huge volcano permits some vine-growing.

capsule, French and occasional English name for the sheath over the top of a cork and bottleneck, otherwise known as a FOIL, just as the capsule cutter is more widely known as a FOIL CUTTER. French wine released for sale within France before June 2019 had to have its capsules embossed with a customs seal, known as a capsule CRD or *capsule congé*, but this is no longer obligatory. The regulation requiring producers to use a different seal for exported wines was dropped in 2011.

Caramany, GNEISS-dominated enclave within the appellation of Côtes du Roussillon-Villages, encompassing three villages: Caramany itself and neighbouring Cassagnes and Bélesta, with vineyards at an average ELEVATION of 250 m/820 ft. The principal grape varieties

grown are Carignan, Grenache, and Syrah, with some LLEDONER PELUT. Wines must contain a minimum of two varieties, with the principal grape making up 40–70% of the blend. R.E.G.

carbohydrates, organic compounds made up of CARBON, OXYGEN, and hydrogen and which include sugars, STARCH, and cellulose. Of particular interest to the wine consumer are the simple sugar molecules GLUCOSE and FRUCTOSE, which together make up the SUGARS in grape juice and which are subsequently fermented into the alcohol which distinguishes wine from grape juice. Sucrose, the sugar molecule made up of glucose and fructose, is manufactured in the leaves of plants, including vines, by PHOTOSYNTHESIS. Sucrose can be converted to all other forms of carbohydrates, such as starch, as a storage compound in the roots and trunks, and cellulose, which is a structural component in all cells. Sucrose is also the basic biochemical building block of plants, and it can be converted to proteins, fats, and organic acids.

Carbohydrate reserves are an important factor in the VINE GROWTH CYCLE. Starch is the principal form of carbohydrate reserve which is stored in the woody vine parts in the autumn. The starch is converted into sugars, which, via RESPIRATION, provide the chemical energy for growing shoots early the following spring. The reason perennial plants, such as vines, can grow to such a large size is the ability to store surplus chemical energy each growing season, which is then available for shoot growth the following season. This allows more rapid growth than for a plant starting out from a seed, which has limited food reserves.

At about VERAISON, when the fruit starts to ripen, the vine begins to replace carbohydrate reserves used earlier that growing season. Sugars are moved into the trunk, arms, and roots, where they are converted to the insoluble storage material starch. As shoots accumulate starch they change colour, from green to brown; this is called CANE RIPENING. Ideally there should be a period of warm, sunny weather after HARVEST during which the leaves can manufacture more

sugars to provide the final topping up of starch reserves. However, this ideal state of affairs can be disrupted, for example by large crops of ripening grapes or late-season shoot growth, which slows ripening and limits the amounts of starch formed. Similarly, an autumn FROST which destroys leaves can interrupt the orderly build-up of reserves in the vine. High levels of carbohydrate reserves of sugars and starches make vines better able to withstand WINTER FREEZE, providing them with a sort of biological antifreeze mechanism. Although starch is the main carbohydrate storage compound, there are some other minor compounds such as AMINO ACIDS and carboxylic acids which show the same pattern of autumn accumulation and spring depletion.

Early shoot growth in spring is entirely dependent on these stored reserves, which are mobilized in the woody parts and moved to the developing shoots. If there are too many new shoots growing for the reserves available, individual shoot growth will be checked. The concept of BALANCED PRUNING ensures that the number of buds retained is proportional to the reserves available. The new shoots become independent of these reserves when the majority of leaves reach more than half the final size, and photosynthesis is sufficient to support further growth.

Keller, M., 'Partitioning of assimilates', in *The Science of Grapevines* (3rd edn, 2020).

carbon is an essential element that is distributed among the atmosphere (present as CARBON DIOXIDE), plants, animals, and the soil. When plant and animal residues and excreta are returned to the soil, they are colonized by a host of microorganisms, aided by larger soil organisms such as EARTHWORMS, which decompose these residues, releasing carbon dioxide and nutrients and deriving energy for their growth. As the many different carbon compounds in the residues are colonized, and as the organisms multiply and then die, the more resistant compounds and newly synthesized carbon compounds gradually accumulate to form a dark brown to black colloidal material

called humus or 'stabilized' ORGANIC MATTER. This cycling of the carbon is important for the nutrition of vines and COVER CROPS, most especially in ORGANIC and BIODYNAMIC VITICULTURE.

carbon, activated. See CHARCOAL.

carbonation, the cheapest and least effective method of SPARKLING WINEMAKING, involving the simple pumping of CARBON DIOXIDE into a tank of wine. In EU terminology, carbonated wines are aerated sparkling wines.

carbon dioxide, or CO_2, a naturally occurring atmospheric gas, commonly encountered as the sparkle in soft drinks, beers, and SPARKLING WINES. Its content in the atmosphere is only about 0.042%; yet upon that small amount depends the growth of all living systems, including humans, plants (including vines), yeasts, bacteria, and all fauna dependent on any of these for food. Not least, it is the ultimate raw material of wine and—via a series of biochemical reactions involving the grapevine, yeast cells, and the consumer—results in both assimilation and production of carbon dioxide.

The cycle begins with the combination of carbon dioxide and water into sugars in the vine leaves by PHOTOSYNTHESIS; conversion in the leaves and berries of some of that sugar into a variety of compounds, including those directly or indirectly responsible for ACIDS, COLOUR, and FLAVOUR in the grapes and wine; and, as the final step, transformation of the grape juice into wine by FERMENTATION. Carbon dioxide is released in substantial amounts during fermentation and typically vented to the atmosphere despite the gas's known role in CLIMATE CHANGE. When wine is consumed, the gas returns whence it came with the metabolism of the alcohol and other wine constituents back to carbon dioxide and water, primarily in the liver and exhaled breath of the wine drinker.

Carbon dioxide passes into vine leaves through small pores, or STOMATA. It is absorbed into cells and hence is 'fixed' in the chloroplasts by the action of sunlight.

The carbon-dioxide concentration in the Earth's atmosphere has been rising since the beginning of the Industrial Revolution, largely due to the burning of fossil fuels, and by April 2019 it had reached 420 ppm, the highest level for some 800,000 years. The implications for climate change—with concomitant changes to ecosystems, already observed for vineyards worldwide—are astonishing but quite understandable because of how this gas absorbs the sun's energy. With increasing awareness of climate change and rising atmospheric carbon dioxide levels, it is worth considering the wine industry's role in what may be the Earth's greatest environmental problem. See CARBON FOOTPRINT. R.E.S.

In winemaking

Carbon dioxide can be used throughout the winemaking process to displace OXYGEN from contact with crushed grapes, MUST, or wine, although NITROGEN is generally preferred for must and wine so that they do not become saturated with carbon dioxide. At some wineries, carbon dioxide is deliberately pumped over white grapes as they are received at the winery and pass through the DESTEMMER in order to minimize OXIDATION.

Carbon dioxide also plays an important role in the fermentation of all wines. YEAST metabolizes starches and sugars to produce water and carbon dioxide. In the case of yeast's metabolic activity in six-carbon sugar solutions such as grape juice, the three main by-products are water, ETHANOL, and carbon dioxide. If excess oxygen is available, the yeast obtains more cell-building energy from the sugar by converting it to carbon dioxide and water. With only a moderate oxygen supply, the yeast produces carbon dioxide and the ethanol that distinguishes wine from grape juice.

While wine is fermenting, substantial quantities of carbon dioxide are given off; while not being inherently toxic to humans, carbon dioxide displaces oxygen so that, in a confined space such as a FERMENTATION VESSEL, suffocation is all too possible. Winery workers must exercise particular caution in this respect.

In most still wines, this carbon dioxide is encouraged to dissipate leaving only very small amounts in the finished wine (400–1,200 mg/l depending on the type of wine), although the more protective the winemaking, the more substantial these traces may be, as in, for example, many German and other light, aromatic white wines. (Winemakers may, however, choose to remove carbon dioxide from such wines by SPARGING them with NITROGEN just before bottling.)

In sparkling wines, however, substantial quantities of dissolved carbon dioxide, between two and six atmospheres, are encouraged to remain in the bottle by one of the methods outlined in SPARKLING WINEMAKING. Lesser quantities of carbon dioxide, between one and

two atmospheres, may be encouraged in wines such as those labelled PERLANT, PÉTILLANT, or FRIZZANTE by inducing a second but less violent fermentation and preserving the carbon dioxide produced.

In order to enhance the freshness and fruitiness of a wine, some winemakers, especially in hotter regions, pursue a deliberate policy of bottling wine, particularly simple, inexpensive white and rosé wine, with up to one atmosphere of carbon dioxide dissolved in it. This is done by processing the wine at very low temperatures, where carbon dioxide is much more soluble in wine, then bottling it early in order to preserve some of the gas given off during fermentation. The warmer the wine is served, the more obvious is the carbon dioxide to the taster.

While most tasters would be surprised and probably shocked to notice any carbon dioxide in a mature red bordeaux (in which case it could even be taken to be an unwelcome sign of FERMENTATION IN BOTTLE), it is not necessarily a fault in some types of white and rosé wines. Portugal's VINHO VERDE provides many examples of this deliberate wine style, as do many young whites from the MOSEL, and some Italian red wines contain a perceptible level of carbon dioxide, sometimes as a result of the GOVERNO practice of adding dried grapes to provoke a second fermentation.

Carbon dioxide also plays an essential role in CARBONIC MACERATION.

Smart, R. E., 'A lump of coal, a bunch of grapes …', *Journal of Wine Research*, 21/2–3 (2010), 107–11.

carbon footprint of wine is a key indicator of the SUSTAINABILITY of grape and wine production since it is a measure of the efforts of those in the grape and wine sector to counter CLIMATE CHANGE. A carbon footprint is the total greenhouse gas (GHG) emissions of an organization, individual, service, or product expressed as carbon dioxide equivalents. CARBON DIOXIDE (CO_2), methane (CH_4), nitrous oxide (N_2O), and some fluorinated gases (refrigerants) are the main GHG, and these increase the average temperature of the Earth and

the atmosphere by absorption of infrared solar radiation. These gases are emitted naturally but have been significantly increased by human activities such as the use of fossil fuels in electricity and heat generation and in transportation.

Carbon footprints are measured using the method of life-cycle assessment (LCA). LCA studies are typically either 'cradle to grave' (taking into account all impacts from extraction and processing of raw materials through to use, recycling, and disposal) or 'cradle to gate' (considering all impacts until the product leaves the producer's premises). For example, an LCA on a bottle of wine may be performed up to the winery gate or also take into account transport, sale, and disposal of the packaging.

Recent studies in several different countries and wine regions have yielded similar results to that of Abbott and colleagues for the export-dominated Australian grape and wine sector. The authors found that emissions due to grape-growing and winemaking were relatively minor components, at 15% and 17% respectively. Glass manufacture and transport were the hotspots, representing 68% of the average life cycle in the study, highlighting the need for lighter bottles, local sourcing, better recycling, reusable bottles, and ALTERNATIVE PACKAGING.

For grape-growing, diesel and electricity use (generated from fossil fuels) are major contributors to emissions. For wineries, electricity use, largely for refrigeration, is the major contributor. Alternative wind and solar energy sources are now being used by pioneers worldwide. The amount of carbon dioxide captured in vineyards (by vines, COVER CROPS, etc.) is not typically counted as a carbon credit. Perhaps surprisingly, carbon dioxide released to the atmosphere from fermentation is not counted as an emission. These emissions and sinks form part of the short-term carbon cycle and are typically excluded in reporting activities. Dr Damien Martin of Plant and Food Research, New Zealand, has calculated that the activities of the world's wine producers typically lead to a net reduction in atmospheric carbon dioxide of 8 tonnes per ha of vineyard per year. The calculation estimates that for each ha almost ten tonnes are

fixed each year by photosynthesis, while each tonne of grapes produces 1.3 tonnes of carbon dioxide during fermentation and a further 0.6 tonnes treating WINERY WASTE. R.E.S., E.W. & K.H.

carbonic acid is the acid formed when CARBON DIOXIDE is dissolved in water, H_2CO_3.

carbonic maceration, red winemaking process in which the first phase of fermentation is conducted in a completely anaerobic atmosphere, which transforms a small amount of MALIC ACID and SUGAR IN GRAPES into ETHANOL, along with traces of many flavourful aromatic compounds, without the intervention of YEASTS. This occurs only if the SKINS remain intact, unbroken by DESTEMMING or CRUSHING.

Other WHOLE-BUNCH FERMENTATION techniques such as SEMI-CARBONIC MACERATION, or the inclusion in the fermenter of a percentage of whole bunches or whole berries as well as crushed grapes, result in some carbonic maceration occurring within the whole berries but with lesser amounts of the distinctive flavours in the wines. Wines made in this way are typically light-bodied, brightly coloured, and fruity, for early consumption, most famously but by no means exclusively in the Beaujolais region of France.

Louis PASTEUR observed in 1872 that grape berries held in air differed in flavour from those held in a CARBON DIOXIDE atmosphere. Michel Flanzy published a study on carbonic maceration in 1935 and

reported that wine produced in this way was much brighter-coloured, less tannic, and more distinctively perfumed, as described below. The aromas can override varietal fruit character but can also add aroma to wines with low fruit intensity.

For full carbonic maceration, intact whole bunches of grapes are placed in a closed fermentation vessel and an anaerobic atmosphere is created, generally obtained by using CARBON DIOXIDE to exclude OXYGEN. A modified version, patented by Stephen Hickinbotham in 1986, involves whole grape bunches placed into a plastic bag supported by a pallet box, into which a small quantity of dry ice in an insulated container has already been placed. The plastic bag is then sealed and sometimes fitted with a one-way valve, to allow carbon dioxide to escape while preventing entry of air.

Carbon dioxide is absorbed by the grape berries, filling the berry to around 50% of its volume. This causes grapes to change from aerobic respiration to fermentative anaerobic metabolism. Intracellular fermentation takes place within the intact berry. Carbonic-maceration character and structure occur best if grapes are kept at temperatures around 30–32 °C/86–90 °F for five to eight days. At lower temperatures over a period of up to three weeks, more subtle and short-term aromas are produced, but the intensity of the characters can vary depending on grape variety or wine style. To complete fermentation, the fruit is destemmed, crushed, and fermented with yeast under normal winemaking conditions, either with the skins or off the skins after PRESSING.

During the anaerobic phase, intracellular reactions involving the enzyme malic dehydrogenase metabolize malic acid into ethanol, SUCCINIC ACID, and aminobutyric acid but without producing any LACTIC ACID. This results in a decrease in TOTAL ACIDITY and an increase in PH of about 0.25 units. The grape alcohol dehydrogenase enzyme transforms SUGAR IN GRAPES into ethanol and carbon dioxide. Only 0.5–2.2% of ethanol is produced, possibly because at this concentration the ethanol begins to disrupt the cell membrane integrity. The quantity of carbon dioxide produced during the first 24 hours is approximately the same as that absorbed. GLYCEROL and

shikimic acid are produced, with shikimic acid degrading to cinnamic acids, then converting to aroma compounds associated with carbonic maceration: benzaldehyde (cherry, kirsch, almond), vinylbenzene (styrene, plastic), and ethyl cinnamate (cinnamon, strawberry, honey). Other ENZYMES can produce volatile aromas that may contribute to carbonic-maceration flavour, including ethyl and methyl vanillate (vanilla), ethyl 9-decenoate (sweet, fruity, quince), and 1-octanol (almond/buttery). Carbonic maceration wines often exhibit lower primary fruit flavours because some fruity ESTERS form only in an oxygen-rich environment during crushing. During carbonic maceration, ethanol acts as a solvent, and ANTHOCYANINS diffuse from the skin into the PULP, turning the flesh pink. Any TANNINS extracted into the pulp at low alcohol concentrations would more likely be from the skin than from the seeds, which could lead to a perception of softer tannins in the wine.

Under commercial winemaking conditions, it is almost impossible to produce a wine that depends wholly on carbonic maceration for the first phase of fermentation. See SEMI-CARBONIC MACERATION and WHOLE-BUNCH FERMENTATION for more common alternatives.

Although Beaujolais is the most famous wine region where carbonic maceration or semi-carbonic maceration is widespread, the techniques are also used for the Beaujolais grape Gamay in other parts of France, in some red burgundy, in Pinot Noir and Shiraz in the NEW WORLD using variations of whole-bunch fermentation, and in the eastern US to decrease naturally high levels of malic acid. It has also been turned to positive use in the southern Rhône, and it assists in making commercial reds from the sometimes tough Carignan grape for early drinking in the Languedoc and Roussillon in southern France —although there is an increasing tendency to blend carbonic-maceration wines with traditionally made wines. Nutrition Research, 63 (2011), 1–15.

Carcavelos, tiny DOC within Portugal's Lisboa region, renowned in its heyday for FORTIFIED WINES. However, its vineyards, planted on CALCAREOUS soils, have almost been obliterated by the westward expansion of the capital city Lisbon along the Tagus estuary (see map under PORTUGAL). A cynic's view of Carcavelos is that it was created by the Marquis of Pombal, Portugal's autocratic 18th-century prime minister, because he had to do something with the grapes from his country residence at nearby Oeiras. He even flouted his own regulations and permitted Carcavelos to be blended with PORT. Thanks to Pombal, Carcavelos enjoyed a brief period of popularity in Britain in the early 19th century (and see AUCTIONS for evidence of its renown even earlier). More recently, a 21st-century partnership between the Municipality of Oeiras and the Ministry of Agriculture kick-started production under the Villa Oeiras brand and has inspired followers (including the Municipality of Cascais). In consequence, while remaining miniscule, the land under vine is increasing. Just 12 ha/30 acres were in production in 2021; new plantings will take full advantage of the 25 ha currently authorized for DOC production.

Carcavelos is predominantly made from white grapes, which must comprise at least 75% Galego Dourado, Ratinho, and ARINTO. Rarer red examples must comprise at least 75% CASTELÃO and Preto Martinho. Most wines are also non-vintage blends but, since 2004, COLHEITA styles have emerged.

Carcavelos is usually fermented dry and fortified with GRAPE SPIRIT to 15–22% alcohol; the spirit is typically sourced from Portugal's brandy heartland, Lisboa's Lourinhã region. A small amount of *vinho abafado* (fermenting grape must preserved by the addition of alcohol) is added after FERMENTATION to sweeten the wine. Regulations introduced in March 2021 provide for a range of sweetness levels based on RESIDUAL SUGAR: Seco (≤65 g/l), Meio-doce (65–130 g/l), and Doce (≥130 g/l). The wines must be aged for at least two years in wood. Longer CASK AGEING gives the wine a nutty character akin to

a tawny port, but, given the proximity of the Atlantic, Carcavelos is lighter-bodied and fresher, with saline notes. R.J.M. & S.A.

Cardinal, red TABLE GRAPE, a CROSS, grown for wine production in Vietnam, Thailand, and Sri Lanka. *Cardinal* is also a (Burgundian) name for a red wine mixed with CASSIS.

Carema, alpine red-wine zone of PIEMONTE in north-west Italy, bordering on the Valle d'AOSTA, is the northernmost zone of Piemonte in which the great NEBBIOLO, here called PICUTENER, is cultivated (although see also VALTELLINA). Viticulture is not an easy task in this mountainous region, and the PERGOLA-trained vineyards on the slopes of a morainic amphitheatre have been wrested from steep gradients by means of TERRACES at 350–700 m/1,150–2,300 ft.

The wine itself has a recognizable Nebbiolo character, with higher ACIDITY and less BODY than the wines of the Langhe or than the group described in SPANNA, making for perfumed and impressively long-lived wines. Carema's total vineyard area was just 17 ha/42 acres in 2020, supplying a growing number of young producers banded together under the Giovani Vignaioli Canavese name. Ferrando, founded in 1890, saved the DOC from obscurity thanks to its legendary Carema Etichetta Nera, a 100% Nebbiolo aged for three years in cask and produced in only the best vintages. The minimum ageing period for DOC wines is two years, in oak or chestnut. The umbrella DOC Canavese includes Carema as well as almost all of CALUSO. W.S.

Carignan, known as Cariñena, Samsó, and Mazuelo in Spain, Carignane in the US, and Carignano in Italy (Bovale Grande on Sardinia), late-ripening black grape variety which was once so widely

planted in the LANGUEDOC and ROUSSILLON that it was France's most planted vine for much of the last century. Thanks to EU bribes, it had fallen to being the sixth most planted red wine grape in France by 2019, when plantings totalled 31,273 ha/77,277 acres.

Nowadays Carignan seems a very odd choice indeed, although presumably it seemed obvious to many *pieds noirs* returning in the mid 20th century from ALGERIA, where the wine industry depended at one time on its 140,000 ha/350,000 acres of Carignan. In much of southern France, its wine is high in everything—acidity, tannins, colour, bitterness—except finesse and charm. This gives it the double inconvenience of being unsuitable for early consumption yet unworthy of maturation. The astringency of basic red from the Languedoc has owed much to Carignan's ubiquity, although blending with Cinsaut or Grenache helped considerably, and CARBONIC MACERATION helped disguise, if not exactly compensate for, Carignan's lack of youthful charm. The vine is not even particularly easy to grow. It is extremely sensitive to POWDERY MILDEW, quite sensitive to DOWNY MILDEW, prone to rot, and prey to infestation by grapevine MOTHS. Its diffusion was presumably beneficial to the AGROCHEMICAL industry. Its bunches keep such a tenacious hold on the vine that it does not adapt well to MECHANICAL HARVESTING and is mainly grown as BUSH VINES.

There must have been some attribute which led to the almost exclusive dissemination of Carignan throughout the Midi in the 1950s and 1960s, and there was: YIELD. The vine can quite easily be persuaded to produce almost 200 hl/ha (11 tons/acre), ideal for a thirsty but not discriminating post-Second World War market. It also buds late, which gave it extra allure as a substitute for the much lighter ARAMON, previously France's number one vine, which had been badly affected by the frosts of 1956 and 1963. It ripens late, too, however, limiting its cultivation to Mediterranean wine regions. The regulations for the Languedoc and Roussillon appellations have been forced to embrace the ubiquitous Carignan, but it is hard to argue that, for example, Minervois or Corbières are improved by their

optional Carignan component. Those wines that depend most heavily on varieties such as Syrah, Grenache, and Mourvèdre and least on Carignan are almost invariably the most successful—with the exception of some wines made with care from well-sited old BUSH VINES, which can make concentrated marvels such as those of Domaine of the Bee in Roussillon, Bertrand Bergé, and Domaine Jones in Fitou.

The fuller-bodied white MUTATION Carignan Blanc can still be found in some vineyards of the Languedoc and, in particular, Roussillon.

Although the vine (like Grenache) may have originated in Spain in the province of Aragón, it is not widely planted there today. Cariñena is not even the principal grape variety in the wine that carries its most obvious Spanish synonym CARIÑENA. It is grown chiefly in Cataluña and also plays a major part in the wines of PRIORAT (where it is also known as Samsó and where some of the finest Carignan-dominant wines in the world are to be found), COSTERS DEL SEGRE, PENEDÈS, TARRAGONA, and TERRA ALTA, so that Spain had total plantings of 5,658 ha/13,981 acres in 2020.

Because of its late-ripening habits, Carignan can thrive only in relatively hot climates. It has been grown in ISRAEL since 1870 and is still widely planted there as a workhorse grape, occasionally producing quality wines from old bush vines. In Italy, there were still 1,684 ha/4,161 acres in 2015: as Carignano in Lazio and most commonly on Sardinia (perhaps as a result of that island's long dominance by Aragón), where it makes strong, rich, velvety reds and rosés, notably some seriously exciting Carignano del Sulcis. A recent survey on Sicily, based on DNA PROFILING, established that around 70% of NERELLO CAPPUCCIO vines are in fact Carignano. It is also grown on Cyprus, in Türkiye, and in Croatia.

The vine, gaining a vowel as Carignane, has been important in the Americas. Although it is rarely seen as a VARIETAL, there were still about 893 ha/2,206 acres in California's hotter regions in 2020, for the vine's productivity and vigour are valued by growers, if not consumers. Old bush vines produce the best wines and are highly

prized. Likewise, Chile's old-vine Carignan is enjoying something of a revival with the support of the Vignadores de Carignan organization. It is also grown (to a much lesser extent) in Mexico, Argentina, and Uruguay. Occasional bottlings of savoury old-vine Carignan have surfaced in South Africa.

Cariñena , town in north-east Spain which lends its name to both a DOP and a vine variety, widely grown in southern France as CARIGNAN. Although it is thought to have originated in the area, the vine (officially known as Mazuelo in Spain) has been widely abandoned here in favour of GARNACHA, which seems better suited to the arid growing conditions in this, the largest of the four DOP zones of the ARAGÓN region (see map under SPAIN), with 14,300 ha/35,336 acres planted. But Cariñena, like so many other Spanish regions, is trying to break with the viticultural and winemaking flaws of the past. Tempranillo and Cabernet Sauvignon have also been planted, and the local red wine rarity Vidadillo rediscovered. Among the white vine varieties that cover one-fifth of Cariñena's total vineyard area, MACABEO and GARNACHA BLANCA have been joined by PARELLADA from Penedès. The CO-OPERATIVES, led by San Valero and Grandes Vinos y Viñedos, have been fully modernized. V. de la S. & F.C.

Carmel Valley, California AVA with a handful of small wineries and 121 ha/300 acres of vineyards draped across steep slopes in the drainage area of the Carmel River, 16–19 km/10–12 miles inland from Carmel Bay. Several wineries throughout the state source fruit from the region, particularly Cabernet Sauvignon and Merlot, which make up more than 70% of plantings. Despite sitting within Monterey County, Carmel Valley does not fall within the bounds of the Monterey AVA and instead sits within the larger CENTRAL COAST AVA. A.Y.

Carmenère is a very minor dark-skinned grape variety in Bordeaux today but was, according to viticulturist Joseph Daurel, widely cultivated in the Médoc in the early 18th century and, with its parent

CABERNET FRANC, established the reputations of its best properties. Daurel reports that the vine is vigorous and used to produce exceptionally good wine but was abandoned because of its susceptibility to COULURE and resultant low yields. It yields small quantities of exceptionally deep-coloured, full-bodied wines that can taste decidedly HERBACEOUS if the grapes are not completely ripe. The PAUILLAC-classed growth Ch Clerc Milon usually includes a small percentage in its ASSEMBLAGE, and the odd VARIETAL emerged in Bordeaux in the early 2000s.

Its new power base is CHILE, where plantings had reached 10,836 ha/26,776 acres by 2020, particularly as a result of correct VINE IDENTIFICATION rather than new plantings. It was discovered in 1994 that a substantial proportion of the vines previously believed to be Merlot are in fact this historic variety, presumably imported directly from Bordeaux in the late 19th century. It ripens even later than Cabernet Sauvignon and if yields are limited—by grafting on to low-vigour ROOTSTOCKS, for example—has the potential to make very respectable wines, combining some of the charm of Merlot with the structure of Cabernet Sauvignon, although for many winemakers it is best as an ingredient in a BORDEAUX BLEND.

Correct identification also grew the official total of Carmenère plantings in Italy from 45 to 1,000 ha between the censuses of 2000 and 2010. Most of these were previously thought to be CABERNET FRANC in northern and north-eastern Italy. Much is used for blending, but the likes of San Leonardo in TRENTINO and Ca'del Bosco in LOMBARDY make a sturdy varietal Carmenero. Even more recently, DNA PROFILING showed that the variety known as CABERNET GERNISCHT in CHINA is in fact Carmenère.

Daurel, J., *Les Raisins de cuve de la Gironde et du sud-ouest de la France* (1892).

Carmignano, historic central Italian red wine made 16 km/10 miles north-west of Florence in a zone noted since the Middle Ages as

one of TUSCANY's finest for red-wine production. The vineyards are located on a series of low hills at 50–200 m/160–650 ft of ELEVATION, unusually low for the SANGIOVESE grape which forms the base of the blend, giving wines with lower ACIDITY and softer TANNINS than those of CHIANTI CLASSICO.

The wines were first given legal status by Cosimo III de'Medici—himself a major proprietor in the Carmignano zone at the villa of Artimino—who included them in his selection of four areas of superior wine production in an edict of 1716 which prohibited other wines from using the names of the selected areas. The grand-ducal wines were sent regularly to Queen Anne of England, who apparently appreciated their quality. The wines were also praised by Giovanni Cosimo Villifranchi (1773) and Cosimo Ridolfi (1831).

The report of the Dalmasso Commission in 1932 (see ITALY and TUSCANY) assigned Carmignano to the nearby zone of Chianti Montalbano, where cooler temperatures, higher elevations, and, crucially, higher yields result in Chianti wines of lighter body and higher acidity more suitable for early drinking. Independent status was restored in 1975, however, with the granting of a DOC for Carmignano, the only Tuscan DOC to require the inclusion of CABERNET SAUVIGNON and/or Cabernet Franc (up to 20%) in a Sangiovese-based blend years before their use became common in the so-called SUPERTUSCANS and long before the production rules of Chianti and Chianti Classico were loosened to allow INTERNATIONAL VARIETIES in the blends. It was awarded DOCG status in 1990. A provision for up to 10% white wine grapes remains, reflecting historic viticultural practices but no longer used by any quality-conscious producers.

The alleged tradition of Cabernet Sauvignon in the zone was of major assistance in detaching it from Chianti Montalbano. The vineyards of Ugo Contini-Bonacossi of Villa di Capezzana, who was instrumental in obtaining the DOC for the region and was the zone's major producer, were grafted with cuttings from Ch LAFITE in the 1970s. He claimed to be reviving a local tradition begun by the Medici. This view is supported by the zone's CONSORZIO, which

maintains that Cabernet Sauvignon vines were planted here as early as the 16th century at the request of Catherine de Medici, then Queen of France, although supporting evidence is lacking.

The wine must be aged for at least eight months in oak or chestnut casks (12 for Riserva) and released after 1 June in the second year following the harvest. Although in the past many Carmignano wines were aged, at least partially, in French BARRIQUES, many producers have returned to ageing the wines in large oak casks, while Fattoria di Bacchereto uses clay AMPHORAE.

The DOC for younger wines and for rosé is Barco Reale di Carmignano (referring to the 'royal park', as distinguished in the Medici edict of 1716). The rosé, often obtained by SAIGNÉE, has a long history here as Vin Ruspo, a reference to peasants drawing off, or 'robbing', the pale juice from the cask at the beginning of fermentation. VIN SANTO di Carmignano has its own DOC. W.S.

Belfrage, N., *Brunello to Zibibbo: The Wines of Tuscany, Central and Southern Italy* (2003).

www.consorziovinicarmignano.it

Carmine, California CROSS whose antecedents include Carignan, Cabernet Sauvignon, and Merlot. It has an intense Cabernet flavour and is planted to a limited extent in the US. Mainly blended.

Carnelian, like CARMINE, a black grape CROSS developed from Carignan, Cabernet Sauvigon, and Garnacha in and specifically for California by Dr H. P. Olmo of DAVIS. It was supposed to be a hot-climate Cabernet, but too many of the Grenache characteristics predominate to make it easy to pick. Its California influence is limited and restricted to the SAN JOAQUIN VALLEY, where total plantings fell to 66 ha/164 acres by 2020. It is also grown to a limited extent but with

surprising success in Western Australia, where it was originally thought to be SANGIOVESE.

Carneros, also known as Los Carneros ('the rams' in Spanish), a moderately cool, windy AVA in California that sprawls across the last, low hills of the Mayacamas Range before it slips beneath San Francisco Bay. The larger part of the AVA lies within SONOMA County; grapes from that portion can also use the Sonoma Valley AVA. The smaller segment, in NAPA County, is equally entitled to use the Napa Valley AVA. The region is one of the state's older wine districts: Agoston HARASZTHY planted grapes in it before 1870. A property originally called Stanly Ranch was famous as a vineyard by 1880. However, persistent fog and wind as well as challenges with sourcing water made vine-growing difficult and, when PHYLLOXERA struck hard in the 1880s, there began a swift slide into a long night.

The move back to Carneros began to gain momentum in the 1970s, then picked up in the mid 1980s, partly on the strength of some impressive Pinot Noirs and as much or more because of traditionally made SPARKLING WINES of Chardonnay and Pinot Noir. Those remain the predominant varieties in the region's 3,237 ha/8,000 acres of vines, though also successful are COOL-CLIMATE Cabernet Sauvignon, Merlot, and Syrah in the northern part of the Napa side and Vermentino on the Sonoma side. L.M. & E.C.B.

www.carneros.com

Carnuntum, Austrian winegrowing region immediately east of Vienna, named after a Roman city whose ruins grace the Danube's shoreline. Its 831-ha/2,053-acre vine surface in 2021 features nearly every grape variety planted in Austria. Considering its GEOLOGICAL and MESOCLIMATIC diversity, it is likely that the region will continue to produce a wide variety of wine styles. But its most ambitious growers

have discovered some highly distinctive combinations of variety and site, as witness the reputation of Gerhard Markowitsch (in Carnuntum's best-known wine village, Göttelsbrunn) as one of Austria's top Pinot Noir producers; or the revival, spearheaded by Dorli Muhr and Dirk van der Niepoort, of BLAUFRÄNKISCH on the once-renowned Spitzerberg, a LIMESTONE-rich remnant of the Carpathians that sits a mere 15 km/9 miles from SLOVAKIA's capital Bratislava and nearly touches the northern tip of BURGENLAND. As of the 2019 vintage, a Carnuntum DAC allows Blaufränkisch and ZWEIGELT for reds, CHARDONNAY, WEISSBURGUNDER, and GRÜNER VELTLINER for whites, as well as cuvées of which the aforementioned varieties comprise at least two-thirds. D.S.

carotenoids, important class of plant PIGMENTS whose red, orange, and yellow colours complement the green of chlorophyll and the blue and red of ANTHOCYANINS. They are derived from the chloroplasts in green grapes. Carotenoids are TERPENOIDS with 40 carbons and belong to the LIPID group of organic compounds. They include two main groups—xanthophylls and carotenes—which are prominent in grapes and provide the skin colour of so-called white grapes, as well as being associated with vine leaf colours in autumn; carotenes also form a substrate for synthesis of many FLAVOUR COMPOUNDS and FLAVOUR PRECURSORS. Carotenoids serve as accessory pigments in the process of PHOTOSYNTHESIS. B.G.C.

Carricante, white wine grape speciality of ETNA on Sicily and dominant grape in the blend for Etna Bianco. Wines are crisp with citrus notes, and the best can age well. Plantings totalled just 710 ha/1,754 acres in 2020.

Carso, or Carso-Kras, small DOC consisting of just 53 ha/131 acres of vineyards in FRIULI in north-east Italy, on a GRAVELLY plateau between Gorizia and Trieste and bordering Slovenia. A smaller

subzone, called Terrano Classico, is situated immediately around the city of Trieste. The DOC produces mainly dark, tannic reds high in acidity made from the Terrano grape (see TERAN), which responds well to BARREL MATURATION. Terrano is often confused with REFOSCO DAL PENDUCOLO ROSSO, which is also allowed in the Carso DOC, in addition to INTERNATIONAL VARIETIES such as Chardonnay, Sauvignon Blanc, GLERA, and Cabernet Sauvignon.

Kras is also a PDO in SLOVENIA. W.S.

www.carsovinokras.it

Cartagène is the traditional, strong, sweet aperitif of the LANGUEDOC in southern France, made, rather like a VIN DE LIQUEUR, by adding grape spirit to barely fermenting grape juice.

Cartaxo, DOP subregion of TEJO in central southern Portugal.

Carthage, ancient city on the north coast of Africa just east of modern Tunis which played a part in wine history as a result of the maritime expansion of the PHOENICIANS who settled there in the late 9th century BCE. A famous passage of the historian Diodorus (20. 8) paints a vivid picture of the country estates of the Carthaginian elite of the late 4th century BCE, flourishing on the fertile soils around Carthage with a mix of farming, which included viticulture. However, at no period did Carthaginian wine figure prominently in trade. It was eclipsed by North Africa's importance as a producer of corn and olive oil, most particularly in the period when it was part of the Roman

Empire. Still, there can be little doubt that Carthage's elite shared the same interest in viticulture as the rest of the Mediterranean world.

It was for them that a large work, written in Punic, of 28 books on agriculture was produced by a certain Mago. Little is known of the writer or of his date; but his work fits most easily into the great explosion of handbooks on agriculture written in the Hellenistic period, particularly in the 3rd and 2nd centuries BCE. Like these other works, Mago's treatise is lost; our knowledge of its contents is entirely derived from references to it and quotations from it in the later writers. Of these the largest number are about vines, although it would be dangerous to infer from this very fragmentary selection that viticulture had particular prominence in his work. While Mago's work probably contained much that was taken from the earlier AGRICULTURAL TREATISES produced in the Greek world, it was not without information based on personal observation. As COLUMELLA (*De re rustica* 3. 12. 5–6) noted, Mago's advice to plant vines on north-facing slopes is particularly appropriate to Africa (see TOPOGRAPHY). Large extracts from Mago were translated into Greek and incorporated in a treatise on agriculture by Cassius Dionysius of Utica, near Carthage (VARRO, *De re rustica* 1. 1. 10). More surprisingly a decree of the senate ordered a translation of Mago into Latin (Columella, *De re rustica* 1. 1. 13). The most likely occasion for this must be in connection with one of the schemes for Roman settlement in North Africa in the period after Rome's destruction of Carthage in 146 BCE. Columella was to call Mago 'the father of country matters', probably primarily because his work in its Latin version gave Romans convenient access to the vast literature on agriculture from the Hellenistic world.

The most famous Carthaginian of all is commemorated in the name of the CO-OPERATIVE and principal producer of CHÂTILLON-EN-DIOIS in the foothills of the French Alps, the Cellier Hannibal.

Cartizze. See PROSECCO.

cartons, method of PACKAGING wine in what are effectively cardboard 'bricks', sometimes known as tetrapacks, that has been particularly popular for everyday wines in Latin American countries such as CHILE. They are becoming more popular elsewhere in the light of concerns about SUSTAINABILITY. Cartons are light, made of renewable materials, exceedingly space-efficient, non-breakable, and relatively easy to recycle. Their CARBON FOOTPRINT is reckoned to be lower than that of any type of wine packaging. They also offer producers a much larger LABELLING area than BOTTLES. They are made mainly from paperboard, with polyethylene and aluminium, often with a resealable plastic closure, and, before opening, can keep wine fresh for between 18 months and two years.

Alko, 'Update of wine packaging LCA: final report Alko Oy' (2021).

Casablanca, relatively cool wine valley in the Aconcagua region of CHILE.

casa vinicola, or AZIENDA vinicola, on the label of an Italian wine indicates a producer who buys in grapes or wine, like a French NÉGOCIANT.

case. Beer and milk may be sold in crates, but, contrary to popular usage, wine is sold in cases of 6 or 12, the basic trading units in the fine-wine trade and much of the wholesale wine trade. As wine PRICES have risen, an increasing proportion of fine wine has been offered in

six-bottle cases, which have long been favoured by the German wine trade, but a 12-bottle case requires less overall packaging and is therefore more SUSTAINABLE. Most cases are made of cardboard outers, with cardboard vertical or papier mâché horizontal dividers. Wine merchants truly dedicated to the mail-order business ensure that they use only particularly strong cases designed to minimize breakage.

Many FINE WINES designed for prolonged AGEING are dispatched from their producers in heavy wooden cases, however, usually made of rough pine, branded with the name, and often the logo, of the producer on the case ends (which can be attractive enough for future use as decoration or table mats). These cases are usually nailed down and can be opened only with a chisel or screwdriver and hammer, often breaking the wooden lid. Wine sold in unopened cases is presumed, in the fine-wine market, to be worth sufficient premium that they are usually designated 'o.w.c.', or 'original wooden cases', in AUCTION catalogues.

A split case may be one that is torn but may also be one that contains six bottles of each of two different wines, or four bottles of each of three different wines. One bottle of each of 12 different wines becomes a mixed case.

casein, the principal milk PROTEIN, is used by winemakers as a FINING agent particularly useful for removing brown colours from white wines. It is also used to a lesser extent in the general CLARIFICATION of young wines. Precipitated from milk by the addition of ACIDS, casein is chiefly used in the form of sodium or potassium caseinate. When this salt is added to cloudy wine, it reacts with some of the wine acid, forming a curd which adsorbs and precipitates most of the very small particles, including the PIGMENTS causing discoloration. In many countries, the use of casein must be declared on the label. See LABELLING INFORMATION. A.D.W.

Casella Family Brands, Australia's biggest family-owned wine producer whose empire has been built on the phenomenal success in the US of YELLOW TAIL. The previous generation, Sicilian immigrants, settled in the small RIVERINA town of Yenda and started a small wine business in 1969. By 2022 the current version owned such historic producers as Peter Lehmann of Barossa Valley, Brands Laira of Coonawarra, Morris of Rutherglen, and Bailey's of Glenrowan. In 2022 they sold off 7,258 ha/17,935 acres of vineyard in New South Wales and South Australia to concentrate on making and selling wine.

cask, wooden container for wine, often used interchangeably with the word BARREL, a cylindrical container small enough to be rolled. The term is also used less precisely, however, for wooden containers of any size—whether larger, immobile containers such as the oval *Fuder* or *foudre* common in Germany and Alsace or the *botte* of Italy—and also including quite large, immovable containers which may or may not be open-topped.

In the 1970s, the Australian wine industry neatly, if misleadingly, coined the term cask wine for wine packaged in a bag packed inside a cardboard BOX, a wine type unlikely to have been either made or aged in wood of any sort (although OAK CHIPS may well have played a part in some).

cask ageing, winemaking practice of AGEING a wine after fermentation in a large wooden container sometimes too old to impart any obvious OAK FLAVOUR. It may well, however, exert some WOOD INFLUENCE and help considerably to achieve natural CLARIFICATION and STABILIZATION. White wines subjected to cask ageing for several months include some of the great white wines of the LOIRE, GERMANY, and ALSACE. Red wines subjected to cask ageing, sometimes for several years, include many of the traditional wines of the RHÔNE, ITALY, SPAIN, PORTUGAL, and GREECE.

The alternatives, and possible supplements, to cask ageing are BARREL AGEING, ageing in inert CONTAINERS such as stainless-steel tanks (with or without the use of INNER STAVES or OAK CHIPS), BOTTLING almost immediately after FERMENTATION as in NOUVEAU wines, and AGEING in bottle.

casse, historic wine FAULT involving spoilage by an excess of IRON, COPPER, or PROTEIN or by TARTARIC ACID precipitation.

cassis is French for blackcurrant and is used often as a tasting note for red wines, particularly red wines based on Cabernet Sauvignon grapes. Dry white wine mixed with some blackcurrant liqueur is known as both a *vin blanc cassis* and KIR (while red wine mixed with blackcurrant liqueur is sometimes called a *cardinal*).

Cassis, small, mainly white-wine appellation in PROVENCE. The encroachment of Greater Marseilles on this old fishing village keeps total plantings to just under 265 ha/654 acres in this sheltered amphitheatre, protected from the mistral by the Cap Canaille, one of the highest cliffs in France.

Three-quarters of the wine is full, dry, and herby white, made mainly from CLAIRETTE and MARSANNE, plus some Ugni Blanc or Sauvignon Blanc for freshness. A little rosé and even less red are also made, mainly from MOURVÈDRE (which ripens easily here, as in nearby BANDOL), GRENACHE, and CINSAUT. Little Cassis is allowed to escape by the annual influx of summer visitors, however.

Castel, France's, probably Europe's, biggest wine company and the world's third largest, was founded in Bordeaux by nine Castel brothers and sisters in 1949 and is still family-owned. As well as owning dozens of Bordeaux châteaux and selling prodigious quantities of wine, Castel is an important distributor of beer and

WATER in France and North Africa. Castel acquired BARTON & Guestier, the Bordeaux NÉGOCIANT, and bought the Nicolas retail chain in 1988, their chief rival Société des Vins de France in 1992, Domaines Virginie in the Languedoc in 1999, the British retail chain Oddbins in 2002 (which it subsequently sold off), and the Burgundy négociant Patriarche in 2011. It is also involved in a JOINT VENTURE for the production of Chinese wine and distribution of French wines in CHINA with CHANGYU and, together with SUNTORY of Japan, owns a Bordeaux négociant and a substantial share of Ch Beaumont and the CLASSED GROWTH Ch Beychevelle.

Castelão, usefully versatile but declining Portuguese red wine grape, with total plantings of 8,934 ha/22,076 acres in 2020, down from more than 14,000 ha in 2000. It makes varied but generally fruity, sometimes surprisingly long-lived, reds all over southern Portugal. It is known variously as Periquita in Setúbal, João de Santarém in Oeste, and Castelão Francês in many regions. DNA PROFILING has shown that Castelão is a natural cross of ALFROCHEIRO and CAYETANA BLANCA.

Castel del Monte, DOC named after the imposing 13th-century octagonal fortress in PUGLIA in the far south-east of Italy, associated with red wine from the NERO DI TROIA grape, although it may also be 100% AGLIANICO or either of the two CABERNETS. Pink versions are also increasingly produced. The same flexible production rules are applied to the white, which was traditionally based on BOMBINO BIANCO, but varietal CHARDONNAY and SAUVIGNON BLANC are also allowed. Confusingly, three parallel DOCGs were created in the early 2010s—Castel del Monte Bombino Nero DOCG, Castel del Monte Nero di Troia Riserva DOCG, and Castel del Monte Rosso Riserva DOCG (minimum 65% Nero di Troia)—though none has the track record for quality this level implies. W.S.

Castelli Romani, extensive but potentially outstanding DOC for the wines of the VOLCANIC hills south-east of Rome in the region of LAZIO (see map under ITALY). Eleven DOCs fall completely within the zone, the most illustrious being FRASCATI.

Since the creation of DOC Frascati in 1966, white varieties have become dominant in the region—mainly MALVASIA di Candia and the superior Malvasia Puntinata. A variety of strains of TREBBIANO is also grown—mainly the insipid Toscano but also Verde and Giallo.

The red CESANESE—both Cesanese di Affile and the slightly more common Cesanese Comune—has begun to make a hesitant comeback, inspired in part by Camillo Mancini's 1888 monograph 'Lazio Viticolo e Vinicolo', in which he hails Cesanese as one of Italy's most outstanding varieties. This recently rediscovered monograph has given a new generation of ORGANIC and BIODYNAMIC producers the inspiration and conviction to revive the region's reputation.

Other potentially interesting DOCs are Cori (based on the local Bellone for whites and Nero Buono for reds), Colli Lanuvini (whites based on Malvasia and reds on Merlot and Sangiovese), and the DOC Roma, which allows Malvasia in blends and varietal bottlings and also in the archaic Romanella (a MÉTHODE ANCESTRALE sparkling wine still surviving thanks to current interest in PÉTILLANT NATUREL wines), as well as reds based on MONTEPULCIANO blended with Cesanese, Cabernet Sauvignon and Franc, and/or Syrah.

Once regarded as avant-garde due to their large-scale production of IGT Lazio wines made from international varieties, Colli Romani producers have begun to increase their range with local varieties, while Viognier—partly or wholly BARREL-FERMENTED—can be convincing, if expensive. But few of these wines, self-consciously detached from the history and traditions of the zone, have provided a key to resolving the area's viticultural problems, which are exacerbated by high vineyard land PRICES, given that the hills are such an attractive place to live for Romans who want to distance themselves from the congestion of the city. W.S.

Mancini, C., *Il Lazio Viticolo e Vinicolo* (1888).

Castets, almost extinct vine, probably selected from an escaped seedling in a forest in the Aveyron, SOUTH WEST FRANCE. It was, unexpectedly, a parent of several NEW VARIETIES bred in SLOVAKIA in the 1970s.

Castilla, Castile in English, old central Spanish kingdom divided by mountains into CASTILLA Y LEÓN, or Old Castile, in the north and CASTILLA-LA MANCHA, or New Castile, in the south. When a wine label refers solely to 'Castilla', it references the VINO DE LA TIERRA indication covering all the municipalities of the autonomous region of Castilla-La Mancha. F.C.

Castilla-La Mancha, known as Castile-La Mancha in English (historically, Castilla la Nueva or New Castile), the lower, southern half of the plateau that makes up central Spain (see map under SPAIN). At ELEVATIONS of 400–1,000 m/1,300–3,500 ft, this is Spain at its most extreme. Winters are long and cold with temperatures often falling below 0 °C/32 °F for days on end. In summer the thermometer regularly rises above 35 °C, even 40 °C/104 °F, and little if any rain falls between May and September. The vast expanse of country which turns green in the spring quickly darkens to burnt ochre in July and August as all but the deepest riverbeds dry up completely. The locals say that they suffer 'nine months of winter and three months of hell'. Despite these fierce conditions, Castilla-La Mancha claims nearly half the total vineyard hectarage of Spain, with drip IRRIGATION having amply compensated for the widespread VINE PULL since 2000. Around 458,300 ha/1,132,484 acres of vineyard yield about 20 million hl/530 million gal of wine (averaging yields of 43 hl/ha, or 2.6 tons/acre). One of Castilla-La Mancha's nine DOP regions, LA MANCHA itself, is planted mainly with the robust white-wine vine AIRÉN.

Despite determined uprooting, there are still an estimated 200,000 ha of DROUGHT-resistant Airén in the zone of La Mancha alone (less than half of them producing DOP wine), making it one of the world's most widely planted vine varieties—although Cencibel (alias TEMPRANILLO) has been catching up fast. By 2020 there were 71,000 ha of Cencibel in Castilla-La Mancha, and it dominates in the VALDEPEÑAS, MONDÉJAR, and UCLÉS DOPs as well. To the east, the variety joins Syrah and such INDIGENOUS VARIETIES as BOBAL, GARNACHA, and MONASTRELL in the Ribera del Júcar and MANCHUELA DOPs. North-west of Toledo, Garnacha produces sturdy reds in MÉNTRIDA. In the far east, Monastrell and Garnacha Tintorera (ALICANTE BOUSCHET) predominate in the ALMANSA DOP.

Today more attention is being paid to local varieties Tinto Velasco (2,000 ha in Spain) and Moravia Dulce (1,900 ha; see MARUFO) as red grapes suited to the region's ever-warmer climate (see CLIMATE CHANGE). The region also grows possibly Spain's most fragrant renditions of MACABEO. ALBILLO Real (not to be confused with Albillo Mayor from RIBERA DEL DUERO) is gaining a reputation for aromatic, rounded white wines.

Another development that contrasts strongly with centuries of BULK WINE production has been a blossoming of distinguished single-estate wines (see VINO DE PAGO) that have vastly outgrown clichés about La Mancha wines, all of them inspired by the pioneering efforts of the Marqués de Griñón at his Dominio de Valdepusa. Also, many of the most interesting wines are not labelled by DOP but instead with the more generic PGI Vino de la Tierra Castilla or even Vino de España.

V. de la S. & F.C.

Castilla y León, Castile and León in English, is the largest of the 17 autonomous regions of Spain. This northern part of Spain's central plateau, at 880–1,000 m/2,900–3,300 ft of ELEVATION, takes up about one-fifth of the entire country. Centred on its capital, the university city of Valladolid, most of Castilla y León is thinly populated table land almost encircled by mountains. It is separated from the hub of Spain

(MADRID and CASTILLA-LA MANCHA) by the central mountain range which rises to over 2,000 m near Ávila and Segovia (see map under SPAIN). To the north, the Cordillera Cantabrica, which peaks at over 2,600 m, deflects the maritime influence of the Bay of Biscay.

The climate here is harsh. Short, hot summers are followed by long, cold winters when temperatures can drop to −10 °C/14 °F. Under often clear skies, temperatures drop quickly after sunset, and even in summer nights are cool. FROST is a threat until mid May. Rain falls mainly in winter and amounts to 400–500 mm/15–19 in a year. Much of the land is poor and unable to support anything other than sheep. However, the river Duero (known as DOURO in Portugal), which cuts a broad valley in the rather featureless plain, provides a natural water source. Grain, sugar beets, and vines are grown along its length.

A regional variant of the red TEMPRANILLO vine, variously called Tinta del País, Tinto Fino, Tinto Aragonés, and Tinta de Toro, is the chief good-quality grape variety in five of the region's 13 DOPs: the well-known RIBERA DEL DUERO, as well as ARLANZA, LEÓN, TIERRA DEL VINO DE ZAMORA, and TORO.

The largest of these is RIBERA DEL DUERO, which extends for about 100 km/60 miles either side of the river and is internationally known for its red wines. Downstream of Ribera del Duero, RUEDA has established itself as Spain's leading white-wine region since the 1990s, while neighbouring TORO, straddling the Duero near the Portuguese border, gained worldwide recognition a decade later. Tierra del Vino de Zamora neighbours Toro and produces a lighter version of it. CIGALES, north of Valladolid, specializes in rosé wine. BIERZO, abutting GALICIA in the north-west, makes fragrant, characterful reds from the MENCÍA grape. León, halfway between Bierzo and Ribera, produces an early-drinking Tinta del País. CEBREROS, part of the Sierra de Gredos neighbouring MADRID, is focusing on delicate high-elevation GARNACHA. To the west is ARRIBES with wines based on the local JUAN GARCÍA.

A category of growing importance is the umbrella IGP Vino de la Tierra de Castilla y León (not to be confused with the Vino de la Tierra de Castilla, which refers to wines from the CASTILLA-LA MANCHA region). Vino de la Tierra de Castilla y León is the appellation preferred by top wineries that were not included in Ribera del Duero when the boundaries were drawn, such as Abadia Retuerta (in Sardón del Duero) or Mauro (in Tudela del Duero), whose wines resemble the best Ribera del Duero. V. de la S. & F.C.

Castillon. Named after the town of Castillon-la-Bataille, the battle referred to being that which brought an end to the HUNDRED YEARS WAR, Castillon Côtes de Bordeaux is a dynamic, well-priced red-wine appellation, part of the Côtes de BORDEAUX group, effectively an eastern extension of ST-ÉMILION in Bordeaux. With 1,958 ha/4,836 acres of vineyard in 2020 on mixed soils of CLAY, LIMESTONE, and some SANDSTONE with SILT, sand, and stones on the alluvial terrace above the river DORDOGNE, it is much bigger than its northern neighbour FRANCS but produces similarly sturdy red wines based on Merlot grapes with generally better structure than regular red BORDEAUX AOC. Vineyards closest to the river tend to produce more supple wine than those at higher ELEVATIONS such as Ch d'Aiguilhe, one of the more important producers. The region, whose land is still relatively affordable, has benefited from the application of expertise from grander RIGHT BANK appellations.

Catalanes, Côtes, is the IGP which covers all the vineyards of ROUSSILLON in France except for the four villages of the appellations of BANYULS and COLLIOURE, for which the IGP is Côte VERMEILLE. Côtes Catalanes will be made by wine growers who do not have quite the right grape varieties in the correct proportions for the appellation—or by those who reject its constraints. The particular interest of Côtes Catalanes is the white wine, often a single-varietal MACABEO or GRENACHE GRIS, in preference to a blended appellation Côtes du

Roussillon. Among the red wines, varietal CARIGNAN from OLD VINES demonstrates the significant improvement in the quality of this once-maligned grape variety, contributing to the rise in its reputation.

R.E.G.

Cataluña, Catalonia in English, Catalunya in Catalan, a proud and industrious region on the Mediterranean coast which encompasses part of southern France (see ROUSSILLON) and part of north-east Spain (see maps under FRANCE and SPAIN), some of whose inhabitants do not consider themselves either French or Spanish or, even if they do, think of themselves as Catalan first. Cataluña is one of Spain's 17 autonomous regions, with Barcelona its capital.

Barcelona and its densely populated hinterland is a hive of enterprise and industry, and it is therefore no coincidence that Cataluña was at the vanguard of Spain's 20th-century winemaking revolution. The region began to stir in the early 1870s when José Raventos began making sparkling wine by the TRADITIONAL METHOD in the town of Sant Sadurni d'Anoia. He founded the giant Codorníu firm, and his foresight generated the CAVA industry, which earned its own Denominación de Origen (see DOP) in 1986.

In addition to most of Spain's Cava, Cataluña produces an eclectic range of wines from traditional, powerful reds to cool-fermented dry whites.

Much of the credit for the transformation of Cataluña's wine industry in the late 20th century must go to the late Don Miguel Torres Carbó and his son Miguel A. Torres (see FAMILIA TORRES), who imported INTERNATIONAL VARIETIES to plant alongside INDIGENOUS VARIETIES such as GARNACHA, MONASTRELL, and TEMPRANILLO (called Ull de Llebre in Catalan), and the Cava grapes, PARELLADA, MACABEO, and XARELLO.

The climate in Cataluña is strongly influenced by the Mediterranean. The coastal belt is warm and equable with moderate rainfall, but conditions become progressively more arid and extreme further inland. There are ten DOP regions—ALELLA, EMPORDÀ, CONCA DE

BARBERÁ, COSTERS DEL SEGRE, MONTSANT, PENEDÈS, PLA DE BAGES, PRIORAT, TARRAGONA, and TERRA ALTA—plus the catch-all DOP CATALUNYA. Of these, Penedès is the most important in terms of quantity, although the late 20th century transformation of Priorat resulted in some of Spain's highest wine prices.

Cataluña has long been an important centre of CORK production and is a particularly important source of corks for sparkling wines.

V. de la S. & F.C.

Catalunya, Catalan name for the region of CATALUÑA and controversial DOP created in the early 21st century for blends made from anywhere in the region. Big bottlers such as FAMILIA TORRES were the chief proponents and are the chief beneficiaries.

Catarratto, Sicilian grape variety that is Italy's second most widely planted white grape after TREBBIANO Toscano and is grown on 29,528 ha/72,965 acres on the island as of 2020. Also known as Catarratto Bianco Lucido (sometimes simply Lucido) and Catarratto Bianco Comune, probably two CLONES of the same variety, Catarratto has been revealed by DNA PROFILING to be a natural Mantonico Bianco × GARGANEGA cross. It is planted almost exclusively in the far western province of Trapani and was in the past much used for the production of MARSALA. Today there is an increasing number of varietal wines or blends with INTERNATIONAL VARIETIES. The variety is specified in the regulations of ten DOC zones and seven IGTs. Any SURPLUS is likely to be distilled or transformed into GRAPE CONCENTRATE. See SICILY for more details.

Catawba, deep-pink-skinned, late-ripening AMERICAN HYBRID of an American species and SÉMILLON. It was extremely popular in the 19th century and is still grown to a certain extent, particularly in NEW YORK State and OHIO. Identified in North Carolina in 1802 even before

CONCORD, it produces white and pink, still and sparkling, rather FOXY wines ranging from dry to very sweet.

catechin and its isomer epicatechin are PHENOLIC compounds (see also FLAVONOIDS) found mainly in grape seeds but also in stems, berry skins, and, in lower amounts, flesh. They contribute to bitterness in wines and are the constitutive units of TANNINS (see also PROANTHOCYANIDINS), which are responsible for ASTRINGENCY and increasing the stability of ANTHOCYANINS (see CO-PIGMENTATION and PIGMENTED TANNINS), leading to longer-lived COLOUR in wines. Because of the increased SKIN CONTACT involved during RED WINEMAKING, catechin concentrations are usually higher in red wines than in whites, but they are involved in browning reactions in both. Catechin may play a role in protecting vine parts from microbial attack as a pre-existing chemical barrier, but it is also produced by vines in response to DOWNY MILDEW infection.

Catechin, epicatechin, and other flavanol monomers such as gallocatechin and epigallocatechin are often referred to as catechins. Like other flavonoids, catechins are antioxidant compounds that may contribute to the HEALTH benefits of moderate wine consumption, particularly with regard to blood pressure. Catechins and related compounds may have a greater effect than that of RESVERATROL and related stilbenes, which are present in wine in much lower concentrations. Also, unlike resveratrol, these compounds are widely present in other fruits and vegetables, cocoa, and beverages such as teas.

The concentrations of catechins vary with vine variety, with PINOT NOIR, then MERLOT, notably high among well-known red wine grapes, and SYRAH lowest. As with resveratrol, cool, damp climates seem to stimulate more catechin synthesis than do hot, dry ones.

cation exchange is a process by which cations (positively charged ions) in solution in a soil exchange with other cations that are held on negatively charged CLAY particles and ORGANIC MATTER. These cations are called exchangeable cations. The quantity of cations, expressed as moles of charge per kilogram of soil, defines the CATION EXCHANGE CAPACITY. Cation exchange can result in concentrations of exchangeable ALUMINIUM in very acid soils (soil PH less than 5) that are potentially harmful to vine roots. Conversely, in soils with high concentrations of soluble salts, the exchange of SODIUM for CALCIUM cations can lead to very high pH soils (greater than pH 9) when the salts are leached out. The structure of such soils is potentially unstable, with the consequence that drainage is impeded and waterlogging can occur. See also ION EXCHANGE. R.E.W.

White, R. E., *Understanding Vineyard Soils* (2nd edn, 2015).

cation exchange capacity (CEC), the amount of positively charged ions a soil can hold, is a significant factor in the degree to which SOIL NUTRIENTS are available to the vine. CEC is determined by SOIL TEXTURE, the amount of ORGANIC MATTER in the soil, and the amount and type of CLAY. Sandy soil has a low CEC. Fine-textured soil such as clay, with a high level of organic matter, tends to have a high CEC.

Cato, Marcus (234–149 BCE), Roman statesman advanced as a writer on agricultural and viticulture matters, known as 'Cato the Elder' or 'Cato the Censor' to distinguish him from his great-grandson.

He grew up on his father's farm near Reate, north-east of Rome, then fought against CARTHAGE in the Second Punic War and afterwards had a distinguished political career. He became known as a strict moralist, castigating the 'new' extravagance, ostentation, and luxury and advocating a return to the 'old' virtues of austerity, honesty, and hard work. He wrote books on many subjects and published his speeches. PLINY the Elder praises him for the breadth of his learning (*Natural History* 25. 4), and COLUMELLA (*De re rustica* 1. 1. 12) and Cicero (*Brutus* 16. 61) honour him as the father of Latin prose. His only surviving work, *De agri cultura* ('Concerning the cultivation of the land'), also known as *De re rustica* ('Concerning country matters'), is important not only because it is the first lengthy prose work in Latin. *De agri cultura* is not divided into books or arranged systematically in any other way: Cato's remarks on viticulture and winemaking are scattered throughout the treatise. The advice he gives is of a severely practical kind. His prime concern is making farming, including winegrowing, profitable through hard work and careful management. For instance, he stresses that the grapes should always be thoroughly ripe when harvested or one's wine will lose its good reputation. And in the making and storing of wine he was aware of the importance of HYGIENE to prevent the wine turning to VINEGAR. After the vintage, the wine jars should be wiped twice a day, each with its own broom. After 30 days, when FERMENTATION is complete, the jars should be sealed, or the wine can be drawn off its LEES if desired as an alternative to LEES CONTACT. The type of estate he has in mind produces chiefly wine and olive oil: hence his extensive section on the construction of presses. H.M.W.

Thielscher, P., *Des Marcus Catos Belehrung über die Landwirtschaft* (1963).

caudalie, French term for a unit of sensory measurement equal to one second's LENGTH of a wine's impact on the palate after swallowing

or spitting.

Cava, Spanish SPARKLING WINES made using the traditional method of SPARKLING WINEMAKING. The term 'Cava' was adopted by the Spanish in 1970 when they agreed to abandon the use of the potentially misleading term 'Champaña'. The word originates in CATALUÑA, which produces most but not all Cava, and where it means 'cellar'. It was here in the town of Sant Sadurní d'Anoia that José Raventós, head of the family firm of Cordoníu, made the first bottles of TRADITIONAL METHOD sparkling wine after a visit to France in 1872. Early growth in the industry coincided with the arrival of PHYLLOXERA, which first appeared in Catalan vineyards in the 1880s. Vineyards that had once made sturdy red wines were uprooted and replanted with MACABEO, PARELLADA, and XARELLO, the triad of grape varieties which is the mainstay of the Cava industry to this day. In 1889, the Raventos family were joined by Pedro Ferrer, who founded the firm of FREIXENET. Codorníu and Freixenet are now two of the largest sparkling wine producers in the world, with their own winery outposts in CALIFORNIA.

Unlike any other Spanish DOP, the Cava *denominación* is not restricted to a single delimited area. However, since Spain joined the EU in 1986, the EU authorities have insisted that Cava should be made from grapes grown in prescribed regions. As a result, the use of the term 'Cava' is restricted to sparkling wines from a list of municipalities in Catalonia, VALENCIA, ARAGÓN, EXTREMADURA, NAVARRA, RIOJA, and the BASQUE country. However, 95% of all Cava is made in Cataluña, mostly in and around the town of Sant Sadurní d'Anoia. Total production amounts to over 250 million bottles yearly, compared with 300 million bottles of CHAMPAGNE.

The light, aromatic Macabeo (the Viura of Rioja) comprises about half of the blend for a typical Cava, its late BUDBREAK making it a popular choice for vineyards prone to spring FROSTS. The productive and indigenous Xarello vine, which thrives at relatively low

ELEVATIONS, is the second most important, and its aromas of fennel and apples are one of Cava's distinguishing features. Parellada performs better above 300 m/900 ft, where it produces finer wines relatively low in BODY. Subirat Parent (ALARIJE) is also used. CHARDONNAY was officially authorized for Cava in 1986; PINOT NOIR was accepted in 1998. The dark-skinned varieties GARNACHA, MONASTRELL, and TREPAT are also permitted, Trepat only in rosé.

To qualify for the DOP, Cava must be made according to the local adaptation of the TRADITIONAL METHOD. The wine must spend at least nine months on its lees before DISGORGEMENT, and attain an ALCOHOLIC STRENGTH of 10.8–12.8% by volume. YIELDS, set at a maximum of 1 hl of must per 150 kg of grapes, are higher than those allowed in Champagne. Most REMUAGE is now carried out automatically in a *girasol* or GYROPALETTE, a Spanish invention which can handle hundreds of bottles at a time.

The perceived mass-market image of Cava has led to a growing disenchantment among better-quality producers. By 2014 a number of them in Penedès—including Albet i Noya, Mas Comptal, Loxarel, and Colet—had left the appellation to join the PENEDÈS DOP.

In January 2019, another group of producers, unhappy with Cava's image and rules against citing subzones on wine labels, withdrew from the DOP to produce quality sparkling wines under their own brand, CORPINNAT. The DOP Cava responded in 2021 with new regulations, including, most notably, extended ageing periods for Cava Reserva (18 months), Gran Reserva (30 months), and Cava Paraje Calificado, a sort of SINGLE-VINEYARD Cava (36 months). To qualify for these superior categories, wines must be sourced from vineyards at least ten years old.

Most importantly, a number of zones and subzones were approved, although it seems too late to draw Corpinnat producers back into the fold. The zones are: Comtats de Barcelona (near Barcelona, with subzones Valls d'Anoia Foix, Serra de Mar, Conca del Gaià, Serra de Prades, Pla de Ponent); Valle del Ebro (north-central Spain, with subzones Alto Ebro, Valle del Cierzo); Viñedos de

Almendralejo in Extremadura; and Levante, in Valencia's eastern highlands. V. de la S. & F.C.

www.cava.wine

cave, French for a CELLAR or winemaking establishment and as close as the French language comes to an equivalent of a WINERY. A caviste is French for a specialist wine retailer. See also CHAI.

cave co-opérative, French for one of France's 600 wine CO-OPERATIVES. They vinify nearly 50% of all AOC wine and 69% of IGP.

www.lacooperationagricole.coop

Cayetana Blanca, high-yielding Spanish white grape variety travelling under many aliases, including Pardina and Jaén Blanco in Spain and Mourisco Branco in Portugal. Official 2020 Spanish vine statistics still distinguished between Cayetana and Pardina, but plantings totalled 34,579 ha/85,447 acres. It produces low-acid, neutral-flavoured wines which oxidize easily. It is particularly popular, as Pardina, in the EXTREMADURA region, especially in Badajoz province on the border with Portugal, where much of its produce is distilled into Brandy de Jerez. In Rioja it may be known as Cagazal, and Baladí is another synonym. The variety is closely related to many other Iberian varieties. There were 844 ha/2,086 acres of Mourisco Branco in Portugal in 2020, mostly in Beiras.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Cayuga White, AMERICAN HYBRID with SEYVAL genes released in 1972 from Geneva in New York (see CORNELL). It is grown in the north-east of the United States and makes fruity white wines.

Cebreros, DOP recognized in 2019 in Ávila in CASTILLA Y LEÓN in west-central Spain, little-known despite its outstanding feature, very old GARNACHA vineyards on steep SLATE slopes rising up to 1,200 m/3,937 ft in ELEVATION. White wines are made from ALBILLO. F.C.

CEC. See CATION EXCHANGE CAPACITY.

celebrity wine. The second decade of the 21st century saw a rash of wines and champagnes launched on the basis of their relationship with a famous (and sometimes not-so-famous) actor, singer, broadcaster, chef, or sports personality. The wines are rarely top-notch, and presumably their prices factor in a commission for said sponsor, but the wine industry has in general welcomed the phenomenon on the basis that these products probably attract some newcomers to the habit of buying and drinking wine.

cell, the structural unit of living organisms, the smallest unit capable of independent existence. YEAST and BACTERIA are examples of single cells, while one grapevine has billions of cells. Each plant cell consists of a protoplast surrounded by a cell wall, but it can be differentiated into a host of forms. A cell in the flesh of a ripe grape berry, for example, can be 0.5 mm/0.02 in in length with a thin, wavy cell wall lined by an equally thin cytoplasm surrounding the vacuole, a 'sea' of water with dissolved sugars, acids, and hundreds of other solutes, otherwise known as grape juice. Other cells within the berry can be entirely different. A PHLOEM element aligns end to end with others to form a tube through which elaborated sap moves in a network throughout the plant. Adjacent fibre cells in the XYLEM are long and slim with thick walls hardened by the wood polymer, lignin. The

complex functioning of the leaf provides other examples of cell forms: STOMATAL cells function to allow carbon dioxide in and oxygen and water vapour out; others function as the 'CARBOHYDRATE factory'; and cells in its dense network of veins are designed to move water and minerals up from the roots (in the xylem) and to move sugars and other elaborated organic nutrients out to the rest of the plant (in the phloem).

Despite this diversity, all cells of a plant have the same genetic information in their nuclei and, with some exceptions, may be separated and cultured as single protoplasts. By TISSUE CULTURE methods, these can then be used for the regeneration of another plant like the parent. The genetic material in each cell will therefore be 'tuned' for its differentiation and functioning by the dictate of its neighbours in that tissue and by its reaction to signals received from other tissues and organs. B.G.C.

Taiz, L., et al., *Plant Physiology and Development* (6th edn, 2018).

cellar, widely used word that is roughly the English counterpart to CAVE, CANTINA, and BODEGA in French, Italian, and Spanish respectively, terms which can be applied to both wine shops and winemaking premises (see WINERY), but the English term is used mainly to refer to a winery or, in its domestic sense (see below), to a collection of wine and the place in which it is stored prior to opening.

Location

Traditional underground cellars have the great advantages of being secure, dark, at a constant low temperature without recourse to external energy sources, slightly damp, and rarely disturbed. As outlined in STORING WINE, these constitute ideal conditions. Few modern dwellings have anywhere that enjoys all these advantages, and to recreate them it may be necessary to spend lavishly on specialist help in constructing or adapting quarters with low lighting levels and specially controlled temperature and humidity (and as few visitors as the expender of all this money and effort can bear). Another option is the use of refrigerated cabinets that can be programmed to maintain certain temperature and humidity levels, but they are expensive and guzzle energy relative to their capacity. Less expensive options include insulating a small room or large cupboard, insulating a space under some stairs, using a dark corner of a distant spare room or a closet against an outside wall, or converting (or building) a secure outhouse (although care must be taken that the TEMPERATURE never falls so low as to freeze the wine and push the corks out). It is important that any makeshift cellar is far from any heat source, even a hot-water pipe and, especially, a boiler, although a constant medium temperature is less harmful than violent temperature swings. Those living on ground level can even excavate, and depend on a trapdoor.

Accessibility is an advantage or disadvantage depending on the cellar owner's personality and attitude towards the cellar. Paying for professional storage may be the only realistic option for some, but in this case cellar records (see below) are essential.

Design

Wine can be stored in the unopened CASES in which it is bought, but this is practical only for wines years away from being ready to drink and requires steady and sturdy shelves. A system which incorporates cases without lids on individual runners is particularly space-efficient. Wine racks take up more room but allow bottles to be kept horizontal and corks damp (not strictly necessary for bottles with SCREWCAPS or SPARKLING WINE) and retrieved individually. Racks with slots for individual bottles offer the best access for very mixed cellars, but larger compartments, or BINS, can be used for larger quantities of bottles of the same wine.

It of course makes sense to keep the wines nearest MATURITY in the most accessible positions and vice versa (which dictates how wines may be kept in double-depth racks). There will be a slight temperature variation between the top and bottom of the cellar. Light levels are also likely to be higher at the top than the bottom, so there are at least two reasons why the fullest, least-fragile, slowest-maturing wines such as vintage port should be stored at the top and bottles as sensitive as, say, those containing sparkling wines should be stored close to floor level.

Contents

There is little point in devoting space and capital to storing wine unless it is difficult or expensive to replace (such as an EN PRIMEUR rarity) or will positively improve as a result of AGEING. There is no such thing as an 'ideal cellar', and an individual's ideal depends entirely on his or her tastes and consumption patterns.

Records

Cellar records are not necessary, but they can add to the pleasure of wine collectors with a love of order and memorabilia. (The other school enjoys the twin elements of chaos and serendipity in plundering their wine cellars.) Traditional cellar records have a good-sized page for each case of wine acquired, stating price, supplier, and date of purchase. Below this a dated tasting note for each bottle tasted can be inserted, together perhaps with details of the circumstances in which it was opened. (Those using professional wine storage need, for obvious reasons, to keep full details of where and since when the wine has been stored.)

INFORMATION TECHNOLOGY can offer other (often much more sophisticated and flexible) possibilities for cellar record-keeping. CELLARTRACKER and its imitators store personal cellar records online.

Sims, P., *The Home Wine Cellar* (2004).

cellar door has a very specific meaning originating in Australia, where it denotes the physical interface between a winery and its visiting customers. See TOURISM.

cellar rat, colloquial term for a relatively junior WINERY worker, especially itinerant ones following in the footsteps of FLYING WINEMAKERS.

CellarTracker, website that houses the world's largest collection of TASTING NOTES, more than nine million by late 2021. This fully searchable database is free to use (a donation is optional) and is made up of contributions from 750,000 (mainly amateur) users all over the globe. It was set up in 2003 by Eric LeVine, then employed

by Microsoft, as a personal cellar-management tool, but the social and knowledge-sharing implications rapidly became apparent, especially for following the AGEING of specific, generally quite fine, wines. The site is also integrated with those of a host of WINE WRITERS.

www.cellartracker.com

cellar work, general term for all the processing steps requiring human intervention or monitoring in WINEMAKING. In the narrower sense of what cellar workers actually do—apart from overseeing grape reception, DESTEMMING, CRUSHING, FERMENTATION, CLARIFICATION, FILTRATION, BLENDING, STABILIZATION, and BOTTLING—it generally entails operating PUMPS, adding FINING agents and other additions or PROCESSING AIDS, and almost constant cleaning (see HYGIENE). Cellars in which small barrels are used for both fermentation and maturation involve the most physical work, including filling, RACKING and moving barrels, TOPPING UP, and possibly STIRRING. See also ÉLEVAGE.

Celts, peoples who inhabited western Europe before the rise of ancient ROME. Many of them were introduced to wine by the Romans, when some were already skilled COOPERS.

The first clear evidence that wine drinking with its attendant rituals was penetrating the courts of the prehistoric BARBARIAN elites in western central Europe (eastern France, southern Germany, and Switzerland) appears in the archaeological record in the 6th century BCE.

Griffon-headed cauldrons, CRATERS, jugs and strainers, and fine painted Attic cups, all of which would have been used at a Greek SYMPOSIUM, were shipped to Mediterranean ports such as Massilia (Marseilles). From there they were transported along the navigable

RIVERS into the hinterland to be used in the complex systems of gift exchange which bound these peoples to the Greek and Etruscan traders of the south. Along with these trappings of civilization came wine. How much of it, if any, was at this stage Greek or Italian is difficult to tell. What is certain is that the large ceramic AMPHORAE in which the wine was transported inland were manufactured along the coast of southern France in the vicinity of Marseilles, suggesting, but not proving, that most of the wine consumed was locally manufactured.

The courts of the elite, places such as Mont Lassois on the main south–north trade route between Burgundy and Paris (where the celebrated Vix crater, a bronze vase 1.64 m/5.4 ft high and clearly made in ancient GREECE, was found), and Heuneburg in Germany, lasted for a comparatively short time. They were flourishing in the 530s and 520s BCE but had ceased to exist by the end of the next century as the old social order collapsed in a turmoil of unrest caused by migrating bands of Celts who were to thrust deep into Italy, Greece, and Türkiye.

By the end of the 3rd century BCE, a new order was beginning to emerge in the western Mediterranean. Rome was growing rapidly in power and had won a decisive victory over the CARTHAGINIANS in Spain, but their military involvement was to last for almost two centuries before the peninsula could be regarded as fully conquered. This meant a continuous movement of military detachments, supplies, and officials using the ports and the roads in southern France linking Italy and Spain. Inevitably the cities and the native tribes of Provence and Languedoc got used to this traffic and no doubt profited from it; so too did Roman entrepreneurs keen to exploit the new markets being opened up. For them the love of wine which the Celtic tribes of the interior so evidently possessed was a heaven-sent opportunity to offload, with profit, the considerable wine surpluses being generated by the large estates of northern and western Italy. As one contemporary writer somewhat incredulously remarked of the Celts of GAUL, ‘They will give you a slave for an amphora of wine thus exchanging the cupbearer for the cup.’ While

this does not necessarily imply the actual exchange rate, it shows which surpluses the two societies were prepared to exchange with each other for mutual benefit.

In the Celtic world it was important for those aspiring to power to host elaborate feasts to entertain their followers and others. The more exotic the commodities offered, the greater the status of the host. Wine from the south was in considerable demand and was avidly consumed. The drunken Celt who took his wine undiluted—something no civilized man would have done—was several times remarked upon by contemporary writers.

Wine was usually transported by sea in large ceramic amphorae made in distinctive styles and fabrics which can be quite closely dated and assigned to specific localities of manufacture. This means that it is possible to study the developing wine trade in some detail, and, since several of the estates produced amphorae with their own identifying stamps, individual marketing strategies can be identified. By studying the relative proportions of Italic and local amphorae in the successive levels of settlement sites in southern France, it is possible to show that throughout the 2nd century BCE, when Provence and Languedoc were finally annexed by Rome, there is little trace in the archaeological record that local wine was drunk at all. In parallel with this, the number of shipwrecks containing amphorae found off the southern French coast increases noticeably, presumably reflecting the corresponding increase in the volume of trade.

Once offloaded at ports such as Massilia and Narbo (Narbonne), the amphorae were transported inland by road or river. En route a *portorium* (or transport tax) was charged at each settlement through which the wine passed, trebling the price charged by the time it eventually reached the native consumers. From the borders of Provincia of ancient Rome, modern Provence, the wine penetrated the territory of the neighbouring tribes. At two locations, one just outside Toulouse and the other at Chalon-sur-Saône, substantial quantities of discarded Italian amphorae have been found. No precise count can now be made, but estimates in the tens of thousands are unlikely to be far from the truth. These must surely be major trans-

shipment points where wine was decanted into skins or BARRELS (for which the Celts of the CAHORS region were particularly famed) for the more arduous journeys by cart into the wild interior. Not all wine was decanted, however. Considerable numbers of amphorae have been recovered from major native *oppida* (towns) at Montmerlhe, Essalois, Jœuvres, and Mont-Beuvray between 20 and 100 km (12–62 miles) beyond the frontier. From here much of it passed into the hands of the local nobility to be consumed with relish in their lavish feasts.

The volume of wine imported into Gaul at this time is difficult to estimate in detail, but a conservative assessment suggests that it may have reached 100,000 hl/2.6 million gal a year. When it is remembered that the largest trading system operating in pre-industrial Europe—the Gascon wine trade to Britain and Flanders in the 14th century (see BORDEAUX)—was 750,000 hl/20 million gal a year, the intensity of the Roman operation can be appreciated.

By the end of the 2nd century BCE Italian wine was reaching all parts of France, mainly along the navigable rivers, but some, still in its amphorae, was being reloaded on to ships in the GIRONDE estuary to be transported along the Atlantic coast of France to Brittany. There much of it was consumed, but a small quantity was carried by Breton sailors on the last leg of its journey via Guernsey to the British port on Hengistbury Head, overlooking Christchurch harbour, constituting the earliest attested importation of wine to ENGLAND, or Britain. One wonders whether after such a journey it was even barely drinkable.

Cunliffe, B., *Greeks, Romans & Barbarians: Spheres of Interaction* (1988).

Tchernia, A., *Le Vin de l'Italie romaine* (1986).

Tchernia, A., 'Italian Wine in Gaul at the end of the Republic', in P. Garnsey et al. (eds.), *Trade in the Ancient Economy* (1983).

Cencibel, synonym for the Spanish black grape variety TEMPRANILLO, especially in central and southern Spain, notably in LA MANCHA and

VALDEPEÑAS, where it is the principal dark-skinned variety.

Central Coast, one of CALIFORNIA's umbrella AVAs, this sprawling wine region technically encompasses nearly all of the land from San Francisco to Los Angeles, inland from the coast almost to the CENTRAL VALLEY. In practice, the important and unique viticultural areas referenced by the name are concentrated in its midsection, the counties of MONTEREY, SAN LUIS OBISPO, and SANTA BARBARA.

Central Otago grows NEW ZEALAND's most southerly grapevines, some of them cultivated beyond the 45th parallel. It is New Zealand's only wine region with a CONTINENTAL CLIMATE and has greater diurnal and seasonal TEMPERATURE VARIABILITY than any other. The region is as dependent on Pinot Noir as Marlborough is for Sauvignon Blanc, representing 80% of the region's vines and 1,626 ha/4,018 acres planted. Pinot Gris is a distant second followed by Riesling.

Gibbston was, with Wanaka, one of the original areas to be planted with vines, as recently as the early 1980s. Gibbston is the coolest subregion and typically the last to be harvested. Alongside BANNOCKBURN in the Cromwell basin, it is regarded as the most prestigious subregion, though there are promising signs from the basin's Lowburn and Bendigo areas, producing some of the ripest styles. Central Otago's often voluptuous and intensely fruity Pinot Noir has helped put New Zealand red wine on the world map.

S.P.T.

Central Ranges Zone, broad Australian zone in NEW SOUTH WALES along the western slopes of the Great Dividing Range comprising the Cowra, Orange, and Mudgee regions.

Central Valley, refers in CALIFORNIA to a broad, fertile, sunny valley that grows more than half the fruits, vegetables, and nuts in the United States. Stretching about 80 km/50 miles across and 725 km/450 miles long, it is divided into the SACRAMENTO VALLEY in the

north, which produces small quantities of wine, and the hot, vast SAN JOAQUIN VALLEY in the south, which supplies the majority of the state's BULK WINE (and TABLE GRAPES and RAISINS). The Sacramento River from the north and the San Joaquin River from the south drain into the Central Valley Delta, which includes such AVAs as CLARKSBURG and, on slightly higher ground, LODI.

CHILE also has a Central Valley which includes the subregions (from north to south) Maipo, Rapel, Curicó, and Maule and which is used as an appellation for wines grown in more than one region.

Central Victoria Zone comprises the wine regions Bendigo, Goulburn Valley, Heathcote, Strathbogie Ranges, and Upper Goulburn in the Australian state of VICTORIA.

centrifugation, winemaking operation of CLARIFICATION using a centrifuge, typically employed in large wineries to quickly clarify wines or to clarify white grape juice before FERMENTATION. The equipment is expensive to buy and run, but the separation force induced by rotation of the centrifuge bowl at around 4,800 rpm is up to 6,000 times greater than that experienced during gravity SETTLING, considerably reducing the time taken to clarify the liquid. When used on juice, in which the difference in DENSITY between the solids and the liquid is smaller than in wine, it is often coupled with FLOTATION to improve the throughput.

A stack of *c.*250 conical discs in the centrifuge divides the feed into many thin layers so particles need to fall only a short distance before they hit a disc and slide down into the periphery of the bowl. Solids are further compacted there and then periodically discharged. Horizontal decanter centrifuges, which are able to process materials with a high solids content such as lees, are sometimes used, but the separation forces and product clarity are typically lower than with disc-stack centrifuges. S.N.

Centurian, CALIFORNIA vine cross with the same parentage as CARNELIAN but released three years later in 1975. The state's total acreage had fallen to 37 ha/92 acres by 2020, all in the central SAN JOAQUIN VALLEY. It has viticultural advantages over Carnelian but no organoleptic distinction.

cépage, French for VINE VARIETY. A VARIETAL wine, one that is sold by the name of the principal grape variety from which it is made, is known as a vin de cépage within France, a term which has had some pejorative sense in comparison with a geographically named wine which qualifies as AOC. High-quality vine varieties such as Syrah (as opposed to such traditional varieties as Carignan and Alicante Bouschet) are described as cépages améliorateurs, or 'improving varieties', in the south of France.

Cerasuolo di Vittoria is SICILY's only DOCG and takes its name from a town in the province of Ragusa in the south of the island. Grapes are grown on red sandy soils with a high ferrous content (see IRON). NERO D'AVOLA (up to 70%) with FRAPPATO (maximum 50%) form the blend of this wine for which the yield has sensibly been capped at 52 hl/ha. Wines that are released after 31 March in the second year following the harvest may be called Classico. In 2014 the DOC Vittoria was created, to allow for varietal bottlings of the increasingly popular Frappato, as well as Nero d'Avola and the white INZOLIA. W.S.

Cerceal, or Cerceal Branco, white Portuguese grape variety with high acidity found mainly in the DOURO, DÂO, and BAIRRADA. Not the same as the SERCIAL of MADEIRA.

Cercial is the BAIRRADA synonym for Cerceal Branco, also known as Cercial do Douro.

Cerdon. See BUGEY.

Cereza, quantitively very significant pink-skinned grape variety in ARGENTINA, where it is second only to Malbec in the total area planted: 26,195 ha/64,729 acres in 2020. A CROSS between CRIOLLA CHICA and MUSCAT OF ALEXANDRIA, and taking its name from the Spanish word for 'cherry', it produces mainly white and some rosé wine of extremely mediocre quality for early consumption within Argentina, typically sold in cardboard packs, as well as being used for GRAPE CONCENTRATE.

Cérons, historic (see BORDEAUX, history) but struggling sweet-white-wine appellation on the left bank of the GARONNE. Just north of BARSAC and SAUTERNES, it produces wines which rarely demonstrate either the finesse of the first or the concentration of the second of these two more famous appellations, possibly partly because much more generous YIELDS are allowed but also because selling prices make sacrifices for quality difficult. In effect, Cérons is a buffer zone between Barsac and the GRAVES, and its dry whites and reds are entitled to the Graves appellation. CLAY is slightly more common here than in Barsac and Sauternes, and the generally flatter land may also play a part in reducing the likelihood of BOTRYTIS. Only 20 ha/49 acres produced sweet whites in 2020. J.R. & J.L.

certified planting material, BUDWOOD, CUTTINGS, and GRAFTED VINES which have normally been through a form of quality assurance to ensure trueness to type, freedom from known VIRUS DISEASES and BACTERIAL DISEASES, and typically designated clonal origin. Various bodies, often government controlled, offer such certification programmes around the world. See CLONE, CLONAL SELECTION, and VINE IMPROVEMENT.

CERVIM, the Centro di Ricerca, Studi, Salvaguardia, Coordinamento e Valorizzazione per la Viticoltura Montana, is an organization created in 1987 under the auspices of the OIV to encourage the preservation of mountain winegrowing. Based in the Valle d'AOSTA of northern Italy, the group includes members in Austria, France, Germany, Greece, Portugal, Slovenia, Switzerland, and Spain, as well as one winery in PERU, in 2022. CERVIM members may use the trademark Cervim-Heroic Viticulture for wines grown at ELEVATIONS of at least 500 m/1,640 ft, gradients exceeding 30%, or on terraces, steep slopes, or small islands (such as Tenerife in the CANARY ISLANDS). Members also benefit from the group's research projects such as SCORPION, aimed at developing autonomous ROBOTS capable of precision PESTICIDE spraying in steep terrain as well as administering ULTRAVIOLET RADIATION treatments to replace AGROCHEMICALS.

www.cervim.org

Cesanese, the red grape variety of LAZIO. The superior Cesanese di Affile clone (once a minor ingredient in the cult wine Trinoro of southern Tuscany and now planted at Passopisciaro, its sister property on ETNA) is very slightly more common than Cesanese Comune, which has larger berries and is also known as Bonvino Nero. Total plantings of both were only 446 ha/1,102 acres in 2015.

César, minor vine speciality of the far north of Burgundy, where it can contribute backbone to such light, soft reds as IRANCY. DNA PROFILING at DAVIS suggested it is a progeny of PINOT and Argant.

Chablis is the uniquely steely, dry, ageworthy white wine of the most northern vineyards of BURGUNDY in north-east France, made, like

all fine white Burgundy, from Chardonnay grapes. Paradoxically, however, in the NEW WORLD, particularly in North America in whose vineyards a wine as austere as Chablis is virtually impossible to produce, the name Chablis has been borrowed as a GENERIC name for the most basic white wine. Happily that practice is now almost insignificant. The true Chablis appellation has increased considerably since the early 1990s and in 2020 included a total of 5,771 ha/14,260 acres of Chardonnay vineyard around the town of Chablis and 19 other villages and hamlets in the Yonne *département*, near the city of AUXERRE. Created in 1938, the Chablis appellation comprises four ranks, of which the top is GRAND CRU Chablis, with seven named vineyards. Then come the PREMIERS CRUS, including 79 vineyard names, many of which are rarely used; then Chablis, by far the most common and infuriatingly variable appellation; and finally Petit Chablis, the lowliest. The best vineyard sites are on the south-west-facing slopes of the valley of the Serein, the small river that flows through Chablis to join the Yonne.

Chablis is quite separate from the rest of Burgundy, divided from the CÔTE D'OR by the hills of the Morvan, so that BEAUNE, for example, is over 100 km/62 miles to the south. In fact, the vineyards of Chablis are much closer to CHAMPAGNE and its southernmost vineyards in the Aube *département* than to the rest of Burgundy, and until early in this century it was not unusual for wine from Chablis to find its way into the champagne makers' cellars in Reims and Épernay.

History

Although it was the Romans who introduced vines to Chablis, as to so many other parts of FRANCE, it was the medieval church, notably the Cistercian MONKS of the nearby abbey of Pontigny, who firmly established viticulture as an essential part of the rural economy, possibly even introducing the Chardonnay vine. (See BURGUNDY, history.)

Towards the end of the 19th century, the Yonne as a whole was a flourishing wine region, with some 40,000 ha/98,842 acres of vines. Vineyards lined the banks of the river Yonne, as far as Joigny and Sens. The best known of these Yonne wines was Chablis, and the name was used to describe the ample quantities of dry white wine then being transported with great convenience along the rivers Yonne and Seine to satisfy the thirsty Parisian market.

Three factors combined were responsible for the sharp decline in the vineyard area at the end of the 19th century. POWDERY MILDEW appeared in Chablis in 1886, though a cure had already been found; likewise for PHYLLOXERA, which first reached Chablis in 1887. However, many growers were reluctant to replant their vineyards, for the opening of the Paris–Lyons–Marseilles RAILWAY in 1856 considerably reduced their share of the Paris market. Thanks to the railways, Chablis lost its advantage of proximity to the capital and was simply unable to compete with the cheap wines of the MIDI, which could now be transported easily to the capital. Consequently the vineyard area gradually declined until it reached a mere 500 ha in the mid 1950s, before the fortunes of the appellation revived.

Climate

Climate has always played an important role in determining the success and quality of Chablis. Essentially the climate is semi-CONTINENTAL, with no maritime influence, so that the winters are long and hard and the summers often, but not always, fairly hot. There is all the climatic uncertainty, and therefore vintage variation, both in quality and quantity, of a vineyard far from the equator.

One key factor in determining how much wine will be produced is the possibility of spring FROSTS, which can damage young vine shoots. Depending on how advanced the vegetation is, the vineyards are vulnerable from the end of March until well into May. Since the end of the 1950s, after a decade of vintages particularly badly affected by frost, various methods of protection evolved. Heaters, or SMUDGE POTS, may be lit in the vineyards; they are expensive but efficient. The alternative technique of using SPRINKLERS to spray the vines with water from the moment the temperature drops to freezing point has also been increasingly practised. Electric cables, cleaner than smudge pots, may also be laid to raise ambient temperatures while taking advantage of France's reduced night tariffs. Such measures can be sufficiently effective to make the difference in some years between a crop of reasonable quantity and virtually no crop at all. It is now perfectly possible to make a viable living from vines in Chablis, whereas in the 1950s growers needed both eternal optimism and another crop, so polyculture was common.

Vineyard expansion

It was the development of effective frost protection in the early 1960s that encouraged today's increase in the vineyard area of Chablis, which has not been without controversy. The seven CLIMATS of Chablis Grand Cru total slightly over 100 ha/247 acres and are all on one slope facing south-west just outside the town. They are Les Clos, Blanchots, Bougros, Vaudésir, Valmur, Preuses, and Grenouilles. There is also, in true Burgundian fashion, an anomaly. The tiny vineyard of La Moutonne is partly in Vaudésir and partly in Preuses, but, for some illogical and doubtless bureaucratic reason, an official INAO decree confirming its status as a grand cru has never been issued, even though its wines certainly demonstrate that it qualifies.

Much of the dispute over the vineyard expansion has centred on the premiers crus. By the early 21st century there were 79 in all, totalling 778 ha/1,922 acres in 2020. Some are often seen on labels, while others are much more obscure, and some such as Vaudevey came into existence only with the expansion of the appellation. Their protagonists argue that they are on slopes that were planted before the phylloxera crisis and that their TERROIR closely resembles that of the long-established premiers crus. Some of the lesser-known vineyards may use a better-known umbrella name, so that for example L'Homme Mort may be sold as Fourchaume, as follows, with umbrella names followed by their associated premiers crus:

Mont de Milieu
Montée de Tonnerre: *Chapelot, Pied d'Aloue, Côte de Bréchain*
Fourchaume: *Vaupulent, Côte de Fontenay, L'Homme Mort, Vaulorent*
Vaillons: *Châtains, Séchet, Beugnons, Les Lys, Mélinots, Roncières, Les Epinottes*
Montmains: *Forêt, Butteaux*
Côte de Léchet
Beauroy: *Troesme, Côte de Savant*
Vauligneau
Vaudevey: *Vaux Ragons*

Vaucoupin
Vosgros: *Vaugiraut*
Les Fourneaux: *Morein, Côte de Prés Girots*
Côte de Vaubarousse
Berdiot
Chaume de Talvat
Côte de Jouan
Les Beauregards: *Côte de Cuissy*

By 2020 some 3,702 ha/9,148 acres of vineyard was planted for AOC Chablis, 12% more than ten years previously and considerably more than was originally envisaged when the appellation was granted, much of the arable land having been given over to vines. By 2020, 1,189 ha of a permitted 1,800 ha of Petit Chablis had been planted.

Notwithstanding the area's northern location and unusual climate, the unique flavour of Chablis wine is commonly claimed to be due to the soil. There remains no explanation of why this might be. The soil is often described as 'Kimmeridgian' though the term actually refers to bedrock, not the soil, and merely indicates the time at which it formed—during the Kimmeridgian age, a subdivision of the Jurassic period, 152–157 million years ago. Kimmeridgian LIMESTONES and MARLS, some with conspicuous fossils, underlie many of the vineyards. This includes the grand cru sites, which are all on the south-west-facing, optimal mid-slope locations (but see COLLUVIUM), whereas the more exposed sites at the top of the slopes yield Petit Chablis wines. They are underlain by a generally similar but younger bedrock usually referred to in a wine context as Portlandian, also a time term though one technically now obsolete (Tithonian is correct). The geology at Kimmeridge and at Portland in Dorset, south-west England, from where the names derive, is quite different from that at Chablis.

Viticultural practices in Chablis are very similar to those in the rest of Burgundy, apart from the overriding need to protect the vines from frost.

The use of oak

In the cellar, as elsewhere in France, winemaking techniques improved enormously in the late 20th century, so that there is a better understanding of such elements as MALOLACTIC CONVERSION and the need for TEMPERATURE CONTROL during fermentation. The most interesting and controversial aspect of vinification in Chablis is the use of OAK, Chablis being the one fine wine area where Chardonnay is not automatically oaked.

Those who want the purest flavour of Chablis, with the firm streak of acidity and the mineral quality that the French describe as *goût de pierre à fusil*, or gunflint, tend to favour STAINLESS STEEL. Domaine Louis Michel is generally considered to be the epitome of this style, although others who employ it successfully, but not necessarily exclusively, include Jean Durup, Domaine de Chantemerle, and Maison Régnard.

Other producers believe that oak barrels allow for a gentle oxygenation of the wine that adds an extra dimension of complexity to its flavour. Producers such as Domaine Vincent Dauvissat and Domaine Raveneau may ferment their wine in vats and then, once the alcoholic FERMENTATION is finished, move the wine into oak for a few months' BARREL MATURATION. Others, such as Domaine Jean Collet and Domaine Jean-Paul et Benoît Droin, ferment in barrel. The proportion of new barrels in a cellar in Chablis can vary. Some producers buy very few each year, wishing to avoid the marked vanilla flavours that new wood can impart, while Domaine William Fèvre, for example, depends on sister company BOUCHARD of Beaune for used barrels. While the 228-l Burgundy barrel is traditional, producers are increasingly moving towards larger barrels such as 500–600-l *demi-muids* or 50-hl *foudres*. Generally only grand cru and premier cru Chablis is matured in wood. Paradoxically it is not unknown for a Chablis that has seen no wood to take on, as it matures, a certain firm nuttiness that suggests some ageing in oak.

The Chablis market

Surprisingly, perhaps, until the early 1980s Chablis was hardly appreciated in France itself as most of it was sold on the export market, usually through the large NÉGOCIANTS of Burgundy, based mainly in Beaune. Currently nearly one-third of all Chablis is vinified by the local CO-OPERATIVE, La Chablisienne, which works well for its appellation. The trend, as elsewhere, has been for an increasing number of producers who originally sold their wine in bulk to négociants to bottle and sell their wine themselves. Some of them have even started their own négociant businesses.

Chablis has always been affected by significant variations in the size of the vintage, and prices have fluctuated accordingly (much more dramatically, for example, than in the more regulated but climatically similar Champagne market). However, some of the commercial instability has disappeared with the growth in the vineyard area so that there is more Chablis available to satisfy world demand. Generally Chablis is a more prosperous appellation than it was in the 1970s, for with the possibility of frost protection the growers are much more certain of making a viable living from their vines than ever before.

Chablis remains one of the great white wines of the world. It is sometimes overshadowed by the greater opulence of a fine Meursault or Corton-Charlemagne, but it has an individuality of its own that sets it apart from the great white burgundies of the Côte d'Or. There is a unique streak of steely acidity, a firm flintiness, and a mineral quality that is not found elsewhere in Burgundy. Like all great white burgundy, it benefits from, but all too rarely receives, BOTTLE AGEING. A premier cru will be at its best at ten years, while a grand cru could easily benefit from 15 or more years of maturation. A 1947 Côte de Léchet, not one of the best premiers crus but from a great vintage, was still showing a remarkable depth of flavour with the characteristic *goût de pierre à fusil* when it was 40 years old. Chacolí. Castilian spelling of the Basque wine TXAKOLI.

chai, French, and particularly Bordelais, term for a place where wine and occasionally brandy is stored, typically in BARREL. Thus a smart Bordeaux CHÂTEAU will have (perhaps) the château building itself with no direct winemaking function, a cuverie (see CUVE) in which fermentation takes place, a first-year *chai* in which the most recent vintage's crop undergoes BARREL AGEING, and a second-year *chai* to which it is moved at some point before the year's end in order to make way for the next year's crop. The NEW WORLD counterpart to the *chai* is sometimes called the barrel hall. See also CAVE.

chalk, a white, highly porous sedimentary rock (35–40% voids) made up of calcium carbonate, usually with impurities of clay and silica. Pale-coloured crumbly rocks and soils are often loosely called chalk, especially if they are CALCAREOUS. However, true chalk, which is relatively rare under vineyards, is dominated by the fossilized remains of coccolithophores, a marine alga that flourished during late Cretaceous times in the still, sunlit, warm ocean waters in what was to become northern Europe. The resulting sea-floor sediment eventually hardened to give the strikingly white rocks and soils that underlie vineyards in southern ENGLAND and parts of northern France. In CHAMPAGNE, the better vineyards are mostly on CLAYS, with only the longer roots reaching the underlying chalk.

As chalk weathers it releases CALCIUM and bicarbonate ions so that only the impurities remain to form a thin soil. Chalk-derived SOILS are valued in viticulture because of their excellent STRUCTURE and free DRAINAGE. However, the underlying chalk has the capacity to store substantial amounts of water. Because vine ROOTS can usually penetrate into the chalk bedrock, a moderated moisture supply is assured regardless of short-term fluctuations in RAINFALL. Most chalk soils are of low FERTILITY, resulting in restricted vine VIGOUR and naturally good CANOPY MICROCLIMATE.

See also ALBARIZA; and see DEACIDIFICATION for the use of chalk in winemaking, and CHALKY as a tasting term. R.E.W. & A.J.M.

Chalk Hill, California wine region and AVA north of Santa Rosa and south-east of Healdsburg. See SONOMA.

chalky, a TASTING TERM typically used metaphorically to describe a wine's TEXTURE, usually dry and finely grained like chalk dust. For some tasters it is an aspect of MINERALITY.

Chalone, small California wine region and AVA in the mountains east of the Salinas Valley. Chalone's reputation was made by the winery of the same name set high in the Gavilan Mountains, notably with Chardonnay, Pinot Blanc, and Pinot Noir. Although Chalone looks directly down to the Arroyo Seco AVA, it remains worlds apart in climate (being above the fog) and soils, which are a unique mix of crystal-laden CALCAREOUS rock and decomposed GRANITE. Despite sitting within Monterey County, Chalone does not fall within the bounds of the MONTEREY AVA and instead sits within the larger CENTRAL COAST AVA. A.Y.

Chalonnaise, Côte, red and white wine-producing region in the Saône-et-Loire *département* of BURGUNDY between the CÔTE D'OR and

the Mâconnais. The Côte Chalonnaise takes its name from the town of Chalon-sur-Saône, which had been an important CELTIC trading centre in ancient GAUL. As well as generic BOURGOGNE Côte Chalonnaise, mostly red from the Pinot Noir grape, there are five village appellations: MERCUREY and GIVRY produce mostly Pinot Noir with small quantities of white wine; MONTAGNY is exclusively a white-wine appellation growing the Chardonnay grape; RULLY offers both red and white wines and is a centre for the sparkling wine industry in a small way; while BOUZERON uniquely has its own appellation exclusively for the ALIGOTÉ grape.

Although the soils in the Côte Chalonnaise are similar to those of the Côte d'Or, being based on LIMESTONE with a complex admixture of other elements, the vineyards are more scattered since there is no regular escarpment to provide continuity of suitable slopes.

Viticultural practices are broadly similar to those in the Côte d'Or. Vinification is sometimes carried out in barrels, although only the best producers use any new OAK. Bottling normally takes place in the summer before the new vintage.

Maximum yields for Mercurey are the same as those for VILLAGE WINES in the Côte d'Or, whereas the other appellations of the Côte Chalonnaise may produce a little more. Although cheerfully fruity while young, few wines from this region have enough body to age well. J.T.C.M.

Chambertin, Chambertin-Clos de Bèze, Chapelle-Chambertin, Charmes-Chambertin, Griotte(s)-Chambertin, Latricières-Chambertin, Mazis-Chambertin, Mazoyères-Chambertin, and Ruchottes-Chambertin, great red GRANDS CRUS in Burgundy's CÔTE D'OR. For more details, see GEVREY-CHAMBERTIN.

Chambolle-Musigny, village and appellation of particular charm in the Côte de Nuits district of Burgundy producing red wines from Pinot Noir grapes. A fine Chambolle-Musigny has a rich, velvety

elegance which rivals the finesse of Vosne-Romanée or the power of Gevrey-Chambertin. There are two GRAND CRU vineyards, Le Musigny and Bonnes Mares (in part), and some fine PREMIERS CRUS, including the exceptional Les Amoureuses.

Le Musigny ranks with Romanée-Conti, La Tâche, Richebourg, Chambertin, and Chambertin-Clos de Bèze as one of the pinnacles of great burgundy (see DOMAINE DE LA ROMANÉE-CONTI, VOSNE-ROMANÉE, and GEVREY-CHAMBERTIN for details of these). The vineyard lies between the scrubland at the top of the slope and the upper part of CLOS DE VOUGEOT, on a slope of 8–10% which drains particularly well through the oolitic LIMESTONE. The soil is more CHALK than CLAY, covered by a fine SILT, a combination which leads to the exceptional grace and power of Le Musigny, an iron fist in a velvet glove.

Of the 10.7 ha/26 acres of Le Musigny which is split between Musigny, Petits Musigny, and La Combe d'Orveau, seven are owned by Domaine Comte de Vogüé. De Vogüé also produce a small amount of Musigny Blanc (previously declassified to Bourgogne Blanc while the vines were young).

Adjacent to Le Musigny lies the premier cru Les Amoureuses, whose reputation and price suggest that this vineyard is worthy of elevation to grand cru. If a little less powerful than Le Musigny itself, the wines of Les Amoureuses demonstrate a very similar style. The next most sought-after premier cru, and the largest, is Les Charmes, although CLIMATE CHANGE has had the effect of shunting quality up the hillside to Les Cras and Les Fuées.

The other grand cru of Chambolle Musigny is Bonnes Mares, situated to the north of the village and overflowing into MOREY-ST-DENIS. The wines show more sturdiness than silkiness, are less graceful than Le Musigny, but have evident power and structure. Bonnes Mares is noted for its ageing capacity. Ownership is spread over more than 30 proprietors, the largest being again de Vogüé. Other notable producers based in Chambolle-Musigny include Domaines Barthod, Roumier, and Mugnier.

See also CÔTE D'OR, and map under BURGUNDY. J.T.C.M.

Chambourcin is a dark-berried FRENCH HYBRID commercially available only since 1963 and popular in the 1970s, particularly around the mouth of the Loire. In 2019 France still grew a total of 498 ha/1,231 acres, mostly in the Loire Valley. This extremely vigorous, productive vine tolerates wet weather well, shows good resistance to DOWNY MILDEW, and produces better-quality wine than most hybrids, being deep coloured and full of relatively aromatic flavour. Its winter hardiness finds it well distributed, if not exactly common, in the US. It was successfully planted by Cassegrain in the warm, damp climate of Hastings Valley in NEW SOUTH WALES in Australia, a culture unfettered by anti-hybrid prejudice, and has since spread up and down Australia's east coast, including Queensland, with outbreaks elsewhere.

chambré, French word also used in English to describe a wine that has been deliberately warmed to room TEMPERATURE before serving (from *chambre*, 'room'). Most rooms nowadays are rather warmer than the ideal serving temperatures for most wines, however.

Champagne, name derived from the Latin term *campania*, originally used to describe the rolling open countryside just north of Rome (see CAMPANIA). In the early Middle Ages, it was applied to a province in north-east France (see map under FRANCE). It is now divided into the so-called 'Champagne pouilleuse', the once-barren but now cereal-growing CALCAREOUS plains east of Reims, and the 'Champagne viticole' (capital letters indicate the geographical descriptions, lower case is used for the wine).

Champagne, with its champagne towns Reims and Épernay, was the first region to make SPARKLING WINE in any quantity, and historically the name champagne became synonymous with the finest, although Champagne is now responsible for less than one bottle in 12 of total world production of all sparkling wine. In common with other French regions making fine wines, notably Burgundy and Bordeaux, champagne has formed the model for other

aspiring winemakers, especially in Australia and the west coast of the United States, employing the same grapes and the same SPARKLING WINEMAKING method as the French originals (known now as the TRADITIONAL METHOD).

History

Champagne was at the crossroads of two major trade routes, north–south between Flanders and Switzerland and east–west from Paris to the Rhine. Its position made it prosperous but also ensured that it has been fought over many times in the course of the past 1,500 years. One of the most important battles in history was fought at Châlons-sur-Marne (now Châlons-en-Champagne) in 455 CE, when Attila the Hun was finally repulsed. Subsequent battles included a savage civil war, the Fronde in the middle of the 17th century. As late as 1914 the famous 'Taxis de la Marne' brought French reinforcements from Paris to repulse the German invaders, who had (briefly) occupied Épernay and reached the outskirts of Reims. But successive conflicts merely interrupted the progress of the vineyard.

Although there are numerous legends concerning earlier vineyards, the first serious mention is at the time of St Rémi at the end of the 5th century CE. For nearly eight centuries after Clovis, first king of the Francs, was baptized in Reims in 496, the city's position as the spiritual centre of France naturally boosted its fame.

Vines had already been planted around the city, mainly by the numerous local abbeys and by the local nobility. But until the 17th century there was no generic 'vin de Champagne'. Since the 9th century, wines from the MONTAGNE DE REIMS south of the city had been known as *vins de la montagne*, those from the Marne Valley as *vins de la rivière*, or river wines. A number of villages, notably Bouzy and Verzenay on the Montagne and Aÿ and Épernay in the Marne Valley, were already being singled out for the quality of their wines. The wine trade was centred on Reims and Châlons-sur-Marne, and the wines had the great advantage of immediate access to the Marne, which joined the Seine just east of PARIS (see RIVERS).

But the wines did not sparkle: they were light, pinkish still wines made from the Pinot Noir grape. In the last half of the 17th century, winemaking greatly improved under the auspices of leading clerical winemakers, led by Dom PÉRIGNON, who transformed the Abbey of Hautvillers, above Épernay, into the region's leading centre of

viticultural progress. The wines' fame grew greatly in the second half of the 17th century when they were introduced to the Court of Versailles, notably by the Marquis de Sillery, a large landowner in the region, and by the Marquis de St-Évremond, who introduced champagne to London society after he was banished to Britain in 1662.

In the cold winters normal in the region, the wines had a tendency to stop FERMENTATION and then to start refermenting in the spring. For a long time this was considered something of a nuisance, as the resulting release of CARBON DIOXIDE was often strong enough to break the flimsy bottles normal at the time. The development of stronger BOTTLES by British glassmakers permitted drinkers to enjoy the resulting sparkle. Indeed it was the café society of London, encouraged by St-Évremond, which probably first enjoyed true 'sparkling champagne' (see contemporary references in ENGLISH LITERATURE).

The habit was taken up by the licentious court round the duke of Orléans, who became regent of France after the death of Louis XIV in 1715, but serious winemakers (and their clients) continued to believe that sparkling champagne was inferior to the still wines of the region. Moreover even the stronger bottles could not reliably withstand the pressure generated by the SECOND FERMENTATION. So, throughout the 18th century, only a few thousand bottles were produced every year, and up to half of them would break.

The champagne business we know today was born in the first 40 years of the 19th century. The first notable step was taken by Madame (VEUVE) CLICQUOT. One of her employees developed the system of PUPITRES to assist in the REMUAGE process. CORKS were improved, and a corking machine developed. Understanding, and then mastering, the second fermentation took longer. The scientist and minister CHAPTAL had understood that 'sparkling wines owe their tendency to sparkle only to the fact that they have been enclosed in a bottle before they have completed their fermentation'. But it took a young pharmacist from Châlons-sur-Marne, Jean-Baptiste François, to enable winemakers to measure the precise quantity of sugar required

to induce a second fermentation in the bottle without inducing an explosive force.

François died in 1838, shortly after he had published his formulae. But within a generation Champagne had become the home of the world's first 'wine industry', one dominated by a number of internationally famous BRAND names. Most of these were those of young entrepreneurs from the Rhineland, such as Messrs KRUG, BOLLINGER, and ROEDERER, who showed greater commercial nous than the local merchants, only a few of whom, apart from Madame Clicquot and Monsieur MOËT, survived.

But for over half a century, until well into the 1950s, Champagne suffered from a number of problems which clouded its earlier successes. The important Russian market collapsed in 1917, and two World Wars, separated by the slump, closed the export markets on which the region depended so heavily. The arrival of PHYLLOXERA in Champagne in 1890 intensified competition from other sparkling wines, from Germany as well as from other areas of France, and intensified the fraudulent habits of some of the region's more unscrupulous merchants, who were wont to import juice and wine for bottling and sale as champagne.

The mood darkened further in 1911, when the first attempts to define the region entitled to produce champagne were introduced. The initial plan's exclusion of the Aube, a region 112 km/70 miles south-east of Épernay, incited Aube farmers to riot; this is turn led some members of the French government to suppress the delimitation entirely, which provoked the infamous April 1911 riots in the Marne. In the end the delimitation was retained, and eventually the Aube was included as a separate 'second zone', although it was included in the main appellation when the boundaries were finally fixed in 1927.

The events of 1911 shook the whole winemaking community, and 25 years later the resulting desire for common action resulted in the combined group of growers and merchants known as the Commission de Châlons, set up in 1935 under the impetus of the remarkable Robert-Jean de Vogüé, head of Moët, and Maurice Doyard, who was

able to rally the growers. At a time when growers were virtually giving away their grapes, the Commission provided them with some stability. Six years later, the desire for joint action led to the formation of the CIVC, the Comité Interprofessionnel du Vin de Champagne, the pioneering attempt, much copied elsewhere, to provide winemaking regions with an organization that would represent all the interests involved.

For 60 years from 1950, the region enjoyed unprecedented prosperity, with sales peaking in 2007 at almost 340 million bottles. Traditional export markets, such as Britain, the United States, Belgium, Japan, and Switzerland, took increasing quantities. Nevertheless the French market has long consumed more champagne than all export markets and accounts for roughly half of total sales by volume. Traditional brands have been less dominant in the domestic market than outside France, where they account for nearly 90% of sales. In recent decades, however, grower champagnes have increasingly gained prominence in export markets around the world, influencing consumer perception despite representing a small fraction of market share.

In the domestic market, nearly half of total sales are made by individual GROWERS, CO-OPERATIVES, and co-operative unions. The first co-operatives in Champagne were founded just before the First World War and grew rapidly in the early 1960s. Today there are 140 co-operatives, some of whom press grapes and make base wines to supply négociant houses, with others making champagnes that can either be sold under their own brands or returned to members for sale under their own label, which is signified by the letters RC before the grower's code on the label. The largest co-operative unions, each of which represents thousands of growers, have become major forces, both in supplying buyers' own brands and promoting brands of their own.

The competition from the co-operatives added to the pressure on the (usually family-owned) MERCHANTS. In the 1960s and 1970s, Moët & Chandon absorbed Mercier and Ruinart, the latter the oldest firm in the region; that union became the basis for LVMH, today by far the

dominant grouping in Champagne. The growers' increasing power was reflected in a rapid rise of grape prices during the 1980s, and while the prices had up until then been dictated by the CIVC, in 1990 the market was freed and buyers allowed to negotiate pricing directly with growers.

Geography and climate

The region permitted to call its wines 'champagne' was strictly defined by law in 1927. It sprawls from Charly-sur-Marne a mere 50 km/30 miles east of Paris along the Vallée de la Marne subregion to the Montagne de Reims subregion and south from Épernay along the Côte des Blancs and its southern extension, the Côte de Sézanne. A separate subregion is the Côte des Bar in the Aube, 112 km south-east of Épernay. While there was a proposal in 2007 to add 45 new communes to the appellation, this has not taken place. In 2020, the appellation comprised roughly 34,300 ha/84,750 acres, up from the 1993 total of 27,500 ha: 66% in the Marne; 10% in the Aisne; and 23% in the Aube. Only one-tenth of the vines are owned by merchants, who can now add to their holdings only under very strict conditions. The remainder is owned by about 16,000 growers (far fewer than there used to be), many of whom own less than a hectare of vines.

Much of the appellation—and Champagne is now the only major French region to have just one appellation—and all the better CRUS are on the slopes of the hills typical of the region. The vines' roots dig deep into CALCAREOUS depths, providing ideal conditions of DRAINAGE and HUMIDITY: while most of the appellation lies on a bedrock of chalk from the Late Cretaceous, the Aube's Côte des Bar is on Kimmeridgian MARL and LIMESTONE, like its neighbour Chablis. The Champagne vineyard's exposure to the cold northern winter inevitably makes grape-growing a precarious operation, with the quality of the wines varying from year to year. As a result, champagne is traditionally a wine blended not only from a number of villages and grape varieties but also from several vintages. The poverty of the soil requires constant addition of FERTILIZER, either the *cendres noirs*, the natural compost found on the region's hilltops, or, until it was outlawed in the late 1990s, finely ground (and curiously multicoloured) household rubbish from Reims or even Paris.

The different qualities of grapes from the region's 319 widely spread crus led to the establishment in 1911 of a scale of prices

according to the status of each commune, called the *échelle des crus*. Since 1990 these prices have no longer been controlled, but in general grapes from the 17 grand cru communes continue to fetch higher prices than those from the 42 communes called premiers crus.

Vine varieties

In the past, a number of grape varieties were planted in Champagne. But today almost the whole vineyard is planted with three: Pinot Noir, Pinot Meunier, and Chardonnay. Pinot Noir, which accounts for just over one-third of the total acreage, is no longer as dominant as it was but still accounts for 38% of all plantings and often provides both structure and complexity to a blend. It thrives most notably on the slopes around the Montagne de Reims, but it's also the primary grape variety of the Aube's Côte des Bar, in the south. Chardonnay, planted on 30% of the total vineyard, has been traditionally grown on the east-facing slopes of the Côte des Blancs but has proved suitable in many other subregions, especially the Côte de Sézanne. In Champagne it grows vigorously and buds early, thus making it susceptible to spring FROSTS. It imparts a certain austerity and elegance to young champagnes, but it is long lived and matures to a fine fruitiness. The remaining 32% is planted with PINOT MEUNIER, a variety much more important in Champagne than anywhere else, particularly in the Marne Valley. It provides many champagnes with an early-maturing richness and fruitiness. Four other grape varieties —Pinot Blanc, Pinot Gris, Arbane, and PETIT MESLIER—are also authorized in the appellation, but all together account for less than 0.3% of total plantings.

Thanks to new CLONES and viticultural methods, the YIELD of grapes has grown greatly: from an average of 3,670 kg/ha in the 1940s to a fixed base of 10,400 kg/ha today, which can be revised upwards or downwards depending on the quality of the year. The first limit was set in 1935. Nowadays, the Comité Champagne sets the yield each year, usually well below the maximum limit set by EU regulations, which is 15,500 kg/ha. Since 1992, 160 (rather than the earlier limit of 150) kg of grapes are required to produce 102 l of juice, which means that the maximum permitted yield is 65 hl/ha.

VINE DENSITY is notably high, and vines are often replanted after 25–30 years. The grapes are usually picked in September, on dates now fixed per grape variety village by village but which are in general

becoming earlier as a result of CLIMATE CHANGE. (ACID levels have also been falling.) They cannot be harvested unless they contain that year's fixed minimum level of POTENTIAL ALCOHOL. But since the level can be as low as 8%, sugar may be added (see CHAPTALIZATION) to boost the alcohol level to 11% after the alcoholic fermentation, and the second fermentation supplements the final ALCOHOLIC STRENGTH by up to another 1.5%. Most champagne is about 12.5% alcohol.

Winemaking

The pressing of the grapes is difficult, since the juice of what is to be a white wine must not be tainted by the skin of the mainly black grapes used. The traditional champagne PRESS is a vertical basket press, holding 4,000 kg/8,800 lb of grapes, a quantity known as a *marc* and a standard unit of measurement in the region. These presses are also called Coquard presses after the name of the manufacturer. A number of other types of press have since been introduced, although the traditional press is valued for the quality of its pressing and is still in widespread use.

Since 1990, all pressing centres have had to comply with certain minimum standards. Traditionally 2,666 l/704 gal were extracted from every *marc*: the first 2,050 l were the *cuvée*, the next 410 l the *premières tailles*, while the final 206 l were the *deuxièmes tailles*. The total yield has now been reduced by 115 l to 2,550 l per 4,000 kg (or 102 l per 160 kg, as the INAO regulations express it) and the *deuxièmes tailles* abolished.

The juice is allowed to settle for 12–48 hours, at a low temperature. A small but increasing number of producers ferment the juice in OAK, but the overwhelming majority of the grapes are fermented in STAINLESS STEEL vats holding 50–1,200 hl (1,320–31,700 gal). The fermentation TEMPERATURE also varies, between 12 and 25 °C/54–77 °F. Most winemakers use a YEAST strain specially developed by the CIVC.

The resulting base wines are called *vins clairs*, and most, but by no means all, undergo MALOLACTIC CONVERSION immediately after the first fermentation. Traditionally champagne has been made from wines from a number of vineyards, and a major part of the work of a *chef de cave* in a champagne house is the art of blending, but many growers (and a few firms) make wines from a single commune or vineyard. Major firms often use wines from up to 200 communes for their blend. They also use 10–50% of *vins de réserve* from earlier vintages, generally stored in stainless steel or concrete vats. Before

the wine is bottled, a measured dose of bottling liquor (*liqueur de tirage*), a mixture of wine, sugar, and specially developed yeasts, is added to the wine. The bottles are then capped, usually with a plastic-lined crown cap. Following TIRAGE, LEES CONTACT, RIDDLING, and DISGORGEMENT, a sweetening DOSAGE is usually added before final corking. A few champagnes are sold without any added sugar at all; most are BRUT.

For more information, see in SPARKLING WINEMAKING, traditional method.

Styles of champagne

Champagne comes in myriad styles. The broadest style category is by the colour of the grapes used: while most champagnes blend white and black varieties, BLANC DE BLANCS is made exclusively from the Chardonnay grape, while BLANC DE NOIRS is made exclusively from black grapes.

This century has seen a FASHION for rosé champagne made either by adding a small proportion of red wine to the blend or, less usually, by letting the juice remain in contact with the grape skins for a short time during fermentation.

Most champagnes are multi-vintage blends, with no age statement on the label, though most producers also make single-vintage champagnes. Historically made three or four times in every decade, vintage cuvées are often made more frequently now, partially due to the warming climate but also as a stylistic choice. While there is nothing intrinsically superior about a champagne from a single vintage, in practice these are often made from a special selection of grapes. All the major firms have also now followed the example of Dom Pérignon (originally made by Moët & Chandon) and Roederer with its Cristal bottling and produce 'luxury', 'de luxe', or PRESTIGE CUVÉES to show their house styles at their best. These are usually, but not always, also vintage-dated.

Champagne producers also label their sparkling wines by sweetness level. By far the most common style is Brut, with a maximum permitted RESIDUAL SUGAR of 12 g/l. Wines with residual sugar less than 6 g/l may be called Extra Brut, while those without any added dosage at all, and with residual sugar under 3 g/l, may be called Brut Nature, Non Dosé, or Zéro Dosage. These bone-dry wines have become more common as warmer vintages have increased grape maturity, but some champagne specialists believe some dosage is essential for a well-balanced champagne and are concerned that undosed champagnes cannot benefit from the effects of any MAILLARD

REACTION. For a listing of the full range of sweetness levels allowed, see DOSAGE.

Champagne labels also include a code printed next to the registered number of the bottler that indicates the type of company that issued the wine:

NM: négociant-manipulant, one of the big houses/firms/négociants
RM: récoltant-manipulant, a grower who makes his or her own wine
CM: coopérative de manipulation, one of the co-operatives
RC: récoltant-coopérateur, grower selling wine made by a co-op
MA: marque d'acheteur, buyer's own brand
SR: société de récoltant, a small family company (rare)
R: récoltant, very small-scale growers (very rare).

Some producers also include a disgorgement date on the back label, as many houses disgorge their wines several times a year or even more frequently, and the flavours can change the longer the wines sit on the lees. A few houses release late-disgorged versions of certain cuvées, such as Bollinger's R.D. (meaning 'recently disgorged') or Jacquesson's D.T. (meaning 'dégorgement tardif'), to highlight the character derived from extra time on the lees.

The small proportion of still wines made in the region are sold under the appellations Coteaux CHAMPENOIS and the rare pink ROSÉ DES RICEYS. RATAFIA de Champagne is a local fortified apéritif.

champagne method. See TRADITIONAL METHOD.

Champenois, Coteaux, appellation used for the relatively rare still wines of CHAMPAGNE in northern France, covering the same geographical area as the sparkling-wine appellation. For every one bottle of still white Coteaux Champenois produced, perhaps 20 of still red Coteaux Champenois are produced (in a good vintage) and 16,000 bottles of sparkling champagne. The wines of this cool region are generally high in acidity and light in body, although the best are becoming richer and more complex as a result of both CLIMATE CHANGE and improved winemaking and viticultural techniques. The village of Bouzy on the MONTAGNE DE REIMS has a particular reputation for its red Coteaux Champenois, partly perhaps because of the appeal of the name Bouzy Rouge, as do Aÿ, Cumières, and Ambonnay. These red wines are typically produced only in the ripest vintages, usually from Pinot Noir but sometimes Pinot Meunier. Due to their lower yields and specialized production, they tend to be priced similarly to the region's sparkling wines.

Chamusca, DOP subregion of TEJO in central southern Portugal.

Chancellor, productive but minor red FRENCH HYBRID developed from two SEIBEL parents. It was long known as Seibel 7053 but was named Chancellor in NEW YORK in 1970. Encountered occasionally in the US.

Changins, federal viticultural research station near Nyon on Lake Geneva, western SWITZERLAND, established in the late 19th century and now part of AGROSCOPE.

Changyu. Changyu Pioneer Wine Co. is China's oldest and largest wine producer and, according to one independent analysis of 2010 turnover, was the world's fourth biggest wine company. It was founded in Yantai, Shandong province, in 1892 by Zhang Bishi, an officer in the Qing government. He introduced VITIS VINIFERA varieties from Europe in 1896. The winemaker then was Maximilian, son of Baron Auguste Wilhelm von Babo, founder of the pioneering viticultural college KLOSTERNEUBERG.

In the 1950s, Premier Zhou Enlai presented Changyu brandy as a diplomatic gift to the Geneva Conference delegates, recorded as 'diplomacy of Gold Medal brandy'. Chairman Mao instructed Changyu to develop its wine production 'so the people may enjoy a bit more wine'. Today it claims to have a total of 20,000 ha/49,400 acres of vineyard potential and an overall production capacity of 200,000 tonnes, much of it focused on basic and mid-market lines.

As for its premium production facilities, in 2002 the company formed a JOINT VENTURE with the French CASTEL group in Yantai to establish Chateau Changyu Castel winery, signalling a new era for Chinese wine in which the word CHÂTEAU takes on the special significance of a dedicated wine estate with TOURISM potential. The primary grape variety is CABERNET GERNISCHT. In 2006, Changyu and Aurora Icewine Co. of Canada built the Golden Icewine Valley in Liaoning Province, capable, it is claimed, of producing half of the world's ICEWINE. Its vineyard holdings of about 333 ha/820 acres are dominated by VIDAL. Thanks to the LAKE EFFECT, winters are cold but not too dry. In 2007 the company used investments from the US, Italy, and Portugal, as well as China, to establish Chateau Changyu AFIP Global north-east of Beijing, with 200 ha of vineyard dedicated principally to upmarket varietal Cabernet Sauvignon and Chardonnay. Chateau Changyu Baron Balboa was built in the extravagant image of a 19th-century French château in Xinjiang in the far west of China with 333 ha of vineyards and a NURSERY planned. Chateau Changyu Moser XV is a joint venture with LENZ MOSER of Austria in Ningxia,

while Chateau Changyu Rena in Shaanxi is Tuscan-inspired and has what is claimed to be the largest underground wine cellar in Asia.

Construction of two more production facilities started in the mid 2010s in Yantai: Chateau Tinlot, named after former OIV chairman Robert Tinlot; and Chateau Koya, dedicated to brandy production (Changyu acquired a cognac house in 2013). They also acquired Kilikanoon Wines in Australia, Viña Indómita in Chile, Marqués del Atrio in Spain, and Ch Mirefleurs in Bordeaux. In 2020, with Tencent, Changyu developed the first national BLOCKCHAIN traceability platform that connects consumer verification with anti-counterfeiting measures (see AUTHENTICATION). Changyu claim to have lifted thousands of farmers out of poverty thanks to their grape contracts. Y.S.

Chapoutier, family-owned merchant-grower based at Tain-l'Hermitage in France's northern RHÔNE. One of the Rhône Valley's great names, established in 1808 and with 32 ha/80 acres of precious HERMITAGE vineyard, it languished somewhat in the late 20th century. During the 1980s, when Chapoutier's peers (GUIGAL and Jaboulet, for example) and numerous small growers were catching the imagination of the wine world with the improving quality of their wines, Chapoutier wines stood out precisely because they seemed unexceptional by comparison. This situation changed dramatically in 1990 when Max Chapoutier's son Michel took over the running of the company, with outspoken passion and an early devotion to BIODYNAMIC VITICULTURE and a real determination to express TERROIR. In 1996, the firm became the first wine producer to have labels in Braille. But what really distinguishes the company is its combination of high-quality wines, often vineyard-designated, and almost restless vineyard acquisition, not just in the Rhône Valley but then Roussillon, Australia, Alsace, and Portugal.

By 2021 Chapoutier owned 1,242 ha/3,069 acres of land, of which about 500 ha/1,235 acres are planted with vines producing 10.7 million bottles. Currently working in this family business are Michel, Corinne, Mathilde, and Maxime Chapoutier.

Walls, M., *Wines of the Rhône* (2021).

Chaptal, Jean-Antoine (1756–1832), French chemist, statesman, and polymath who rose from humble beginnings to be appointed Minister of the Interior under Napoleon. He was the son of an apothecary and studied chemistry at the University of MONTPELLIER, where a Chair of Chemistry was founded for him in 1781. In 1798 he was elected a member of the Chemistry Section of the Institut de France and was a leading figure of early 19th century industrialization in France, becoming first President of the Société d'encouragement pour l'industrie nationale and one of the main organizers of the Paris Expositions in 1801, 1802, and 1806. He is best known in wine circles for his *l'Art de faire le vin* (1807) and his support for the concept of increasing the ALCOHOLIC STRENGTH of wine by adding sugar to the must, the procedure now known as CHAPTALIZATION. After the French Revolution of 1789, there was a considerable increase in the amount of poor-quality wine made in France. This provided the incentive for Chaptal to compile his famous *Traité théorique et pratique sur la culture de la vigne* (1801). As a practical scientist Chaptal was particularly concerned at the declining reputation of French wines, increasing ADULTERATION AND FRAUD in the wine trade, and ignorance on the part of many French wine producers about the scientific advances that could help them. He firmly believed that it was perfectly natural, and desirable, to add sugar to MUST in order to improve it. Although he encouraged farmers to use GRAPE CONCENTRATE, he recognized that sugar from cane or beet was also capable of having a similar effect. Chaptal's treatise synthesizing beneficial winemaking techniques current at the beginning of the 19th century marked a turning point in the history of wine technology. It was translated into Italian, Spanish, German, and Hungarian. Two American versions appeared, and James BUSBY published a translation in Australia in 1825. P.T.H.U.

Gough, J. B., 'Winecraft and chemistry in 18th century France: Chaptal and the invention of chaptalization', *Technology and Culture*, 39 (1998), 74–104.

chaptalization, common winemaking practice, named after its French promulgator Jean-Antoine CHAPTAL, whereby the final ALCOHOLIC STRENGTH of a wine is increased by the addition of sugar to the grape juice or MUST, before and/or during FERMENTATION, although if it is added before the higher sugar level will make it harder for the YEAST to multiply. Contrary to popular belief, Chaptal did not invent the process, which had been the subject of common experiment, not least by the innovative French chemist Pierre-Joseph Macquer.

Although the practice is still commonplace in northern Europe, potential alcoholic strength is increasingly raised by adding products other than beet or cane sugar (particularly grape products of which there is often a surplus in many wine regions). See ENRICHMENT for more details.

In 1993, the EU, concerned about its wine SURPLUS, officially announced its disapproval of chaptalization and its intention to curb the practice because it tended to encourage higher YIELDS. Although this announcement made little difference to winemaking practices, chaptalization, once routine in northern Europe, is becoming less common, partly because grapes tend to be picked later and riper, perhaps partly because of CLIMATE CHANGE.

Producers of Pinot Noir, most notably in Burgundy but also in Oregon and elsewhere, often add sugar during alcoholic fermentation, particularly towards the end, even if some might not readily confess to it. The aim is not primarily to increase the final alcohol level but to extend the fermentation and thereby improve the

flavour and texture of the wine. It is said that earlier picking followed by this fractional chaptalization (which is less disruptive to yeast metabolism) often produces better results than fruit picked later with higher sugar levels.

Regulation (EU) No 1308/2013 of the European Parliament and of the Council of 17 December 2013.

char, term sometimes used of barrels. See TOAST.

Charbono, the California name for the virtually extinct DOUCE NOIRE of the Savoie region in the French Alps, also known as Corbeau and Charbonneau. Charbono clings to existence on 30 ha/74 acres on the North Coast, especially in the Napa Valley. As varietal wine it can be difficult to distinguish from Barbera grown under similar circumstances. DNA PROFILING has shown it is identical to the BONARDA of Argentina.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

charcoal, or oenological charcoal, adsorbent material occasionally used in wine processing to remove COLOUR and off-flavours caused by BOTRYTIS, SOUR ROT, and SMOKE TAINT. Charcoal is obtained by the dry distillation of wood or other carbon-rich animal and plant materials. The sort of charcoal most frequently used in winemaking is generally known as activated carbon, which has been processed to increase its surface area and its capacity for adsorption.

In winemaking it is used mainly to adsorb the colloidal pigment polymers responsible for amber or brown colours in white wines, for example in the manufacture of Pale Cream SHERRY, or to lighten the

colour of MUST destined for rosé wines. Off-flavours in wine are occasionally removed using a grade of oenological charcoal with a smaller pore size, transforming an unsaleable wine into a neutral one for use in a basic blend. However, this may have an extremely negative effect on the quality of the wine by removing positive colour, flavour, and aroma compounds.

AWRI, 'Treating smoke-affected grape juice with activated carbon'. www.awri.com.au/wp-content/uploads/2021/02/Treating-smoke-affected-grape-juice-with-activated-carbon.pdf.

Chardonel, cunningly named vine CROSS of SEYVAL BLANC and CHARDONNAY made at New York State's Geneva experimental station (see CORNELL) in 1953. Originally tested in eastern US under the name GW9, it was named and released only in 1990. The variety is more resistant to WINTER FREEZE, POWDERY MILDEW, and BOTRYTIS than Chardonnay and is planted to a limited extent in cooler American states. Wines may resemble either Seyval Blanc or Chardonnay.

Chardonnay, a name so familiar to wine lovers around the world that many do not realize that it is the name of a white grape variety. In its Burgundian homeland, Chardonnay has long been the sole vine responsible for all of the finest white BURGUNDY. As such, in a region devoted to geographical labelling, its name was known only to vine-growers. All this changed with the advent of VARIETAL labelling in the late 20th century, when Chardonnay virtually became a BRAND. It is perhaps fitting that a variety so governed by the whims of FASHION should have seen considerable stylistic changes in the sorts of wine sought by its legion of fans. Until the mid 1990s, rich, oaky varietals were the height of modishness, but this has been followed by a trend towards leaner, more appetizing, and definitely less oak-dominated Chardonnays.

Chardonnay-mania reached a peak in the late 1980s, and the variety was subsequently planted so widely that a glut was assured in the late 1990s. The reaction to this glut led to a shortage of Chardonnay in the early 21st century in Australia, for example. There is hardly a country in which wine is produced that does not at least try to produce commercially acceptable Chardonnay in marketable quantities. During a single decade, the 1980s, the world's total area planted with Chardonnay vines quadrupled, to nearly 100,000 ha/247,000 acres—and by the mid 2000s it had surpassed 174,000 ha/430,000 acres. According to an OIV report in 2017, total global plantings were 210,000 ha, although the rate of increase had definitely slowed, thanks to what has been called the 'Bridget Jones effect', by which Chardonnay came to be associated with mass-market demand (see ABC). So popular is Chardonnay that synonyms are rarely used (although some Austrians in Styria persist with their name Morillon). The wine's relatively high level of alcohol, which can often taste slightly sweet, probably played a part in this popularity, as for a time did the obvious appeal of the OAK so often used in making Chardonnay. But it is not just wine drinkers who appreciate the broad, easy-to-appreciate if difficult-to-describe charms of golden Chardonnay. (The AWRI's initiative, analysing the component parts of each major variety's flavour, found Chardonnay a particularly nebulous target, identifying flavour compounds also found in, among other things, raspberries, vanilla, tropical fruits, peaches, tomatoes, tobacco, tea, and rose petals.)

Vine-growers appreciate the ease with which, in a wide range of climates, they can coax relatively high yields from this vine, whose natural VIGOUR may need to be curbed by either dense planting, low-vigour ROOTSTOCKS or CANOPY MANAGEMENT. Wine quality is severely prejudiced, however, at yields above 80 hl/ha (4.5 tons/acre), and yields of 30 hl/ha or lower are usually needed for seriously fine wine. Growers' only major reservation is that it buds quite early, just after Pinot Noir, which regularly puts the coolest vineyards—those of Chablis, CHAMPAGNE, and Chile's CASABLANCA Valley, for example—at risk from spring FROSTS. It can suffer from COULURE and occasionally

MILLERANDAGE, and the grapes' relatively thin skins can encourage rot if there is rain at harvest time, but it can thrive in climates as diverse as those of CHABLIS in northern France and Australia's hot RIVERLAND. Picking time is critical for, unlike Cabernet Sauvignon, Chardonnay can quickly lose its crucial acidity in the latter stages of ripening.

Winemakers love Chardonnay for its reliably high ripeness levels and its malleability. It will happily respond to a far wider range of winemaking techniques than most white varieties. The Mosel or Vouvray winemaking recipe of a long, cool fermentation followed by early bottling can be applied to Chardonnay. Or it can be treated to BARREL FERMENTATION and/or BARREL MATURATION, some of the highest-quality fruit being able to stand up to new oak. It accommodates each individual winemaker's policy on the second, softening MALOLACTIC CONVERSION and LEES STIRRING without demur. Chardonnay is also a vital ingredient in most of the world's best SPARKLING WINE, not just in Champagne, demonstrating its ability to age in bottle even when picked early. And, picked late, it has even been known to produce some creditable BOTRYTIZED wines, notably in the Mâconnais, Romania, and New Zealand. Chardonnay blends happily with other less fashionable, cheaper varieties such as Chenin Blanc, Sémillon, or Colombard to meet demand or PRICE POINTS at the lower end of the market. But perhaps this is because its own character is, unlike that of the other ultra-fashionable white, Sauvignon Blanc, not too pronounced. Chardonnay from young or over-productive vines can taste almost aqueous. Basic Chardonnay may be vaguely fruity (apples or melons), but, at its best, Chardonnay, like Pinot Noir, is merely a vehicle for the character of the vineyard in which it is grown (see TERROIR). As in many other ambitious wines fashioned in the image of top white burgundy, its 'flavour' has sometimes been that of the oak in which it was matured or the relics of the winemaking techniques used (see above). When the vineyard site is right, yields not too high, acid not too low, and winemaking skilled, Chardonnay can produce thrilling, savoury, dry, full-bodied wines that will continue to improve in bottle for one, two, or, exceptionally, more decades but —unlike Riesling and the best, nobly rotten Chenin Blanc and

Sémillon—it is not a variety capable of making whites for the very long term, and white burgundies, in particular, have shown a tendency to PREMATURE OXIDATION.

Chardonnay's origins were long considered obscure, but DNA PROFILING finally provided the answer to this mystery. Along with a host of other varieties common in north-eastern France, it is the progeny of Pinot Noir and GOUAIS BLANC (see PINOT).

There is a rare but distinct pink-berried mutation, Chardonnay Rose, as well as a headily perfumed Chardonnay Blanc Musqué version, sometimes used in blends. Some of the 31 official French CLONES of Chardonnay have a similarly grapey perfume, notably 77 and 809, which have been quite widely planted and can add a rather incongruously aromatic note to blends with other clones of the variety. The arguably over-enthusiastic application of CLONAL SELECTION techniques in Burgundy means that growers can now choose from a wide range of Chardonnay clones specially selected for their productivity, particularly 75, 78, 121, 124, 125, and 277. Those seeking quality rather than quantity are more likely to choose 76, 95, and 96. Many New World wine regions began their love affair with Chardonnay on clones such as the Mendoza clone, only to find it rekindled by the introduction of better clones from Burgundy, sometimes known as Dijon clones. In California, the Wente HERITAGE CLONE is held in high regard.

In France the total area planted with Chardonnay—44,151 ha/109,099 acres in 2019—has long been second only in rankings of pale-skinned varieties to the Cognac and Armagnac grape Ugni Blanc. Chardonnay is significant in every single French wine region except for Alsace and Bordeaux and is particularly so in greater Burgundy, the Languedoc, and Champagne, where Chardonnay constitutes about one-third of the vineyard area. Chablis is quintessential Chardonnay country, and plantings totalled more than 6,000 ha by 2019. In the Burgundian heartland, the CÔTE D'OR, Chardonnay plantings had increased to 2,572 ha by 2019 at the expense of ALIGOTÉ but were outnumbered two-and-a-half times by those of Pinot

Noir, whereas in the Côte CHALONNAISE and the MÂCONNAIS to the south Chardonnay is twice as common overall as Pinot Noir, Mâcon Blanc being by far the most common (and affordable) incarnation of white burgundy. Although the regulations allow Aligoté into Beaujolais Blanc and Pinot Blanc into white wines labelled Bourgogne and Mâcon, most of these less expensive white burgundies are in practice made predominantly from Chardonnay. To the initial horror of the INAO, there has been an increasing trend towards slipping the word 'Chardonnay' on to white burgundy labels to increase their appeal to non-French consumers.

In the Languedoc, Chardonnay was first planted to add international appeal to the lemony wines of LIMOUX. By 2000 there were nearly 9,000 ha of Chardonnay in the Languedoc, a total that had grown to 16,610 ha by 2019, more than 7,000 of them in the hot Hérault *département*, although this is essentially red-wine country.

Chardonnay is grown in virtually all European wine-producing countries and makes copies of white burgundy of varying qualities, even if much of Spain south of Cataluña (where it plays a part in CAVA) is too hot, and Portugal wisely tends to concentrate on its INDIGENOUS VARIETIES. Even Germany, Rieslingland, now grows Chardonnay on 2,377 ha of vineyard, and it is an important ingredient in the sparkling wine production of ENGLAND.

Italy has a long history of Chardonnay cultivation, especially on its subalpine slopes in the north. Total plantings across the country in 2015 were 19,769 ha/48,850 acres. For decades, Italians were casual about distinguishing between their Pinot Bianco (PINOT BLANC, also known as Weissburgunder in the Italian Tyrol) and their Chardonnay (traditionally called Gelber, or Golden, Weissburgunder in the Italian Tyrol). Alto Adige Chardonnay was the first Italian Chardonnay accorded DOC status, in 1984, although the vine has since been working its magic on producers all over Italy from Puglia to Piemonte and, of course, Aosta towards the French border. Nowadays much of Italy's Chardonnay is produced, often without much distinction, in Friuli, Trentino, and, to a more limited extent, the Veneto, where much of it is used as ballast for GARGANEGA. Some fine examples are

produced in favoured sites in both Friuli and Trentino, but a considerable proportion is siphoned off to become SPUMANTE, as it is in Lombardy, where it can add finesse to some fine fizz. Chardonnay gained ground rapidly in Italy in the 1990s, being planted in Tuscan spots where Sangiovese is difficult to ripen. Piemonte, cooler than Tuscany, has, not unsurprisingly, had more overall success with the variety. See under these geographical names for more details of Italian Chardonnays.

Much less dramatic Chardonnay is also produced in Switzerland, particularly in Geneva, the Valais, and Bündner Herrschaft (see map under SWITZERLAND). In AUSTRIA, where the variety is also known as Morillon in STYRIA, Chardonnays include relatively rich, oak-matured versions; lean, aromatic styles modelled on their finest Rieslings; and sweet, BOTRYTIZED wines. The variety is planted throughout Eastern Europe but, with the notable exception of some fine, artisanal Slovenian examples, yields and temperatures are often too high for real distinction.

Few would have believed in 1980, when California had just 7,200 ha/18,000 acres of Chardonnay, that by 1988 the state's total plantings would for a while overtake France's (rapidly increasing) total. In the 21st century, France more than caught up, even though Chardonnay remains California's most-planted variety with a 2020 total of 36,699 ha/90,684 acres. Thanks to the red-wine boom, the rate of new plantings reached a peak in the mid 1990s. See under CALIFORNIA for more detail of the state's evolving styles of Chardonnay.

Chardonnay has been embraced with equal fervour throughout the rest of North America, from British Columbia in CANADA to Long Island in NEW YORK, although it is usually more restrained in character than the once stereotypical rich California style. In 1990, Chardonnay overtook Riesling to become the most planted variety of any hue in WASHINGTON State, but red wine is now far more important, and the 2017 Chardonnay total of 3,149 ha/7,782 acres makes it only the most-planted white wine grape. Chardonnay is also increasingly well regarded in Oregon (where plantings totalled 1,039 ha/2,568 acres in

2019 and the introduction of Dijon clones has had a profound effect on quality) as well as Virginia and Texas. The scale of America's romance with Chardonnay in general and oak-aged Chardonnay in particular was reflected in the international COOPERAGE business in the 1990s.

Various South American countries have been seeking out cooler spots to imbue their Chardonnay with real verve and concentration. CHILE's Pacific-influenced regions, most notably the Casablanca Valley and San Antonio/Leyda, and the high-elevation vineyards of Argentina's Uco Valley are the most obvious examples. Their best wines combine fruit purity and accessibility. In ARGENTINA, where the variety has shown impressive finesse, Chardonnay overtook Ugni Blanc, Chenin Blanc, Sémillon, and Sauvignonasse in the 1990s to become the country's second most planted white wine grape after Torrontés. Total Argentine plantings were 5,853 ha by 2020. Chile has even more, 10,919 ha in 2020, and Chardonnay was the country's most planted white wine grape for the first decade of this century, but Sauvignon Blanc is now way ahead. The Australian wine industry's all-important export trade was long centred on its particularly user-friendly and frequently adapted style of Chardonnay. Rich fruit flavours, often disciplined by added acid and flavoured by OAK CHIPS, were available at carefully judged price points. Such was the strength of demand for AUSTRALIAN Chardonnay in the late 1980s that the area of Chardonnay vines increased more than fivefold during the decade so that in 1990, Chardonnay, with its 4,300 ha/10,600 acres, became Australia's most-planted white wine grape variety (although 1,300 ha were too young to bear fruit). Plantings peaked in 2007 with more than 32,000 ha, but reaction to a glut left total Chardonnay plantings at 21,442 ha in 2015, slightly less than those of Cabernet Sauvignon, Australia's second most popular variety after Shiraz. The style of typical Australian Chardonnay changed more rapidly than any other nation's with steeliness, almost austerity, now seen as virtues. Nevertheless, the average life expectancy of typical Australian (and many other non-European) Chardonnay is short, but glorious exceptions abound in cooler spots such as the Adelaide Hills,

Victoria, and Tasmania and can give fine white burgundy a run for its money.

NEW ZEALAND's love affair with Chardonnay was relatively short. Only in the last decade of the 20th century did Chardonnay plantings outnumber those of the Sauvignon Blanc that has now been anointed queen of Kiwi vines. By 2022 total plantings of Chardonnay, just over 3,000 ha/7,413 acres, had fallen to less than one-eighth those of Sauvignon Blanc, even though the naturally high acidity of New Zealand wines suits Chardonnay so well. Chardonnay has had a chequered history in South Africa. Planting material in the late 1970s and early 1980s was frequently smuggled rather than submitted for QUARANTINE, and at one time significant quantities of AUXERROIS contaminated the authenticity of 'Chardonnay' vineyards. For a while Chardonnay was the country's third most planted white wine grape, albeit a long way behind Chenin Blanc and Colombard, but in 2006 Sauvignon Blanc, as in New Zealand, overtook Chardonnay, whose plantings in 2020 were just 6,587 ha.

Although Chardonnay can thrive in relatively hot climates (such as Australia's irrigation zones), it has to be picked before acids plummet (sometimes before the grapes have developed much real character, although this is usually caused by excessively high yields), and it does require relatively sophisticated techniques, including TEMPERATURE CONTROL, in the cellar. This is why it is not especially well suited to hot Mediterranean wine regions, and well-balanced Chardonnays with real interest from the likes of Greece, Israel, and Lebanon tend to be exceptions.

Charentais, IGP for TABLE WINES made in the Cognac region of France, following the river Charente to the Atlantic. A MARITIME CLIMATE keeps average annual temperatures at a cool 13 °C/55 °F and provides plenty of HUMIDITY; annual precipitation averages 800–1,200 mm/31–47 in. LIMESTONE soils dominate. White wines are made mainly from SAUVIGNON BLANC and CHARDONNAY; UGNI BLANC and COLOMBARD are widely grown but mainly for distillation or PINEAU DES

CHARENTES. Reds and rosés rely on Bordeaux varieties and pinot noir. Four subregions are allowed on wine labels: Charente-Maritime, Île de Ré, Île de Olérin, and St-Sornin.

Charlemagne , king of the Franks 768–814, crowned Holy Roman Emperor in 800, the man who ushered in civilization, order, and prosperity after the long Dark Ages, ruling a Christian kingdom based at Aachen (Aix-la-Chapelle) which included virtually all of France, Belgium, Germany, and Switzerland.

Charlemagne's name is associated by modern wine drinkers with one of the greatest white burgundies, Corton-Charlemagne (whose vineyards include a plot known as Le Charlemagne), produced on land he gave to the Abbey of Saulieu in 775 (see ALOXE-CORTON for more detail). Charlemagne's secretary and biographer Einhard tells us, however, that Charlemagne was a moderate man: he never drank more than three cups of wine with dinner, and he hated to see people drunk (*Life of Charlemagne*, ch. 24). Only a temperate man is truly interested in wine: when he renamed the 12 months of the year in his native language, he called October 'windume-manoth', the month of the wine harvest (Einhard, ch. 28).

This Old Frankisch name reflects the growing importance of wine in the Carolingian era, for under Charlemagne and his heirs more and more vines began to be grown. Viticulture had of course been long established in a large part of Charlemagne's empire. The Greek colonists had introduced winegrowing to Massilia (now Marseilles) from 600 BCE onwards. When the Romans, under Julius Caesar, conquered Gaul in 51 BCE, they gradually expanded the small-scale viticulture of the Gauls, who had drunk mainly beer. The Roman settlers planted their first vineyards in southern Gaul, and by the 2nd century wine was grown extensively in most of Gaul. The Romans also planted vines in the MOSELLE Valley, on the left bank of the Rhine, and in the areas we now know as ALSACE, the PFALZ, and RHEINHESSEN.

The spread of Christianity was one reason for the expansion of viticulture that took place during Charlemagne's reign and continued

for another two centuries afterwards. The Church needed a daily supply of wine to celebrate the EUCHARIST. Also, monasteries, many of which were new foundations, needed wine for the monks and their guests (see MONKS AND MONASTERIES), and vineyards were planted all over northern France and even southern Belgium.

The Rule of St Benedict permitted a modest daily ration of wine, more on holy days and feast days; important guests who stayed at the monastery had to be suitably entertained, for they might one day repay the monks generously for their hospitality. Monasteries usually had their own vineyards, and often these had been donated by local landowners who hoped for a place in heaven. Bishops also wanted wine, not just for the day-to-day running of their households but also as a status symbol to put themselves on a par with the nobility of the district. Bishops, like monks, had their own vineyards, and some bishops may even have moved their sees to be nearer vineyards: at least, this may explain why the bishopric of Langres moved south to Dijon (at the north of the CÔTE D'OR), that of Tongres to Liège in modern Belgium, and that of St-Quentin to Noyon north of Paris. Thus Christianity fostered the production of two grades of wine, wine for daily consumption and a superior kind that was designed to impress prestigious guests.

In 816, the Council of Aachen added a third category of ecclesiastical viticulture. The Council prescribed that a college of canons, living under monastic rule, should be attached to every cathedral and that the canons should grow wine. Often they tended vineyards adjacent to those of their bishops; collegiate churches could be founded elsewhere in the diocese as well, and they also acquired their own vineyards.

Unlike education, viticulture was not the preserve of the Church, however: laymen also grew wine. The factor that decided where they established their new vineyards was not TERROIR but ease of transport. If the enterprise was to be commercially viable, the area had to be near a navigable RIVER or within easy reach, by road, of a major town or city. This is why so much wine was grown around PARIS, AUXERRE, and in CHAMPAGNE, despite the fact that it was too cold

there for the vine to yield ripe and abundant fruit. If the summer had not been hot, there was nothing for it but to drink thin, acidic wine until the following autumn, unless one could afford to buy better wine from elsewhere. An interesting document from the last decade of the 8th century deals with the management of vineyards in secular ownership. It is known as the 'Capitulare de villis', or 'Concerning estates' (a capitulary being a collection of ordinances). Linguistic evidence and local references show that it was drawn up for Aquitaine, which was administered by Charlemagne's son Louis the Pious before he succeeded his father. The list of plants and herbs which it says must be grown in the estate's market garden owes more to the library than to real horticulture, but the advice it gives on winegrowing is sound and practical. Not only should the king's inspectors claim the portion of the vintage that is the royal household's due, but they should also oversee hygienic procedures in the vineyard. Wine PRESSES should be clean, and grapes should not be trodden with the feet. Wine that is to be sent to the palace should be put into proper wooden BARRELS instead of leather wineskins. An inventory of the entire estate should be drawn up each Christmas, including the wine it has produced that autumn and any older wine left over.

The 'Capitulare de villis' has no connection with Charlemagne himself, and there is no solid evidence that he initiated the planting of any vineyard, although parts of France and the RHEINGAU were first planted in his day. Viticulture flourished not because of a *dirigiste* policy but because political unity had brought prosperity. External threats, most importantly from the Moors and the Magyars, could not be prevented and had to be dealt with, but, within the frontiers of the Holy Roman Empire, peace reigned, and viticulture was so successful that there was a surplus of wine. Landowners had to resort to the right of 'banvin', by which none of their tenants was allowed to sell wine until the lord had sold his own. In the south, wine was part of everyday life; in the north it was more of a luxury item, but it could still be obtained readily.

How different things were in England! When the English scholar Alcuin, friend of Charlemagne and tutor to his court at Aachen, went back to his native country for a visit, he complained bitterly in a letter, dated 790, to a Frankish ex-pupil. The wine has run out, and his stomach aches with sour beer: please send wine. Beer has its uses, but it is not a civilized drink. In the 8th century, the Frankish kingdom was a better place for a wine drinker to be than Anglo-Saxon England.

Charles Sturt University, one of Australia's foremost research and teaching institutions for grape-growers and winemakers. Courses started in 1976 within the Riverina College of Advanced Education, Wagga Wagga, New South Wales (NSW), to satisfy the need within the rapidly growing wine industry for a teaching institution in addition to ROSEWORTHY. In 1989, the College combined with other regional teaching institutions in NSW to form Charles Sturt University (CSU). The School of Agricultural and Wine Sciences offers Bachelor of Wine Science, Bachelor of Viticulture, and Bachelor of Wine Business degrees in either viticulture or wine science over six years part-time by online studies, with on-campus residential schools and workplace learning. Initially a controversial option for the wine industry, online is now a widely accepted means of learning, allowing students to continue in their current profession while studying. There is also a Bachelor of General Studies (Science), which may be exited earlier at Diploma or Associate Bachelor stages for the student to transfer to

the above or other courses. CSU also offers postgraduate studies leading to Doctor of Philosophy and Master of Philosophy qualifications.

In 1997, CSU formed an alliance with the NSW Government's Department of Primary Industries and the NSW Wine Industry Association to form the National Wine and Grape Industry Centre, which undertakes industry-focused research and extension services to assist the wine industry in applying best practice. N.B.

Charmat, see TANK METHOD.

Charneco, Portuguese white wine, probably fortified, popular in England in the 16th and 17th centuries and mentioned by Shakespeare in *The Second Part of Henry VI*. It is probably the forerunner of BUCELAS. R.J.M.

Charta (pronounced 'karta'), an association of RHEINGAU wine producers founded in 1984 and the designation given to one or two special Riesling bottlings made annually by each member in accordance with the association's standards for YIELDS, MUST WEIGHTS, and permissible vineyards of origin. (Paradoxically, these may not be labelled with the names of specific vineyards.) Charta Rieslings must be finished TROCKEN or HALBTROCKEN—a stricture intended as homage to tradition—and pass three BLIND TASTING tests, after which they are bottled in tall flute-shaped bottles embossed and labelled with a double Romanesque arch. (Some estates use this as an opportunity to commission Charta-dedicated ARTISTS' LABELS.) The qualitative impetus behind this association and its wines is often rightly associated with the subsequent emergence of ERSTES GEWÄCHS and GROSSES GEWÄCHS as quality wine categories, although the number of participating growers has fallen steadily in recent years from a high of nearly 50. D.S.

Chasan, light-skinned, early-budding CROSS of Palomino Fino (known in France as LISTÁN) and Pinot (originally said to be Chardonnay) made under INRA auspices by French AMPELOGRAPHER Paul Truel. It is planted on a limited scale in the Midi, particularly in the Aude *département*, and France's total plantings were just 428 ha/1,058 acres by 2018.

Chassagne-Montrachet, village in the Côte de Beaune district of Burgundy's CÔTE D'OR more famed for its white wines from the Chardonnay grape than for its equally plentiful red wines from Pinot Noir. Until the mid 1980s, the village produced more red wine than white, but the significant premium for white Chassagne led to considerable planting of Chardonnay, even on relatively unsuitable soils. The five-year average (2015–19) of production saw 3,670 hl of red and 10,148 hl of white Chasssagne-Montrachet, including PREMIERS CRUS.

The better soil for Pinot Noir, limestone MARL with a red gravel content, lies mainly on the south side of the village towards Santenay and incorporates most of the village appellation, although the PREMIERS CRUS La Boudriotte, Morgeot, and especially Clos St-Jean make excellent red wines. Red Chassagne-Montrachet tends to be somewhat hard and earthy when young, mellowing with age but rarely achieving the delicacy of truly fine red burgundy.

The fame of Chassagne rests with the white wines at village, premier cru, and especially GRAND CRU level. Chassagne shares the Le Montrachet and Bâtard-Montrachet vineyards with neighbouring Puligny and enjoys sole possession of a third grand cru, Criots-Bâtard-Montrachet (see MONTRACHET for more details). Among the premiers crus, the most exciting are En Cailleret, Grande Montagne, La Romanée, Grandes Ruchottes, Blanchot Dessus, and Vide-Bourse. Suitable white-wine soil tends to have more oolitic LIMESTONE and less marl in its make-up.

The white wines of Chassagne are noted for their steely power, less rounded than MEURSAULT when young, sometimes similar to

PULIGNY-MONTRACHET if less floral. Good vintages from good producers such as Ramonet and the extended Colin, Gagnard, and Morey clans should age from five to ten years.

See map under BURGUNDY. J.T.C.M.

Chasselas, even if by no means the most revered white grape variety, is widely planted under dozens of names around the world and has a particularly long, intriguing history. DNA PROFILING suggests its origins lie in French SWITZERLAND, where it certainly produces its finest wines today, often called Fendant, its common synonym in the Valais. Chasselas is still Switzerland's most planted white wine grape and is particularly common in the canton of Vaud, where more than 60% of the 2020 total of 3,606 ha/8,911 acres are grown. Individual villages all over French Switzerland but particularly on the northern bank of Lac Léman have won acclaim for their TERROIR-specific interpretations of what can be a relatively neutral grape.

In France, it is rather despised, not least because, as Chasselas Doré, it is France's most common TABLE GRAPE. Total French plantings had declined to just over 500 ha by 2019. It is rapidly disappearing from Alsace, where it is regarded as the lowest of the low and is generally sold as EDELZWICKER or under some proprietary name that excludes mention of any grape variety. Planted in the area responsible for Pouilly-Fumé, it makes the distinctly inferior white labelled Pouilly-sur-Loire and, as might be expected, approaches respectability only as it nears Switzerland, in SAVOIE. Here it is the main grape grown in the *département* of Haute-Savoie on the south side of Lake Geneva in the Vin de Savoie CRUS of CRÉPY, MARIGNAN, Marin, and Ripaille.

The variety's long history has enabled it to spread far and wide. In Germany, where it is known as Weisser GUTEDEL and is grown on 1,105 ha/2,731 acres, mainly in BADEN, it has been known since the 16th century. It is no longer nearly as important in central Europe as it once was but can still be found in Hungary, Romania, Russia, and Serbia. Outside Europe it is most important in Chile.

château may be French for 'castle' but in wine parlance it usually means a vine-growing, winemaking estate, to include the vineyards, the cellars, often the wine itself, and any building or buildings on the property, which can range from the non-existent (as in the case of Ch Léoville-BARTON, for example, which is made in the cellars of Ch Langoa-Barton), through the most rudimentary shack, to the sumptuous classical edifice called Ch MARGAUX. The term is most commonly used in BORDEAUX, where the 18th edition of the FÉRET guide lists more than 14,000 châteaux, although common use of the term developed only in the second half of the 19th century, when the owners of the great estates could afford to build grand lodgings to go with them. Only five of the original 79 properties in the Médoc, Graves, and Sauternes listed in the famous 1855 CLASSIFICATION, for example, were described as châteaux then. Bordeaux proprietors soon learnt the value of a Château prefix and have long adopted the policy of renaming properties almost at will, in particular suffixing their own surname as, for example, Ch Prieuré-LICHINE and Chx Mouton- and Lafite-ROTHSCHILD. The word 'château' is by no means uncommon outside Bordeaux, however, mainly within but sometimes outside FRANCE (where it tends to lose its circumflex). According to current French law, the word 'château' may be used only of a specified plot, or collection of plots, of land, which means that it is perfectly possible for CO-OPERATIVES, for example, to produce a wine labelled as Château Quelquechose (see CHÂTEAU BOTTLING). Some producers make a range of wines carrying the name of the property but reserve the word 'château' for their top bottlings.

château bottling, the relatively recent practice of BOTTLING the produce of a CHÂTEAU on that property. Such a wine is said to be château bottled, or *mis(e) en bouteille au château* in French, an expression used throughout France but particularly in BORDEAUX. (Its counterpart in BURGUNDY is DOMAINE BOTTLED, while in the NEW WORLD the term ESTATE BOTTLED is often used.)

Initially all wine was sold in BULK, and subsequently it was up to the MERCHANTS, whether in the region of consumption or production, to put the wine into bottle. Even as recently as the mid 20th century, the great majority of wine left the property on which it was produced in BARRELS. ADULTERATION AND FRAUD was therefore all too easy among less scrupulous merchants and particularly tempting in the wake of the world wine shortages which followed POWDERY MILDEW and PHYLLOXERA at the end of the 19th century.

It was the young Baron Philippe de ROTHSCHILD who did most to promote château bottling when he took over Ch MOUTON ROTHSCHILD in the early 1920s. He succeeded in persuading all the first growths (and Ch Mouton Rothschild of course) of the wisdom of bottling all of their principal output, the so-called GRAND VIN, on their own territory. This involved a certain amount of investment, but the resulting reliability and cachet more than compensated.

Good bottling lines require a level of investment that is unrealistic for many a small wine property, however, so contract bottlers and mobile bottling lines are much in demand, and producers may not be able to bottle at the precise time they would prefer. Others still bottle by hand, some with scant regard for HYGIENE and consistency. Such considerations mean that bottling at source is not necessarily superior to careful BULK TRANSPORT of the wine to a top-quality bottling plant.

Château-Chalon, extraordinary wine made in the JURA region of eastern France with its own small appellation named after the hilltop village where it is produced. In the 17th century or even earlier, the abbesses from the Abbey of Château-Chalon may have been the first in the region to make a VIN JAUNE style of wine, historically named 'Vin de Garde'. Unlike other Jura appellations, Château-Chalon must be a *vin jaune* and thus must be made exclusively from SAVAGNIN grapes grown on the local grey MARL. (Other wines produced by local growers are entitled to the Côtes du Jura appellation.) In 1952 the appellation was the first in France to instigate vineyard inspections pre-harvest before the vintage is approved. The noble decision was

made not to bottle any wine under the appellation in 1974, 1980, 1984, and 2001. Like all *vin jaune*, the wine must be kept for at least six years and three months before bottling, most of this time spent in partially filled, untouched casks under *voile*, the local benevolent FILM-FORMING YEAST. The resulting wine is exceptionally spicy and mineral-rich, pale to deep golden, and long lasting. It must be bottled in a special *clavelin* bottle containing 62 cl, supposedly the amount of wine that remains from a litre of wine kept in a cask in Ch-Chalon for six years. The result is a wine that shares some flavour characteristics with SHERRY but has more finesse, working well as a gastronomic partner (especially with the local Comté cheese and poultry of Bresse, also AOC products) and as a candidate for extended BOTTLE AGEING. It is said to develop 'curry' flavours in bottle, thanks to the compound SOTOLON. With only 55 ha/136 acres planted, production volumes vary wildly, from zero to, in a good year, around 1,600 hl/42,267 gal.

W.L.

Château-Grillet, one of France's smallest wine appellations and one of the few with a single owner (see also DOMAINE DE LA ROMANÉE-CONTI). Château-Grillet's few hectares of vineyard represent an enclave within the CONDRIEU zone between the communes of Vérin and St-Michel-sur-Rhône in the north of the northern Rhône. A virtual amphitheatre carved out of the granite shelters the narrow terraces of VIOGNIER vines from the north winds. Already appreciated by Thomas JEFFERSON in the late 18th century, Château-Grillet has always been in single ownership. Until it was bought by François Pinault, owner of Ch LATOUR, in 2011, it belonged to the Neyret-Gachet family and descendants. Annual production was barely 2,000 cases of Château-Grillet's distinctive fluted brown bottle, one of the last to grow from 70 to 75 cl. Between the 1970s and the 2010s, the wine maintained its high price more by its rarity than because it was obviously one of France's finest wines.

The new team in charge of the original 3.5-ha/8.6-acre estate make a second wine, sold as Côtes du Rhône, and are refining the style, which is less headily perfumed than the best Condrieu and

always dry. Since converting the estate to BIODYNAMIC VITICULTURE and refurbishing the winery, quality has become more reliable. The result is a restrained, taut wine which may improve in bottle for a decade or even two. The latest addition to the range is Condrieu La Carthery, produced from a few rows of vines that border the Château-Grillet growing area at the top of the amphitheatre. M.C.W.

Châteaumeillant, small, isolated AOC in central France around the town of Châteaumeillant between ST-POURÇAIN and TOURAINE (see map under FRANCE). Mainly GAMAY with some Pinot Noir and a little Pinot Gris produce red and VIN GRIS from 83 ha/205 acres of sandy CLAY soils over SANDSTONE, SCHIST, and GNEISS. One CO-OPERATIVE dominates production.

Châteauneuf-du-Pape, the oldest, largest, and most qualitative of all the CRUS of the southern RHÔNE, producing mainly powerful, potent, full-bodied red wines and a much smaller volume of full-bodied, opulent whites.

The first written references to wine produced here date back to 1157, but it is with the arrival of the popes that winemaking takes on a greater significance. The wine takes its name, which means 'Pope's new castle', from the relocation of the papal court to Avignon in the 14th century and in particular from the construction of summer quarters just north of the city in a village once known as Calcernier for its limestone quarry. It is now called Châteauneuf-du-Pape. The Gascon Pope Clément V (after whom Ch Pape-Clément in PESSAC-LÉOGNAN is named) arrived at Avignon in 1309 and is supposed to have ordered the planting of vines, but it was his successor John XXII who is credited with developing a papal vineyard in Châteauneuf-du-Pape.

By the end of the 18th century, wines were being exported to Europe and the United States, and the name of Châteauneuf-du-Pape began to be recognized internationally. Its reputation steadily grew

with the establishment of several large private estates until the arrival of PHYLLOXERA in 1866, which ravaged the vineyards.

Reconstruction of the vineyards was financially devastating, and the Châteauneuf-du-Pape vignerons were just some of those affected by the ADULTERATION AND FRAUD that were rife in the early 20th century. By 1923, the most energetic and well connected of their number, Baron Pierre Le Roy de Boiseaumarié (1890–1967) of Ch Fortia, had successfully drawn up a set of rules for the production of Châteauneuf-du-Pape, with the co-operation of his peers, which was the prototype for the entire AOC system. Thus France's first appellation was granted on 14 May 1936. Among what have now become the usual regulations, it involved the first geographical DELIMITATION of the original production zone. Another notable feature was the minimum specified ALCOHOLIC STRENGTH, 12.5%, which must be achieved without the aid of external sugar addition, or CHAPTALIZATION. Hand-picking and TRIAGE of picked grapes was mandated, and rosé production was disallowed.

Perhaps it is because of the antiquity of Châteauneuf-du-Pape's wine regulations that so many VINE VARIETIES are permitted by the appellation. Today 18 varieties are authorized, and any permitted grapes can be used for reds or whites, in any proportion. That said, GRENACHE makes up about 80% of red varieties planted in Châteauneuf-du-Pape, with yields officially restricted to just 35 hl/ha (2 tons/acre). It can produce wines which combine concentration and structure with the usual sweet fruit of Grenache, although it is particularly prone to COULURE.

MOURVÈDRE is an increasingly popular ingredient, although it needs the warmest MESOCLIMATES to ripen fully, while SYRAH from the northern Rhône has also been planted by producers who admire its TANNINS and structure. CINSAUT is also grown but to a declining extent. Of the other permitted dark-skinned varieties, MUSCARDIN, VACCARÈSE, PICQUEPOUL Noir, TERRET Noir, and COUNOISE, only the last is grown to any significant extent, and it has its admirers. For white Châteauneuf-du-Pape, the most common varieties are Grenache Blanc, CLAIRETTE,

BOURBOULENC, and ROUSSANNE. Clairette Rose and Piquepoul Blanc are also grown. Piquepoul Gris, Grenache Gris, and Picardan are very rare.

The appellation covers around 3,200 ha/7,907 acres of relatively flat vineyards at varying ELEVATIONS and ASPECTS above the river in Châteauneuf-du-Pape and the neighbouring communes of Bédarrides, Courthézon, Orange, and Sorgues. The highest point is 128 m/420 ft above sea level. The terrain is traditionally characterized by large pebbles, or *galets roulés*, some of them several inches across, which cover many of the more photographed vineyards, supposedly retaining heat and speeding the RIPENING process of the traditionally low-trained BUSH VINES. Soils in Châteauneuf-du-Pape are more varied than this, however (see soil map in Johnson and Robinson, 2019), and those at the celebrated Ch Rayas, for example, are predominantly sandy without a GALET in sight. Other main soil types are a compacted red SANDSTONE locally known as *grès rouge* and LIMESTONE. Most wines are blends from different subzones, particularly the classic blends some estates call their Tradition bottlings, though highly priced Special Cuvées have proliferated since the late 1980s, some of which are SINGLE-VINEYARD WINES. The size and diversity of the TERROIR and the number of producers make for a stylistically varied appellation.

Red wines are typically fermented in large old oak *foudres* or CONCRETE tanks, and they can be matured in these vessels or in smaller oak BARRELS. New oak tends to be reserved for Syrah or Mourvèdre rather than Grenache. The challenge of growing Grenache in this hot, Mediterranean climate is that sugar levels can rise quickly, leading to alcohol levels that can reach 17%. However, when the alcohol is balanced with adequate acidity, tannins, and concentration of fruit, the wines can be powerful, long-lived, and impressively complex. An increasingly popular way of achieving this is WHOLE-BUNCH FERMENTATION. Though many red Châteauneufs are drunk young, the most qualitative wines tend to show their best after 10 years in bottle. Today there are over 300 producers.

At just 8% of production, white Châteauneuf-du-Pape is a relative rarity, and it may be made according to a wide range of formulae. The wines are almost always full-bodied, and most should be drunk young, although some, such as the white wines of Ch de Beaucastel, Clos des Papes, and Domaine de Beaurenard, can develop for 25 years or more in bottle and sit alongside the finest white wines of France. See also RHÔNE. M.C.W.

Johnson, H., and Robinson, J., *The World Atlas of Wine* (8th edn, 2019).

Châtillon-en-Diois, small appellation for still, dry wines in the cooler eastern half of the Diois growing area in the Drôme Valley, between the northern and southern RHÔNE. Reds and rosés must be at last 75% GAMAY, with optional Pinot Noir or Syrah; whites are from Chardonnay and/or ALIGOTÉ. The local sparkling wine, CLAIRETTE DE DIE, is much more common. M.C.W.

Chaume, hillside hamlet surrounded by 60 ha/150 acres of praised CHENIN BLANC vineyards dedicated to sweet wines. From 2014, it became the only PREMIER CRU of the LOIRE under the Premier Cru Coteaux du LAYON Chaume AOC. See also QUARTS DE CHAUME.

Chautagne, CRU in the upper Rhône Valley north of Chambéry whose name may be added to the French appellation SAVOIE. Production is dominated by the CO-OPERATIVE, and it is best known for its red wines, in particular from Gamay but also from Pinot Noir or the local MONDEUSE. W.L.

Chaves, westernmost DOC subregion of TRÁS-OS-MONTES in north-east Portugal, with predominantly GRANITIC soils and relatively high amounts of rain and humidity. S.A.

Chehalem Mountains, wine region and AVA within the WILLAMETTE VALLEY of Oregon.

Chelois, Seibel FRENCH HYBRID planted to a very limited extent in the north-eastern US but starting to attract attention in NEW YORK's Finger Lakes.

Chelva, leading Spanish TABLE GRAPE also grown for RIBERA DEL GUADIANA in Extremadura, western Spain. Also known as Montúa. Spain's plantings totalled 4,832 ha/11,940 acres in 2020.

Chenanson, productive CROSS of GRENACHE Noir and Jurançon Noir planted on about 450 ha/1,112 acres in southern France in 2019, presumably popular because it is more productive and deeper-coloured than Grenache.

Chénas, the smallest of the ten BEAUJOLAIS crus, in the far north of the region and often in the shadow of MOULIN-À-VENT, not because of quality but because the latter appellation appropriated many of the commune's best LIEUX-DITS. From just 230 ha/570 acres divided between the villages of Chénas and La Chapelle de Guinchay, the wines can be hard to find, but they merge the best qualities of Moulin-à-Vent and FLEURIE. J.F.B.

Chenin or Chenin Blanc, in its native region often called Pineau or Pineau de la Loire, is probably the world's most versatile grape variety, capable of producing some of the finest, longest-living sweet whites and a wide range of fine dry whites. It is also responsible for a considerable volume of sparkling wine; in SOUTH AFRICA, where it is by far the most planted variety, it is even used as the base for a wide range of FORTIFIED WINES and spirits. Although in its most common high-yield, NEW WORLD form its distinctive flavour reminiscent of

honey and damp straw is usually lost, it retains the naturally high acidity that dogs it in some of the Loire's less ripe vintages but can be so useful in hot climates.

South Africa, with a 2020 total of 17,147 ha/42,371 acres, has almost twice as much Chenin planted as France's 2019 total of 10,362 ha/25,605 acres, which has remained unchanged for the last two decades. On the Cape, Chenin is prized for its acidity, productivity, and good resistance to disease and wind. The vine may have been one of the original collection imported in 1655 by Jan van Riebeeck. A dedicated band of Chenin Blanc specialists has emerged in South Africa, focusing on the best sites and on restoring to high-quality production old vineyard blocks.

In the 1980s, CALIFORNIA also had more Chenin planted than France, but total plantings had fallen to about 1,726 ha/4,265 acres by 2020. In stark contrast to South Africa and the Loire, California has very few champions of the variety, and most of it is used as the usually anonymous base for everyday commercial blends of reasonably crisp white of varying degrees of sweetness, often blended with the much more widely planted French COLOMBARD. Both of these workhorse varieties are planted primarily in the hot, dry Central Valley, a setting that might be described as the antithesis of Chenin's Loire homeland. (It also presumably helps extend quantities of, and add acidity to, cheaper wines labelled Chardonnay.) Chappellet's Chenin can be worth AGEING, and in Clarksburg at the north end of the Central Valley it can take on a distinctive melony, musky flavour. In New Zealand it has almost disappeared, and Millton is virtually the only producer to understand the variety. Australia grew just over 415 ha in 2022 and treated it largely with disdain as low-cost (high-yielding) blending material, usually extending Chardonnay, Sémillon, and Sauvignon Blanc. Plantings had fallen to about 1,744 ha in Argentina by 2020 and to under 40 ha in Chile.

The variety was exported to Israel to establish vineyards there at the end of the 19th century.

If Chenin appears to lead a double life—biddable workhorse in the New World, superstar in ANJOU-Saumur and TOURAINE—it seems clear

that the explanation lies in a combination of climate, soil, and yield. In California's Central Valley, the vine is often expected to yield 10 tons per acre (175 hl/ha), while even the most basic Anjou Blanc should not be produced from vines that yield more than 45 hl/ha. It is hardly surprising that Chenin's character seems diluted outside the Loire, where it has been known for centuries under various names such as Plant d'Anjou and Pineau de la Loire. Unpublished DNA PROFILING at INRAE suggests that Chenin is a natural cross between SAVAGNIN and SAUVIGNONASSE. It is also a half-sibling of VERDELHO and SAUVIGNON BLANC as well as a parent of Meslier St-François.

The vine is vigorous and has a tendency to bud early and ripen late, both of which are highly inconvenient attributes in the cool Loire Valley (though hardly noticeable characteristics in the hotter vineyards of the New World). CLONES that minimize these inconveniences have been selected, and 14 are now officially sanctioned in France. It is prone to BOTRYTIS BUNCH ROT—usefully so for LATE HARVEST styles.

About one-third of all France's, which means the middle Loire's, Chenin was abandoned in the 1970s, often in favour of Cabernet Franc in Anjou-Saumur and Touraine and to make way for the temporarily more fashionable Gamay and Sauvignon de Touraine in the east of the middle Loire. It is today most planted in the heart of Anjou-Saumur and Touraine, as well it might be to judge from the superlative quality of the best wines of such appellations as ANJOU, BONNEZEAUX, Coteaux de l'AUBANCE, Coteaux du LAYON, JASNIÈRES, MONTLOUIS, QUARTS DE CHAUME, SAUMUR, SAVENNIÈRES (the grape's one definitively dry appellation), VOUVRAY, and CRÉMANT de Loire.

In most of the best Loire Chenins and certainly all of the great sweet wines, Chenin is unblended, but up to 20% of Chardonnay or Sauvignon is allowed into an Anjou, and even more catholic blends are allowed into whites labelled Val de Loire. If middle-Loire white has any character at all it is that of Chenin, increasingly valued as the region's signature grape, in contrast to the widely planted Sauvignon Blanc and Chardonnay. While basic Loire Chenin exhibits simply

vaguely floral aromas and refreshingly high acidity (together with too much SULFUR DIOXIDE if made in one of the more old-fashioned cellars), the best have a physically thrilling concentration of honeyed flavour, whether the wine is made sweet (MOELLEUX), dry/*sec* (an increasingly popular style, often incorporating some BARREL AGEING), or *demi-sec*, together with Chenin's characteristically vibrant acidity level.

It is undoubtedly this acid, emphasized by a conscious distaste for MALOLACTIC CONVERSION and concentrated in some years by BOTRYTIS, that helps preserve the finest Chenins for decades after their relatively early bottling. (In all of these respects, together with lateness of ripening and a wide range of sweetness levels that are customary, Chenin is France's answer to Germany's RIESLING.)

Chenin with its high acidity is a useful base for a wide range of sparkling wines, most importantly Saumur Mousseux but also Crémant de Loire and even some rich sparkling Vouvrays, which, like their still counterparts, can age beautifully. Treasured for its reliably high acidity and useful perfume, it is also an ingredient, with Mauzac and Chardonnay, in the sparkling wines of LIMOUX.

Cheval Blanc, Château, very fine BORDEAUX property in ST-ÉMILION. In 1832, Henriette Ducasse married Libourne négociant Jean Laussac-Fourcaud, bringing with her 12 ha/30 acres of land including part of the narrow GRAVEL ridge that runs through Figeac and neighbouring vineyards and reaches PETRUS just over the border in POMEROL. This became Ch Cheval Blanc, which, in the International London and Paris Exhibitions in 1862 and 1867, won the medals still prominent on its labels. In 1892, Albert reversed the order of his double surname, and it remained in the Fourcaud-Laussac family until 1998 when it was sold to Bernard Arnault, chairman of LVMH, and Belgian businessman Albert Frère. Pierre, one of the LURTONS, has been general manager since 1991.

The estate has 39 ha of vines: 51% Cabernet Franc, 47% Merlot, and 2% Cabernet Sauvignon. A total of 53 very different plots have

been identified and, since an ultra-modern CHAI was built in 2011, have been picked and vinified separately. Average production is about 7,000 dozen bottles a year. Le Petit Cheval is the second wine. The high percentage of CABERNET FRANC, a variety felicitously originally favoured by Jean Laussac-Fourcaud which has proved particularly well-suited to the CLAY soils of Cheval Blanc, gives the wines a deep colour and a rich, concentrated blackcurrant bouquet and flavour. Merlot is mostly planted on plots with more gravel. Although excellent wines were made towards the end of the 19th century and before the First World War, the property's international reputation was made with the 1921, which had enormous concentration and sweetness. Other very successful wines were made in the 1920s and even in 1934 and 1937, but its more modern fame was achieved with the rich, porty 1947—quite different from the style aimed at today. A Sancerre-like dry white wine, Le Petit Cheval Blanc, is grown on part of what was Ch La Tour du Pin Figeac, acquired in 2006.

Chevalier-Montrachet, great white GRAND CRU in Burgundy's CÔTE D'OR. For more details, see MONTRACHET.

Cheverny in the middle LOIRE was promoted to full AOC status in 1993 and produces a wide range of wines from its 532 ha/1,315 acres in the north-east corner of TOURAINE near Blois (see LOIRE map). Light reds and rosés may be made from Pinot Noir and Gamay with a minimum of 15% Cabernet Franc or Côt (MALBEC). But most Cheverny is based on Sauvignon Blanc, typically blended with a little Chardonnay, Chenin Blanc, and/or MENU PINEAU, and can offer a good-value northern riposte to SANCERRE and POUILLY-FUMÉ. Wines made from the local ROMORANTIN grape have their own 48-ha appellation Cour Cheverny.

Chian wine, from the island of Chios, was highly prized in both ancient and medieval times. See AEGEAN ISLANDS and DRIED-GRAPE

WINES for more details.

Chianti, the name of a specific geographical area between Florence and Siena in the central Italian region of TUSCANY, associated with tangy, dry red wines of varied quality. The Chianti zone is first identified in documents of the second half of the 13th century which named the high hills between Baliaccia and Monte Luco 'the Chianti mountains' but without reference to the actual wine (although see TUSCANY, history). In the 18th century the name was applied to the townships of Castellina, Radda, Gaiole, and Greve (including Panzano) that formed the nucleus of the medieval League of Chianti under Florentine jurisdiction. These townships became one of the very first wine regions anywhere to be officially demarcated, in an edict drawn up in 1716 by Cosimo III, Grand Duke of Tuscany to protect authenticity and combat fraud. In the 1930s the Italian government's Dalmasso commission enlarged this historic zone to capitalize on the Chianti name (see CHIANTI CLASSICO).

The legally oenological Chianti extends over 15,500 ha/38,285 acres and includes eight subzones that can appear on wine labels: Colli Fiorentini, CHIANTI RUFINA, Montalbano, Colli Senesi, Colline Pisane, Colli Aretini, Montespertoli, and Terre di Vinci; other parts of this extended region may produce wine labelled simply Chianti. There are quality-oriented producers outside the Chianti Classico heartland, but much of the wine that qualifies for the basic Chianti appellation lacks distinction.

Production regulations for Chianti and its seven subzones have always been less strict than for Chianti Classico. SANGIOVESE, the main variety in the wines, may represent as little as 70% of the blend compared with the minimum 80% for Chianti Classico, and white wine grapes may comprise up to 10% of the blend, except in Chianti Colli Senesi. (In 2022 proposals to lower the minimum of Sangiovese to 60% of the blend had been sent to Rome for approval.) Maximum permitted YIELDS at 9 ton/ha (8 for Colli Senesi) are higher than Chianti Classico's 7.5 ton/ha, while the minimum alcohol of 10.5%

(11% for Colli Arentini, Colli Fiorentini, Colline Pisane, Montalbano, and Montespertoli; 11.5% for Colli Senesi; 12% for Riserva) indicates a tolerance for less ripe fruit compared with Chianti Classico's 11.5% minimum.

Large volumes of Chianti are bought by bottlers furnishing large retailers at the lowest possible price, a practice which has done little to incentivize investments and increase overall quality. In what is widely considered a concession to the Chinese market especially, in 2019 the CONSORZIO increased the allowed RESIDUAL SUGAR from 4 to 9 g/l. The very irregular quality of wine labelled simply Chianti has always had a detrimental effect on Chianti Classico's reputation, especially when the latter shifted its focus from quantity to quality from 1984 onwards when all of Chianti was elevated to DOCG status. Chianti has applied to use the GRAN SELEZIONE category, a further slap in the face of Chianti Classico, which originally created it to set its top wines apart from Chianti proper. As Gran Selezione is part of Italy's legal framework, Chianti Classico seems powerless to claim the category exclusively for its own use. W.S.

Nesto, B., and Di Savino, F., *Chianti Classico: The Search for Tuscany's Noblest Wine* (2016).

www.consorziovinochianti.it

Chianti Classico, the heartland of the CHIANTI zone, was given its fundamental geographical DELIMITATION by the Medici Grand Duke Cosimo III in an edict of 1716, one of the first examples of such legislation, and was defined as the townships of Radda, Gaiole, and Castellina in addition to the township of Greve (including Panzano).

In 1924 the 'Consortium for the defence of Chianti wine and its symbol of origin' was founded to fight the cheap imitations seeking to take advantage of the growing international demand for Chianti Classico. At the request of the CONSORZIO in 1932 a government

committee, known as the Commissione Dalmasso, was sent to the region to demarcate the original, CLASSICO zone; much to the frustration of the Consorzio, the commission enlarged the zone with six additional subzones. The new enlarged region was what is now more or less Chianti proper, defended by the commission on the basis of presumed common oenological practices rather than suitability or historical evidence. To integrate such a large and diverse area, the production regulations set up by the Dalmasso commission were decidedly flexible, with regulations requiring only 50–80% Sangiovese, the region's most important red variety, while allowing the inclusion of the white Malvasia and Trebbiano, believed to have been traditionally interplanted with red varieties in the area's vineyards.

Little is known of the precise varietal composition of the wines before the 19th century, although the work of Cosimo Villifranchi (1773) suggests that the wine was a blend dominated by CANAIOLO with smaller amounts of Sangiovese, MAMMOLO, and MARZEMINO. Modern Chianti can be said to have been invented by Baron Bettino RICASOLI, who, in a letter in 1872, synthesized decades of experimentation and recommended that the wine be based on Sangiovese ('for bouquet and vigour') with the addition of Canaiolo to soften the wine. Malvasia was suggested as appropriate for wines to be drunk young, although its use was discouraged for wines intended for AGEING.

By the 1960s the old sharecropping system was officially abolished, leading to an exodus of workers looking for paid work in the growing industrial cities in the north. Mixed agricultural estates were transformed into a monoculture, without much attention paid to VINEYARD SITE SELECTION for the many newly planted vineyards. The government promoted high-yielding CLONES of Sangiovese as well as the white Trebbiano, believing that a focus on quantity rather than quality would help to improve the economic state of the region. The DOC regulations of 1967, guided by the 'Ricasoli formula', therefore required 10–30% of the white grapes Trebbiano and Malvasia. Because of the resulting low quality and the fact that 100%

Sangiovese wines were now outlawed, several quality-oriented producers decided to opt out of the DOC system and produce instead, often using new winemaking techniques such as BARREL MATURATION, wines labelled VINO DA TAVOLA which gained swift recognition (see SUPERTUSCANS). This presented the Consorzio with an embarrassing and absurd situation.

From the beginning of the 1980s the Consorzio finally understood that, for Chianti Classico's quality—and price—to increase, it needed to focus on improving the output from its vineyards. By then most vineyards, planted in the 1960s and exhausted from excessive yields, had to be replanted. The Consorzio launched Chianti Classico 2000, an in-depth study into clones, ELEVATIONS, and soil compositions, the results of which were freely divulged to the producers. At the same time, many investors from outside the region arrived, attracted by the low land prices. Many of these incomers had little prior knowledge of winegrowing and relied heavily on consultant OENOLOGISTS. Overall wine quality improved considerably. INTERNATIONAL VARIETIES were often added to make the wines more appealing to international palates.

At last, in 1996, Chianti Classico became autonomous, was granted its own DOCG, and was therefore no longer a subzone of Chianti. The suffix Classico was to be restricted to the original 7,000-ha/17,500-acre zone, with stricter regulations such as lower yields and a minimum 80% Sangiovese. Most Chianti Classicos made today are 100% Sangiovese, or Sangiovese with local varieties, as the focus has shifted away from international varieties and BARRIQUE ageing.

Despite many a marketing campaign aimed at distancing itself from generic Chianti, the Consorzio of Chianti Classico has still to make the difference clear to the general public. The region is already subdivided into nine communes (Greve in Chianti, San Casciano in Val di Pesa, Tavarnelle Val di Pesa, Barberino Val d'Elsa, Castellina in Chianti, Poggibonsi, Radda in Chianti, Gaiole in Chianti, and Castelnuovo Berardenga), but the Consorzio refused to condone subzone naming on labels. Instead, in 2014 the Consorzio added GRAN SELEZIONE to the top of the denomination pyramid, which

consists of Chianti Classico as its base and Chianti Classico RISERVA (with a mandatory 24 months of ageing) above it. While relentlessly promoted by the Consorzio, to its frustration Chianti has also requested the use of the category, which, as it is part of Italy's legal framework, cannot be claimed exclusively by Chianti Classico.

However, in 2021 the Consorzio finally announced the introduction of UGAs (*unità geografiche aggiuntive*), naming 11 communes or subzones allowed to appear on labels as a suffix to Chianti Classico. The communes are: Castellina, Castelnuovo Berardenga, Gaiole, Greve, Lamole, Montefioralle, Panzano, Radda, San Casciano, San Donato in Poggio, and Vagliali. However, going against the grain, the Consorzio still sees Gran Selezione as the ultimate relevance and restricts UGAs to communal wines only. W.S.

Chianti Rufina, north-eastern and smallest of the seven subzones that form CHIANTI. Rufina was first identified as an area of superior production in Cosimo III de' Medici's grand-ducal edict of 1716, which names the zone Pomino, a village within Rufina, after the famous estate of the Albizi family. Pomino, now owned substantially by FRESCOBALDI, has its own DOC for blends of INTERNATIONAL VARIETIES, but the delimited zone of the DOC of 1967 followed to a substantial extent the territory first delimited by Cosimo III, with an extension to the west of the confluence of the Sieve and Arno rivers.

The vineyard soils of Rufina are similar to those of CHIANTI CLASSICO, consisting of GALESTRO, ALBERESE, and LIMESTONE at ELEVATIONS of 200–700 m/655–2,300 ft. It is said that these higher elevations are responsible for the wines' trademark acidity and longevity, but relatively few modern Rufina wines demonstrate these qualities. Only a fraction of the region's growers bottle wine; most sell their grapes to NÉGOCIANTS or bottlers, who often sell the result as Chianti rather than Chianti Rufina since it entails less bureaucracy.

All this obscures the fact that the best of Rufina can truly be outstanding (as evidenced by the wines of Selvapiana), if producers eschew high yields and the inclusion of 30% of international varieties (and up to 10% white varieties) in what is a historic Sangiovese-based wine. Rufina's potential at least equals that of Chianti Classico, but the region has been slow to emulate the latter's continued efforts to improve overall quality. Realizing this, in 2018 the Rufina Consorzio presented research that identified the best vineyards of 19 producers. Beginning with the 2017 harvest, these vineyards can appear on labels of wines made from 100% Sangiovese from these plots after ageing 36 months, 24 of which must be in large oak casks. W.S.

www.chiantirufina.com

Chiavennasca, synonym for the noble NEBBIOLO vine and grape in VALTELLINA.

Chidiriotiko, dark-skinned grape variety planted on the Greek island of Lesbos.

Chignin, CRU near Chambéry whose name can be added to the eastern French appellation SAVOIE. Most Chignin is a scented dry white made from the local JACQUÈRE grape variety, although the name may be used for VARIETAL reds, too. Chignin-Bergeron is technically a

separate CRU with a slightly smaller geographic area, based on rich, dry white wines from ROUSSANNE, Bergeron being a local name for the grape. W.L.

Chile. With a particularly varied climate and topography, this long, narrow South American country on the Pacific Ocean was long associated with reliable, inexpensive wines, but the current generation of winemakers has proved that it can produce more than bargains. The Spanish may have introduced viticulture, but since the 19th century France has had the greatest influence on the Chilean wine industry, primarily with Bordeaux varieties such as Cabernet Sauvignon, Merlot, and CARMENÈRE. However, in Chile's climate and soils, each of them has achieved a local identity very different from that of Bordeaux. In addition to these varieties, the 21st century has also seen the rediscovery of varieties such as PAÍS (aka Listán Prieto), CARIGNAN, and CINSAUT which have contributed to the diversity of Chilean wine today.

Chile has been one of the world's most energetic wine exporters since the 1990s. In 2021, vineyards covered 210,000 ha/518,921 acres, and total wine production was about 13.4 million hl/354 million gal, nearly 70% of which was destined for export.

History

The VITIS VINIFERA vine, and deliberate cultivation of it for wine, was brought to the Americas by the Spanish (see SOUTH AMERICA, history). Cortés imported vine cuttings, or more probably seeds, directly from Spain to Mexico where the first successful American vintage was produced, but it is not clear whether the vines first cultivated in the mid 16th century at Cuzco in PERU, the progenitors of the Chilean wine industry, came from Mexico or directly from Europe. It is generally agreed, however, that Spanish settlers brought the vine to Chile some time in the 1550s, the vine probably arriving in the Central Valley with Juan Jufre and Diego Garcia de Cáceres in 1554. This was partly so that the early Spanish settlers could celebrate the EUCHARIST with its produce. Specific grape varieties mentioned by the Jesuit priest Alonso Ovalle include Moscatel, Torontel, Albilho, Mollar, and 'the common black grape' (presumably related to PAÍS).

Some early vineyards were ransacked by native peoples, notably in the far south of the country, but the capital Santiago has been associated with continuous wine production for more than four centuries. In the 17th century, Spain attempted to protect its export trade of wine to South America by banning new plantings of vineyards there, but with little success. Indeed, in 1678 the Chilean governor recommended not only that the ban be lifted but also that vineyards should be actively encouraged. In the 18th century, Chile was known for the quantity and affordability of its wines, much to the dismay of some Spanish wine producers.

At that time, and into the early 19th century, the wines were fairly primitive by modern standards, commonly sweetened with boiled, concentrated MUST, for example. It was Chile's great good fortune that an energetic Frenchman, Claudio Gay, persuaded the Chilean government to set up the Quinta Normal, an experimental nursery for all manner of exotic botanical specimens, including European vines, as early as 1830. This meant that Chile had its own collection of *vinifera* cuttings safely banked in viticultural isolation before the onset

of the world's late 19th century vineyard scourges of POWDERY MILDEW and PHYLLOXERA, although it was private enterprise which, as so often, provided the spur to the nation's wine industry.

Now independent of Spanish domination, wealthy Chileans began to travel and experience a wider world, which included the fine wines of Europe. One of these was Silvestre Ochagavía Echazarreta, who in 1851 imported a range of vine varieties. These cuttings were to form the basis of Chile's modern wine industry. A class of gentlemen farmers was emerging in Chile, some of whom had made their fortunes as a result of Chile's rich mineral deposits. Owning a vine-growing country estate on the fertile land outside Santiago, preferably run by one of the many French refugees from phylloxera, was a sign of success in 19th-century Chile.

It was not long before Chile could boast the world's only healthy wine industry, both viticulturally and financially, run effectively by ten rich families (several of them of Basque origin) and their descendants. The industry, still (as today) substantially in private hands, was so profitable, and per capita wine consumption so high, that it was increasingly energetically taxed and constricted as the 20th century wore on. Restrictions on both planting vineyards and alcohol consumption placed a brake on the industry; by the early 1980s, wine prices had plummeted and about half of Chile's vineyards had been pulled up. It was not until the return of free trade and democracy in the 1980s that the industry began to recover. Between 1987 and 1993, more than 10,000 ha/25,000 acres of vineyard were planted with INTERNATIONAL VARIETIES, significant investments were made in winemaking technology, and the focus of the wine industry switched from quantity for the domestic market to quality for export markets.

Today, Chile's wine-related activity continues to be concentrated among just four companies—CONCHA Y TORO, Santa Rita, Santa Carolina, and San Pedro—which account for approximately 80% of the country's total production. Yet, over the last two decades, investors from other fields of commerce have more recently entered the fray via the likes of Ventisquero, Matetic, and Casas del Bosque.

Foreign investment has also come from California (KENDALL-JACKSON, MONDAVI), France (Chx MOUTON ROTHSCHILD, Lafite-ROTHSCHILD, and others), and Spain (FAMILIA TORRES). In addition, a number of smaller, independent producers have emerged, some banding together to form producers' groups such as MOVI (Movimiento de Viñateros Independientes) and Chanchos Deslenguados. Some of Chile's most diverse and exciting wines today come from members of these organizations.

Geography and climate

Chile extends nearly 4,300 km/2,670 miles north to south. It is also very narrow (at its narrowest it is barely 95 km/59 miles wide). Squeezed between the Pacific Ocean and the Andes (80% of Chile is mountainous), land suitable for viticulture is limited, although quite varied. Of the 136,288 ha/336,774 acres planted in 2018, nearly 74% was dedicated to red wine grapes.

Although Chile's vineyards stretch from latitude 23 to 46° S, the great majority of Chilean wine is produced in latitudes 32–38° S. A northern hemisphere counterpart to these latitudes would be North Africa and southern Spain, but in Chile temperatures are considerably mitigated by the influence of the Pacific and its cold Humboldt current.

Until the 1980s, Chile's finest wines (primarily Cabernet Sauvignon) came from sectors close to the Andean foothills in the Maipo Valley, while the simple, keenly priced VARIETAL wines for which Chile was best known abroad were grown on the fertile, well-irrigated lands of the Central Valley. This 1,000-km-long plateau nestles between two mountain ranges: a relatively low coastal range, with peaks reaching 300–800 m/1,000–2,600 ft; and the Andes, which can reach elevations of 6,000 m here. The valley is dissected by many rivers which carry torrents of melted snow from the Andes to the Pacific during the growing season: IRRIGATION made easy.

Although there are distinct variations between individual regions and subregions (see below), the climate in the Central Valley is generally MEDITERRANEAN, with warm, dry summers and annual rainfall averaging 300–800 mm/12–31 in restricted to the winter, thanks to the effect of the Pacific high-pressure area. Rainfall in the Central Valley tends to increase both in the south and east, on the slopes of the Andes. On the valley's western edge, summer temperatures average 15–18 °C/59–64 °F and may rise to 30 °C/86 °F, with clear skies, strong sunlight, and relatively low humidity of just 55–60%. On the valley's eastern edge, however, because of cold air drainage from the Andes at night, there is a much wider DIURNAL TEMPERATURE RANGE,

contributing to particularly good levels of ACIDITY and COLOUR in grapes.

Since the early 1980s, more attention has been paid to developing viticulture in cooler wine zones such as Casablanca Valley, established in 1982. The San Antonio and Limarí Valley regions, developed in the latter half of the 1990s, are the most obvious examples of more daring viticulture in less reliable climates. Projects that bear particular mention include the Flaño family's Viñedos de Alcohuaz winery, at 2,000 m/6,652 ft ELEVATION in the Elqui Valley, and Casa Marín, trailblazers in Lo Abarca, just 4 km/2.5 miles from the cold Pacific Ocean in the San Antonio Valley.

Southern regions such as Bío-Bío and Malleco are also being developed for serious wine production. In carefully selected sites in places such as Mulchén and Traiguén, vines can yield good white wines and some exciting reds, especially Pinot Noir, although FROST and excessive rain may prejudice quality south of Temuco. Meanwhile traditional and historic zones such as Itata have been rediscovered by wineries from the central zone such as De Martino and Miguel Torres, who are crafting wines from the region's old Cinsault, País, and Moscatel de Alejandría vines.

Regions and soils

Traditionally, Chile's wine regions were divided from north to south following administrative and provincial divisions rather than according to likely TERROIR effects. This system is slowly being modified. A first step was the 2013 geographical divisions of the wine valleys into Andes, Entre Cordilleras (between mountain ranges), and Costa (coastal). This transversal division from east to west aims to reflect the impact of the effects of the Andes as well as the Pacific—both cooling influences—in contrast to the valleys, where the climate tends to be warmer. Dozens of exceptions are already evident, but this general division is at least a first step towards recognizing the influence of Chile's mountainous topography and the Pacific Ocean on the character of its wines.

From north to south the main wine regions, with their most significant subregions, are as follows (see map):

Coquimbo: Elqui, Limarí, Choapa
Aconcagua: Aconcagua, Casablanca, San Antonio (including Leyda)
Central Valley: Maipo, Rapel (including Cachapoal, Colchagua), Curicó (including Teno, Lontué), Maule (including Claro, Loncomilla, Tutuven and its subregion Cauquenes)
Southern region: Itata, Bío-Bío, Malleco
Austral region: Cautin, Osorno

In general, Chile's vineyards are planted on flat, fertile land where water is readily available either naturally or through irrigation, so that vine root systems are relatively shallow. ALLUVIAL soils predominate in Aconcagua and are also present to the south in Maipo, although here there are LOAMS and occasionally CLAY soils too. In both the Maipo region and the Cachapoal district of northern Rapel, there are mixtures of loam, clay, and SAND, some of which may be subject to SOIL EROSION on slopes. Soils are similar in southern Rapel and Maule, while VOLCANIC soils extend from south of Curicó to the Bío-Bío region,

interrupted only by sand and sandy loam around Linares. Some parts of Cachapoal, Colchagua, and the Southern region suffer from relatively poor drainage, can be quite swampy, and may need no irrigation.

Coquimbo Coquimbo, 500 km/311 miles north of the capital Santiago, primarily comprises the Limarí and Elqui Valleys (as well as the little-developed Choapa Valley) and was historically focused on TABLE GRAPES and Chile's own CONTROLLED APPELLATION grape spirit pisco, to which nearly 9,172 ha/22,664 acres of vineyards were dedicated in 2018. Another 3,147 ha/7,776 acres of vineyards are dedicated to wine production, mostly in Limarí and Elqui. There is intense SUNLIGHT throughout the year and less than 100 mm/4 in of annual rainfall. Although some fine wines have emerged, water shortages are threatening the region's survival, a factor that historically dissuaded vine growers from planting here. It wasn't until the mid 1990s that Viña Francisco de Aguirre started to produce exciting table wines in the Limarí Valley, 20 km from the Pacific coast where Viña Tabalí had been established by the early 2000s. The cooling ocean influence plays an important part in delaying ripening in both Limarí and Elqui, which, in combination with rocky soils of clay and LIMESTONE, yields some of the region's best wines.

Aconcagua Named after the river which bisects it, Aconcagua is made up of three distinct zones. The interior of Aconcagua is one of Chile's hottest, driest wine regions, with summer temperatures often above 30 °C/86 °F. Soils are mainly alluvial, and the region produces some good red wines. To the west is the intermediate region, a much gentler climate cooled by coastal breezes. This is home to the Aconcagua vineyards responsible for such Chilean classics as Don Maximiano from Viña Errázuriz and Seña, grown closer to the coast. A third area is on the hillsides of the coastal range in Manzanar, strongly influenced by cold breezes off the Pacific Ocean. With clay and stony soils and gently rolling hills, this new area is part of the westward expansion taking place in several Chilean valleys and already producing exceptional Chardonnay and Pinot Noir.

Casablanca and San Antonio Although both zones are coastal and, politically speaking, belong to the Aconcagua Valley, Casablanca and San Antonio—the two largest sources of cold-climate whites in Chile—are different in various aspects. Casablanca's vineyards are cooled to Winkler Region I (see CLIMATE CLASSIFICATION) by cool morning fogs, the result of the Pacific's icy Humboldt current (which has a similar effect thousands of miles up the coast in California). Frequent cloud cover slows ripening and reduces the average number of clear days per year to 180, as opposed to 240–300 in the interior. Spring FROSTS are a real hazard, but specialist grape-growers and most of the big companies have planted varieties such as Sauvignon Blanc, Chardonnay, and Pinot Noir extensively since the region's beginnings in the early 1980s. As the region runs from east to west, temperatures rise with distance from the ocean, and there can be more than a month's difference in harvest dates between eastern Casablanca (also known as Upper or Alto Casablanca) and the western zone (Lower or Bajo Casablanca). Soils vary enormously, although they generally tend to be sandy in Alto Casablanca and become increasingly GRANITIC with a higher clay content with proximity to the coast.

Planting began in San Antonio in the late 1990s. Climate, soils, and topography are quite similar to Bajo Casablanca. The landscape typically features rolling hills, clay, and granitic soils; like nearly all of Chile's coastline, it is cooled by coastal breezes. San Antonio Valley and its most planted area, Leyda, runs north–south, parallel to the coast, with an average direct distance from vineyard to ocean of 15 km/9 miles. Sauvignon Blanc is the valley's flagship variety, and promising Pinot Noir, Chardonnay, and sparkling wine is also made.

Maipo The most famous wine region in Chile, surrounding the capital Santiago, is not one of the largest. In 2018, some 11,584 ha/28,624 acres of vines were recorded, with a clear predominance of red over white grapes. Cabernet Sauvignon and Chardonnay were the most widely planted, although Merlot, Carmenère, and Sauvignon Blanc are also important. Annual rainfall averages just 300 mm/12 in, most of it falling in the winter. IRRIGATION is common, although the water can be quite saline around the Maipo river from which the region takes its name. Maipo is famous for producing Chile's most lauded Cabernet Sauvignon, especially towards the foot of the Andes Mountains, in areas such as Macul, Pirque, and Puente Alto.

Rapel About 150 km south of Santiago, Rapel had more than 45,142,000 ha/111,548 acres of vineyards in 2018 and is divided into two subzones: Cachapoal to the north and Colchagua to the south. Both are transversal valleys running from the Andes to the Pacific Ocean, which results in pronounced differences in the wines depending on their proximity to the cooling influence of the Andes (Alto Cachapoal and Alto Colchagua). Some of Chile's finest red wines come from the Andean foothills here, especially in individual zones such as Apalta, where French-owned winery Casa Lapostolle and Viña Montes have helped develop the region's reputation for fine Merlot, Carmenère, and Syrah. Cabernet Sauvignon, Carmenère, and Merlot are the most planted grape varieties, and the region has become especially known for full-flavoured red wines. Wineries such as Santa Emiliana, Santa Rita, Undurraga, and Viña Montes all made considerable vineyard investments in Colchagua in the 1990s. The latest trend in Rapel, specifically in Colchagua, has been to take maximum advantage of its transversal characteristics by exploiting coastal zones such as Lolol and especially Paredones (just 15 km/9.3 miles from the Pacific), which produces Pinot Noir and Sauvignon Blanc to rival those of Casablanca and San Antonio.

Curicó Formed by the subregions Lontué and Teno, Curicó Valley was put on the international map when Miguel Torres (see FAMILIA

TORRES) arrived there in 1979. By 2018, the valley had 19,653 ha/485,563 acres planted. Curicó has two MESOCLIMATES. Towards the east, around Molina and north of the Claro river, the climate is cooled by Andean breezes. To the west, the coastal range minimizes the ocean influence, and the climate is warmer, sometimes notably hot and dry. Even though the valley does not have any particular speciality, the wide range of varieties planted are generally good quality.

Maule The largest wine region in Chile's Central Valley, Maule covers some 34,155 ha/84,398 acres according to official records (although there are some doubts about the efficiency of filing vineyard statistics in this region of smallholders). In its wide territory, the climate can vary from very warm in the central plains to cloudy and cool towards the coast. The PAÍS vine variety used to dominate plantings, especially in the rain-fed areas, and it has been the traditional raw material for the historic *pipeño*, a peasant wine designed to quench thirst. A new generation of producers has rescued this variety, using it to craft wines of great freshness and juiciness, often labelled Secano Interior. Maule also has more CARIGNAN planted than any other valley, and the variety is now undergoing a revival among Chilean producers. The grapes from old vines in DRY-FARMED coastal zones provide the raw material for members of VIGNO (Vignadores del Carignan/Carignan Vintners), an association that aims to promote this long-forgotten variety, planted on the smooth granite slopes of the valley, in old *secano* (unirrigated) vineyards. Maule also has more than half of Chile's 800 ha/1,976 acres of SÉMILLON, once the most widely planted variety in the country (before Sauvignon Blanc and Chardonnay arrived in the late 1980s) and today undergoing a lively revitalization thanks to wineries such as J. Bouchon, Roberto Henríquez, and Carmen.

Southern region Southern Chile had 12,837 ha/31,720 acres of vines in 2018, split evenly between red and white grapes. Formed by Itata, Bío-Bío, and the newer Malleco subregion, this region is more

open than Maipo and Rapel, lacking the protection of a high coastal range, so rainfall is higher and average temperature and sunshine hours are lower. By far the most common vine variety is PAÍS, planted on a total of 4,130 ha/10,205 acres and now the object of a strong revival led by small producers such as French winemaker Louis-Antoine Luyt as well as large wineries such as Concha y Toro. With more than 842 ha/2,080 acres planted, CINSAUT is the region's rising star, especially in the DRY-FARMED zones of Itata, where it produces both simple, thirst-quenching wines as well as complex reds offering a sense of place. The most widely planted white-wine grape is Moscatel de Alejandría (MUSCAT OF ALEXANDRIA), with 3,962 ha/9,790 acres. Little by little, it is being taken more seriously by wineries such as De Martino who vinify it carefully with fine results. However, research in the early 1990s in the Chillán area suggested that, with drip irrigation and appropriate training systems such as the LYRE, good-quality wine from the best-known INTERNATIONAL VARIETIES could be made here. The proof of that lies in the Mulchén and Negrete areas where wineries such as Cono Sur produce crisp Riesling and ripe Pinot Noir. And Malleco, a region 650 km/403 miles south of the capital first planted during the mid 1990s by Felipe de Solminiach, partner in Viña Aquitania, is now home to a small but solid community of producers. Chardonnay and Pinot Noir excel in its cool clay and granite soils.

Austral Region Located about 925 km/574 miles south of Santiago, this is Chile's southernmost wine region. Formed by the valleys of Osorno and Cautín, it is cool and rainy, with only 28 ha/68 acres of vines planted in its VOLCANIC soils, but wineries from the north such as Casa Silva and Miguel Torres, together with smaller projects such as Coteaux de Trumao and Trapi del Bueno, are finding success with varieties such as Chardonnay, Sauvignon Blanc, and Pinot Noir.

Viticulture

IRRIGATION is essential in nearly all Chilean vineyards and, as in Argentina, is made possible by the melting snows of the Andes, diverted along a series of canals and channels as well as through the use of deep wells that exploit groundwater. DRIP IRRIGATION was introduced only in the early 1990s. As a result of this ready and plentiful water supply, most vineyards have good access to water during the growing season. On the slopes of the coastal range in the west of southern regions, rainfall is often sufficient, as it is in most of the Southern region. FERTILIZERS are widely employed, but their use is regulated to avoid an excess of VIGOUR. Drip irrigation allows FERTIGATION in some of the more viticulturally developed areas.

Average YIELDS in Chile are about 70 hl/ha (4 tons/acre). Over-irrigated, high-yielding vines can experience difficulties in RIPENING. This is particularly true of varieties which ripen relatively late, such as Cabernet Sauvignon and Chile's speciality CARMENÈRE, or of high TRAINING SYSTEMS. There is a predictably rich cultural diversity of training and trellis systems in Chile. Some vines, particularly those dedicated to TABLE GRAPES, are trained in variations on the TENDONE system in the high, arbour-like *parrón* trellis which encourages shade (like the *parral* of ARGENTINA). The standard Spanish practice of growing unstaked vines as free-standing BUSH VINES has been common since the Spanish conquest but is today usually restricted to País, Carignan, and Moscatel vines, notably from Maule Valley to the south. The Bordeaux post-PHYLLOXERA immigrants introduced row trellising to Chile at the end of the 19th century, and this has evolved in two distinct ways. Low, narrow rows of vines that are traditional in Europe tend to be double GUYOT pruned or SPUR PRUNED cordons, depending on variety, and used mainly to produce better-quality wines. More common for basic wine production are more widely spaced vines (sometimes with cross-pieces, described as Californian), which permit the increasingly common phenomenon of vineyard MECHANIZATION. In the 1990s, most new plantings were in long narrow rows 2–2.5 m/6.5–8 ft apart, with vines planted 1.2–1.5 m apart.

Australian CANOPY MANAGEMENT techniques were introduced in some vineyards in the early 1990s.

HARVEST of wine grapes begins at the end of February for such early-maturing varieties as Chardonnay, continues through to the end of April for Cabernet Sauvignon, and can last well into May for Carmenère.

No Chilean vine-growers feel they need to study ROOTSTOCKS, since the country is free of phylloxera and the consequent need for grafting. Some FIELD GRAFTING has been undertaken, however, in the rush to increase the proportion of fashionable grape varieties planted. And such is the prevalence of NEMATODES in Chilean vineyards, because of *vinifera*'s low resistance to them relative to American vine species, that some authorities suggest using American rootstocks to combat this problem. Chile's vines are by no means free of VIRUS DISEASES: POWDERY MILDEW and BOTRYTIS BUNCH ROT are annual and potentially extremely costly vine diseases, with VERTICILLIUM WILT another serious vine health hazard. DOWNY MILDEW infections occurred in some areas for the first time during the heavily EL NIÑO-influenced 1997–8 growing season. The absence of summer rains means that SPRAYING is generally much less frequent than in many other wine regions, however. ORGANIC VITICULTURE has been becoming more prevalent.

Vine varieties

VINE IDENTIFICATION arrived relatively late in Chile. Conscious of its unique status as a wine-producing country yet unravaged by phylloxera, Chile imposes a particularly strict QUARANTINE on imported plant material, which has helped to maintain certain aspects of its viticultural isolation. The quality and identity of the vines grown was the most dramatic example of this. Most vines called Sauvignon by the Chileans, for example, were almost certainly Sauvignon Vert, SAUVIGNONASSE (or Friulano), and occasionally Sauvignon Gris, rather than the more familiar Sauvignon Blanc. Only a small but increasing proportion of Sauvignon Blanc, almost exclusively based on CLONES developed in California, had been planted by the early 1990s, and even by the mid 2000s official statistics claiming 7,400 ha/18,300 acres of Sauvignon Blanc and just 200 ha of Sauvignon Vert probably did not reflect the true proportions of these two varieties. Thanks to the new plantations and more fastidious differentiation between Sauvignons Blanc and Vert, official statistics for 2018 suggest there are 15,222 ha/37,614 acres of Sauvignon Blanc versus 448 ha/1,107 acres of Sauvignon Vert.

Similarly, vines called Merlot are usually in fact a mixture, and sometimes a FIELD BLEND, of Merlot and the old Bordeaux variety CARMENÈRE, first identified as such in Chile in 1994. The vine identification required to distinguish Merlot from Carmenère is continuing, and since the mid 1990s the word 'Carmenère' has increasingly appeared on wine labels both as a varietal wine and, perhaps more suitably, an ingredient in a blend.

Until the 1990s, the most commonly planted grape variety was the dark-skinned PAÍS, identical to the CRIOLLA CHICA of Argentina and the MISSION of California, a direct descendant of Listán Prieto cuttings imported by the Spanish colonists. Although the variety is currently undergoing a revival, plantings have been declining since the 1980s, when there were some 30,000 ha planted; by 2018 there were just

10,319 ha/25,498 acres, the great majority planted in the southern Maule and Bío-Bío regions.

Today Cabernet Sauvignon is the most important variety in Chile by quite a margin, with 40,204 ha/99,346 acres planted, followed by Sauvignon Blanc, Merlot, and Chardonnay. MUSCAT OF ALEXANDRIA counts just over 4,368 ha, about half the total planted in the mid 2000s. The early years of this century saw a dramatic increase in plantings of Syrah, which totalled 7,528 by 2018, and Pinot Noir with a total of 4,045 ha (60% as much as is planted on the CÔTE D'OR).

Such new plant material as is allowed in has come mainly from DAVIS, as well as from European nurseries. The idea of clonal material, absent in the Chilean viticultural scene until the early 1990s, is now common when it comes to new vineyard plantations.

Winemaking

Chile has undergone possibly the most dramatic technological revolution in the wine world. Wineries were for decades underfunded as the domestic market could be satisfied with often oxidized white wines and faded reds made with the most traditional of equipment. All wines were made from grapes trucked, often in very high temperatures with scant regard for OXIDATION, to wineries equipped with little in the way of TEMPERATURE CONTROL; they were made exclusively in vats made either of CONCRETE or the coarse local *raulí* (evergreen beech) WOOD, usually coopered many decades previously. In the late 1980s, however, the wine industry made a commitment to the long-term future of Chile as a wine exporter and began to invest in the equipment necessary for that goal. Outside investors assisted the influx of both equipment and expertise, and since then the wineries of Chile were invaded, at a pace usually determined by the enterprise's size and cash flow, by pneumatic PRESSES, OAK BARRELS, STAINLESS STEEL, and modern filters. Today one is likely to find a fair share of ceramic eggs, terracotta AMPHORAE, and other earthenware vessels in addition to concrete and steel tanks, a nod to current trends in low-intervention winemaking. China , vast Asian country with its own indigenous vine species (see VITIS) but a relatively short modern tradition of growing VITIS VINIFERA grapes to make wine. In recent decades, China's development as a wine-producing nation has evolved alongside the country's rapid modernization, holding the world's third largest vineyard area (after

SPAIN and FRANCE), albeit mostly planted to TABLE GRAPES. As consumption growth has slowed in recent years, the domestic industry has become increasingly focused on quality production in a bid to target a minority of more engaged consumers.

Ancient history

Various grape species have long been grown in China, including *Vitis amurensis* (see below). Geological fossils show that *Vitis romanetii Roman du Caill. ex Planch*. existed in Linqu county, Shandong province, 26 million years ago, while the earliest chemically attested instance to date of grapes being used in a fermented beverage was during the seventh millennium BCE at the Neolithic site of Jiahu, Henan. The earliest written record of grapes in China is in the poem *Qi Yue* in the *Odes of Bin* from the *Classic of Poetry* (*Shijing*), dating back to the Shang Dynasty (*c.*1600 BCE–*c.*1000 BCE):

> In the sixth month partake of plums and grapes; in the seventh, cook vegetables and pulses; in the eighth, knock the jujube harvest down; in the tenth, reap rice and ferment the wine for spring, for the benefit of the elders.

The introduction of *vinifera* to China can be dated to the 4th century BCE. In *On Ancient Central Asian Tracks: Brief Narrative of Three Expeditions in Innermost Asia and Northwestern China*, Marc Aurel Stein describes the tidy plots of vineyard sites outside the courtyards of houses in the ancient city of Niya (1st–3rd century CE), 150 km/93 miles north of the modern Minfeng county, in the Shan Shan prefecture of Xinjiang. A 1959 archaeological investigation of Niya excavated relics from an ancient tomb (carbon-14 dated to 2,295±75 years old) decorated with patterns of grape bunches as well as dried grapes in containers. It appears, therefore, that there was viticulture here dating back to the 3rd to 1st centuries BCE. Archaeological expeditions in southern TURKMENISTAN and UZBEKISTAN, which unearthed grapes as well as text descriptions and decorations of grapes from a 4th-century BCE residential site, also suggest that *vinifera* may well have been introduced to China from Central Asia along the Silk Road.

Two notable old varieties of *vinifera*, both TABLE GRAPES, are the dark-skinned Dragon's Eye (*Longyan*) and pale Mare's Teat (*Manai*), the former long grown along the path of the Great Wall and, for even

longer, also in far western China. Their import to and successful cultivation within China demonstrates that viticulture prospered in many such western parts of the territory. Wine was also made from the native grapes of the *Vitis thunbergii* species, found naturally in the provinces of Shandong and Jiangxi, from the *Vitis heyneana* of Guangxi province, *Vitis davidii* of Jiangxi and Hunan provinces, and *Vitis amurensis* from north-eastern China (Liaoning province).

References to grape-derived alcohol in ancient sources are rare and often found as an 'exotic' beverage, as can be seen from this Tang Dynasty (618-907 CE) poem set in the western Chinese borderlands:

> Wonderous wine in the moon-glowing cup, I desire to drink, but am urged onwards by the *pipa*
> Please do not mock me for battle-field drunkenness, for up to now how many have returned safely from war?

This poem, unlike many, clearly states that the wine is produced from grapes. Indeed, a challenge in understanding the history of (grape) wine is that Chinese does not distinguish between alcohols from different sources: the relevant character 'jiu' literally means alcohol in any form, so it is difficult to distinguish wine from beer or spirits. In fact, most references to 'wine' in literature and the arts refer to grain-based alcohol, either distilled (*baijiu*) or an oxidized rice wine (*huangjiu*). Thus, it is hard to clearly state which classical references refer to wine from grapes and which to alcoholic drinks in general.

Modern history

China is usually considered a NEW WORLD country mainly because its modern wine industry traces its roots to as recently as the late 19th century. At this time, the development of the modern Chinese wine industry began to emerge under the influence of foreign settlements, particularly Catholic missionaries. In 1892, Zhang Bishi, a native of Guangdong, who had been stationed in southern Asian countries in service of the Qing government, returned to China and established the CHANGYU winery in Yantai, the longest continually existent winery in China to date. Zhang introduced over 100 *vinifera* varieties from Europe and apparently employed the then Austrian consul as his winemaker. Shang Yi winery was set up by French Catholics in 1910 in the suburbs of Beijing mainly to supply wine for Mass, becoming known as the Beijing Winery. Other early wineries include Yi Hua winery (in Shanxi) established by Chinese nationals in 1921, and the Chang Bai Shan and Tung Hua (Tonghua) wineries in Jilin, set up and managed by the Japanese during the Japanese Occupation.

In 1949, the wineries were expanded by the new Communist government and, for reasons of economy, resulted in the blending of grape wine with other juices, water, colouring agents, and fermented cereals. The industry remained highly unsophisticated until after 1978 when China opened again to the outside world.

Tiansai Skyline of the Gobi, a grape oasis in the desert at the foot of the Tianshan Mountains in Xinjiang's Yanqi Basin in north-west CHINA, was established in 2010. Thanks to IRRIGATION from mountain snowmelt, they have pioneered varieties such as MARSELAN and MALBEC and are highly regarded for their CHARDONNAY. © NYSH Productions

After 1979 foreign investment was encouraged, and the following year Cognac giant Rémy Martin set up the first JOINT VENTURE winery

—the Sino-French Joint Venture Winery (Dynasty)—with the Tianjin Agriculture Bureau. Xinjiang's first Western-style winery, Lou Lan, was established by the state in the 1970s (although is now in private hands). In 1988, the state-owned enterprise China National Cereals, Oils, Foodstuffs Import & Export Corporation (COFCO) started making Great Wall–branded wines in Hebei. Both Dynasty and Great Wall applied modern winemaking techniques to produce simple, medium-dry white table wines from the local Dragon's Eye, MUSCAT OF HAMBURG, and other local table grapes. China's first 'château-style' wine estate to plant and produce VARIETAL and vintage-dated wines, Huadong, was started by Englishman Michael Parry just outside Qingdao in 1985 and bore the appellation Tsingtao. In 1987 Pernod Ricard set up the Dragon Seal winery on Beijing's outskirts. All such ventures relied on imported vinification equipment, European vine cuttings, and foreign OENOLOGISTS, with other Chinese wineries following their lead.

Beginning in the mid-to-late 1990s, the Chinese government, motivated by HEALTH concerns and concern for grain supplies, encouraged the development of fruit-based alcohol rather than traditional grain-based drinks, while wine consumers switched from favouring white to red wine. *Baijiu* (white spirits) producers began to make or bottle wines. Between 1996 and 2004, more than 100 new wineries, state-owned and private, were established. Even high-ELEVATION Yunnan turned to wine production with the Shangrila Wine Company planting vineyards in the late 1990s.

In recent years, regions have exploded with projects, with some of the largest, such as the CITIC Guoan group (Niya brand, previously Vini Suntime), setting up in Xinjiang and Ningxia. At the same time, smaller Chinese family-owned wineries have been emerging from behind the behemoths to take their place on the world stage: these include Silver Heights in Ningxia (2007), Tiansai Skyline of the Gobi in Xinjiang (2010), and Longting in Shandong (2013).

In addition, foreign companies have continued to establish JOINT VENTURE projects including Pernod Ricard's Helan Mountain, LVMH's Domaine Chandon (Ningxia) and Ao Yun (Yunnan), and DBR Lafite's

Domaine de Long Dai (Shandong), bringing further international expertise to China’s vineyards and wineries.

Geography and climate

The vast majority of the ~783,000 ha/1,934,835 acres of Chinese vineyards (2021) are planted with TABLE GRAPES and RAISINS. Most viticultural areas are in a band at latitude 33–40° N across the north of the country stretching from the largest area in Xinjiang (over 20% of vineyard area) to Ningxia, Gansu, Shanxi, Hebei, and Shandong. The extreme north (Liaoning province) is devoted to ICE WINE production, and the most southerly vineyards are in high-elevation Yunnan.

Overall, China's climate is not highly amenable to wine production: winters can be extremely arid and cold, while in the summer and autumn the monsoon rains bring high humidity resulting in FUNGAL DISEASES and ROT. This ripening period-specific humidity affects nearly all of China's vineyard areas, though effects are greatly reduced in the desert-like conditions of China's far west (Xinjiang).

European styles of VINE TRAINING can be seen only where WINTER PROTECTION is unnecessary for vines. Historically, the most important of these areas was Shandong (19,500 ha/48,185 acres in 2021) protected from winter extremes by its MARITIME CLIMATE, although this can also bring heavy rainfall and disease pressure during ripening. In the far south in Yunnan province, the Shangri-la area—close to Tibet and shared between Yunnan and Sichuan provinces—has a long, frost-free season in its steep valleys located at elevations of 1,600–2,900 m/5,249–9,514 ft. above the Mekong river. At such low latitudes (27–28 °N), the high elevation moderates temperatures and valley winds reduce fungal disease pressure.

For all other areas, vines require winter protection due not only to extremely low temperatures but also to the desiccating winds that sweep across northern China. In the far west, Xinjiang has the lowest natural rainfall (around 80 mm/3 in); but irrigation water is available through the Tianshan snow-capped mountains and Bositeng Lake. This huge province is generally divided into northern and southern areas, with varying elevations of over 1,000 m to the sub-sea-level

area of Turpan (155 m/500 ft below). The naturally dry environment, high summer temperatures, along with plentiful sunshine and flat plains (mainly sandy LOAM over GRANITE) mean that vines are relatively disease-free and require only minimal SPRAYING. Much of the wine produced in its 33,500 ha/82,780 acres (2021) is sold in BULK.

To the east of Xinjiang lie Ningxia and Gansu, with similar monsoon-influenced CONTINENTAL CLIMATES featuring very arid winters and hot, potentially moist, summers with relatively limited rainfall (290 mm/11 in). Both have high sunshine hours and are cooler than Xinjiang but have similarly short growing seasons with winter burial needing to be completed by mid November.

Ningxia, particularly the subregion of Donglu, Helan Mountain, has been massively developed in recent years with the support of local government. There are around 34,000 ha/84,015 acres of vineyard with plans to expand to 66,000 ha/163,089 acres by 2025, all irrigated by the Yellow River, located on plains of gravelly and sandy soils (the region lies directly east of the Tengri desert). Gansu is much smaller: accounting for just 2,000 ha/4,942 acres (2021) of vineyard area for wine with a shorter frost-free period relative to Ningxia.

Moving towards the east, Shanxi (2,500 ha/6,177 acres) and Hebei (7,000 ha) experience less severe winters, requiring less extreme winter protection but encountering greater disease pressure from more marked monsoonal influence. Finally, in Liaoning (700 ha/1,729 acres) to the far north, winter protection is essential against the frigid temperatures, and cold-hardy cultivars are preferred.

Grape varieties

The modern era of selecting and breeding table and wine grapes (see VINE BREEDING) started in China in the 1950s, with one key aim being to breed red wine varieties with cold resistance. The highly cold-resistant Mongolian species VITIS AMURENSIS has been widely used in crossings with *vinifera* to create varieties which can survive below −20 °C/−4 °F. For example, the cold-resistant Beichun, Beihong, and Beimei varieties were bred in Beijing in 1954 by crossing MUSCAT OF HAMBURG with *amurensis*. Other crosses were also created by organizations such as the Shandong Grape Experiment Station and the Zhengzhou Fruit Research Institute, including: Meichun, Meiyu, Meinong, Hongzhilu (all Merlot × Petit Verdot crosses), Quanbai (Riesling × Petit Verdot), Quanyu (Riesling × Muscat of Hamburg), as well as Yan 73, and Yan 74 (Alicante Bouchet × Muscat of Hamburg), which are found in limited qualities to this day.

However, most commercially cultivated wine grapes today are standard INTERNATIONAL VARIETIES. The original stocks from the wineries established at the turn of the 20th century continued to be cultivated, including Cabernet Gernischt, confirmed by DNA PROFILING to be CARMENÈRE. During the 1950s and 1960s, Soviet bloc consultants brought in varieties such as RKATSITELI and SAPERAVI, which are mainly found in Xinjiang. Since the late 1970s, many cuttings have been brought in from the US and Europe, but lack of quality control and expertise resulted in widespread problems with FANLEAF DEGENERATION and other viruses. China's first vine NURSERY was established in the north of the Shandong Peninsula in the early 2000s as a joint venture between COFCO and the French nursery Arrive and was rapidly followed by others. However, the selection of varieties was relatively narrow until the 2000s when both government agencies such as the Ningxia Grape Development Bureau and private wineries began to import a wider range including AGLIANICO, TEMPRANILLO, MALBEC, and MARSELAN.

Black varieties account for over 80% of wine grape plantings. With Cabernet Sauvignon at 60,000 ha/148,263 acres, the next three main varieties, Merlot, Carmenère and CABERNET FRANC, account for only 18,000 ha/44,478 acres in total. Other black varieties include SYRAH, PINOT NOIR, SAPERAVI, PETIT VERDOT, CARIGNAN, and a small percentage of the above-mentioned Chinese varieties with a growing area of Marselan, favoured due to its disease resistance, high YIELD, and plentiful PHENOLICS. Malbec is also expressing great potential in Xinjiang, where conditions are comparable to ARGENTINA. Of white varieties, CHARDONNAY and Riesling (principally WELSCHRIESLING but also some true RIESLING) account for 6,000 ha/14,826 acres, with PETIT MANSENG, also notable for high disease resistance, emerging as a Shandong potential star.

Viticulture

Traditionally grapes were supplied on contract, grown on intensively subdivided lands with farmers making final decisions, thus accounting for the high proportion of table grapes, which are less risky and achieve higher prices due to the demand and respect for quality fruit in the domestic market. The traditional viticultural practices of fan trellis systems (see TRAINING SYSTEMS), dense foliage, high YIELDS, heavy IRRIGATION, peanut/bean inter-row plantings, and early picking to avoid disease (combined with grape prices being determined by weight) all hindered quality grape production. Thus, in the modern era, wineries are actively negotiating land leases to be able to manage their vineyards directly. However, the rural workforce is increasingly ageing as young Chinese move to cities, making LABOUR shortages and costs an issue in some regions. Vineyard development is also hindered by the limited lease-span (30 years) given on agricultural land (in China all land is owned by the state), making long-term investment a challenge.

WINTER PROTECTION is essential in most regions and accounts for about one-third of viticultural costs (providing increased pressure for mechanization throughout China). It is achieved mainly through earth-burial as GEOTEXTILES are hard to anchor in the high winds and do not combat desiccation well. Vines are also generally unearthed very late in the season (even after BUDBREAK in some cases) due to the dangers of desiccation from dry spring winds. As the vine ages, burial also becomes more problematic as trunks need to be bent down to assist burial, which can result in damage. Plant material is divided between ungrafted and GRAFTED because winter burial of young vines can also result in graft damage. Thus, many newly established vineyards still plant ungrafted materials, as PHYLLOXERA is not widespread. Winter protection also means that Chinese vineyards have unique TRAINING SYSTEMS to facilitate this practice, with all the traditional fan systems lacking a unified fruit zone (resulting in uneven ripeness). Modern vineyards have established *changzi*

training (slanting trunk with renewed CORDON) to overcome this problem.

IRRIGATION is widespread, traditionally done by flooding but now with most areas converted to drip for conservation and SUSTAINABILITY. Most disease pressure is related to the monsoonal rain influence and dense canopies. ANTHRACNOSE, POWDERY MILDEW, DOWNY MILDEW, DEAD ARM, and WHITE ROT are commonplace. Some wineries are attempting ORGANIC VITICULTURE but the majority rely on modern FUNGICIDES. Harvest and spraying dates are also difficult to manage under the traditional farmer-co-operation model, giving another reason for wineries to move to the CHÂTEAU model.

Winemaking and wine styles

Despite the popularity of the medium-dry white styles of the 1980s and 1990s, since 2000 China has wholeheartedly embraced dry red, Bordelais winemaking, due in part to perception of the health benefits and to the influence of Bordeaux as the then main choice of overseas training for Chinese oenologists. Heavy extraction and use of excessive new oak, along with a lack of knowledge of international styles, resulted in many clumsy wines in the early 2000s. Owing to high levels of warmth and sunlight, high alcohol levels also present a challenge and can co-exist with unripe tannins and greenness (due to traditional fan training systems and lack of harvest timing control). But breakthrough success emerged when Helanqingxue Winery's Jiabeilan 2009 Grand Reserve achieved a Decanter Trophy in 2011, spurring many into a quality direction. The investment of multinationals such as LVMH (Chandon and Ao Yun) and Pernod Ricard has also added more international expertise; and recent years have seen Chinese students returning from overseas (US, Australia, Germany) bringing greater experience of global styles, resulting in the emergence of sparkling wines, medium-dry rosés, lighter reds, and more focus on whites. NATURAL WINES have also begun to appear with some experimenting with fermentation in traditional Chinese ceramic pots.

In 2021, China's wine industry received arguably its greatest boost when the government promulgated plans to triple the current vineyard area in Ningxia by 2035 and to increase wine production value to more than US$30 billion (more than seven times its current size). However, perhaps the greatest challenges for Chinese wine production lie in convincing domestic consumers, who have become increasingly enamoured of imported wines, to return to Chinese wine while courting international consumers to experiment with this new country of origin.

E.R. & F.W.

Chinon, the largest red-wine appellation of the LOIRE by volume located around the royal city of CHINON in the TOURAINE district in which a small amount of rosé and in-demand dry white CHENIN BLANC are also produced. CABERNET FRANC, locally called Breton, is the main grape variety, and if CABERNET SAUVIGNON is allowed up to 10%, its presence is anecdotal while Chenin plantings are on the rise. Chinon's vineyards stretch south of the Loire on both banks of the Vienne over 2,400 ha/5,900 acres after expanding its western boundaries from Candes-St-Martin to Seuilly just east of SAUMUR-CHAMPIGNY in 2016 (Chinon had fallen to a few hundred hectares in the 1950s). Yet the majority of the wines are made on the right bank with Cravant-les-Coteaux as the main producing commune. Protected by forests to the east and west and by small hills called *puys*, Chinon enjoys one of the warmest climates of Touraine, and its wines tend to be more concentrated than those of its neighbours. Two main styles of wines are made from three distinct soil types. Lighter reds, close in style to St-Nicolas-de-Bourgueil, come from the *varennes*, a local name for the ALLUVIAL terraces of the Loire and the Vienne, with elegant examples produced in Panzoult. The more structured, barrel-aged CABERNET FRANC wines are made on the steep yellow and white TUFFEAU slopes (like in BOURGUEIL) and the sandy LIMESTONE plateaus covered with FLINTY clay (knowns as *perruches*), with Beaumont-en-Véron, Chinon, and Cravant as lauded areas. Single vineyards already praised by the region's most famous son, the early 16th century writer Rabelais, appear frequently on wine labels. Once considered little more than light refreshment, Chinon wines have become more satisfying with improved viticulture to reach ideal maturity. The top wines of growers such as Baudry or Philippe Alliet can be cellared a decade or more, and, although a good proportion of wine ends up in merchants' blends of variable quality, an ambitious generation is taking root in the area. See LOIRE, including map. P. Le.

chip budding, a popular method for the BUDDING of vines, with a long history. It is known as the yema bud in Europe and California.

During the first growing season of the ROOTSTOCK, a piece is cut from its original wood and a matching chip piece with a bud is cut from a SCION cutting. The chip is inserted in the stock with CAMBIUM zones matching, then wrapped tightly with budding tape . Chip budding, which may take place at any time of year, may also be used for TOP GRAFTING.

See also FIELD GRAFTING.

Chiroubles, highest ELEVATION of the BEAUJOLAIS crus, producing wines that can be refreshing but also rustic. The soils continue the mix of sandy and denser GRANITE in neighbouring FLEURIE and MORGON but wines can be strident or tart when young. Total vineyard area is a modest 301 ha/743 acres. J.F.B.

chitosan, a natural POLYSACCHARIDE derived from chitins, the principal components of the cell walls of fungi and plants and found in the skeletons of insects and the shells of crustaceans. While chitosan's mode of action is not fully understood, it is promoted as a versatile PROCESSING AID, especially for its antimicrobial properties, for example in relation to BRETT, LACTIC ACID BACTERIA, and ACETOBACTER. Only chitosan derived from the fungus *Aspergillus niger* has been authorized by the OIV and the EU for use in winemaking. It has also been found to be effective as an antioxidant, as an adjunct in CLARIFICATION, and to remove COPPER from wine. In the vineyard, trials suggest spraying vines with chitosan may increase PHENOLIC compounds in grapes.

Castro Marín, A., et al., 'Relevance and perspectives of the use of chitosan in winemaking: a review', *Critical Reviews in Food Science and Nutrition*, 61/20 (2021), 3450–64.

Chitry, commune near AUXERRE whose name may be appended to that of BOURGOGNE.

chloroanisoles. See HALOANISOLES.

chlorosis, vine disorder in which parts or all of the foliage turn yellow due to lack of chlorophyll. The most common and extreme chlorosis is that which is visible in spring and early summer and is caused by IRON deficiency, which is common in CALCAREOUS soils. Lime-induced chlorosis became a problem in parts of France as an

indirect consequence of the PHYLLOXERA invasion at the end of the 19th century, since AMERICAN VINE SPECIES sourced initially in the eastern US and used as phylloxera-resistant ROOTSTOCKS were more prone to iron deficiency than were the original VITIS VINIFERA root systems. This problem, known in French as *chlorose calcaire*, has been largely overcome now by the selection of lime-tolerant rootstocks suitable for calcareous soils, such as 41 B or the newer Fercal. In Burgundy and Champagne, where soils tend to be high in limestone, it has been difficult to find rootstocks with sufficient lime tolerance for healthy vine growth. This sensitivity of early post-phylloxera rootstocks to lime-induced chlorosis may provide part of the explanation for an apparent drop in quality in post-phylloxera wines, according to some historical authorities.

Chlorosis is a common symptom of deficiencies of other nutrients such as NITROGEN, SULFUR, and MAGNESIUM. It can also be caused by some VINE DISEASES. The effect may be general, as for FANLEAF DEGENERATION virus, or more localized, as in, for example, the so-called oil spot on leaves due to DOWNY MILDEW infection. R.E.S.

Chorey-lès-Beaune, village near (*lès* in old French) BEAUNE in Burgundy producing red wines from Pinot Noir grapes. Chorey lies in the plain below the main D974 road, as do most of the appellation's vineyards. There are no vineyards of PREMIER CRU status, and much of the wine is sold as Côte de Beaune-Villages. The best-known producer based here is Domaine Tollot-Beaut. A good Chorey is similar to a village SAVIGNY-LÈS-BEAUNE or a lesser ALOXE-CORTON. A tiny quantity of white Chorey-lès-Beaune is made from Chardonnay.

Christianity and wine. See EUCHARIST, RELIGION, BIBLE, MONKS AND MONASTERIES, and MISSIONARIES.

Cienna, NEW VARIETY bred in Australia from the Spanish SUMOLL and CABERNET SAUVIGNON and released, with its sister variety Tyrian, in 2000. Both varieties have good sugar-to-acid ratios, low PH, good colour and flavour, and adequate yields. Cienna is very tannic.

Cigales, DOP in northern Spain, north of Valladolid in CASTILLA Y LEÓN (see map under SPAIN), higher and cooler than TORO, with impressive average VINE AGE. This DOP has traditionally produced dry rosé wines made from Tinto del Pais (TEMPRANILLO) and some GARNACHA grapes, but an increasing number of dry reds show real potential. Since 2011, regulations allow the production of white wines based on VERDEJO, as well as sparkling and sweet wines. F.C.

Ciliegiolo, widely dispersed Italian red grape variety of Tuscan origin named after its supposed cherry-like flavour and colour. It has been declining in extent, although it can make some excellent VARIETAL wines, particularly Sassotondo's Maremma examples, and can be a usefully soft blending partner for SANGIOVESE, particularly in CHIANTI. DNA PROFILING revealed that Ciliegiolo is a progeny of Sangiovese and Muscat Rouge de Madère (or Moscato Violetto). Plantings totalled 897 ha/2,216 acres in 2015.

cincturing, viticultural practice that involves removing, with a knife or special tool, a ring (3–8 mm/0.1–0.3 in wide) of conducting tissue (PHLOEM) around a TRUNK, CANE, or SHOOT, normally to improve FRUIT SET. Also called girdling or ringing in English and *incision annulaire* in French, the technique is more widely used for TABLE GRAPES than for wine production, which can rarely justify the necessary LABOUR cost. Cincturing stops both the upwards and downwards flow of nutrients and plant hormones, until the wound heals over. R.E.S.

cineole. See EUCALYPTUS CHARACTER.

Cinsaut, sometimes written Cinsault, is a red grape variety known for centuries in the Languedoc region of southern France that has much in common with GRENACHE. Although it has good drought resistance and its best wines by far come from vines that yield less than 40 hl/ha (2.3 tons/acre), it can all too easily be persuaded to yield generously and unremarkably. The wines it produces tend to be light, soft, and, in extreme youth, aromatic and charmingly cherry-fruited. Although prone to ROT, it is particularly well adapted for rosé production and is widely planted throughout southern France, especially in the Hérault and Var *départements* in the Languedoc and Provence respectively. It differs from Grenache by virtue of its long history, its shorter growing season, and its easier adaptation to MECHANICAL HARVESTING.

There was a threefold increase in French plantings in the 1970s, when Cinsaut was officially sanctioned as an 'improving' grape variety with which to replace ARAMON and ALICANTE BOUSCHET, mainly in the Aude and Hérault *départements*. Since then, the economic realities of quality's supremacy over quantity have slowed Cinsaut's fortunes, and Languedoc producers have been much more likely to plant a variety with as much character and cachet as Syrah, Merlot, Mourvèdre, or Cabernet Sauvignon. Cinsaut is used almost exclusively to add suppleness, perfume, and immediate fruit to blends (typically compensating for the ubiquitous but curmudgeonly CARIGNAN), although all-Cinsaut rosés are increasingly common.

It is an approved but hardly venerated ingredient in the CHÂTEAUNEUF-DU-PAPE cocktail and is often found further east in Provence, as well as on CORSICA, where it is mostly blended, with only 247 ha/610 acres remaining in 2019.

Total French plantings of Cinsaut fell throughout the 1980s to less than 50,000 ha/123,500 acres (still more vineyard than Cabernet Sauvignon) and by 2019 were only 19,885 ha/49,137 acres. The variety was most important in the 1950s and early 1960s when ALGERIA, then constitutionally part of France, was an important wine producer and depended particularly heavily on its healthily productive 60,000 ha of Cinsaut. Since Algerian wine was then used primarily for

blending in France, notoriously for adding body to less reputable burgundies, some of this North African Cinsaut may still be found in a few older bottles of 'burgundy'. It is still common in MOROCCO and has long played an important part in the wine industry of LEBANON, where it formed the backbone of the wine industry for 160 years and is now experiencing a resurgence in popularity.

Cinsaut has in its time played a major part in South as well as North Africa (which makes it all the stranger that South Africa has had little ROSÉ culture). Having been imported from southern France in the mid 19th century, it was South Africa's most important red-wine vine until the mid 1960s and was overtaken by Cabernet Sauvignon as the Cape's most planted red grape variety only in 1993. In 2020, it was South Africa's sixth most planted red wine grape with 1,701 ha/4,203 acres in total, its old vines increasingly treasured. Cinsaut was once known carelessly as Hermitage in South Africa (although there is no Cinsaut in the northern Rhône). Thus South Africa's own grape variety speciality, a cross of Pinot Noir with Cinsaut, was named PINOTAGE, now much more respected in South Africa than Cinsaut.

In both France and Australia (where its fortunes waned rapidly in the 1970s and 1980s), Cinsaut has occasionally been sold as a table grape under the name Oeillade even though it is not related to OEILLADE NOIRE. In southern Italy, it is known as Ottavianello and is planted around Brindisi, producing light, unremarkable red wines. Cinsaut can also be found in Türkiye.

Cirò, with Terre di Cosenza, currently the only DOC of any quantitative significance in the southern Italian region of CALABRIA.

citric acid, a common plant acid, abundant in some fleshy fruits such as lemons but rare in grapes. The grape is unusual among fruits in that its major acid is TARTARIC ACID (and MALIC ACID), rather than citric acid, whose concentration in the juice of most grape varieties is only about one-twentieth that of tartaric acid.

Citric acid is also one of the ACIDS used in winemaking for the purposes of ACIDIFICATION. It is inexpensive but unsubtle and is used almost exclusively for inexpensive wines. It is always added after rather than before fermentation, since it can be converted to ACETIC ACID by the yeast. It is produced commercially by fermenting SUCROSE solutions; very small amounts are recovered from processing citrus fruits. It is also used extensively after cleaning with caustic soda. In the EU it is not permitted for ACIDIFICATION, but it can be used to prevent CASSE if BLUE FINING is not possible. See also DIACETYL.

B.G.C. & A.D.W.

CIVC. Thanks to the Comité Interprofessionnel du Vin de Champagne, CHAMPAGNE is one of the most thoroughly organized wine regions in the world. The CIVC was established in 1941 as a co-operative organization grouping champagne GROWERS, CO-OPERATIVES, shippers, and houses under its auspices. Growers/co-operatives on the one hand and merchants/champagne houses on the other each have a president to represent them. The CIVC is charged with organizing and controlling the production, distribution, and promotion of the wines of Champagne, as well as undertaking fundamental research for the region. Until 1990 it set a price for the grapes and still intervenes, as in pandemic-struck 2020 for instance, to regulate the size of the harvest and decide whether any of it should be 'blocked', or retained as juice rather than vinified and sold. The CIVC is financed by a levy on production and a tax on champagne sales.

The CIVC is also responsible for tenaciously defending the Champenois's exclusive right to use the word 'champagne'. A landmark victory was won in the English courts in 1960, and since then the name has achieved legal protection in most major markets, although not in the United States for established brands. The CIVC has fought a number of battles to ensure that the name Champagne is not used for other products, including a cigarette and a brand of perfume.

N.F. & J.R.

Clairet, dark-pink wine style that is a speciality of the BORDEAUX region, recalling the sort of red wines that were shipped in such quantity in the Middle Ages from Bordeaux to ENGLAND and which originally inspired the English word CLARET. Dark-skinned grapes are fermented in contact with the skins for about 24 hours before fermentation of this lightly coloured wine continues to dryness. Bordeaux Clairet should be drunk as young as possible.

Clairette is a much-used name for southern French white grape varieties. Clairette Ronde, for example, is the Languedoc name for the ubiquitous UGNI BLANC, and various Clairettes serve as synonyms for the much finer BOURBOULENC.

True Clairette Blanche, however, is a very old Languedoc variety grown on a total of 2,254 ha/5,570 acres of French vineyard in 2019, being allowed into a wide range of southern Rhône, Provençal, and Languedoc appellations, even lending its name to three (see below). Clairette is a traditional variety well suited to poor, dry soils. Its small, thick-skinned grapes ripen relatively late but can ripen dangerously fast at the end of the growing season. In the southern Rhône, it is particularly popular for adding aroma and acidity to a blend, not least with the fatter GRENACHE BLANC. Clairette is widely distributed throughout the eastern Midi, especially in the Gard, where it produces CLAIRETTE DE BELLEGARDE, and in the Hérault for CLAIRETTE DU LANGUEDOC, two of the Languedoc's earliest CONTROLLED APPELLATIONS, presumably because these white wines were so unlike the typical produce of the Midi. Its other stronghold is the Drôme *département* since Clairette is the main ingredient in CLAIRETTE DE DIE and CRÉMANT DE DIE.

Partly because it was an ingredient in PICARDAN, the variety spread far and wide, including to southern RUSSIA, in the 19th and early 20th centuries. At one time there were sizeable plantings in Algeria. It is known as Clairette Blanche in South Africa, where it was once as widely planted as in France. Some old plantings can still be found.

Clairette de Bellegarde, very small AOC which can be used exclusively by the commune of Bellegarde that lies at the heart of the larger AOC COSTIÈRES DE NÎMES. The wines, which must be made of 100% CLAIRETTE Blanche, are soft, with low acidity, yet can have impressive longevity. In 2020, just 180 hl/4,755 gal were bottled under the appellation. M.C.W.

Clairette de Die, the most important appellation in the Diois region centred around the town of Die near the river Drôme, a tributary of the Rhône between Valence and Montélimar. According to PLINY, wine has been made here since Roman times. Die's gently fizzing wines may predate those of Champagne.

Two different sorts of sparkling Clairette de Die are made. Clairette de Die Brut is a dry sparkling white wine made from 100% CLAIRETTE by the transfer method (see SPARKLING WINEMAKING) and has an alcoholic strength of 11–12%. It makes up about 5% of production. The other 95% is Clairette de Die Méthode Ancestrale, a gently sparkling, grapey white wine made from at least 75% MUSCAT BLANC À PETITS GRAINS, the rest Clairette, by the *méthode dioise ancestrale*. It is bottled with at least 35 g/l RESIDUAL SUGAR (though 50–55 g/l is more common) and 7–9% alcohol.

The Diois also produces CRÉMANT de Die, a TRADITIONAL METHOD dry sparkling wine.

Three-quarters of the sparkling wines made under these sparkling Diois appellations are made by local CO-OPERATIVE Jaillance.

Local still wines may qualify as CHÂTILLON-EN-DIOIS. Whites may also qualify as Coteaux de DIE. M.C.W.

Clairette du Languedoc is a slightly more important appellation than CLAIRETTE DE BELLEGARDE, again exclusively from the CLAIRETTE grape. One of the named subappellations of the southern French LANGUEDOC AOC, it lies north-east of Pézenas. The appellation has suffered an extremely confused image as, despite its relatively small

production (100 ha/247 acres in 2020), it is allowed a wide array of wine styles, from an ultra-modern, early-picked, yellowish-green, dry white wine for early drinking to a deep brown RANCIO, sweet VIN DE LIQUEUR. M.S.

Clare Riesling. See CROUCHEN.

claret, English (not American) term generally used to describe red wines from the BORDEAUX region, or red bordeaux. 'Claret' has also been used as a GENERIC term for a vaguely identified class of red table wines supposedly drier, and possibly higher in TANNINS, than those wines sold as generic burgundy (although, in the history of Australian wine SHOWS, it has been known for the same wine to win both claret and burgundy classes).

History

In medieval France, most red wine was the result of a short FERMENTATION, usually of no more than one or two days. The short period of contact with the grape skins meant that the resultant wines were pale in colour and were probably very similar to the rosés of today. Such wines exported from Bordeaux were known as *vinum clarum, vin clar*, or CLAIRET, and it is from the last of these that the English term 'claret' is derived. Other much darker wines were also made by pressing the remaining skins, effectively the same as modern PRESS WINE, and these were known as *vinum rubeum purum, bin vermelh*, or *pinpin*.

Although the term *clairet* was widely used during the medieval period in France, the word 'claret' does not appear to have been used at all extensively in England until the 16th century. In the second half of the 17th century, a new type of wine, of much higher quality and deeper colour, began to be produced in the GRAVES and on the sands and gravels of the MÉDOC to the north-west of Bordeaux. These wines, the provenance of specific properties, where close attention was paid to grape selection, improved methods of vinification, and the use of new oak BARRELS, became known by the beginning of the 18th century as New French Clarets, and the earliest and most famous of them were HAUT-BRION, LAFITE, LATOUR, and MARGAUX (see BORDEAUX, history). clarete is a historic Iberian term for a wine somewhere between a rosé and a light red. It is etymologically, though not oenologically,

related to CLARET. In PORTUGAL a niche revival of the style has led to regulation: since 2017 *clarete* can be used only to label very light-coloured red wines made exclusively from red grapes with an ALCOHOLIC STRENGTH which is no more than 2.5% above the minimum legal requirement. In Spain, *clarete* remains a blend of white and red grapes and is seeing a renaissance in CIGALES and RIBERA DEL DUERO.

S.A. & F.C.

claret jugs. See DECANTERS.

Clare Valley, wine region in SOUTH AUSTRALIA with a strongly CONTINENTAL CLIMATE and warm summer days and cool nights. This combined with differences in soil, ELEVATION, degree of slope, and ASPECT enables the region to produce some of Australia's finest Riesling as well as excellent Shiraz, Cabernet Sauvignon, and Malbec. While wines are sturdy and powerful, alcohol levels are generally lower than those of the Barossa Valley or McLaren Vale.

clarification is the progressive removal of solid particles of matter from MUST or wine and should not be confused with STABILIZATION. At the must stage, it involves the removal of particles of grape skins, stems, seeds, and pulp and is carried out only when making white or rosé wines. If they are not removed, there is a risk of OXIDATION and off-flavours in the finished wine. Red wines are not commonly clarified before fermentation because the skins are fermented with the juice (see RED WINEMAKING).

Clarification can usually be accomplished by simply holding the liquid in a storage tank until the larger particles settle (see SETTLING) and then pumping, or RACKING, the clear upper layer from the compact layer of solids at the bottom of the tank. The clarified must is then warmed to start the fermentation. Pectin-splitting ENZYMES are sometimes added to aid the settling of the solids.

Settling is too slow for a large winery, so recourse is made to mechanical methods such as CENTRIFUGATION, but a centrifuge is an expensive piece of equipment, using a large amount of electricity, and is therefore not suitable for smaller wineries. FLOTATION, another mechanical method of clarification, is cheaper and quicker and used by larger wineries but works really well only on must.

The degree of clarification of must is important because some of the solid particles act as nutrient for the yeasts during FERMENTATION due to the amino acids, minerals, and vitamins adsorbed on their surface. Too much clarification can result in a fermentation that is difficult to start. The style of the wine may also influence the degree of clarification. With Chardonnays, for example, it may be desirable to have a relatively high proportion of grape solids which produce various characters during fermentation. Winemakers may wish to eliminate most grape solids from the juice of more aromatic varieties in order to accentuate varietal fruit flavours.

After the completion of fermentation, another clarification takes place to rid the new wine of all colours of the products of fermentation, also known as the gross LEES. These are mainly the yeast cells, both dead and viable, plus cellular matter from the grape. When treating wine that has been fermented in barrels and then racked and returned to fresh barrels, the residual cloudy matter that gathers in the bottom of the barrels is known as the fine lees. This is highly valued by winemakers because it is the source of added complexity to the maturing wine.

Settling of the solids at this stage of the process is comparatively rapid because there is a greater difference in density between wine and its particulate matter than between sugar-laden must and grape solids. The wine can be racked off comparatively easily but will still be hazy, so further treatment will be needed. A large winery will probably use a centrifuge, but smaller establishments will use a series of FILTRATIONS.

Further treatment, known as STABILIZATION, is usually necessary.

D.B.

Clarksburg, California wine region and AVA covering 37,630 ha/92,985 acres along the Sacramento–San Joaquin River Delta. The delta channels cool Pacific air that helps moderate the warm inland temperatures, allowing varieties such as CHENIN BLANC to thrive; other high-acid whites such as ALBARIÑO and VERMENTINO are being established there as well. Much of the AVA is composed of deep-soiled islands surrounded by marshlands and river tributaries, so most vineyards achieve sizeable yields. E.C.B.

classed growth is a vineyard, estate, or château included in a wine CLASSIFICATION. The term is used almost exclusively in BORDEAUX for those châteaux included in the 1855 classification of the Médoc and Sauternes, the 1955 classification of Graves, and sometimes for those properties included in the regularly revised St-Émilion classification. The term is a direct translation of the French 'CRU classé'.

Classic, official German wine designation introduced in 2000, though little used outside Germany, for dry-tasting wines (maximum 15 g/l RESIDUAL SUGAR) vinified from traditional grape varieties, harvested at at least 12% POTENTIAL ALCOHOL (11.5% in the Mosel). It is not to be confused with the term KLASSIK as used (principally) in AUSTRIA.

classical art, wine in. Wine was so deeply embedded in the culture of the classical world that it is inevitable that it would figure prominently in the art of that world. The vessels used for mixing and drinking wine (see CRATER, for example) were frequently decorated with scenes which played on the association with wine. Most notably, the fine Attic Black and Red Figure pottery of the 6th and 5th centuries BCE sometimes contains rural scenes of men harvesting grapes and treading them, as well as scenes from the *komos* (revels) and the SYMPOSIUM, in which the craters and cups are depicted in use.

Sometimes it is possible to suspect an ironic commentary taking place. A famous Red Figure cup by the so-called Dokimasia painter has scenes of revelry around the outside with the awkward spaces under the handles filled by men crouched or crawling, the worse for drink, while inside the cup an old man is depicted being sick. Another playful irony is that nearly all these scenes can be found translated to another world, in which men are replaced by satyrs, uninhibited by the conventions of human society and presided over by the god DIONYSUS. Not surprisingly, Dionysus achieves a greater prominence in the art of the world of drinking than his place in the pantheon would suggest as his due. Feasting and banquets with wine also form the subject of some of the most memorable frescos from the tombs of the ETRUSCANS, where, for example, the Tomb of the Leopards at Tarquinia beautifully illustrates the funeral meal held near the tomb in honour of the dead.

Scenes of the vintage and the pressing of the grapes, with the role of humans frequently played by *amorini*, cupids, are found in great numbers at all periods throughout the Roman world, in paintings, sculptured reliefs, sarcophagi, decorated glass, and ivory plaques. Part of the explanation for the popularity of the themes, particularly on sarcophagi, is the obvious mystical symbolism of the vine and wine. Scenes of country life, including vines and the vintage, play a significant part in Roman painting from the 1st century BCE onwards and are most elaborately and impressively illustrated in mosaic. The vintage and tasks connected with viticulture, such as pruning and the cleaning and pitching of DOLIA, are often found in mosaics which illustrate the seasons or the tasks of the rural calendar. As a genre, these had a long history, which went back to the Hellenistic period in mosaic and may be connected with illustrated manuscript calendars. Fine examples in mosaic come from GAUL (St-Romain-en-Gal) and North Africa (the Maison des Mois at El Djem). From the 3rd century CE the elite of North Africa adorned their houses with mosaics which reflected the work of their estates. One of the most remarkable examples of realism in classical art must be the mosaic of the

Labours of the Fields from Cherchel in Algeria, with men hoeing between TRELLISED vines.

The potential of the vine and wine as mystical symbols also explains why this was one of the themes of classical art which was most easily taken over by Christianity. A key monument is the church of Santa Costanza on the Via Nomentana in the north of Rome, a work of such rare beauty as to justify on its own a visit to that city. Santa Costanza was the mausoleum of Constantina, the daughter of Constantine, the first Christian emperor. Her huge porphyry sarcophagus has cherubs engaged in the vintage, a theme which is taken up by the remarkable mosaics which run round the ceiling of the ambulatory. The themes are traditional. Nothing is specifically Christian in these mosaics, but they are given a Christian connotation by the other, more overtly Christian, mosaics which would have adorned the dome. J.J.P.

Dunbabin, K. M. D., *The Mosaics of Roman North Africa* (1978).

classical texts. The vine and the olive are the plants that characterize Mediterranean civilization. To grow them is the sign of a settled, not a nomadic, existence. Their products can be used as part of the daily routine: olive oil for cooking and washing, wine for drinking, or to mark a special occasion in the life of a community, when people would anoint their heads with fragrant oil and drink the best wine. In wine-producing countries, wine can be an ordinary drink or a luxury item: classical literature reflects both.

This starts with HOMER (the end of the 8th century BCE) and HESIOD (*c.*700 BCE), the earliest Greek authors. Wine is mentioned frequently in the grander context. In Hesiod's *Works and Days*, the cultivation of the vine is part of the order of nature as laid down by the gods: the

secular and the religious were not distinct spheres. HERODOTUS' *Histories* (5th century BCE) have many observations on wine and its uses among foreign nations. The Greeks had no books on agriculture, but THEOPHRASTUS (*c.*370–*c.*287 BCE) could be called the first systematic botanist. A very late Greek author, ATHENAEUS (*fl.* 200 CE), is a good source of information on the wines of his day.

Among the Romans, VIRGIL (70–19 BCE), HORACE (65–8 BCE), and MARTIAL (*c.*30–103/4 CE) are the poets who display a particular interest in wine: Virgil chiefly in the *Georgics*, Horace throughout his poems, and Martial in many of his epigrams on the mores of his time. PLINY the Elder (23/4–79 CE) devoted an entire book of his *Natural History* to all aspects of wine. Other prose writers wrote treatises on agriculture: CATO (234–149 BCE), VARRO (116–27 BCE), COLUMELLA (1st century CE), and the derivative PALLADIUS (4th century CE). H.M.W.

classical wines. See GREECE and ROME for general comments, as well as CAECUBAN, FALERNIAN, MASSIC, OPIMIAN, and SURRENTINE wines specifically.

classical world. See ancient GREECE and ancient ROME.

Classico, Italian term appended to the names of various DOC or DOCG wines to indicate that they have been produced in the historic zone, that which, at least in theory, offers the ideal conditions of soil and climate and gave the wine its name.

The name of the wine *without* the adjective Classico is usually applied to a significant expansion of the original production zone into areas which generally, but not always, cultivate the same grape varieties but in different, and usually less satisfactory, conditions, frequently with more lenient production requirements. The origins of

this practice, which occurred well before the establishment of the DOC system in the 1960s and has often been driven by economic motives, lie in the regulation of the use of the name CHIANTI established by the Dalmasso Commission in the 1930s (see CHIANTI CLASSICO). This precedent was widely followed as the various DOCs came into being between 1963, when the law regulating the demarcation of Italy's wine regions was passed, and 1975; since then a number of Italy's historically important wines are now produced in both a Classico and a regular version. These include BARDOLINO, CALDARO, CHIANTI, CIRÒ, Garda, ORVIETO, SANTA MADDALENA, SOAVE, TERLANO, VALPOLICELLA, and VERDICCHIO.

The practice, not dissimilar to the creation of Germany's notorious GROSSLAGEN, reflects a permanent tension in Italy's DOC system. Often the most quality-conscious producers keen for promotion to DOCG status lobby for it to be restricted to the original Classico zone but find themselves opposed by big companies with holdings throughout the enlarged zone. However, in some cases, Classico zones themselves are seen to be underperforming.

classification of various wine estates and vineyards is in general a relatively recent phenomenon, dictated by the increasingly sophisticated wine market of the last 150 years or so. It has to a certain extent been superseded by the even more recent phenomenon of SCORING individual wines.

There were earlier instances of classifying individual vineyards, however. The vineyards of JURANÇON in south-west France were officially evaluated as early as the 14th century. Tax collectors in GATTINARA did the same in the 16th century. In 1644, the council of Würzburg in FRANKEN rigorously ranked the city's vineyards according to the quality of wine they produced (see GERMAN HISTORY). The first mention of a classification of TOKAJ vineyards dates from 1700, although the classes were not ratified until 1737 (and the vineyards probably not officially mapped until 1786 under Emperor Joseph II).

Bordeaux

BORDEAUX, with its plethora of fine, long-lasting wine from well-established estates and its well-organized market, is the wine region which has been most subject to classification of individual châteaux. The most famous wine classification in the world is that drawn up in 1855 of what became known as the CLASSED GROWTHS of the MÉDOC, and one GRAVES (see over). In response to a request from Napoleon III's 1855 Exposition Universelle in Paris (possibly so that dignitaries there should effectively know what to be impressed by), the Bordeaux BROKERS formalized their own and the market's ranking with a five-class classification of 60 of the leading Médoc châteaux plus the particularly famous and historic Graves, HAUT-BRION; and a two-class classification of SAUTERNES and BARSAC. This classification merely codified the market's view of relative quality as expressed by the prices fetched by individual estates' wines. (It also formalized previous informal lists of those wines widely regarded as the best by the likes of Thomas JEFFERSON, Wilhelm Franck, Alexander HENDERSON, and Cyrus REDDING.) The brokers issued the 1855 classification through the Bordeaux Chamber of Commerce and were careful to explain that it was based on a century's experience. Within each of their classes, from FIRST GROWTHS, or PREMIERS CRUS, down to fifth growths, or cinquièmes CRUS, the brokers listed châteaux in descending order of average price fetched. Thus, it is widely believed, LAFITE, the 'premier des premiers', headed the list because it commanded prices in excess even of LATOUR, MARGAUX, and Haut-Brion (although others have argued that the first growths were simply listed in alphabetical order). In the original classification, the term CHÂTEAU was rarely used.

The 1855 classification has endured remarkably well considering the many and various changes to the management and precise extent of individual properties since it was compiled, with only Chx MOUTON ROTHSCHILD and Léoville-BARTON in the same hands. Ch Dubignon-Talbot has not produced wine since the arrival of

PHYLLOXERA in the late 19th century. Edmund PENNING-ROWSELL notes that Palmer's low ranking may have been influenced by the fact that the property was in receivership in 1855 and that Cantemerle, a property relatively new to the Bordeaux market, was added to the bottom of the list in a different hand. The only official revision of this much-discussed list took place in 1973, when, after much lobbying on the part of Baron Philippe de ROTHSCHILD, Ch Mouton-Rothschild made the all-important leap from top of the second growths to become a first growth (although see also SUPER SECOND). It could be argued that such a classification contains an element of self-preservation in that highly classified properties are thereby able to command prices which sustain the investment needed to maintain their status, although the history of Ch Margaux in the 1960s and 1970s demonstrates that other factors may affect this hypothesis, and in the 1980s and 1990s many Bordeaux proprietors, for example Ch Léoville Las Cases, were driven by competition and ambition to invest, and in some cases price, at a level above that suggested by their official ranking.

The 1855 classification of Sauternes and Barsac is also printed on p. 182. Reflecting price and the *réclame* then attached to sweet wines, it elevated Ch d'YQUEM to premier cru supérieur, a rank higher even than any of the red wine first growths, and listed 11 châteaux as first growths and 14 as seconds.

Other than Haut-Brion's inclusion in the 1855 Médoc classification, the wines of the Graves district were not officially classified until 1953. This one-class list, slightly augmented in 1959, appears on p. 182. It avoided some possible controversy by employing a democratically alphabetical order. It should be said, however, that there is a wide differential between the prices commanded by Ch Haut-Brion and its close rival Ch La Mission-Haut-Brion, for example, and those fetched by Chx Bouscaut and de Fieuzal. The Graves district was subsequently divided into Graves and PESSAC-LÉOGNAN.

The classification of ST-ÉMILION, formally drawn up in 1955, is most frequently reviewed and amended and therefore most controversial. Modifications were published in 1969, 1985, 1996, 2006, 2012, and 2022 (see pp. 181–2 for this latest version). The updated rules

published in 2018 focus on the vineyard boundaries (which cannot be extended between reclassifications), a tasting of the ten previous vintages (15 for the highest ranking), prices, the reputation and distribution of the wines and the estate's efforts at promotion (including tourism), and technical aspects. The top tier comprises the premiers grands crus classés, subdivided into A and B, then the much bigger tier, the grands crus classés. The 2006 classification was disputed and suspended in the spring of 2007, and then reinstated in 2009. The 2012 classification, which was conducted by a commission of recognized wine experts from outside Bordeaux nominated by the INAO, also resulted in several legal disputes. In 2021, two of the then four grands crus classés A, Chx Ausone and Cheval Blanc, withdrew because they did not agree with the judging criteria. A third, Ch Angélus, left in early 2022, and others have followed. The deceptively grandiose rank of GRAND CRU (minus the classé) is awarded annually to scores of individual wines as part of the AOC system and is therefore separate from this decadal classification.

POMEROL is the only important fine-wine district of Bordeaux never to have been classified, although its star PETRUS is conventionally included with Chx Lafite, Latour, Margaux, Haut-Brion, Mouton-Rothschild, Cheval Blanc, and Ausone as an honorary first growth.

There have been regular attempts to revise and assimilate the various classifications of Bordeaux, most notably that drawn up by Alexis LICHINE in 1959. Most serious writers on bordeaux make their own revisions, more or less confirmed by the market.

See also CRU BOURGEOIS for those MÉDOC properties classified as just below the status of a fifth growth.

Burgundy

Burgundians were also well aware of the considerable variation in quality of the wines produced by different plots of land, or CLIMATS, as they are known in Burgundy. In 1855, Dr Lavalle published his influential *History and Statistics of the Côte d'Or*, which included an informal classification of the best vineyards. This was formalized in 1861 by the Beaune Committee of Agriculture, which, with Lavalle's assistance, devised three classes. Most *climats* included in the first class eventually became grands crus when the AOC system was introduced in the 1930s. See under BURGUNDY for a full list of Burgundian grands crus, and see under individual village names for details of their premiers crus.

Elsewhere

Few other regions of France have anything approaching an official classification, although see ALSACE for a list of those vineyards accorded grand-cru status, CHABLIS for details of crus in this northern outpost of Burgundy, and CHAMPAGNE for some details of the classification of individual villages there.

There have been attempts, typically by WINE WRITERS or producers' associations, to produce classifications of the best vineyards, or best wines, of many countries, notably Germany (see GROSSE LAGE) and Italy (see VERONELLI), but these have generally been too controversial to be widely adopted. With the exception of the DOURO, where individual vineyards have been classified for the quality of port they produce, the wine regions of Portugal and Spain are in too great a state of flux to submit satisfactorily to classification, like those of eastern Europe and the rest of the Mediterranean. See also VINO DE PAGO.

In the New World, Australia prefers to classify not vineyards but individual wines, often much blended between areas, by awarding them medals and trophies in their famous SHOWS. Langton's Classification of Australian Wine, produced periodically, distinguishes wines on the basis of track record and reputation at AUCTION. In North America, on the other hand, it seems that classification may never appeal to the democratic California wine industry. See also CLIMATE CLASSIFICATION.

Bordeaux

The Official Classification of Médoc and Graves of 1855

First Growths (Premiers Crus)

	Commune	Appellation		Commune	Appellation
Ch Lafite-Rothschild	Pauillac	Pauillac	Ch Haut-Brion*	Pessac	Graves, now Pessac-Léognan
Ch Margaux	Margaux	Margaux			
Ch Latour	Pauillac	Pauillac	Ch Mouton Rothschild**	Pauillac	Pauillac

Second Growths (Deuxièmes Crus)

	Commune	Appellation		Commune	Appellation
Ch Rauzan-Ségla	Margaux	Margaux	Ch Brane-Cantenac	Cantenac	Margaux
Ch Rauzan-Gassies	Margaux	Margaux	Ch Pichon Baron	Pauillac	Pauillac
Ch Léoville Las Cases	St-Julien	St-Julien			
Ch Léoville-Poyferré	St-Julien	St-Julien	Ch Pichon-Longueville, Comtesse de Lalande	Pauillac	Pauillac
Ch Léoville-Barton	St-Julien	St-Julien			
Ch Durfort-Vivens	Margaux	Margaux	Ch Ducru-Beaucaillou	St-Julien	St-Julien
Ch Gruaud-Larose	St-Julien	St-Julien	Ch Cos d'Estournel	St-Estèphe	St-Estèphe
Ch Lascombes	Margaux	Margaux	Ch Montrose	St-Estèphe	St-Estèphe

Third Growths (Troisièmes Crus)

	Commune	Appellation		Commune	Appellation
Ch Kirwan	Cantenac	Margaux	Ch Cantenac-Brown	Cantenac	Margaux
Ch d'Issan	Cantenac	Margaux	Ch Palmer	Cantenac	Margaux
Ch Lagrange	St-Julien	St-Julien	Ch La Lagune	Ludon	Haut-Médoc
Ch Langoa-Barton	St-Julien	St-Julien	Ch Desmirail	Margaux	Margaux
Ch Giscours	Labarde	Margaux	Ch Calon-Ségur	St-Estèphe	St-Estèphe
Ch Malescot St-Exupéry	Margaux	Margaux	Ch Ferrière	Margaux	Margaux
Ch Boyd-Cantenac	Cantenac	Margaux	Ch Marquis d'Alesme Becker	Margaux	Margaux

Fourth Growths (Quatrièmes Crus)

	Commune	Appellation		Commune	Appellation
Ch St-Pierre	St-Julien	St-Julien	Ch La Tour-Carnet	St-Laurent	Haut-Médoc
Ch Talbot	St-Julien	St-Julien	Ch Lafon-Rochet	St-Estèphe	St-Estèphe
Ch Branaire-Ducru	St-Julien	St-Julien	Ch Beychevelle	St-Julien	St-Julien
Ch Duhart-Milon	Pauillac	Pauillac	Ch Prieuré-Lichine	Cantenac	Margaux
Ch Pouget	Cantenac	Margaux	Ch Marquis-de-Terme	Margaux	Margaux

Fifth Growths (Cinquièmes Crus)

	Commune	Appellation		Commune	Appellation
Ch Pontet-Canet	Pauillac	Pauillac	Ch du Tertre	Arsac	Margaux
Ch Batailley	Pauillac	Pauillac	Ch Haut-Bages-Liberal	Pauillac	Pauillac
Ch Haut-Batailley	Pauillac	Pauillac	Ch Pédesclaux	Pauillac	Pauillac
Ch Grand-Puy-Lacoste	Pauillac	Pauillac	Ch Belgrave	St-Laurent	Haut-Médoc
Ch Grand-Puy-Ducasse	Pauillac	Pauillac	Ch de Camensac	St-Laurent	Haut-Médoc
Ch Lynch-Bages	Pauillac	Pauillac	Ch Cos-Labory	St-Estèphe	St-Estèphe
Ch Lynch-Moussas	Pauillac	Pauillac	Ch Clerc-Milon	Pauillac	Pauillac
Ch Dauzac	Labarde	Margaux	Ch Croizet-Bages	Pauillac	Pauillac
Ch d'Armailhac***	Pauillac	Pauillac	Ch Cantemerle	Macau	Haut-Médoc

* This wine, although a Graves, was universally recognized and classified as one of the original four first growths.
** This wine was decreed a first growth in 1973.
*** Previously Ch d'Armailhaq, Ch Mouton-Baron-Philippe, and Ch Mouton-Baronne-Philippe.

clay refers to a particular type of MINERAL found in some rock types and in soil. It is also a generic description of sediment or soil that is made up of small, plate-like particles. Soils described as 'clays' have a high content of clay minerals but may also contain fine particles of calcium carbonate (in soils formed on LIMESTONE) and QUARTZ (in soils that have been weathering over a long period of time). Because of their negative charges and large surface areas, clay minerals hold large amounts of exchangeable cations (see CATION EXCHANGE).

Clay-sized particles interact with soil ORGANIC MATTER to form the basic building blocks of SOIL STRUCTURE. Different clay minerals predispose to variations in the stability of a soil's structure. For example, kaolinite clays tend to support stable structures, whereas montmorillonite clays (also known as smectite), which show marked swelling when wet and shrinkage on drying, may cause structural instability, especially if sodium cations are present. Such instability in subsoils can result in poor DRAINAGE and waterlogging, which is detrimental to healthy vines. Mica-type clays can hold significant amounts of POTASSIUM cations within their structures, which is slowly released on exchange with other cations in the soil water. Vine uptake of this potassium may adversely affect grape and wine quality. Clay can be important in vineyard subsoils because of its water-holding capacity, as in parts of POMEROL, for example. R.E.W.

For clay FERMENTATION VESSELS, see AMPHORA, QVEVRI, TALHA, TINAJA, and PITHARI.

cleanliness, an important quality in wine (a wine should not have any off-odours) and in wineries, for which see HYGIENE.

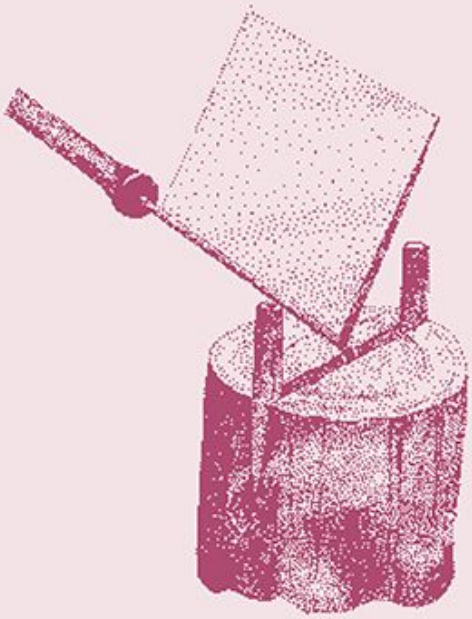
cleanskin, a term used in Australia and New Zealand to describe a wine sold without any indication of the producer's identity, particularly useful in a time of glut.

cleft grafting, a popular method for changing VINE VARIETY in the vineyard (see TOP GRAFTING). The severing of the TRUNK may be at ground level or just below the head; the latter is preferred because DESUCKERING is simpler, less vine training is required, and the extra wood of the trunk aids the rapid establishment of the new vine. The trunk is cut horizontally in early spring and the stump split across the middle to about 5 cm/2 in depth. SCION pieces of one or two nodes are prepared from dormant CANES with a long-tapered wedge. After the trunk is split and spread, the pieces are inserted one on each side so that CAMBIUMS of ROOTSTOCK and scion are matched to facilitate their bonding. The wounds are sealed with grafting mastic, then with paint. NOTCH GRAFTING is an alternative. See diagram.

Cleft graft

1 The vine is cut off and the stump is split

2 The split is prized open and scions are inserted



3

4 The graft is sealed

B.G.C.

Clendenen, Jim (1953–2021), founded Au Bon Climat winery in SANTA MARIA VALLEY in a shed by Bien Nacido vineyard in the 1980s and stuck admirably to the lessons he had learnt in Burgundy, even when they resulted in Pinot Noirs and Chardonnays much leaner than were then in FASHION. They contrasted markedly with the man himself, in terms of both restraint and, alas, longevity.

Clevner, name used for various forms of PINOT. In SWITZERLAND it is often applied to PINOT NOIR or Blauburgunder grown in the canton of Zurich. In ALSACE Clevner or Klevner are usually synonyms for PINOT BLANC, but see also KLEVENER DE HEILIGENSTEIN.

climat, French, particularly Burgundian, term for a specific vineyard site defined by, as the name suggests, all of its climatological as well as geographical characteristics, otherwise known as TERROIR. Thus the Burgundian grower uses the word *climat* interchangeably with 'vineyard'. A *climat* is generally but not always smaller than a specific appellation. The term *climat* may for example be used to refer to a grand cru such as Richebourg. To further complicate matters, most appellations have over the centuries been subdivided into small parcels, each with its own traditional name, known by local geographers as a LIEU-DIT.

climate, long-term WEATHER pattern of an area, an extremely important variable in the winemaking equation. For more details, see MACROCLIMATE in particular but also CLIMATE CLASSIFICATION, CLIMATE CHANGE, CONTINENTALITY, COOL-CLIMATE VITICULTURE, LATITUDE, MEDITERRANEAN CLIMATE, RAINFALL, SUNLIGHT, TEMPERATE, TEMPERATURE, TEMPERATURE VARIABILITY, WARM-CLIMATE VITICULTURE, and, importantly, CLIMATE AND WINE QUALITY. For details of climate on a smaller scale, see MESOCLIMATE and MICROCLIMATE.

climate and wine quality. Climate influences both the QUALITY and styles of wine that a region can produce best. At the extremes, a climate can be so unsuitable for grape-growing that to produce good wines regularly is impossible or, at best, uneconomic. Cooler climates are best suited to producing light, delicate, and aromatic wines, while very hot climates are most suitable for FORTIFIED WINE production.

Temperature

Average mean TEMPERATURE during RIPENING strongly influences potential wine style. Defining grape maturity as that appropriate to making dry TABLE WINES, mean temperatures averaging above about 21 °C/70 °F in the final month to maturity lead to a rapid loss of MALIC ACID from the grapes and to lower TOTAL ACIDITY and generally higher PH in the juice. Conversely, an average mean temperature below about 15 °C/59 °F in the final month minimizes acid loss to the point that acid levels may be too high. There is also often a risk that the grapes will not ripen fully at all.

Average conditions during ripening cannot be estimated directly from raw climatic statistics because they depend in part on when ripening occurs. That, in turn, depends on the heat requirements of individual VINE VARIETIES to reach maturity. Some are early maturing and have a relatively low total heat requirement. These will ripen successfully in cool climates, and in hot climates ripen very early. Late-maturing varieties need a long, warm growing season and a high heat total to ripen at all. Jones classifies the main wine-grape varieties into four maturity groups (see CLIMATE CLASSIFICATION).

Beyond that, individual grape varieties differ in their optimum ripening temperatures for quality. Many of the early-maturing varieties are best when ripened under relatively cool conditions. The berries of some of them are very sensitive to heat, particularly red-wine varieties such as Pinot Noir. Such varieties nevertheless need warmth during ripening to give enough colour and body for red wines, a contradiction which explains their limited and specialized climatic adaptations. Other equally early-maturing varieties, usually for white wine, can tolerate considerable heat during ripening and can give good quality across a wide range of climates. Chardonnay, Verdelho, and to a lesser extent Sauvignon Blanc are good examples. Late-maturing varieties such as Grenache, Mourvèdre, Carignan, and Muscat of Alexandria need not only high heat totals to reach maturity but also moderately high temperatures during ripening for maximum wine quality.

Temperature variability

Whereas potential wine style depends broadly on average mean temperature during ripening, quality appears to be related at least as much to short-term temperature variability from day to day and week to week. See TEMPERATURE VARIABILITY and DIURNAL TEMPERATURE RANGE.

Sunlight

Contrary to common perception, cool viticultural climates are probably more limited by their low temperatures than by lack of SUNLIGHT. Sunlight duration acts mainly by controlling sugar in grapes and therefore potential wine alcohol content at a given stage of physiological ripening. In practice, however, the relative contributions of sunlight and temperature are hard to distinguish because low temperatures and low sunlight hours tend to go together. Poor seasons in cool climates are usually both cloudier and colder.

Paradoxically, sunlight duration appears to limit wine style and (sometimes) quality as much in warm as in cool climates, even though their sunlight hours over the season are usually greater. The explanation lies in rates of RESPIRATION. Vines respire more sugar at high temperatures for their normal metabolism but do not photosynthesize any faster; they therefore need more sunlight hours to generate a sugar surplus for ripening the fruit. It is why, for instance, Australia's often cloudy Hunter Valley produces only table wines despite being very warm; and why mild to warm, but cloudy, regions of northern New Zealand such as Auckland produce predominantly light table wines. Similar factors appear to apply through much of central and northern Italy.

Regions with unlimited sunlight hours and high sunlight intensity are nevertheless not necessarily at an advantage because they commonly suffer from excessive TEMPERATURE VARIABILITY, low relative humidities, and WATER STRESS (see below). But in the absence of these adverse factors, ample sunlight does appear to be universally beneficial. A strong and constant sugar flow to the ripening berries assures not only their sweetness and sufficient alcohol in the wine but also that colour, flavour, and aroma compounds are not limited by a lack of sugar substrate for their formation.

Timing of the sunlight is important. Studies such as that of Gadille in Burgundy show that the most critical period for quality is around the start of ripening (August in most European viticultural regions). Good conditions then assure an ample reserve of sugar in the vine,

both for early conversion in the leaves and berries into flavour and aroma compounds, or their precursors, and so that sugar and flavour ripening of the berries can continue unabated under the cooler and less sunny conditions normally encountered later. (See also ULTRAVIOLET RADIATION.)

Rainfall

The general implications of rain for viticulture are discussed under RAINFALL.

For wine quality, the biggest impacts of too much or too little rainfall occur during ripening. Most agree that any severe WATER STRESS at that stage is deleterious. On the other hand, heavy rain during the ripening period, especially if accompanied by lack of sunshine, commonly results in incomplete ripening and thus a poor vintage. Heavy rain close to maturity is especially damaging because it can cause berry splitting and subsequent fungal infection of the bunches (see BOTRYTIS BUNCH ROT). This occurs most typically in certain varieties with tight bunches, such as Chenin Blanc and Zinfandel, and where the vines were under drought stress prior to the rain.

Relative humidity and evaporation

Strong evaporative demands place the vines under water stress, which, in extreme cases, can cause leaf loss and substantial collapse of vine metabolism. Obvious fruit damage often follows through excessive exposure to the overhead sun. Milder water stress can still reduce PHOTOSYNTHESIS and sugar production in the leaves and hence reduce both quantity and fruit quality. Mechanisms are discussed more fully under EVAPORATION and HUMIDITY.

Wind

The effects of WIND STRESS are largely on vine health and yield, via reduced disease incidence on the one hand and closure of the leaf STOMATA and especially direct physical damage on the other. Dry winds may also reduce wine quality through increased evaporation, as explained above.

At the same time, the daily alternating land and sea breezes of the summer months that occur with some regularity in coastal regions of the dry continents markedly benefit both vine physiological functioning and wine quality. They are especially important in Australia and on the west coast of the United States, and they are doubly advantageous: dry land winds at night and in the early morning reduce the risk of FUNGAL DISEASES; then mild, humid afternoon sea breezes reduce stresses on the vines and greatly improve day conditions for photosynthesis and ripening. The same applies on a reduced scale around inland lakes and rivers. See TOPOGRAPHY and TERROIR.

Summary

Two climatic types appear to offer the best compromises for both viticulture and wine quality. The first is that boasting cool-to-mild growing-season temperatures and uniform-to-predominantly-summer rainfall, such as is found in western and central Europe. Within that context, the best vineyard sites have specialized MESOCLIMATES with more than usual sunshine, warmth, and length of frost-free period.

The second broad climatic type is the winter-wet/summer-dry MEDITERRANEAN CLIMATES, where summer heat is regularly moderated by afternoon sea breezes or high DIURNAL TEMPERATURE RANGE, and irrigation can be supplied in late summer if needed and permitted. Advantages over the uniform and summer-rainfall climates include more reliable summer sunshine and less risk of excessive rain and humidity during the ripening period.

For more detail, see TEMPERATURE, TEMPERATURE VARIABILITY, SUNLIGHT, RAINFALL, HUMIDITY, and WIND. See also COOL-CLIMATE VITICULTURE and CLIMATE CHANGE.

climate change. Growing grapes for wine is a climatically sensitive endeavour, with narrow geographical zones providing the best production and quality characteristics. Winegrowing is therefore at greater risk from climate change than more broadly grown agricultural crops.

WEATHER and climate present three distinct spatial/temporal scales of risks and challenges to viticulture and wine production: first, individual weather events, which are mostly short term and localized (e.g. HAIL, WINTER FREEZES, FROST, excessive heat or heavy rain); second, climate variability, which is measured on seasonal to decadal timescales and typically regionalized (e.g. DROUGHT or wet periods, warm or cold periods); and third, climate change, which is recognized as long term and regional to global in scale (e.g. warming, cooling, changes in moisture regimes). In addition, one factor often influences and/or changes another—climate variability can change the frequency of individual weather events, and climate change can alter the nature of climate variability.

Historically climate change has been brought about by both internal and external natural processes such as volcanic events, ocean/snow/ice dynamics, solar variation, and meteoroid impacts. However, it is becoming increasingly evident that contemporary and future climate changes have become greatly influenced by human behaviour, through changes in atmospheric composition, deforestation, desertification, urbanization, and ocean acidification, which together alter the Earth's surface and atmosphere and the way each holds and distributes heat. Probably the greatest concern for future climate change comes from increasing fossil-fuel consumption and rising CARBON DIOXIDE (CO_2) levels in the atmosphere. To study climate change, scientists use empirical methods (based on observations and/or proxy data, such as tree rings), dynamic methods (based on complex three-dimensional, mathematical models of our Earth–atmosphere system), or a combination of the two. Models are also used to better understand the magnitude of human influences on global climates through attribution science, a field of research that is largely used in climate studies. Attribution research

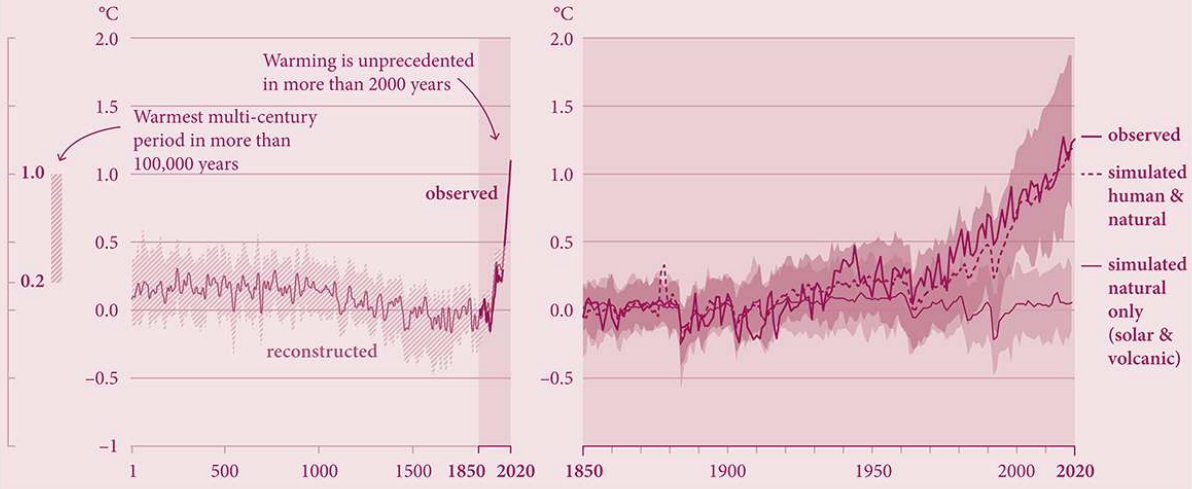
attempts to test whether—and by how much—human-induced climate change may be responsible for changes in temperature and precipitation along with extreme weather events.

The frequency and severity of WILDFIRES such as the 2004 Geysers Fire in SONOMA County's Mayacamas Mountains are increasingly attributed to CLIMATE CHANGE. This fire appears to have burnt out when it reached DRIP-IRRIGATED vineyards owned by JACKSON FAMILY WINES near the top of the forested ridgeline. 4,947 ha/12,225 acres were charred in five days. © George Rose

Changes in the global temperature relative to 1850–1900, from the 2021 Intergovernmental Panel on Climate Change (IPCC) Summary for Policymakers

(a) Change in global surface temperature (decadal average) as **reconstructed** from palaeoclimate archives (1–2000) and directly **observed** (1850–2020), both relative to 1850–1900 and decadally averaged. The vertical bar on the left shows the estimated temperature (very likely range) during the warmest multi-century period in at least the last 100,000 years, which occurred around 6,500 years ago during the current interglacial period (Holocene). The shading with white diagonal lines shows the very likely ranges for the temperature reconstructions.

(b) Changes in global surface temperature (annual average) as **observed** and simulated using **human & natural** and **only natural** factors (both 1850–2020). Graph lines show the multi-model average, and shading shows the very likely range of simulations.



Historical and contemporary climate changes

The grapevine is one of the oldest cultivated plants and, along with the process of making wine, has resulted in a rich geographical and cultural history (see ORIGINS OF VINICULTURE). This history has shown that wine-growing regions developed throughout Eurasia when the climate was most conducive. In addition, records of dates of harvest and yield for European viticulture have been kept for nearly a thousand years, revealing large swings in growing-season temperatures and productivity. For example, Pfister's historical research describes how during the medieval Little Optimum, roughly 900–1300 CE, average temperatures were up to 1 °C/1.8 °F warmer, with vineyards planted as far north as the coastal zones of the Baltic Sea and southern England. Recorded harvest dates for northern Europe from the High Middle Ages (12th and 13th centuries) show that fruit was ripening in early September, as compared with late September to mid October during the late 20th century, and that growing-season temperatures were roughly 1.7 °C/3 °F warmer. However, during the Little Ice Age (14th to late 19th centuries), temperature declines were dramatic, resulting in northern vineyards being abandoned and growing seasons so short that harvesting ripe grapes even in southern Europe was difficult. Labbé and colleagues examined grape-harvest dates in Burgundy from 1354 to 2018, finding that outstanding hot and dry years that were outliers in the past have since 1988 become the norm, with many years since 2000 the warmest on record. The research also shows that harvest dates from 1988 to 2018 were 13 days earlier than the average of the previous 600-plus years: mid September instead of late September to early October. Data from 2014 to 2021 show this trend continuing, with harvest dates earlier than mid September, as early as 20 August in the extremely warm 2020 vintage.

Today our understanding of climate change and the potential effects on VITICULTURE and wine production has become increasingly important as changing levels of greenhouse gases and alterations in Earth surface characteristics bring about changes in the Earth's

radiation balance, atmospheric circulation, and hydrologic cycle. In its latest report, the Intergovernmental Panel on Climate Change (IPCC) stated that warming of the climate system is unequivocal and that, since the middle of the 20th century, many of the observed changes are unprecedented over decades to millennia. Each of the last four decades has been successively warmer than any decade that preceded it since 1850. Global surface temperatures were 0.95–1.2 °C/1.71–2.16 °F higher in 2011–2020 than in 1850–1900. However, temperature changes have not been globally uniform, and the warming trends have been found to be asymmetric with respect to seasonal and diurnal cycles, with greatest warming occurring during the winter and spring and at night (resulting in a smaller DIURNAL TEMPERATURE RANGE).

Averaged globally, the eleven warmest years on record have all occurred since 2005. Other climate-related observations include: the Greenland and Antarctic ice sheets losing mass over the last few decades; glaciers on average continuing to shrink worldwide; decreases in snow-cover extent in the northern hemisphere and floating ice in the Arctic Ocean; global mean sea level rising on average 20 cm over the past century; and worldwide precipitation over land having increased by 5–10%. Furthermore, changes in many extreme weather and climate events have been observed in every region across the globe, including changes in the frequency, severity, and even geography of HEATWAVES, heavy precipitation, droughts, extreme fire events (see WILDFIRES), hail, and tropical cyclones. The IPCC has indicated that extreme-event occurrences are increasingly attributed to human influences on the climate system.

Contemporary research shows that the impact of climate change on viticulture and wine has been widespread. Numerous effects on plant growth, fruit characteristics, and pest and disease issues (see below) have been observed in wine regions globally, with indications that they are likely to continue in the future. Many studies around the world have documented changes in average climate conditions that have produced warmer and longer growing and DORMANT periods. Growing-season temperatures in many of the best wine-producing

regions in the world increased 1.43 °C/2.57 °F during 1900–2017. Trends between day and night temperatures vary by region, with some seeing much more significant warming at night and others seeing more heat-stress events through higher daytime temperatures. In addition to warmer growing seasons with greater heat accumulation, many of the world's wine regions have experienced a decline in FROST frequency and shifts in the timing of frosts. However, cold extremes still occur, and warmer spring temperatures leading to early BUDBREAK can lead to severe FROST DAMAGE, as in much of Europe in 2017 and 2021, for example. Furthermore, warmer winters and lack of winter DORMANCY disrupt the vine's internal clock, ultimately affecting vine growth and productivity the next year.

Grapevine PHENOLOGICAL timing has shown strong relationships with the observed warming in wine regions, with trends ranging from 5 to 30 days earlier over numerous CULTIVARS and locations (Jones et al. 2012, Cameron et al. 2021). Changes are greatest for the timing of VERAISON and harvest, and interval lengths between the main phenological events have also shortened, with the length of time from BUDBREAK to FLOWERING, flowering to veraison, or veraison to harvest dates shortening by two weeks or more. An analysis over all locations and cultivars shows that grapevine phenology has been responding by roughly 5–10 days per 1 °C/1.8 °F of warming over the last 30–50 years. With this earlier and more rapid plant growth, the potential for changes to ripening profiles and wine styles is evident. Many regions have seen trends towards higher sugar and lower acidity levels that are significantly correlated with increases in temperatures. As a result of these changes in GRAPE COMPOSITION, combined with changing consumer preferences (see HANG TIME, for example), higher alcohol levels have been observed in many regions. Furthermore, research in some regions shows that harvests that occur earlier in the summer, in a warmer part of the growing season, will result in hotter fruit being harvested, typically leading to loss of flavour and aroma compounds, as well as the potential for greater

BERRY SHRIVEL unless irrigation is increased (Webb et al.). See HARVEST COMPRESSION.

Research on climate change effects on pest and disease pressure indicates that we are likely to see increases in populations and severity but also shifts to new areas further towards the poles, with warmer winters and warmer night temperatures (discussed below).

Soil interactions with climate, pests, and disease also strongly influence YIELD and wine quality. Numerous studies have shown that SOIL EROSION, degradation, and SALINITY are likely to be major indirect effects of climate change on viticulture and wine production. Climate change is expected to lead to a more vigorous hydrological cycle, including more total rainfall and more frequent high-intensity rainfall events. Furthermore, a changing climate and societal demands on water will increase the pressure to restrict irrigation, ultimately increasing rootzone salinity with a greater impact on wine quality over time.

In addition, researchers have found that increases in carbon dioxide will cause more vegetative growth (see VIGOUR) in grapevines and the need for increased water-use efficiency, although the increased growth is likely to come at the expense of grape quality. However, while we understand some of the issues surrounding the impact of CO_2 on growing grapes, research is only now starting to explain more fully how increasing CO_2 concentrations along with warmer temperatures and changes in available water relate to vine growth, phenological timing and phase lengths, yield formation, fruit ripening and composition, and, most importantly, wine quality. Finally, an important indirect effect of increased CO_2 for the wine industry has also been identified: changes in the texture of OAK wood may alter its suitability for wine barrel production.

Future predicted climate changes

Current climate modelling—using predictions based on a range of future CO_2 emissions, which are the largest contributors to total increases in temperatures—projects that the globally averaged surface temperature will likely increase 1–5.7 °C/1.8–10.3 °F by 2081–2100 relative to what was seen globally during the 1850–1900 period. The projected warming will likely continue to exhibit interannual-to-decadal variability and will not be regionally uniform, with variation in the rate of warming and whether the warming comes from greater increases in daytime or night-time temperatures. Research suggests that wine-region growing-season temperatures will increase by approximately 2 °C/3.6 °F by 2050, with increased seasonal TEMPERATURE VARIABILITY. However, the warming rates in wine regions are likely to vary: locations in the northern hemisphere are expected to warm more than those in the southern hemisphere. In addition, regions at higher LATITUDES or inland are expected to warm more than those in coastal zones (Jones & Schultz). Both observations and models also suggest that in most viticultural locations in Australia and California, for example, this projected warming is likely to lead to a decrease in rainfall and/or snowpacks in the surrounding mountains, leading to greater WATER STRESS and reductions in water resources in the future.

Global studies have shown broad shifts to higher latitudes, with COOL-CLIMATE VITICULTURE found further north in Europe and North America today (Jones & Schultz). Similar poleward shifts have been seen and are projected in the southern hemisphere, although this is likely to affect only small areas of New Zealand, Tasmania, and the southern regions of Argentina and Chile, due to landmass limitations. Regional research by Moriondo and colleagues on spatial modelling of suitable zones for viticulture in Europe and the western US shows latitudinal, coastal, and elevation shifts from historic wine regions. Similar results have been found elsewhere, with estimations that potential viticultural area could expand in some regions while contracting in others.

Future climate change of the magnitudes predicted will have numerous effects on society and natural ECOSYSTEMS. Likewise, it presents numerous potential influences on, and challenges to, the wine industry, including additional changes in the timing of grapevine phenology, likely to result in a disruption of balanced composition and flavour in grapes and wine. In addition, the changes are not likely to be uniform across all regions and varieties but are likely to be related to climatic thresholds for optimum growth and quality. Furthermore, the warming will clearly force decisions on the mix of varieties grown and the wine styles produced in particular regions: those that currently have a cool climate will have a greater choice of viable varieties, while in many of today's warmer regions the future climates will be challenging for optimum grape growth and wine production from most varieties (Santos et al. 2021a). Current and future adaptations to changes in climate are many; they include better understanding of the cultivar limits to climate conditions, changes in vineyard management strategies (see PRECISION VITICULTURE), winemaking refinements, developments in soil–rootstock compatibility, and continued plant breeding and genetic research (Santos et al. 2021b).

While the Earth's climate is always changing, strong regional identities have developed in terms of cultivars and wine styles. Therefore, any future climate change has the potential to influence cultural change. To prepare for the future, the wine industry will most certainly need to help mitigate future changes in climate and integrate planning and adaptation strategies to adjust to those changes that the IPCC says may be irreversible due to past and future greenhouse-gas emissions. The effect of climate change on vineyard pests and diseases

Over the last few decades, climate change has correlated with the migration of some vineyard pests and diseases. In France, for example, the FLAVESCENCE DORÉE phytoplasma and the associated LEAFHOPPER vector *Scaphoideus titanus* were first described in Armagnac in 1956. The disease has been found in Bordeaux (1994) and has been increasing in the area ever since. The vector still seems to be moving further north, to Saumur-Champigny (2006) and then Burgundy and Champagne in 2012. The related phytoplasma disease *bois noir* (see GRAPEVINE YELLOWS) now occurs in southern Germany. The European grapevine MOTH (*Lobesia botrana*), originating from the warmer Mediterranean areas, also seems to be travelling northwards, replacing the cool-climate vine moth (*Eupoecilia ambiguella*) in some areas of the Loire Valley. This northwards insect migration is generally considered to be due to the impact of warming on insect distribution, which is known to be one of the first biological indicators of climate change.

Some vineyards in the southern hemisphere are facing warmer and drier weather conditions, which, in theory, should not favour increases in disease development. In both hemispheres, however, trends towards higher temperatures are combined with more irregular and more intense rainfall. Generally, warmer and wetter conditions increase fungal disease pressure by encouraging more infection cycles. In European vineyards, DOWNY and POWDERY MILDEWS and BOTRYTIS BUNCH ROT are now considered more aggressive. By the mid 2010s powdery mildew was a more common phenomenon in Champagne than ever before, perhaps because of warmer temperatures. BLACK ROT, even though it was introduced more than a century ago from the US, has been spreading in many European countries, from Germany to Hungary and even to places with warm, dry climates such as Portugal and central Italy. More generations of grapevine moths, mites, and leafhoppers are generally observed with higher temperatures, and additional late-season flights of insects such as European grapevine moths have been regularly observed in

PHEROMONE traps in warm years in the Bordeaux region, even if without an increase in actual damage by the mid 2010s.

Pathologists studying grapevine pests and diseases face a similar dilemma. Are recent changes in the distribution or impact truly part of longer-term effects brought about by climate change, or are they due to changes in, for example, vineyard management, PESTICIDE use, or global transport, or are they a genuine movement into a new ecological niche for a species?

Climate modelling is also allowing scientists to assess how climate change might influence pest and disease occurrence in the future. For example, Salinari et al. simulated likely future downy-mildew attacks in Acqui Terme in north-west Italy for the decades around 2030, 2050, and 2080. The modelling predicted an increase in temperature and a decrease in precipitation; the former outweighed the latter in terms of influence and was sufficient to predict increased disease pressure and more severe epidemics. Two more sprayings would be required early in the season. However, pests and diseases may also change over the longer term. Fungi, for example, are able to adapt themselves not only to climate change but also to the types of AGROCHEMICALS used for their control. This is another challenge in situations with higher disease pressure, where more sprays are required to ensure sufficient control. Unfortunately, more reliance on chemical applications can favour development of resistant fungal strains. The grapevine as host plant has also to be considered in terms of its sensitivity to pests and diseases in a changing climate. Whether climate change will make grapevines more sensitive or more resistant to pests and diseases is a difficult question since both pest/disease and the vine are affected by either higher temperatures and/or increased carbon dioxide concentration (Pugliese et al., Reineke and Selim). Crossing resistant cultivars (see DISEASE-RESISTANT VARIETIES) with sensitive VITIS VINIFERA varieties that have high qualitative traits could be a key factor in successfully adapting to changing vineyard climates. climate classification, the description and grouping of climates for viticultural purposes.

History

Climate classification is a way of categorizing the world's climates based on a region's biome (i.e. the dominant collection of plants and animals that occupy the habitats of that region). The most familiar classification scheme is probably the one devised by Köppen used in geography and ecology.

Specialized classification systems have been developed for viticulture. The first scientific study of viticultural climates was that of the French researcher A. P. de Candolle in the mid 19th century, a time when reliable climatic data were just starting to become available. De Candolle observed that BUDBREAK in European vineyards corresponded closely with the dates on which average mean temperature reached 10 °C/50 °F. He proposed that useful heat for vine growth and RIPENING could be measured by the amount that actual mean temperatures exceed 10 °C. Therefore, a summation of the excesses for all growing-season days would give a measure of the total plant-usable heat.

Numerous applications of the heat-summation concept have been developed for viticulture. The first extensive practical use of de Candolle's method was in 1944 in California, where AMERINE and WINKLER classified observations of temperatures above 10 °C/50 °F (growing degree days, GDD) in the state over a fixed vine-growth and ripening season, from 1 April to 31 October, into five classes, which they called regions. These regions broadly correlated with those geographical areas in California with cool to warm to hot climates for general grape-ripening capabilities and wine styles (see table). Subsequent research by Jones and colleagues examining temperature conditions in western US vineyards and in New Zealand identified the need to update this classification by creating additional classes at both the lower and upper ends since the original classification did not encompass today's cool and hot limits.

The wine regions mentioned in the rightmost column include examples from the coolest to the warmest in each of Winkler's categories. The location of the weather station (in brackets) may not be within the vineyards. There will be some wine-producing regions that are split across two Winkler regions; for example, parts of Bordeaux are in Region III.

Class/Region	C° units	F° units	General ripening capability and wine style	Region (weather station location)
Too cool	<850	<1500	Most varieties could not ripen consistently.	
Region Ia	850–1111	1500–2000	Only very early-ripening varieties achieve high quality, mostly hybrid grape varieties and some *Vitis vinifera*.	Nova Scotia (Kentville), Sussex (Eastbourne), Champagne (Reims)
Region Ib	1111–1389	2000–2500	Only early-ripening varieties achieve high quality, some hybrid grape varieties but mostly *Vitis vinifera*.	Rhine Valley (Geisenheim), Marlborough (Blenheim), Burgundy (Dijon)
Region II	1389–1667	2500–3000	Early and mid-season table-wine varieties will produce good-quality wines.	Coonawarra (Coonawarra), Piemonte (Turin), Bordeaux (Mérignac)
Region III	1667–1944	3000–3500	Favourable for high production of standard- to good-quality table wines.	Rioja (Logroño), Sonoma Valley (Sonoma), Margaret River (Margaret River)
Region IV	1944–2222	3500–4000	Favourable for high production but acceptable table-wine quality at best.	Napa Valley (St Helena), southern Rhône (Avignon), Stellenbosch (Nietvoorbij)
Region V	2222–2700	4000–4900	Typically only suitable for extremely high production; fair-quality table wine or table-grape varieties destined for early-season consumption are grown.	Madeira (Funchal), Patras (Patras), Jerez (Jerez de la Frontera)
Too hot	>2700	>4900	Likely more suited to table grapes and raisins.	

Although successful in California, the Winkler Index (WI), is not fully accepted elsewhere. It works well in California partly because temperatures there are quite closely correlated with other climatic factors possibly related to viticulture and wine quality: directly with total SUNLIGHT, and inversely with HUMIDITY (see also CLIMATE AND WINE QUALITY). Temperature alone thus gives a reasonably adequate index of all the relevant climatic variables, but it also, more importantly, is the prime driver of vine PHENOLOGY.

The Huglin Index, developed in Europe, uses a similar formula but gives more weight to maximum temperatures, making an adjustment for longer day lengths found at higher latitudes and usefully differentiating coastal from inland areas. It thus reveals CONTINENTALITY and LATITUDE differences.

Tonietto and Carbonneau used the Huglin Index along with a dryness index, which corresponds to the potential water balance of the soil, and a cool-night index, developed as an indicator of night-time temperature conditions during maturation. The authors combined the three indices into the Multicriteria Climatic Classification System that represents the variability of some viticultural climates worldwide.

In Australia, Smart and Dry developed a classification that involves five separate climate elements: temperature, sunlight, rainfall, evaporation, and humidity. They preferred to use the simple statistic

of average mean temperature for January (MJT; July in the northern hemisphere) as a usable index of summer heat. It is complemented by an index of continentality (the difference between mean summer and winter temperatures) to show the amplitude of swings in temperatures through the year, together with indices of sunlight, humidity, and water relations. The resulting five-variable classification gives a reasonable overview of viticultural climates and has been used for VINEYARD SITE SELECTION and regional comparison.

Also in Australia, Gladstones developed the Biologically Effective Degree Days (BEDD) index. In essence it is a method of predicting an average ripening date for any defined grape maturity type in any environment. It employs growing-season temperature summations over a 10 °C/50 °F base but with refinements that entail (1) imposing an upper limit (19 °C/66.2 °F) on the monthly average mean temperatures, beyond which no further increases are credited; (2) a correction factor proportional to the average day length of each month (long days giving greater biological effectiveness for a given greater mean temperature; see LATITUDE); (3) a correction for each month's average daily temperature range (a narrow range resulting in greater effectiveness, for a given mean). These considerations in the BEDD provide a predicted ripening date that forms the basis for evaluating or comparing environments as to their likely grape-variety adaptations and potential wine quality.

Other systems based on temperature have been simpler. Prescott in Australia found that the average mean temperature of the warmest month gave essentially as good a climatic indication as the seasonal temperature summation. Jones used average growing-season temperature (GST) for the seven-month growing season (see COOL-CLIMATE VITICULTURE), which classifies cool, intermediate, warm, and hot climates for viticulture and wine production. The GST index is very strongly correlated with growing degree days and is being increasingly recognized and used in wine-region climate classifications. G.V.J.

climate effects on vine diseases. The climate has a major effect on VINE DISEASES, and this interaction can be a major factor determining where grapes are grown. The most commercially important are FUNGAL DISEASES, and these are normally encouraged by warm, humid, and rainy conditions. Most of the world's viticulture is therefore carried out in regions with dry summers and less attendant risk of disease, for example the Mediterranean area. However, as the risk of fungal disease decreases, the likelihood of DROUGHT increases; in those parts of Europe where irrigation is generally prohibited (such

as southern France), the effects of drought can be substantial. Some regions such as California, Chile, and Western Australia can be so dry during summer that DOWNY MILDEW, one of the worst vine fungal diseases, is generally not present.

Sometimes climate effects on vine disease are subtle and difficult to discern. For example, the phytoplasma disease FLAVESCENCE DORÉE is known to occur in epidemics, with severity varying markedly from year to year. This is thought to result from climate-induced natural variations in population levels of the insect vector. While the insect population swings are dramatic, the weather perturbations responsible are typically so slight as to be barely distinguishable from the average. RAINFALL (and sometimes dew) has a major effect on diseases, especially those caused by fungi. Water is important for spore germination and dispersal by splashing, as for DOWNY MILDEW and DEAD ARM, and so a rainy spring can cause epidemics of these diseases. Rain near the time of harvest causes grape berries to split, allowing many BUNCH ROT fungi and bacteria to gain entry and ruin the fruit. Many fungi spores such as those of BOTRYTIS BUNCH ROT and downy mildew germinate in high humidity. The fungal disease POWDERY MILDEW develops in the shade of dense vine canopies and is also encouraged by overcast weather. Rainfall during winter makes PRUNING wounds susceptible to invasion by TRUNK DISEASE fungi. In years of low rainfall and drought conditions, the presence of root-damaging pests such as PHYLLOXERA and NEMATODES are more evident.

TEMPERATURE is a major factor in disease development and spread, with temperatures of 20–27 °C/68–81 °F favouring the germination of powdery-mildew spores. Freezing winter temperatures can cause vine trunks to split, allowing the entry of the CROWN GALL bacterium.

WIND is important in spreading diseases: for example, BACTERIAL BLIGHT is spread in wet, windy weather. Otherwise wind generally helps reduce disease by drying leaves and fruit after rain and dew.

Climate effects on disease have a significant effect on wine quality, and there is no more important example than that of botrytis bunch rot. Intermittent rainy, humid, and warm weather near the time of

harvest causes anguish to grape-grower and winemaker alike, because of the risk of losing both yield and quality. Yet, following infection, a change to dry weather can encourage the formation of NOBLE ROT. Costs of grape production are higher when the weather induces disease because of the need for treatments and possible crop loss. R.E.S.

Clinton, dark-skinned *Vitis riparia* × *Vitis labrusca* AMERICAN HYBRID. It is planted in Brazil, and its wine has a pronounced FOXY flavour. It has also been known in Italian SWITZERLAND.

clonal selection, one of the two principal means of improving a vine variety (the other being the elimination of VIRUS DISEASES). Clonal selection is the practice of selecting a single superior plant in the vineyard and then taking cuttings from this vine for PROPAGATION. The selection is generally made with a particular attribute such as YIELD or fruit RIPENESS in mind. Clonal selection contrasts with MASS SELECTION, where a group of superior vines is selected.

Grapevines, in common with many other perennial crops, are produced by vegetative propagation—that is, by using cuttings which are genetically identical. (This contrasts with agricultural field crops, which are multiplied by seeds that are different one from another—although sexual reproduction leading to the production of seedlings is the means by which NEW VARIETIES are created.) In vegetative propagation, each bud from a so-called 'mother vine' essentially gives rise to a plant of the same CLONE (except for those very rare cases in which a bud MUTATION has taken place).

Clonal selection for vines was first demonstrated in 1926 in Germany, where it has been most widely practised. Other European countries have also developed clonal-selection initiatives, but the practice is less well developed in some countries of the NEW WORLD.

Clonal selection depends on the fact that adjacent vines in a vineyard of the same variety may be different, sometimes discernibly different. More often the differences can be established only after some years of careful measurement. Differences on a vine-to-vine scale would not normally be expected from soil variation. There are two possible explanations: a difference in genetic make-up between the vines due to mutations, or a difference in the incidence of diseases in the vines.

It is important to be able to tell the difference because some diseases are 'graft transmissible' (i.e. they are carried from one vine generation to the next in CUTTINGS; see below). The most common and commercially important transmissible disease agents are VIRUSES. Such disease agents are transmitted by careless selection of the BUDWOOD or ROOTSTOCK material used at GRAFTING (and thus a human influence). However, diseases caused by viruses, VIROIDS, FUNGI or PHYTOPLASMA are sometimes transmitted by NEMATODES or INSECTS.

There has been disagreement among viticultural scientists working in this area as to whether genetic difference or virus diseases are more significant in causing vine-to-vine differences. Professor Helmut BECKER, an acknowledged authority on clonal selection based at GEISENHEIM in Germany, argued for the genetic difference principle, while the virologists led by Austin Goheen of the University of California at DAVIS believed that virus infection was the more important. Most viticulturists would now agree that both influences are important.

Whether the vine-to-vine difference in the field is due to mutation or to a disease, the effects can be passed on to myriad new vines obtained by vegetative propagation. This is the basis of the viticultural technique of clonal selection.

The process of clonal selection is necessarily long and requires considerable investment of resources. To make reliable field selections requires several years of records (up to nine are used in Germany) followed by comparative trials of many different clones of the one variety for evaluation. After waiting three years for the first harvest, five to ten more years are necessary to monitor yields and

fruit ripeness. Clonal selection should also involve making trial wine to assure trueness to VARIETAL type. Selected clones may not therefore be released until 15 or more years after the initial selection in the field. And, given the possibilities of both mutation and the spread of viruses by natural means, clonal selection should be an ongoing process. There has already been a release of second-generation clones in Germany; fields originally planted to one clone have been selected again for 'clones of clones'.

There is no doubt that clonal selection has played an important part in improving both yield and wine quality from modern vineyards. When grafting became popular in the 1880s to overcome phylloxera, virus diseases were inadvertently spread. Many vineyards planted as late as the 1960s contained off-types, rogue vines (i.e. not the intended variety), and virus diseases. As more healthy and true-to-type planting material becomes available as a result of clonal selection, then these problems disappear. Most reputable nurseries worldwide will provide only plants propagated from clonally selected rootstocks and scions.

Mechanisms for clonal selection and propagation vary from country to country. Generally the studies are conducted by government-funded scientists (although it is not unusual for a leading Bordeaux château, for example, to be doing its own clonal selection from vines naturally adapted to that property). In France, the extent to which planting material was infected by viruses up to the mid 1940s led to the formation of the Institut des Vins de Consommation Courante (IVCC). This organization and its affiliates tested selected clones and supplied CERTIFIED PLANTING MATERIAL. France AgriMer now oversees the certification process, although the research is generally carried out by the Institut Français de la Vigne et du Vin (IFV). In Germany, certification was introduced voluntarily after the First World War, and the scheme later became law. The EU adopted guidelines for propagation material in the early 1990s. In Australia, South Africa, and New Zealand, there are well-established VINE IMPROVEMENT programmes utilizing clonal selection as well as virus elimination. In California, the programme is conducted by the FOUNDATION PLANT

SERVICES at the University of California at Davis. In South Africa, there is a Vine Improvement Association, and a number of organizations specialize in heat treatment to eliminate viruses (see THERMOTHERAPY).

For many vine varieties, the differences in appearance and performance between clones with the same virus status is small. This suggests that genetic differences are generally minor and that the mutation rate is low. Some varieties, such as Pinot Noir, show extreme variation between clones, which indicates that it is a very old variety that has had time to accumulate many mutations. While varieties have for some time been distinguishable by DNA PROFILING, it is only very recently that genome testing has been able to distinguish clones (see CLONE).

It is difficult to understand the effect of clonal selection on commercial wine quality since so many vineyards are planted with mixed clones. While most Old World countries have a wide range of clones available, sometimes (because of limited importations) a New World country might have only a few for any one variety. An extreme example is Sauvignon Blanc in New Zealand, where all commercial plantings up until the early 1990s can be traced to a single clone imported from the United States. Some producers and researchers are critical of the limited availability of only improved clones from nurseries. They argue that either MASS SELECTION or a range of clones produces better, more characterful wine than a single virus-free, moderate- to high-yielding clone. Unfortunately, some clones were released on the basis of purely viticultural evaluation, which has fuelled suspicion about their effect on wine quality.

R.E.S.

clone in a viticultural context is a single vine or a population of vines all derived by vegetative PROPAGATION from cuttings or BUDS from a single 'mother vine' developed by deliberate CLONAL SELECTION.

Vine nurseries may sell a range of different clones of each vine variety, each with different attributes and characteristics and individually identified by numbers and/or names. In Germany, for example, there is a formal process of clonal evaluation and a systematic numbering system. Normally government agencies are involved in selection, evaluation, and distribution to nurseries, and often the availability of clones and their acceptance varies regionally. Some clones are so outstanding that they become internationally distributed. Clones of Riesling from GEISENHEIM in Germany are examples of this. In the 1990s, there was considerable interest in Burgundian (sometimes called Dijon) clones; see particularly CHARDONNAY and PINOT NOIR.

After decades of unsuccessful research, DNA studies have been able to distinguish clones by comparing the complete genome of a variety. This was achieved in 2017 for Nebbiolo (98 clones) and in 2021 for Cot/Malbec (14 clones), opening the door for genomics-based CLONAL SELECTION.

Though rarely used, the term subclone refers to a clone obtained by induced or spontaneous mutation of an existing clone or one that is the result of EPIGENETIC changes in the vineyard. R.E.S & J.V.

clos is French for 'enclosure'; any vineyard described as a *clos* should be enclosed, generally by a wall. This is a particularly common term in Burgundy but is also used elsewhere. Similarly, the term *cuve close* refers to the sealed tank which gives its name to a bulk method

of SPARKLING WINEMAKING. The first new-wave producers of PRIORAT adopted this term for their single-vineyard wines.

Clos de la Roche, leading red GRAND CRU in Burgundy's CÔTE D'OR. For more details, see MOREY-ST-DENIS.

Clos de Tart, Clos des Lambrays, and Clos St-Denis, red GRANDS CRUS in Burgundy's CÔTE D'OR. For more details, see MOREY-ST-DENIS.

Clos de Vougeot, also known as Clos Vougeot, famous walled vineyard in BURGUNDY created originally by the monks (see MONKS AND MONASTERIES) of Cîteaux. Between the 12th and early 14th centuries the Cistercians purchased or received as donations the land, much of which needed clearing and planting, which subsequently became known as the Clos de Vougeot. By 1336, the 50-ha/120-acre plot was complete and enclosed by stone walls on all sides.

The Cistercians maintained ownership until the French Revolution, when all clerical estates were dispossessed, although Dom Goblet, the monk responsible for the vineyards and the wine, had a sufficiently fine reputation to retain his job in the short term. In due course, Clos de Vougeot was sold on to Julien-Jules Ouvrard in 1818, the year before he bought DOMAINE DE LA ROMANÉE-CONTI, and remained in single ownership until 1889. Since then ownership has fragmented so that today there are over 80 proprietors.

A small chapel and rudimentary buildings, damaged during the religious wars, were rebuilt and enlarged in 1551, becoming the current Ch du Clos de Vougeot, a major tourist attraction. It is also home to the CONFRÉRIE des Chevaliers du Tastevin, a brotherhood which organizes copious feasts and the tastings for the Tastevinage. For this, producers submit wines to a jury; those selected are entitled to use the 'tasteviné' label, which should enable the wine to be sold more easily or at a higher price.

For more historical detail, see BURGUNDY, history. The vineyard and wines of Clos de Vougeot are described under VOUGEOT. J.T.C.M.

closures for wine containers are necessary to avoid excessive contact with OXYGEN and have changed remarkably little until recent times. CORKS are still the principal closures used for wine BOTTLES, just as they were more than two centuries ago when bottles became strong enough to allow for a closure. Closures need to offer a reliable seal, present an inert surface to the wine, have an OXYGEN TRANSMISSION RATE comparable to that of cork, be easy to remove, and be available at a relatively low cost (<$0.50 each). Alternative closures have become increasingly common since the mid 1980s, thanks primarily to a rise in the incidence of CORK TAINT.

Historical context

Cork was known in ancient EGYPT and GREECE, where it was used alongside other materials to provide AMPHORAE with a wide variety of airtight stoppers. Roman authors such as CATO, writing in the 2nd century BCE, refer to the need to seal jars with cork and pitch when the fermentation was complete. However, this use of cork does not appear to have continued into the early medieval period, possibly because the main potential supply of European cork was in southern Iberia, which had been conquered by the Moors in the 8th century. Medieval illuminations illustrate barrels generally sealed by wooden stoppers, with cloth frequently placed between the barrel and the stopper to provide a more airtight seal. Pitch and wax were also sometimes used to give additional protection. In the long period during which wine was mainly stored in and served from the BARREL, the most common stopper was some form of BUNG.

With the development of stronger glass bottles during the 17th century, it was necessary to devise new methods of stoppering. Glass stoppers, ground to fit individual bottles and tied to them with thread, were therefore introduced and survived well into the 19th century. Indeed, as they are found in DECANTERS, they remain in use to this day, now also used for bottled wine (see below). However, such stoppers are expensive, and gradually from the beginning of the 17th century cork became the most frequent substance used to seal bottles. The use of corks also required the invention of another piece of equipment, the CORKSCREW or, as it was first called, the bottlescrew. The earliest corks were not pressed completely into the bottles and so could be pulled out without excessive difficulty. However, by the end of the 17th century the introduction of corkscrews enabled corks to be fully inserted into the necks of bottles. P.T.H.U.

Pecci, A., et al., 'Use and reuse of amphorae. Wine residues in Dressel 2–4 amphorae from Oplontis Villa B (Torre Annunziata, Italy)', *Journal of Archaeological Science: Reports*, 121 (2017), 515–21.

Simon, A. L., *Bottlescrew Days: Wine Drinking in England during the 18th Century* (1926).

Modern closures

Modern technology, prompted by an increasing awareness of the extent of CORK TAINT and bottle-to-bottle variability, offers a range of alternatives to the traditional cork. These include synthetic closures (see below), SCREWCAPS, CROWN CAPS (largely for sparkling wine), and AGGLOMERATE CORKS. However, few have a proven track record for long-term AGEING, and there is still considerable attachment on the part of many wine drinkers to the ritual of pulling a cork, so premium wines meant for ageing are still closed with a cork in most markets.

The alternatives capitalize on the frustration with the variable performance of natural cork as well as cork taint. At additional cost, cork producers now offer analysis of each cork sold, to eliminate any taint. However, so far there is no method to evaluate the OXYGEN TRANSMISSION RATE of each cork before its use. It should be noted that all closures have variability due to inherent differences in the closure (natural corks are, not surprisingly, the most variable), the bottle, and the sealing process. There is currently a range of novel closures, such as ProCork (a natural cork sealed at both ends with a barrier membrane to protect the wine from oxygen and taint) and glass stoppers such as Vinolok. Others have come and gone.

Synthetic closures

Also known as 'plastic corks', these have appealed to producers on the basis of cost and reliability. They satisfy the wine drinker's need to wrestle with a CORKSCREW while alleviating the risk of CORK TAINT, but they have the disadvantage of not being biodegradable, and some are difficult to extract from, and reinsert into, the neck of the bottle. The better synthetic closures now available are made by an extrusion process with a separate smooth plastic sleeve. Nomacorc, the dominant brand of synthetic corks, has released a series of closures offering different oxygen transmission rates to suit different wine styles. Another concern surrounds the capacity of synthetic closures to 'scalp' flavour by absorbing volatile components from the wine (see FLAVOUR SCALPING). Natural corks also do this but to a lesser extent. More research is needed on the possibility of contamination by non-volitile components that could affect taste of a wine. Synthetic closures are cheaper than most natural corks and have the advantage that, unlike screwcaps, they do not require producers to adopt new bottles and BOTTLING lines.

cloudiness. See SUNLIGHT.

cloudy wine. See FAULTS and STABILIZATION.

Cloudy Bay, seminal winery in the Marlborough region of NEW ZEALAND, the brainchild of David Hohnen of Cape Mentelle in WESTERN AUSTRALIA. Its debut release in export markets of a moodily labelled varietal Sauvignon Blanc in 1985 created a reputation for Marlborough Sauvignon and a cult following for Cloudy Bay almost overnight, even though the grapes were bought in and that vintage's wine made under contract at another winery. The enterprise, based in its own premises since 1986, became a distant offshoot of the

VEUVE CLICQUOT, and hence LVMH, empire in 1990. It also produces Marlborough Chardonnay and Pinot Noir, a sparkling wine Pelorus, and, since the 2010 vintage, a Pinot Noir from Central Otago.

cluster, alternative, viticultural term for a BUNCH of grapes.

CMO, abbreviation for the EU's common market organization, its regulatory framework for wine.

Coal River Valley, the second largest wine-growing region in TASMANIA, located just north-east of Hobart.

Coastal Region, a conveniently extensive wine region in SOUTH AFRICA, home to several of the country's most important wine districts and wards, including CONSTANTIA, Darling, FRANSCHHOEK, PAARL, STELLENBOSCH, SWARTLAND, TULBAGH, and WELLINGTON. The name appears on labels of a substantial proportion of South African wines.

cochylis, better known as the vine moth. See MOTHS.

Cockburn, PORT house which became the brand leader in the important British market with the launch in 1969 of its Special Reserve ruby. This premium ruby transformed the market, which had hitherto been split between basic ruby port sold in pubs and vintage port for the wealthy. Consequent demand for Douro grapes led to new plantings, the first significant economic growth for the valley's farmers since the 1920s. Cockburn's were wine merchants in Leith, Edinburgh, in the 18th century. In 1815 Robert and John Cockburn set up a port company in Portugal and by 1870 were the second biggest exporter. In 1847, the brothers Henry and John Smithes joined the company, which became Cockburn Smithes & Co. John Smithes married Eleanor Cobb and both the Smithes and Cobb

families remained in the firm for generations. Their grandson, John Smithes (1910–99), was a pioneer in the 1930s, experimenting with CLONAL SELECTION at Quinta do Tua and identifying TOURIGA NACIONAL as one of the best grapes. The last family member Peter Cobb joined Cockburn's in 1960 and retired in 1999. In 1962, Cockburn's became part of Harveys of Bristol and subsequently part of the Allied-Domecq conglomerate, which sold it to the American whiskey distillers Beam in 2005. The next year Beam sold Cockburn's vineyards and stocks of wine to the SYMINGTONS, who acquired the brand in 2010. Cockburn had a fine reputation, commanding high prices, for their vintage ports in the mid 20th century, but had some unconventional views on vintage port; it declared the lighter 1967 rather than 1966 against the popular vote but decided against declaring 1977 and 1980 before releasing a 1983. Cockburn's have long sourced wines in the higher reaches of the DOURO, owning Quinta do Vale Coelho since the 1890s and purchasing in 1978 Quinta do Ataide, where they made some of the first batch plantings of Touriga Nacional. Ataide has 171 ha/423 acres of vineyard including a 2.25-ha experimental plot with 53 INDIGENOUS VARIETIES. In 1989 Cockburns acquired Quinta dos Canais, a 272-ha property on the north bank of the Douro, which had long provided the backbone of Cockburn vintage port, Ataide is now largely used for the production of unfortified Douro wine and the Symingtons are hard at work rebuilding Cockburn's reputation as a producer of vintage port. R.J.M.

Cocks et Féret. See FÉRET.

Cococciola, white-wine variety of PUGLIA and ABRUZZO, where it is blended with TREBBIANO. There were 1,671 ha/1,678 acres in 2015.

Coda di Volpe Bianca, ancient, full-bodied white grape grown near Naples in CAMPANIA. Plantings had fallen to 77 ha/190 acres by 2015.

Códega, Douro synonym for SÍRIA, Portugal's widely planted white wine grape.

Códega de Larinho, particularly soft, tropical-fruited white wine grape most common in the DOURO and TRÁS-OS-MONTES regions of northern Portugal. There were 942 ha/2,328 acres planted in 2020.

co-fermentation, the simultaneous fermentation of two or more varieties in the same vessel, is said to lift a wine's floral aromas, enhance its TEXTURE, and improve the brilliance and intensity of the colour.

The technique has its origins in Europe, most notably in the CÔTE RÔTIE appellation in the northern Rhône. Here, the red variety SYRAH is co-fermented with the white variety VIOGNIER. Up to 20% Viognier is permitted, but 5–10% is more usual. This practice found increased favour in Australia and other parts of the NEW WORLD from the 2000s. Co-fermentation does not have to be a combination of red and white grapes—in the United States, for example, co-fermentation may originally have been a natural consequence of FIELD BLENDS such as ZINFANDEL and PETITE SIRAH. Another notable historical example is found in the CHIANTI region of Italy, where the primary red grape, Sangiovese, was traditionally fermented with small amounts of the red variety Canaiolo Nero and the white varieties Trebbiano and Malvasia, although this practice has become uncommon.

Research by Dr Roger Boulton, Professor of Enology and Chemical Engineering at DAVIS, indicates that red varieties may contain low levels of co-factors (sometimes known confusingly as co-pigments), which are said to aid CO-PIGMENTATION and thus the formation of deeper and more stable colour in red wines. The addition of a variety with higher levels of co-factors may aid co-pigmentation, and co-fermentation may originally have been adopted because it was seen to increase colour stability and intensity.

When Syrah, or Shiraz, and Viognier are co-fermented, there are many different techniques used to add the Viognier: whole fruit at the crusher; whole grapes, or pressed skins and grapes or just juice added to the crushed Shiraz must.

Differing harvest dates may put constraints on co-fermentation but these can be overcome by modern REFRIGERATION techniques. Further research is needed to ascertain the best combinations of varieties and the best proportions. Too many white grapes might simply dilute the colour of a red wine. T.R.C. & J.E.H.

Boulton, R., 'The copigmentation of anthocyanins and its role in the color of red wine: a critical review', *American Journal of Enology and Viticulture*, 52/2 (2001), 67–87.

co-inoculation. See MALOLACTIC CONVERSION and YEAST.

Colares, exceptional but now minuscule DOC wine region in Sintra on the west coast of Portugal, just north of the capital Lisbon (see map under PORTUGAL). These vineyards were spared from the PHYLLOXERA pest in the 19th century thanks to their SANDY composition but have struggled to survive today's commercial pressures. Located on a narrow strip of sand dunes on the clifftops above the Atlantic, with roots anchored in the CLAY below, 50% of the UNGRAFTED VINES are RAMISCO. Made principally from MALVASIA de Colares, which is genetically distinct from other known Malvasia grapes, white Colares is distinctly salty and mineral, sometimes like a FINO sherry, while Ramisco can be reminiscent of a particularly austere PINOT NOIR.

The region was badly hit by the collapse of the Brazilian market in 1930, and a year later the Lisbon government created the Adega Regional, a CO-OPERATIVE winery, which all growers were eventually obliged to join for their wine to be entitled to the Colares denomination. In 1990, the EU forced the government to abolish the Adega Regional's monopoly. As at 2021, the DOC comprised just 15 ha/37 acres of vineyard (down from over 1,800 ha in the 1930s).

Ramisco and Malvasia de Colares are also being planted in Sintra's CALCAREOUS soils; the resulting wines (classified IGP Lisboa) show increasing promise, if not the same structure or intensity as Colares DOC. R.J.M. & S.A.

Mayson, R. J., *The Wines of Portugal* (2020).

Woolf, S. J., and Opaz, R., *Foot Trodden: Portugal and the Wines That Time Forgot* (2021).

Colchagua, part of the Rapel subregion of the Central Valley of CHILE. CARMENÈRE excels in its warm climate and GRANITE soils.

cold soak, MACERATION technique particularly popular for Pinot Noir.

colheita, Portuguese word meaning 'crop' or HARVEST and, by extension, VINTAGE. It also signifies a style of PORT or MADEIRA from a single year aged in wood for at least seven or five years respectively before bottling. These wines may also be labelled 'Single Harvest'. R.J.M.

collage, French term for FINING.

collar rot, one of the FUNGAL DISEASES of the vine which particularly attacks young vines growing in cool, moist soil, caused by the *Pythium* fungus. The vines are weakened and may die. Vines grafted on to Rupestris St George ROOTSTOCKS are most susceptible. Control is achieved by removing soil from the base of the trunk and reducing soil moisture. R.E.S.

collecting wine became a popular hobby in the 1980s. Americans in particular have tended to call anyone who buys FINE WINE a collector rather than a wine enthusiast, connoisseur, or *amateur* (the French term), suggesting that the thrill lies in acquisition and

possession rather than in consumption. Ever since the development of cylindrical BOTTLES in the 1730s, when it first became possible to maintain a personal CELLAR, there have been individuals whose purchasing patterns amounted to building up a specific collection of certain wines. The rapid economic growth of the late 1970s and 1980s, however, together with a succession of good vintages to be bought EN PRIMEUR and the emergence of a truly international consumer wine press (see Robert PARKER, for example), resulted in the emergence of a significant group of serious wine collectors around the globe (notably in the United States, Germany, and Asia). They communicate and trade with each other through the AUCTION houses, fine-wine merchants, and the specialist BROKERS, but the collecting instinct seems weaker in those born after 1990, or even 1980.

colli, singular *colle*, is Italian for 'hills', and its use in a wine name indicates that the wine is produced on slopes of a certain ELEVATION (it is an almost direct equivalent of France's CÔTE, Côtes, and Coteaux). Accordingly, articles about Colli Somewhere are listed not under Colli but under S for Somewhere.

Elevation is obviously in the eye of the beholder, however, and the word *colli* is used to describe both mere knolls and near-mountainous viticulture at elevations of over 500 m/1,600 ft. *Colli* and its variations can be found not only as the title of various DOCs but also as a part of their descriptive apparatus: CHIANTI, for example, is produced in the Colli Senesi and the Colline Pisane (Chianti dei Colli Senesi, Chianti delle Colline Pisane). The absence of the word does not imply that a given wine is produced in the flatlands; much of Italy's finest wine—BARBARESCO, BAROLO, BRUNELLO DI MONTALCINO, VINO NOBILE DI MONTEPULCIANO—is produced from HILLSIDE VINEYARDS without that fact being indicated in the wine's name. Vineyards in VALTELLINA often reach more than 700 m; ETNA's vineyards can reach over 1,000 m.

Collines Rhodaniennes, IGP which loosely follows the northern RHÔNE growing area. Around two-thirds of production is red, mostly Syrah. Around one-third is white, commonly made with Viognier. Only a very small amount of rosé is produced. Soils are predominantly GRANITIC. The wines of SEYSSUEL, close to the city of Vienne, are of particular interest. M.C.W.

Collio, or Collio Goriziano, is a qualitatively important, predominantly white wine DOC zone on the north-eastern border of Italy with Slovenia.

Collio, a corruption of COLLI, Italian for 'hills', is in the province of Gorizia. Half of what was once a single wine zone was annexed in 1918 by Italy, with the border running straight through vineyards. The other half is now known as Goriška Brda (see SLOVENIA). Before the Second World War, Collio extended much further eastward, and some of these sites are among the very finest of the entire zone. However, plans to create a supranational Collio/Brda denomination has yet to come to fruition as has the joint application in 2017 for UNESCO World Heritage Site status.

Within the region of FRIULI, Collio is the fourth biggest DOC in terms of area planted and volume of production after FRIULI GRAVE, ISONZO, and FRIULI COLLI ORIENTALI, but its fragrant and lively whites, which account for 85% of total production, have created an image of quality for Friuli throughout the world. Collio's red wines, overwhelmingly from MERLOT and CABERNETS SAUVIGNON and FRANC, tend to resemble LOIRE reds, at times with a similar vegetal quality and a certain lightness of body and texture.

The territory itself extends across the hills from the Judrio river in the west—the former boundary between Austria and Italy and now Collio's boundary with the climatologically similar Colli Orientali—to the Slovenian border in the east. Vines are planted on a CALCAREOUS marl alternating with layers of SANDSTONE called 'FLYSCH of Cormons' after an important township in the heart of the zone.

After two World Wars had ravaged the zone, it was rebuilt on viticulture, which became even more important at the beginning of the 1960s when the sharecropping system was abolished and many growers seized the chance to buy vineyards. Pinot Grigio became the inevitable cash cow and was planted widely. Other international, mainly white, varieties, notably Sauvignon Blanc and Chardonnay, as well the red Bordeaux varieties followed suit, and the early adoption of modern vinification techniques, particularly TEMPERATURE CONTROLLED fermentation, resulted in what were then Italy's cleanest, most modern wines.

With an international market awash in modern VARIETAL whites, today Collio struggles to maintain its former pole position. However, in the past Collio was a white wine made from local varieties, predominantly RIBOLLA Gialla with FRIULANO and MALVASIA Istriana, and labelled Collio without the suffix BIANCO. Today 12 varieties are allowed in the blend, while an additional 12 white and four red varieties can be suffixed to Collio on varietally labelled wines.

The rediscovery of a 1767 document which includes a CLASSIFICATION of Collio's vineyards into nine categories has sparked interest in Collio's subzones, though they remain theoretical so far. Plans to introduce a new DOC category, Collio Classico, for the classic blend of Ribolla Gialla, Friulano, and Malvasia Istriana have led to nothing, while a young generation who could forge change are hampered by high vineyard prices.

A beacon of hope remains in Josko Gravner, who came full circle in his career, having embraced stainless steel and international varieties only to then reject them in favour of Ribolla Gialla, SKIN-FERMENTED as was the historical practice, in QVEVRI. While Gravner is considered by many a radical, his minimalism and devotion to Ribolla puts into sharp contrast those paying only lip service to the variety that is intrinsic to Collio. W.S.

Colli Orientali del Friuli. See FRIULI COLLI ORIENTALI.

Collioure, one of the prettiest seaside villages on the Mediterranean coast just north of the Franco-Spanish border, is also an AOC for heady, deep, usually red table wines whose aromas of ripe fruits and spice reflect the fact that Collioure comes from exactly the same area as BANYULS. The characteristics of the vintage determine what proportion of the grapes become Collioure rather than Banyuls, with cooler vintages resulting in more Collioure. And with the decline in the popularity of VIN DOUX NATUREL, most estates now focus on Collioure. The BUSH VINES are mainly planted on steep SCHIST terraces, making any MECHANIZATION well-nigh impossible. Yields are inevitably tiny. GRENACHE NOIR is the principal grape variety for the red and rosé wine, with Syrah, Carignan, and Mourvèdre. There is also a tiny amount of COUNOISE, not found elsewhere in Roussillon. The full-bodied whites are made mainly from Grenaches Blanc and Gris.

R.E.G.

colloid, substance consisting of ultramicroscopic particles suspended in another substance. Wine colloids are very finely divided solids in particles with diameters ranging from about five nanometres to one micrometre. These are principally large organic molecules, most of which are polymers made of POLYSACCHARIDES including PECTINS and of smaller molecules such as PHENOLICS, PIGMENTED TANNINS, and TANNINS (see POLYMERIZATION). They do not contribute to a wine's VISCOSITY. When FINING and FILTRATION are successfully

accomplished, less than 20% of colloids are removed so that wine quality is not affected. D.D. & V.L.

colluvium is material that has moved downslope under the influence of gravity, whereas ALLUVIUM is transported by RIVERS. The difference is significant for viticulture given that HILLSIDE VINEYARDS—usually characterized by a thin veneer of rock fragments commonly derived from the bedrock that caps the hill—are generally considered superior to those on plains and valley floors, where alluvium dominates. The grand cru vineyards of CHABLIS, for example, are sited mid-slope on the famous Kimmeridgian bedrock, but a substantial proportion of the colluvium that coats the slopes consists of fragments of the younger Portlandian hilltop limestone.

Studies by Wittendal have suggested that the majority of the grand cru vineyards in Burgundy's CÔTE D'OR are on colluvium. Colluvial sediment can comprise any geological material: for example, VOLCANIC bedrock in Coombsville, NAPA Valley; SCHIST and GNEISS in Central Otago, NEW ZEALAND; and GRANITE on the slopes flanking the Curicó Valley in central Chile. A.J.M.

Wittendal, F., 'Great Burgundy wines: a principal components analysis of "La Côte" vineyards', paper prepared for the 11th Œnometrics Conference 2004, Dijon, France. citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.184.8571&rep=rep1&type=pdf.

Colombard is a natural cross of CHENIN BLANC × GOUAIS BLANC. This widely planted Charentais white grape variety was traditionally blended with UGNI BLANC and FOLLE BLANCHE, but considered inferior to both, as an ingredient in cognac. As Colombard's star waned in France, almost half of total plantings being pulled up in the 1970s, it waxed quite spectacularly in California, where, as French Colombard,

it became the state's most planted variety of all, providing generous quantities of reasonably neutral but reliably crisp base wine for commercial, often quite sweet, white blends to service the prevailing FASHION for white wine.

Its disadvantages of being prone to rot and POWDERY MILDEW are much lesser inconveniences in the hot, dry Central Valley, where almost all of California's Colombard is planted. And Colombard's disadvantages for the distillers of Charentes—that its wine is more alcoholic and less acid than that of the other cognac varieties—are positive advantages for consumers of the wine in its undistilled state.

The annual rate of planting of French Colombard in California slowed to a standstill towards the end of the 1980s and then picked up briefly in the early 2000s, but by 2020 total plantings were 6,950 ha/17,173 acres (whereas Chardonnay's total was more than 90,000 acres).

It would take some sorcery to transform Colombard into an exciting wine, but pleasantly lively innocuousness is well within reach for those equipped with STAINLESS STEEL and TEMPERATURE CONTROL. In a nice example of transatlantic switchback, the producers of the Armagnac region set about duplicating California's modern winemaking transformation of the dull Colombard grape on their own varieties surplus to brandy production, thus creating the hugely successful Vin de Pays des Côtes de Gascogne. Colombard plantings have been steadily growing in France. It is the most planted variety in the Gers *département* where more than half of France's 2019 total of 11,500 ha/28,417 acres was concentrated, although it is grown all over SOUTH WEST FRANCE.

It is even more widely planted, as Colombar, in SOUTH AFRICA, where it was once important to the local brandy industry, and is now also popular for cheap, commercial off-dry white. Total Cape plantings have remained steady, with 10,507 ha/25,963 acres recorded in 2020, making it the country's second most important wine grape, just ahead of Cabernet Sauvignon. As in Australia, it provides usefully crisp blending material with Chenin Blanc and the

much more fashionable Sauvignon Blanc. Australia's total plantings had fallen to 1,386 ha in 2022, mainly in the irrigated inland regions.

Colombia , South American country with a tropical climate and a relatively short history of viticulture. Colombia long depended on imported wines and spirits from Spain and developed a taste for sweet FORTIFIED WINES such as MÁLAGA. The initial output of the first vines planted here in the 1920s and 1930s was therefore directed towards this style of wine, as well as to the production of TABLE GRAPES. When wine imports from non–South American countries were punitively taxed in the mid 1980s, however, consumers became accustomed to the dry table wines of Chile and Argentina, and Colombia began to produce small quantities of dry wines from VITIS VINIFERA vines. The main grape-growing zone is in Boyacá department north-east of the capital Bogotá, where wineries such as Marqués de Puntalarga and Viñedo Ain Karim have set up shop. Annual precipitation in Boyacá is about 1,360 mm/53.5 in, with significant rainfall throughout the year. DOWNY MILDEW is the principal hazard, and vines have to be defoliated by hand in order to provide a short period of DORMANCY (see TROPICAL VITICULTURE). The country had 4,292 ha/10,060 acres of grapevines in 2020 according to the OIV, up from 2,591 ha/6,400 acres of vines in 2013. E.M.G.

Goldstein, E., *Wines of South America* (2014).

Colorado, a state in the midwest United States split by the Rockies, a mountain range that runs along the Great Divide. The wine industry is concentrated on the western slope, the mountainous terrain offering multiple high-desert MESOCLIMATES and the highest-ELEVATION vineyards in the US.

Most plantings of grapes and fruit trees in the western slope followed the construction of the Grand Valley Canal in 1883, which brought irrigation water to an area that may see maximum precipitation of 30 cm/12 in annually. While grape-growing thrived on

a small scale up until PROHIBITION, Colorado's first modern commercial winery, Ivancie Cellars in Denver, was not established until 1968. At this time, VITIS VINIFERA varieties were introduced into the Grand Valley, marking the birth of a wine region in Colorado.

By 2021, Colorado had 160 wineries, two AVAs, and 324 ha/800 acres of vineyards. Soils on the western slope range from Cretaceous Mancos SHALE and Gyproc Mesa CLAY to sandy LOAM. *Vinifera* makes up 80% of the state's plantings; with an increase in climatic challenges in the 2010s, HYBRIDS now make up 20% of the state's vineyards.

The Grand Valley AVA extends along the bottom of the steep north-west flank of the Grand Mesa, the largest flat-top mountain in the world. At 1,219–1,494 m/4,000–4,900 ft, it boasts 3800 F° growing degree days (GDD; see CLIMATE CLASSIFICATION) supporting 202 ha/500 acres of varieties in 2020, including, in decreasing order of acreage, Cabernet Sauvignon, Riesling, Merlot, Cabernet Franc, and Chardonnay.

The West Elks AVA, on the broader south-western side of the Grand Mesa in Paonia, is even higher, at 1,676–2,134 m/5,500–7,000 ft, with 2400 F° GDD. Its 40 ha/100 acres are planted mainly to Riesling, Pinot Noir, Chardonnay, and Gewürztraminer.

The state's vineyards face unique weather challenges, including late spring and early fall FROSTS and unpredictable WINTER FREEZE events. PHYLLOXERA, discovered in 2015/16, is slow-spreading, as the short growing season limits the pest's population cycle; confirmed positive acreage was near 5% in 2022. Summers bring intense ULTRAVIOLET RADIATION and triple-digit Fahrenheit temperatures, causing sugar levels to shoot up quickly while other ripening parameters such as colour, flavour, and PHENOLICS lag behind. Yet over the past 50 years advances in technology, training, education, and information sharing have resulted in dramatic improvements in the quality and recognition of Colorado's wines. J.B.E.

Colorino, rare, deep-coloured dark grape variety used traditionally to add colour to blends in CHIANTI and VINO NOBILE DI MONTELPULCIANO. Four different varieties of Colorino can be distinguished. They are capable of adding TANNINS and colour to Sangiovese without the aromatic impact of Cabernet Sauvignon, once considered essential because of perceived demand for a certain style.

colour of wines. Wines are classified as red, white, rosé, or ORANGE but can vary widely in colour within these broad categories, sometimes with little obvious distinction between a light red and a dark rosé.

Red wines

Red wines derive their colour from the natural organic red/blue ANTHOCYANIN pigments, of which there are varying concentrations in the skins of darker-skinned grapes (only TEINTURIER grape varieties have red pulp). These concentrations depend on the VINE VARIETY, the RIPENESS of the grape, viticultural practices, and the environmental conditions such as soil and weather, all of which may affect YIELD. The amount of anthocyanins leached into the resulting wine depends on many factors including BERRY SIZE, homogeneity of berry ripeness, and length and temperature of the MACERATION of skins and new wine, together with the extent to which techniques to encourage EXTRACTION such as PUMPING OVER and PUNCHING DOWN are used. All these factors influence the intensity of colour in a young red wine.

Although the actual hue of a young red wine is influenced partly by the grape variety (Cabernet Sauvignon grape skins, for example, are blue-black, while those of Grenache are much more crimson), this is much less so than one might expect. A more important influence is the acidity of the grape juice. In low PH solutions, anthocyanins exist in bright-red-coloured forms, while as pH rises they change to a more colourless form. In general, therefore, the more acid the grape juice, the brighter the colour—although very high-acid grapes may be unripe and deficient in available anthocyanins.

The anthocyanins as they occur in the grape are responsible for the colour of a red wine only in its very early life. In a red wine more than a few weeks old, the colour is due increasingly to products formed from anthocyanins, including PIGMENTED TANNINS, which are polymeric species resulting from reactions of anthocyanins with tannins. Pigmented tannins and other derived pigments have a wide range of colours, from orange to purple, but the purple species tend to be less stable so that brick-red pigments gradually become predominant.

Red wines which undergo BARREL AGEING also tend to have more stable colour than those which do not, because small amounts of

OXYGEN promote the formation of the wine's pigmented tannins. During AGEING, reactions of the phenolics and anthocyanins continue, forming an ever-increasing diversity of larger pigmented tannins. The larger ones aggregate and precipitate as SEDIMENT, depleting the wine of pigment.

The bleaching effect of SULFUR DIOXIDE on grape anthocyanins also means that red wines with a high level of free sulfur dioxide tend to be paler than they would be with a lower level. However, most of the red pigments generated in wine by anthocyanin reactions are resistant to sulfite bleaching so that this effect decreases as the wine ages. Also, if red wines are bottled with high sulfur-dioxide levels, the normal chemical interactions among the phenolics and other wine constituents to generate BOUQUET are disrupted.

The colour of a young red wine can vary from blackish purple (as in a vintage PORT, for example) through many hues of crimson to ruby. With age, red wines take on brick and then amber hues, lightening with time. The colour at the rim of a glassful of wine can give the most telling indication of the hue and therefore age of a wine, while looking straight down through a glassful of wine from above can clearly reveal the intensity of colour (see TASTING).

During the 1990s, winemakers tended to make ever-deeper-coloured red wines. This trend was encouraged by the increasing importance of large comparative tastings in JUDGING WINE. Because many (though by no means all) of the world's best red wines are deeply coloured (particularly those based on Cabernet Sauvignon and Syrah grapes, for example), there was a tendency among wine judges to favour deeply coloured wines. This led to a considerable increase in the number of red wines which owe their deep colour to over-EXTRACTION and/or colour added in the form of OENOCYANIN, TEINTURIER wines, or proprietary colouring agents such as California's Mega Purple made from RUBIRED grapes, which offer concentrated anthocyanins without tannins and often a little extra sweetness. However, the taste for deeply coloured wine has started to recede in

the 21st century in line with a growing appreciation of lighter and fresher red wines.

See also RED WINEMAKING and RED WINES for more information, including names for red wines in languages other than English.

White wines

Although red wines are red, white wines are not white. Very occasionally they are colourless, but they usually range from pale green through straw, pale copper, and deep gold to amber.

The stems, skins, and pulp of the light-skinned grapes used for making white wines contain a large and complex mixture of PHENOLICS similar to those found in dark-skinned grapes but not the red/blue-coloured ANTHOCYANINS. The absorption of light by these white-wine phenolics occurs mainly in the ultraviolet range but extends into the visible range sufficiently to cause a light yellow colour in the wines we call 'white'. After CRUSHING of the grapes, these phenolics are exposed to oxygen and to the acids and other constituents of the grape juice, which causes a number of enzymatic and chemical reactions (including OXIDATION and POLYMERIZATION) which result in changes of colour from light yellow to amber and eventually to brown. To minimize extraction of phenolic compounds into the must and subsequent oxidative browning, white wines are usually made with minimum SKIN CONTACT. Although most white wines are made from light-skinned grapes, white wines may be made from dark-skinned grape varieties (see BLANC DE NOIRS) using minimum skin contact and/or CHARCOAL treatments.

Different 'white' grape varieties contain a slightly different array of phenolics, which results in differently coloured wines. Palomino and Pinot Blanc, for example, are particularly prone to oxidation and browning, while Riesling has traces of non-phenolic compounds which can cause a greenish tinge to the basic yellow.

Must browning is due to enzymatic oxidation and is highly dependent on the phenolic content (especially hydroxycinnamic acids) of the juice. During fermentation, yeast cells can absorb some of the brown polymerized materials which are then removed with the LEES. (Much the same phenomenon allows the use of quite distinctly pale-pink base wines from Pinots Noir and Meunier in the blend for BOTTLE FERMENTED sparkling wines which, after DISGORGEMENT, are

white.) Some varieties used for white wines such as Gewürztraminer and Pinot Gris have greyish pink to purple skins and tend to result in deeply coloured wines with a strong pinkish yellow hue.

Careful protection from oxidation in pre-fermentation stages (for instance by addition of SULFUR DIOXIDE or ASCORBIC ACID) reduces must browning but maintains a rather high level of phenolics in the wine, especially if some skin contact has led to extraction of CATECHINS or PROANTHOCYANIDINS. This may result in increased browning susceptibility of the wine and, under some circumstances, may produce a pink tinge to the basic yellow.

With age, small amounts of oxygen act on phenolic compounds to brown them and apparently deepen a white wine's colour. With extreme AGEING of many decades, a very old white wine can be the same medium-intensity amber colour as a red wine of the same age.

White wine colour is also affected by the wine's levels of pH and sulfur dioxide; low pH and high sulfur dioxide concentration has a bleaching effect—as has hydrogen peroxide, which is occasionally used to make wine look paler.

Wines made from grapes affected by NOBLE ROT tend to have a particularly deep golden colour. Those which have been given extended skin contact tend to brown relatively early, while young white wines subjected to BARREL FERMENTATION and LEES CONTACT tend to be markedly paler than those fermented in STAINLESS STEEL and then transferred to cask for barrel ageing because darker pigments are absorbed by the lees.

During the 1990s, white wines in general became paler, as unintended oxidation became rarer, barrel fermentation more common, and barrel ageing more skilfully handled. See also WHITE WINEMAKING, WHITE WINES, and ORANGE WINE.

Rosé wines

These wines, which vary enormously in hue and intensity, owe their combination of pink colour and white-wine characteristics either to a very short SKIN CONTACT with dark-skinned grapes, or, for some everyday wines and pink sparkling wines, to the BLENDING of red and white wines. The proportions of anthocyanins, hydroxycinnamic acids, and tannins in the wine, depending on the grape variety and winemaking process, influence the pigment composition and thus the colour. In addition, wines that are pale bluish pink are likely to be the results of PROTECTIVE techniques, while those with an orange tinge may well have been exposed to some (possibly deliberate) oxidation. While a blindfolded taster can in some circumstances find it difficult to distinguish between low-tannin red wines and fuller-bodied white wines, it can be almost impossible on the basis of taste alone to distinguish a rosé wine from a white one.

See also ROSÉ WINEMAKING, ROSÉ WINES, and AGEING. J.R. & V.C.

Columella, Lucius Junius Moderatus , important, but long uncredited, source of information on wine production in ancient ROME. Little is known about his life except that he was born in Gades (Cádiz near JEREZ) and that he was an officer in the Roman army in Syria. He composed his treatise on farming, *De re rustica*, in 60–5 CE. It is divided into 12 books, all in prose except the tenth, on gardens. This book was written in hexameter verse as an addition to VIRGIL's *Georgics*, which Columella admired. Columella's work shows by far the best grasp of technical detail of all the surviving Roman treatises on farming, and this is particularly clear in his treatment of VITICULTURE. Books 3 and 4, the most important of the treatise, deal with vine-growing, but much practical advice on winemaking is also contained in Book 12, which outlines the duties of the bailiff's wife. He discusses what grape variety to use in which type of soil; yield in relation to labour and capital outlay (he assumes that a well-managed vineyard will yield at least 20, and possibly 30, AMPHORAE

per iugerum, approximately 20 hl/ha (1.1 tons/acre)); planting; propagating; pruning; training and dressing; grafting (Books 3–4); the vintage; and winemaking (Book 12). Half of an earlier, shorter work called *De arboribus* ('On trees') also survives; it has a section on vines which is much briefer than the corresponding sections of *De re rustica*. H.M.W.

Martin, R., *Recherches sur les agronomes latins* (1971).

White, K. D., *Roman Farming* (1970).

Comité Interprofessionnel, body representing all interests concerned with the production of a certain wine and the French counterpart to the CONSORZIO of Italy and Spain's CONSEJO REGULADOR. The model for all such organizations was the CIVC of Champagne.

Commandaria, a deep amber sweet wine produced from partially dried grapes from the island of Cyprus with flavours of orange peel, walnut, and raisins and an alcohol content usually around 15%.

The Mediterranean island was known for sweet wines, called Nama, long before the Knights Hospitallers (or Knights of St John) made Cyprus their headquarters in 1281. Like all religious orders, the Knights acquired land on a large scale and grew wine. Their organization was strictly hierarchical, divided into priorates, then bailiwicks, and lastly commanderies. A commandery was a manor or group of manors under the authority of a commendator. Each commandery had its vineyard or vineyards, and the wine shipped from them became known as Commandaria. (See the history of CYPRUS.)

In 1993, Commandaria became the first Cypriot wine to be granted full legal protection covering both its geographical origin and production techniques. Now a PDO, Commandaria must be produced within a strictly defined region comprising 14 wine-producing villages in the Troodos foothills about 30 km/20 miles north of Limassol, from the red grape variety MAVRO and/or the white XYNISTERI, grown as

BUSH VINES, and planted at a low VINE DENSITY of 2,000–2,750 vines per hectare. The demarcated area includes only vineyards planted at 400–900 m/1,312–2,953 ft in ELEVATION; those on the north-western side are mainly planted in CALCAREOUS soils, while those on the steeper, higher north-eastern side are largely VOLCANIC. (Both grape varieties are usually used, but a few lighter, subtler versions of Commandaria are made from white grapes only.) Total area planted as of 2022 was 424 ha/1,048 acres.

The grapes are picked very ripe to overripe, with minimum MUST WEIGHTS of 13 °Baumé for Xynisteri and 14 for Mavro, then sun-dried for about two weeks, on mats on the ground or on racks above ground, to a concentration of at least 21 or 23 °Baumé respectively. After fermentation, the wine must have an alcoholic strength of at least 10% without FORTIFICATION and no more than 1.5 g/l VOLATILE ACIDITY. At that point, the wine may but need not be fortified by the addition of grape spirit at 95–96% or with grape distillate at around 70% alcohol to a maximum of 20% actual alcohol. Its total POTENTIAL ALCOHOL must be at least 22.5%.

The wine must be aged for at least two years in wood, although in practice ageing is at least five years. Mainstream producers use a SOLERA-like system called *mana* in which older barrels are topped up with younger wines, although recently single-vintage Commandarias have appeared as part of the revival of the island's long wine heritage.

Although even within Cyprus it is of very limited commercial importance, Commandaria is one of the world's classic sweet wines.

See also DRIED-GRAPE WINES. C.G. & A.M.

Vrontis, D., and Thrassou, A., 'The renaissance of Commandaria: a strategic branding prescriptive analysis', *Journal for Global Business Advancement*, 4/4 (2011), 302–16.

Commanderie, common French term for a CONFRÉRIE.

commune, French for ‘village’ or ‘parish’. The Italian counterpart is a comune.

competitions, wine. Well-run reputable wine competitions can be extremely lucrative for the organizers and can play an important part in marketing, which is why some wine labels are adorned with MEDALS and the like, and some retailers’ lists and shelves are dotted with lists of awards. Care should be taken when studying these claims to ensure that the competition was a recent and respected one and that the successful wine was exactly the same bottling as the one on offer. Three of the most ambitious and successful international wine competitions have their roots in the UK: the International Wine and Spirit Competition, the International Wine Challenge, and the Decanter World Wine Awards. They attract thousands of entries from around the world, and most of their garlanded wines are of genuinely superior quality. Most wine competitions in wine-producing countries are national rather than international. Some of France’s most important are associated with agricultural shows, especially those of Paris and Mâcon. Some of the more respected of the many wine competitions held regularly in the US are Dan Berger’s International Wine Competition, the Critics Challenge International Wine Competition, the Indy International in Indiana, the Long Beach Grand Cru, the Los Angeles International Wine Competition, the Pacific Rim International, the San Diego International Wine & Spirits Challenge, the San Francisco International Wine Competition, the San Francisco Chronicle Wine Competition, the Sunset International Wine Competition, the TEXSOM International Wine Awards, and the New York Wine Classic for NEW YORK wines only. The explosion of interest in wine in CHINA has been accompanied by a rash of wine competitions there. It should be remembered, however, that few of the world’s most revered producers enter such competitions, and certainly none of those wines that are available in only very limited quantities ever do. It is difficult to imagine there will ever be a wine competition which will identify

the best, rather than the best of those who have something to gain by entering.

In Australia they are known as wine SHOWS. For more details of how competitions and wine shows work, see JUDGING WINE.

Completer, ancient white grape variety grown in Graubünden in eastern Switzerland. The wine produced—distinctive, pungent, acidic, and full-bodied—is a speciality of Bündner Herrschaft. DNA PROFILING at DAVIS showed in 2004 that Completer is one of the parents of LAFNETSCHA. Subsequently, a few vines of Completer discovered among Lafnetscha vines supported this parentage and the unanticipated presence of Completer in the Valais. J.V.

Complexa, Portuguese red-wine variety bred from CASTELÃO, Tintinha, and MUSCAT OF HAMBURG in the 1960s and introduced to MADEIRA as an experimental, deeper-coloured, softer alternative to TINTA NEGRA.

complexity, a TASTING TERM of approval when applied to FLAVOUR in wine, and a characteristic commonly viewed as a central component of wine QUALITY. Complex wines possess multiple flavours as well as flavour diversity. The term implies coherence: chaotic or jarring flavours are not considered complex. The term can also be used, typically when describing older wines, to suggest intricate subtlety, requiring sustained mental effort to grasp, as with a complex puzzle. A.H.

compost, the name given to the product of microbial action on organic wastes under controlled conditions in piles or windrows. Compost can be created from WINERY WASTE, typically POMACE, and it may be mixed, for example, with animal manures and sometimes with municipal garden waste, which encourages microbial action and resultant high temperatures. The compost must be turned regularly

to maintain aerobic conditions and be kept at a temperature of 55 °C/131 °F for at least three days to destroy pathogens and weed seeds. Compost is applied to vineyard soils and, being rich in ORGANIC MATTER and NUTRIENTS, improves water storage and vine growth. However, compost-making and distribution requires handling large quantities of material, and for this reason most vine-growers around the world use manufactured FERTILIZERS as a source of nutrients, and may incorporate mown COVER CROPS or prunings into the soil as a source of organic matter. The use of compost and other organic soil amendments is an integral part of ORGANIC and BIODYNAMIC VITICULTURE. R.E.S.

computers. See INFORMATION TECHNOLOGY.

Comté Tolosan, a wide-ranging IGP covering the whole of SOUTH WEST FRANCE. This is a haven for those wishing to avoid the rules or boundaries of the AOCs. The wines range from the superb (Ch Cabidos) to the unmentionable. P.S.

Conca de Barberá, DOP of 3,800 ha/9,390 acres of vines in Spanish CATALUÑA, sandwiched in between PENEDÈS, COSTERS DEL SEGRE, and TARRAGONA (see map under SPAIN). At around 500 m/1,600 ft in ELEVATION, this DOP experiences cold winters, and hot summer days are tempered by cool winds from the sea. Miguel Torres of Penedès (see FAMILIA TORRES) recognized the grape-growing potential of the LIMESTONE country around the Castillo de Milmanda and makes two of his most ambitious SINGLE-VINEYARD WINES there: the white Milmanda and the red Grans Muralles. At one time, most of Conca de Barberá's grapes were used to produce CAVA, but today more still wines are made, particularly some interesting rosé and red wines from the local TREPAT vine. V. de la S. & F.C.

concentrated grape must. See GRAPE CONCENTRATE.

concentration, umbrella term for any winemaking operation which serves to remove volatile substances, mainly water, from grape juice, must or wine. Its most common application has been in the production of GRAPE CONCENTRATE. However, a range of concentration techniques is used on grapes, juice, and MUST to produce more concentrated wines, often only on a certain portion of the grapes or liquid. The traditional SAIGNÉE method entails the bleeding of free-run juice from the must after a short pre-fermentation MACERATION period. More complex techniques are described below.

One component in a mixture can be concentrated using differences in boiling points, in freezing points, or in molecular size. The usual technique for making grape concentrate is to use differences in boiling points in a low-pressure, low-temperature evaporator. While very effective in concentrating sugar, this technique has the disadvantage of also removing volatile FLAVOUR COMPOUNDS.

A more recent technique, used since 1989 in some parts of France as an alternative to ENRICHMENT, involves evaporating grape must under vacuum. The water in the must evaporates at temperatures of about 20 °C/68 °F, no hotter than fermentation temperatures and therefore involving no dangerous loss of flavour. In practice, to achieve an acceptable rate of evaporation temperatures much higher have to be used, which can have a negative effect on the flavour of the final wine (see FLASH DÉTENTE). The equipment needed (known in French as a *concentrateur sous vide*) is relatively expensive but has the advantage of being able to handle unclarified grape must. Increasingly, though, vacuum concentrators are being superseded by REVERSE OSMOSIS machines.

Freeze concentration uses differences in freezing points to make a range of sweet wines of varying qualities. The EISWEIN of Germany and Austria and the ICEWINE of Canada and elsewhere is made by picking frozen grapes from the vine, crushing them, and filtering the must without allowing the mixture to thaw so that water is removed

in the form of ice. Ice crystals are collected on the filter along with the more usual grape solids (skins, etc.), and the result is grape juice with a lower concentration of water but a higher concentration of SUGARS, ACIDS, and other SOLUBLE SOLIDS.

Natural freezing on the vine is replicated by producers in such different regions as SAUTERNES (where it is called CRYOEXTRACTION) and NEW ZEALAND. Grapes, musts or juice can be frozen by using special chillers, dry ice (the solid form of carbon dioxide) or liquid nitrogen. This technique can also be used selectively, not just for sweet white wines but also on grapes destined to make dry white wines, not all of which are fully ripe. Since just-ripe grapes freeze at 0 °C/32 °F but fully ripe grapes freeze only at −6 °C or below, the mixture of grapes is chilled before crushing to an intermediate temperature so that it yields only the ripest juice (although it will yield nothing if there are no ripe grapes in the first place). The technique can only be practised on individual batches of grapes, however, so is relatively labour-intensive.

One final method of concentrating grape must is also the oldest: desiccation. See DRIED-GRAPE WINES.

Because in general these methods remove only water from the grapes, juice or must, all other components are concentrated. An increased concentration of fermentable SUGARS results in a wine with a higher ALCOHOLIC STRENGTH. Increased concentrations of PHENOLICS in many cases result in red wines with more BODY, potential for AGEING, and possibly more flavour. Increased ACIDITY, however, can result in wines that are aggressively tart, especially in less ripe years or in cooler wine regions. In some cases, particularly in cooler areas, musts which have been concentrated may have to be further subjected to DEACIDIFICATION, although in TEMPERATE climates TOTAL ACIDITY is usually only very slightly raised once TARTRATES have been precipitated.

Concentration is also used as a TASTING TERM. A.O.

OIV, 'International Code of Oenological Practices'. www.oiv.int/en/technical-standards-and-documents/oenological-practices/international-code-of-oenological-practices.

Concha y Toro. The dominant wine producer in Latin America was founded in Pirque, CHILE, in 1883 by Don Melchor Concha y Toro, a prominent businessman and politician. Its 2021 total of 11,624 ha/28,723 acres made it one of the world's leading vineyard owners. Since the mid 20th century, efforts have been focused on modernization and developing export markets.

The Casillero del Diablo ('the Devil's Cellar') BRAND is one of the world's most successful, with global sales of over six million cases annually (2.6 million of which are in the UK).

In 1993 the company founded Cono Sur winery to provide more innovative styles of wine, specializing in Pinot Noir. It was an early espouser of SUSTAINABILITY, a policy now applied throughout the group. Other significant winery projects followed, including Bodega Trivento in Mendoza in 1996 (now the fourth largest winery in Argentina) and vineyards in the cool Limari Valley in northern Chile. In 2011 Concha y Toro acquired Fetzer and Bonterra in Mendocino, California, thereby extending its vineyard holdings outside South America for the first time. In 2021 the company achieved B Corp certification across its entire group of wineries.

Concha y Toro is distinguished by the quality of its winemakers, wines, and management at virtually all price levels. Its top wines include Don Melchor Cabernet Sauvignon, Carmín de Peumo Carmenère, and the Terrunyo wine range. Since 1997, Concha y Toro has had a JOINT VENTURE, Almaviva in Puente Alto, with the Rothschilds of Ch MOUTON ROTHSCHILD.

Since the 1980s the company has been led by Eduardo Guilisasti, whose family have a majority shareholding (27.8%) of Viña Concha y Toro Family of Wineries, as it is now known. His siblings Rafael, Pablo, and Isabel are also closely involved in the running of the business.

Concord, the most widely planted vine variety grown in the eastern United States, notably in NEW YORK State, where there were more than 7,642 ha/18,883 acres in 2011. It started life as a chance seedling of an American vine species with the American hybrid CATAWBA. The pronounced FOXY flavour of its juice—synonymous with 'grape' flavour in the US—makes its wine an acquired taste for those raised on the produce of VITIS VINIFERA vines. It was named after Concord, Massachusetts, by Ephraim W. Bull, who introduced it, having planted the seeds of a WILD VINE there in 1843. It is particularly important for the production of GRAPE JUICE and grape jelly, but 5–10% of it is used to produce a wide range of wines, some KOSHER, often with some considerable RESIDUAL SUGAR. Viticulturally, the vine is extremely well adapted to the low temperatures of New York and is both productive and vigorous. It is planted in many eastern states of the US and widely in Washington State, where most of its grapes go into juice and GRAPE CONCENTRATE. Concord is also widely found in Brazil.

Huber, F., et al., 'A view into American grapevine history: Vitis vinifera cv. 'Semillon' is an ancestor of 'Catawba' and 'Concord'', *Vitis*, 55/2 (2016), 53–6.

concrete, popular since the 19th century for the construction of large FERMENTATION VESSELS and tanks for storage and AGEING, though upstaged by the introduction of shiny STAINLESS STEEL vats from the 1970s onwards. Nevertheless, concrete's greater thermal inertia, longevity, cost-effectiveness, and overall influence on wine QUALITY are still appreciated by many top producers, including Bordeaux's PETRUS, and the material is experiencing a renaissance. Traditionally lined with epoxy resin to prevent direct contact between the concrete and the wine and to make cleaning easier, especially the removal of TARTRATE crystals, concrete tanks do have the potential disadvantage of allowing very little OXYGEN exchange, which is important in the evolution of TANNINS. Some producers therefore prefer unlined

concrete for its greater oxygen ingress. Since the early 2000s, so-called concrete eggs have been gaining in popularity among a small group of producers around the world because the shape not only offers a high level of contact between the wine and the LEES but also appears to encourage convection currents that improve fermentation kinetics. They range in size from around 500 to 1,500 litres (130–400 gal) and are usually unlined but treated with tartaric acid solution before use. Early adopters include Michel CHAPOUTIER, South Africa's Eben Sadie, and Alfred Tesseron at Ch Pontet-Canet.

Condado de Huelva, Spanish DOP of 2,900 ha/7,166 acres of vines in ANDALUCÍA, close to the city of Huelva between the JEREZ region and the border with Portugal (see map under SPAIN). Nowadays few of its wines, which have typically been FORTIFIED and made in the image of its neighbour SHERRY, are exported, but the region has a long history (see SPAIN, history). In 'The Pardoner's Tale', Chaucer refers to the wines of Lepe, a small town just outside the modern Condado de Huelva DOP and a notorious source of blending wine; by the early 16th century the wines of Huelva were being exported to northern Europe and the emerging colonies in South America. From the 17th century, however, much of Huelva's production was sold to Jerez, where it was blended anonymously into sherry SOLERAS. Huelva became a DOP in its own right in 1964. The principal grape is the rather neutral ZALEMA along with a little PALOMINO (15% of the vineyard area).

Most wines here are white and dry, but there are several specialties that speak to the closeness of Jerez. Condado PÁLIDO is a pale, dry, FORTIFIED WINE matured in a solera under a blanket of FLOR, therefore not unlike FINO sherry. Condado Viejo is a RANCIO style of wine aged in a solera and resembling a somewhat rustic Jerez OLOROSO. Vinos de Licor are MISTELA-like fortified sweet wines. Vino Naranja, literally 'orange wine', is Spain's only aromatized wine (through maceration with orange peel) with an appellation of origin (and bears no relation, therefore, to ORANGE WINE).

V. de la S. & F.C.

Condrieu, small AOC in the far north of the northern RHÔNE that is likely to be the original source of VIOGNIER, its sole grape variety. This appellation encompasses seven right-bank communes (which happen to span three *départements*: the Rhône, Loire, and Ardèche) just south of the red-wine appellation CÔTE RÔTIE where the river turns a bend and the best vineyards are exposed to the south and south-east (see map under RHÔNE). The vine has probably been cultivated here for two millennia, since nearby Vienne was an important Roman city, although the total Condrieu vineyard fell to fewer than 10 ha/25 acres in the mid 1960s, when the wine was virtually unknown outside local restaurants and other fruit crops were much more profitable.

When the appellation was established in 1940, there were just three communes (Condrieu, Vérin, and St-Michel-sur-Rhône), but in 1967 the appellation was extended further south to include a succession of remote parcels of land dotted along the communes of Chavanay, Malleval, St-Pierre-de-Boeuf, and Limony. In 1986, another revision removed all vineyards over 300 m/984 feet in ELEVATION to include only the best exposed slopes. The vineyards of Condrieu now stretch across 14 km/8.7 miles north to south, covering 209 ha/516 acres in 2020. It is climatically similar to Côte Rôtie, with cold winters and with summers whose warmth is concentrated by the sloping vineyards and captured by the dark GRANITIC soils.

At one time Condrieu was a sweet or medium-sweet wine, but today almost all is made dry, and the wines are always full-bodied. Vinification methods are variable, with differing opinions on such fundamentals as the desirability of MALOLACTIC CONVERSION, LEES STIRRING, and use of OAK.

The ageability of Condrieu is a contentious topic. Most believe it is at its best in the first few years after bottling, when its floral perfume is at its most exuberant. After eight to ten years, the wines take on a more nutty, honeyed aroma, and those from the best sites are sustained by an inner salinity, which provides structure even if they are low in acidity.

France's only other all-Viognier appellation, CHÂTEAU-GRILLET, is an enclave within the Condrieu zone. M.C.W.

Conegliano , town in the VENETO region of north-east Italy that was home to Italy's first school of OENOLOGY, founded by Antonio Carpenè and Giovanni Battista Cerletti in 1876 as the Scuola di Viticoltura ed Enologia di Conegliano. Renamed the Scuola Enologica G. B. Cerletti, the school's influence extends all over Italy as it has trained many of Italy's producers and OENOLOGISTS. Along with Valdobbiadene, the town is also the centre of PROSECCO production.

Over more than a century, the University of Padua's agricultural department developed its research and training programmes in viticulture and oenology at Conegliano. Today its campus brings together the Centro Interdipartimentale per la Ricerca in Viticoltura ed Enologia (CIRVE); the Scuola Enologica G. B. Cerletti; the Centro Regionale per la Viticoltura, Enologia e Distillati; and the Centro di Ricerca per la Viticoltura di Conegliano (CRA-VIT), established in 1923 and now with further units around Italy.

Since 1967, CRA-VIT's work at Conegliano has focused on viticulture, with four central units concerned with AMPELOGRAPHY and VINE IMPROVEMENT, biology and protection, PROPAGATION, and cultivation techniques. It is the main experimental viticultural station in the Veneto with a 9-ha/22-acre nursery for an ampelographical collection of VINE VARIETIES established in 1951 and home to the Italian national register for grape cultivars. Another 20 ha were added in 1963, accommodating a total of over 2,000 varieties. The station is responsible for CLONAL SELECTION and ROOTSTOCK research.

One of CRA-VIT's first directors was Professor Dalmasso, whose Dalmasso Commission made a significant report on the state of the Italian wine industry (see ITALY). His successor Professor Manzoni produced many crosses (see INCROCIO Manzoni) still cultivated today. In 1933, Conegliano became involved in combating ADULTERATION AND FRAUD in the Veneto and then also, from 1965, in FRIULI. In 1986 the adulteration and fraud service became independent. W.S.

Conegliano-Valdobbiadene, DOCG for PROSECCO from the original production zone on the hills between these two towns in Italy's VENETO. Colli di Conegliano covers the same area but is the DOCG for the production of still white wines based on Manzoni Bianco (see INCROCIO), reds of Cabernets Sauvignon and Franc, and two rare PASSITO wines, Refrontolo and Torchiato di Fregona.

confréries, French 'brotherhoods' or associations, dedicated in particular to advancing the cause of various foods and drinks throughout France. More than 150 of them, most of them founded in the second half of the 20th century, are devoted to such various products as macarons, jams, olives, and local shellfish. A high proportion of them, almost half, are based on specific wines and other alcoholic drinks. One of the most famous is the Confrérie des Chevaliers de Tastevin in Burgundy (see CLOS DE VOUGEOT). The Commanderie du Bontemps du MÉDOC et des Graves, founded in Bordeaux in 1949 by the energetic Henri Martin, is also well known and is the LEFT BANK answer to the oldest of these *confréries*, the Jurade de ST-ÉMILION. The latter dates from the late 12th century, when the town councillors of this ancient town were given particular powers and responsibilities by the English crown which then governed it (see BORDEAUX, history); it was reconstituted in 1947. These *confréries* are devoted to an annual programme of pageantry, feasting, robe-wearing, and the *intronisation* (enthronement) of honorary converts to the cause.

connoisseurship of wine is a (disappearing) art in search of a less emotive name. The word connoisseur in English, like its counterpart *connaisseur* in French, conjures up a frightening vision of an elderly male so steeped in wine, wine knowledge, and wine prejudices as to be completely unapproachable. Much more attractive and widely acceptable terms are those which convey not just knowledge but an element of relish, such as 'wine lover', 'wine

enthusiast', or the common and attractive French term *amateur du vin*. None of these terms, incidentally, has any connotation of gender.

Whatever the drawbacks of the term, connoisseurship or wine expertise is an art that can give pleasure, and it involves less an arid grasp of the precise ENCÉPAGEMENT of each vineyard and the fermentation regimes for each vintage than an intelligent appreciation of how wines are likely to taste in a given environment, at a certain stage in their evolution, before or after other wines, and, importantly, with different foods. This is what consumers rather than producers are for. Experience can contribute to connoisseurship, but only if the consumer tastes with humility, attention, and an open mind. Mentors are useful, but some newcomers to wine have an instinctive grasp of connoisseurship. A true connoisseur meets each wine halfway and tries to show it in the best possible light, in stark contrast to professional wine JUDGING. Some wine drinkers seem determined to judge rather than enjoy wine. See wine TASTING, AGEING, SERVING, and FOOD-AND-WINE MATCHING. A connoisseur is not necessarily a wine BORE; and while deep pockets help, they are not a prerequisite.

Consejo Regulador, Spanish term meaning 'regulating council' (see COMITÉ INTERPROFESSIONNEL). Spanish wine law is administered through a network of *Consejos Reguladores* representing each DOP. They comprise vine-growers, wine producers, and merchants who between them decide on the ground rules for their region. These days some producers, especially the younger generation, are leaving the DOP system in search of more freedom or because they do not feel represented by it. F.C.

Consorzio, Italian word for a consortium or association of winegrowers, NÉGOCIANTS, and CO-OPERATIVES representing the interests of a single wine region or DOC/DOCG. However, since the 2008 reforms of the EU wine market, the consorzio role has changed drastically. QUALITY CONTROL, which used to be the consorzio's

concern, is now in the hands of a neutral third party, and consorzios are now concerned more with promotion and marketing, while several have added to this the ambitious task of routing COUNTERFEIT wines in the international market. If at least 60% of production is controlled by consorzio members, a mandatory levy, referred to as *erga omnes*, can be imposed on any producer wishing to use the relevant DOC or DOCG name on labels, whether they are a member or not. Its counterpart in France is the COMITÉ INTERPROFESSIONNEL; in Spain the CONSEJO REGULADOR. W.S.

Constantia, legendary 18th- and 19th-century dessert wines from the Cape, SOUTH AFRICA, then a Dutch colony. Their fame was never matched by any other New World wines, and at their height they commanded more prestige, sold at more fabulous prices, and enjoyed more crowned patronage than the most celebrated wines of Europe (with the possible exception of Hungarian TOKAJI). Constantia was even ordered by Napoleon from his exile on St Helena.

The Cape wines were grown on a subdivision of the 750-ha/1,850-acre Constantia Estate just outside Cape Town, founded in 1685 by an early Dutch governor, Simon van der Stel. However, it was Constantia's subsequent owners who achieved acclaim and prosperity, principally Hendrik Cloete, who purchased and restored one of the subdivisions in 1778. Quality and fame gradually diminished in the late 19th century, partly as a result of the Cape's declining importance to the British wine market and partly because Constantia's higher labour costs, especially after the abolition of slavery in 1834, and the lower yields associated with its cool climate made wine production economically marginal. By 1885 Cloete's estate was bankrupt, and under the name of Groot Constantia it has been state-owned ever since. In 1975, its management passed into the hands of a control board and in 1993 into a trust. In recent times Groot Constantia has made sound, increasingly impressive, conventional wines. A neighbouring privately owned estate, Klein (Little) Constantia, an 1823 deduction from Groot Constantia, was the first to take up the challenge of recreating the legend. It replanted

vineyards with Muscat of Frontignan (MUSCAT BLANC À PETITS GRAINS) in the early 1980s and now produces a white dessert wine known as Vin de Constance to local and international acclaim.

The sweet wines of Constantia, both red and white (the latter the more expensive), were made principally from this small-berried Muscat and its dark-berried mutation, probably including the lesser MUSCAT OF ALEXANDRIA, the dark red PONTAC, and CHENIN BLANC. Records show that slightly under 50% of Constantia wine in the early 19th century was sold without any varietal claim. Analyses of recently opened bottles (still perfumed with a tang of citrus and smoky richness) reveal they were probably unfortified although high in alcohol, apparently confirming records that the grapes were left on the vines long after ripeness to achieve shrivelled, but not BOTRYTIZED, concentration (see DRIED-GRAPE WINES for more details of the technique). Other stories suggest the wines may have been FORTIFIED by shippers for protection on the long, rough, and hot journey across the equator to Europe.

Today Constantia is a demarcated wine ward in Cape Town's southern suburbs, on the slim peninsula pointing into the south Atlantic, cooled by the sea for relatively slow summer ripening with average daily temperatures of 18–21 °C/64–70 °F and very wet but moderate winters (average annual rainfall over 1,000 mm/39 in). Rich, loamy Table Mountain SANDSTONE and decomposed GRANITE soils nurture vigorous growth, and even shy-bearing classic vines require ruthless TRIMMING and CROP THINNING. Here a handful of vineyards have, since the mid 1980s, once again been producing classic wines from land once part of the historic estate developed by Governor van der Stel.

Constellation Brands, holding company of Constellation Wines, is a leading international producer and marketer of virtually all forms of alcoholic beverage, and it has certainly done its bit for the mergers and acquisitions sector. Thanks to consistent acquisition, it became the world's largest wine business in 2004. In 2006 it acquired Canada's biggest wine company Vincor, only to sell it in 2016. In 2011 it had refocused on its American roots and sold off to what would become ACCOLADE all of the Australian, South African, and UK interests it had so recently acquired. In 2021, in an effort to concentrate on what it regards as its premium brands—including Robert MONDAVI and The Prisoner in California, Ruffino in Italy, and Kim Crawford in New Zealand—the company sold off about 30 brands to E. & J. GALLO and in 2022 despatched more to the WINE GROUP.

consultants are used with increasing frequency in wine production. Consultant VITICULTURISTS are particularly useful since those who operate on an international scale can impart knowledge gleaned from a wide variety of different vine-growing environments, although strictly local specialists such as David Abreu in northern California can forge an international reputation. Like viticulturists, the more energetic consultant OENOLOGISTS can use their expertise in both hemispheres, although their work is necessarily limited by the timing of HARVEST. One of the first internationally famous consultant oenologists was Professor Émile PEYNAUD. Today his best-known successor from Bordeaux is Michel ROLLAND, although dozens of other highly respected consultants operate in Bordeaux alone, and there are now hundreds of winemakers who travel the globe and offer, if not consultancy, then hard graft (see FLYING WINEMAKERS). Consultants play an increasingly important role in wine production everywhere but have long been particularly important in Bordeaux, California, and Italy, where today specialist, often local, consultants are preferred for their intimate knowledge of each TERROIR. Examples include Sangiovese expert Castelli, while Simonit & Sirch are agronomist consultants specializing in a specific type of PRUNING.

Many restaurateurs and hoteliers, most airlines, and even some wine retailers employ consultants in their wine selection. Some well-heeled collectors also take INVESTMENT advice from consultants.

consumption of wine throughout the world fell from a peak of around 285 million hl/7,500 million gal a year in the years 1976–80 to about 225 million hl in the early 2000s, then peaked at about 255 million hl in 2007 only to fall in the wake of the global financial crisis to under 240 million hl in 2014. The next peak was about 247 million hl in 2017, but total consumption in 2020 was less than 235 million hl, largely thanks to pandemic-related restrictions. Total world PRODUCTION continues to be considerably more than this, resulting in a global wine SURPLUS that is most acute in Europe, the most important producer and consumer of wine if regarded as a continent. But on a national level, by 2014 the US had decisively pulled ahead of France to become the world's biggest consumer of wine. The main reason for the drop in global consumption has long been sharp falls in average wine consumption by France and Italy, traditionally the world's two most important producers and consumers of wine, but since 2017 consumption in China—quite recently the world's fifth most important wine market—also declined considerably. The countries in which most wine is estimated to have been consumed in 2021 were, in declining order, the US, France, Italy, Germany, UK, Spain, China, Russia, Argentina, and Australia.

National annual per capita wine consumption figures in litres according to the OIV are to be found in Appendix 2.

containers for wine are used at four main stages in a wine's life: during the FERMENTATION that creates it; during its MATURATION; for its TRANSPORT; and for SERVING it. Moreover, while wine containers have changed throughout history, they have also varied through space, with each winemaking region becoming characterized by vessels of different dimensions.

Historical context

Many different materials were used for drinking and serving wine in the ancient world, particularly in CHINA. In prehistoric times in the eastern Mediterranean and the Caucasus, wine was generally put in earthenware jars, such as the Georgian QVEVRI, or sometimes into wooden containers, soon after the grapes had been trodden or pressed. This basic fermentation technology remained the norm until the 20th century, when VATS or tanks of CONCRETE and STAINLESS STEEL were introduced. The basic receptacles used for storing and transporting wine in classical antiquity were pottery AMPHORAE, which varied greatly in size and shape but which could be sealed, thus preventing the potentially harmful access of OXYGEN. Larger pottery vessels for storing wine in the Roman world were known as DOLIA. During the 1st century BCE, experiments were also undertaken in transporting wine in these *dolia*, anchored amidships, but their use did not persist. By the end of the 2nd century CE, amphorae production declined in Italy, although it continued in other parts of the eastern and southern Mediterranean, and most wine began to be transported long-distance in wooden BARRELS. For short distances, numerous other vessels, in particular animal skins, were also used, especially in Iberia.

Throughout the medieval period, wooden barrels served as almost the only vessels used for maturing and transporting wine, and their sizes came to reflect local custom and requirements. The standard barrel size in England, for example, the BUTT or PIPE, was fixed by statute in the 15th century at 126 imperial gallons (572.8 l). However, in southern Italy at the same time their wooden *botti* held about 454 l, while in Bruges the butt had a capacity of about 910 l; in Spain it varied from 454 to 477 litres. Meanwhile, it had been discovered in Germany that wines from good vintages with a high sugar content kept in larger barrels, providing they were not subjected to RACKING, lasted longer. This led to the construction of huge wooden tuns, containing thousands of litres, among the most famous of which were

the Strasbourg Tun of 1472 and the Heidelberg Tuns of 1591 and 1663.

For serving wine, small jugs made of pottery were generally used during the medieval period. However, from the 16th century onwards, glass BOTTLES became more frequent for this purpose, and by the second half of the 17th century these bottles began to be used to store and mature wines. Bottle shapes evolved so as to allow extended AGEING, and thus were born both VINTAGE wines and CONNOISSEURSHIP. Moreover, the use of bottles enabled completely new types of wine, such as CHAMPAGNE, the New French CLARETS, and vintage PORT, to be produced from the 17th century onwards.

Modern times

For details of containers used for fermentation, see FERMENTATION VESSELS, which may be either open topped or closed and may have a capacity as big as 300 hl/7,925 gal. Wines are matured prior to bottling in closed containers (to avoid OXIDATION), either in tanks made from materials such as STAINLESS STEEL, CONCRETE, or POLYETHYLENE or in some form of COOPERAGE, from small, new barrels to large, old casks, or in clay AMPHORAE, QVEVRI, TINAJAS, TALHAS, and PITHARI, or concrete eggs, or even glass BONBONNES or globes. Wine may be blended in even larger tanks holding up to 15,000 hl. Wine is transported either in BULK, usually in food-grade 250-hl stainless steel tankers or disposable 'flexitanks', or in bottle. When transport containers are used for shipping wine in bottle, care is taken by some fine-wine merchants and some fine-wine producers that the wine is shipped only in reefers, or temperature-controlled containers, and sometimes only during cooler times of year. This is particularly important for wines which have undergone a minimum of FILTRATION and vital for NATURAL WINES. For more details, see TRANSPORT.

The most common container for wine on its final journey to the GLASS, occasionally via a DECANTER, is the bottle, but see PACKAGING for the increasing number of alternatives.

contaminants, potentially harmful substances found in wine as a result of air or water pollution (see SMOKE TAINT, for example); vineyard treatment RESIDUES; poor winery HYGIENE; contaminated pallets, packaging materials or transport containers; ignorance; or ADULTERATION AND FRAUD. They are often difficult to identify and very potent, with extremely low perception thresholds, although the ability to detect them is not universal even among professional tasters. A contaminant becomes a TAINT only once it can be smelt or tasted.

Ignorance is possibly the most forgivable reason for contamination since the scope of what is regarded as, and can be measured as, a

contaminant grows wider with the rapid progress of science and measuring techniques. LEAD, for example, which was deliberately added to wines by the Romans, is now known to be a serious neural toxin. ETHYL CARBAMATE, on the other hand, has been regarded as a contaminant only since the late 1980s. And it was only in the 1990s that the contaminating effect of some apparently innocuous treatments of wooden beams in some winemaking establishments became apparent (see TRIBROMOANISOLE).

Nowadays, contamination as a result of poor winery hygiene is extremely rare, although it may be caused by products such as chlorine sanitizers that are designed to clean the winery but which form chlorophenols when they come into contact with phenols in rubber, resin, or plastic fittings, resulting in plastic or medicinal off-flavours in contaminated wine. A leak of brine from a refrigerant unit is another possible hazard. Research by Chatonnet et al. detected levels of phthalate contamination that exceeded the EU's specific migration limits for alcoholic drinks in 11% of the French wines tested, thought to be due mainly to the epoxy-resin coatings inside older vats.

Pollution is difficult to guard against. Wine producers are increasingly wary of some AGROCHEMICALS, however. Orthene, a fungicide used widely in the early 1980s with no ill effects apparent during winemaking, produced a range of wines with an extremely unpleasant smell after several years' BOTTLE AGE. Many German wines made in the early to mid 1980s, particularly the 1983s, exhibited this particular contamination. The ST-ESTÈPHE property Ch Phélan-Ségur destroyed its entire 1984 and 1985 production because of Orthene contamination. Even after a particular product has been banned, it may still contaminate the environment. Chlorophenols, for example, are active ingredients in wood preservatives, fungicides, and biocides that have been used over many years and form HALOANISOLES. American authorities in particular have regularly applied stringent tests to imported wines for traces of suspected contaminants, such as procymidone from agrochemical residues. Other potential

contaminants from the vineyard include hydraulic oil leaked from mechanical harvesters or spray drift from PESTICIDES.

The wine trade, like every other commercial activity, has its villains, but they are increasingly rare. Fortunately, very few of the substances which the least scrupulous producers are tempted to add illegally to wine (SORBITOL, for example) are harmful—with the notable and horrifying exception of lethal doses of METHANOL added to one Italian producer's wines in 1987.

See also ADULTERATION, which sometimes involves the deliberate addition of contaminants. J.R. & J.E.H.

Chatonnet, P., et al., 'Contamination of wines and spirits by phthalates: types of contaminants present, contamination sources and means of prevention', *Food Additives & Contaminants: Part A*, 31/9 (2014), 1605–15.

continental climate is one with a high degree of continentality, defined as the climatic effect that results from locations being insulated from the influences of oceanic or large bodies of water (see LAKE EFFECT). This is typically measured as the difference between the average temperature of its hottest month and that of its coldest month. Climates with a wide annual range are called continental; those with a narrow range, MARITIME.

LATITUDE influences continentality. In the tropics, annual temperature swings are usually small even in continental interiors. The larger land masses of the northern hemisphere have the greatest continentality (see RUSSIA and CANADA, for example), while in the middle latitudes of the southern hemisphere (30–60° south of the equator) the effect of continentality is smaller, as continental areas are not as large at higher latitudes (see SOUTH AMERICA and SOUTH AFRICA, for example). Mountain ranges also influence continentality, acting as a topographic barrier affecting airflow and creating a rain shadow of warmer and drier zones on the leeward side of the mountains.

Wine regions with continental climates are more variable, typically experiencing colder winters, greater spring FROST risk, and hotter summers, often with higher humidity and precipitation, than those located closer to the coast or to a large body of water. Common measures used in viticulture that capture aspects of continental climates are the mean temperature of the warmest month (January/July, depending on the hemisphere, hence MJT), the Huglin Index (see CLIMATE CLASSIFICATION), and seasonal or DIURNAL TEMPERATURE RANGE. For the effects on ripening, see CLIMATE AND WINE QUALITY.

continuous method, SPARKLING WINEMAKING process developed in the USSR and at one time used in Portugal. It has now been largely phased out in Russia in favour of the TANK METHOD.

Contra Costa Country, once-prolific wine-growing region situated at the juncture of SAN FRANCISCO BAY and Suisun Bay where generally hot weather is moderated by afternoon breezes. The region is home to more than 405 ha/1,000 acres of vineyards planted in generally SANDY soils, several of them dating to the 19th century. The oldest and highest-quality CARIGNAN, MOURVÈDRE, and ZINFANDEL fruit is generally owned or consistently purchased by several dozen wineries located elsewhere in the North Coast, though the AVA hosts several smaller wineries in and around the town of Brentwood. A.Y.

contract winemaking. See CUSTOM-CRUSH FACILITY.

contrada, plural *contrade*, signifies a district, quarter, or a hamlet in Italian. *Contrade* are common throughout the whole of Italy but nowadays and in a wine context are almost exclusively associated

with Etna; the term is widely but incorrectly understood to stand for 'single vineyard'. See ETNA for more detail. W.S.

controlled appellations, or appellations of origin, a method of LABELLING wine and regulating quality that is modelled on France's AOC system. Controlled appellations such as the EU's protected designations of origin (PDO) are distinguished within the broader category of GEOGRAPHICAL INDICATIONS by the inclusion of strict rules governing viticultural and winemaking practices that reinforce a close link between the inherent characteristics of the wine and its place of origin. Typical controls will include restrictions on YIELD, grape varieties, and vine-management techniques. The restrictions of the controlled-appellation model make them less common outside Europe; even within Europe, controlled appellations are criticized on the grounds that they limit innovation and tend to maintain traditional practices unquestioningly. (See Appendix 1 for a complete list of controlled appellations for which particular grape varieties are specified, with their permitted grapes.)

In 2021, the OIV published the following definition of appellation of origin: 'Any denomination recognised and protected by the competent authorities in the country of origin, consisting of or containing the name of a geographical area, or another denomination known as referring to such area, which serves to designate a wine or spirit beverage as originating in that geographical area, where the quality or characteristics of the wine or spirit beverage are due exclusively or essentially to the geographical environment, including natural and human factors, and which has given the wine or spirit beverage its reputation.'

In the United States, all geographical DELIMITATIONS (including AVAs) are legally known as 'appellations of origin', although they do not include rules on viticultural and winemaking practices.

cooking with wine. Good wine used in the kitchen adds depth and dimension to a dish in the way that spices, herbs, vinegars, and

stocks can. The recipes of Apicius, the most famous Roman chef, show that wine was commonly used in his sauces, and it has found a place in the kitchen ever since.

Wine is an essential ingredient in many dishes and can be used in every stage of cooking, from marinating raw ingredients to providing the final finish to a dessert. It is all the more curious, therefore, that so little research has been done into exactly what happens to wine during cooking, particularly as a result of the application of heat.

The boiling point of ETHANOL is 78 °C/172 °F, considerably lower than that of water, so any wine used in cooking becomes progressively less alcoholic if heated to above 78 °C for any length of time. As a sauce is 'reduced' with wine, the other components in the wine such as RESIDUAL SUGAR, ACIDITY, and FLAVOUR COMPOUNDS become more or less marked.

The most common ways in which wine is used in the kitchen are listed below.

Deglazing: pouring wine (or another liquid such as stock) into a pan in which something has been roasted or sautéed in order to dissolve the remnants of that operation in the liquid to make a sauce. Wine adds body and depth to the sauce, as in *beurre blanc*, for example.

Marinade: a method of imparting extra flavour, and/or tenderizing, which takes the form of cooked and uncooked marinades in which the wine may be combined with other ingredients to add savouriness, sweetness, and acidity and to intensify flavour.

Stocks: wine is often used instead of, or as well as, water, to provide the essential base for soups, stews, and sauces or when cooking dishes such as risotto.

Court-bouillon: a method of cooking fish, shellfish or white meat in which herbs and spices are infused in white wine and water in which the food is subsequently poached.

Sauces: many of the so-called 'small sauces' based on the mother sauces of classic cuisine use wine to deglaze, to reduce, and to add liquid, flavour, acidity and/or sweetness. Examples include

bordelaise using red wine, *périgueux* using madeira, and *sauce Robert* using white wine.

Stews and casseroles: wine, preferably from the same area as the dish, is an integral part of many regional stews and casseroles in wine-producing regions, for example *boeuf bourguignon*.

Jellies: poached foie gras set in a Gewurztraminer jelly is an Alsace speciality. Sweet jellies can be made from Sauternes or any other sweet wine.

Desserts: wine has a surprisingly wide range of applications for sweet foods and pâtisserie. Red wine is used for poaching pears and macerating strawberries (a speciality of Bordeaux), while wines such as MARSALA and SHERRY are used in, respectively, zabaglione and English trifle. In Italy, strong, usually sweet wines, typically VIN SANTO, are served with dry biscuits which are moistened in them.

There is much debate about the necessary quality of cooking wine, some regarding the saucepan or stockpot as the ideal repository for any wine considered too nasty to drink, others insisting that only the finest wine will do. At one extreme, if using a faulty (e.g. CORKED) wine, the fault will show in the finished dish, but on the other hand the full range of volatile FLAVOUR COMPOUNDS of a great wine will not survive the application of any fierce or prolonged heat.

Empirical research suggests that wines which are very tannic, well-aged or relatively fruitless on the palate are the least suitable for cooking. Wines with soft TANNINS (if red), good acidity, and plenty of ripe fruit are the all-round best choices. FORTIFIED WINES and sweet wines are some of the most reliable options, bringing more flavour and depth to dishes than most other wine styles.

Ultimately, however, the choice of wine depends on several factors, all of which have an impact on the different molecular components of wine. The length of cooking time and the intensity of heat have the greatest impact on flavour and structure, whether to denature or accentuate, and accompanying ingredients also interact with the wine chemically and/or sensorially (cream softens acid, acid counteracts sweetness, strong proteins such as those in beef flank

counterbalance tannins). Important, too, is the role the wine serves, whether tenderizing or bringing flavour, texture, richness, sweetness, acidity, or bitterness.

As contradictory opinions indicate, however, it is clear that much more research is needed in this area before we can separate myth from science. M.P.L. & T.D.C.

cool-climate viticulture and WARM-CLIMATE VITICULTURE are indefinite terms as the transition between different viticultural climates is an approximation. The term 'cold-climate viticulture' is typically used to refer to those wine regions that experience WINTER FREEZE and where WINTER PROTECTION of vines is essential. Hot-climate viticulture produces mainly TABLE GRAPES and RAISINS; it cannot, in general, produce high-quality wine grapes of any kind. In between are a range of climates suited to successfully growing wine grapes that have been defined in various CLIMATE CLASSIFICATION indices. For example, cool climates are defined by Regions Ia, Ib, and II on the Winkler Index, the very cool and cool classes on the Huglin Index, and within 13–15 °C on the growing-season average-temperature index.

The distinguishing characteristic of cool viticultural climates is that they will regularly ripen only early-maturing grape varieties such as CHASSELAS, MÜLLER-THURGAU, GEWÜRZTRAMINER, CHARDONNAY, PINOT NOIR, and GAMAY; and only in especially warm MESOCLIMATES can varieties such as RIESLING, and some red varieties considered early to mid season, be ripened. Ripening also tends to take place under cool to mild conditions due to shorter growing seasons. This combination of climate and variety leads to wines which, at their best, are fresh, delicate, and aromatic. Most are white or only pale red, because full

development of ANTHOCYANIN pigments and TANNINS in the grape skins generally needs greater warmth.

Major areas of cool-climate viticulture would certainly include the northern half of France (the LOIRE, CHAMPAGNE, CHABLIS, BURGUNDY, and BEAUJOLAIS); LUXEMBOURG, GERMANY, SWITZERLAND, DENMARK, and AUSTRIA; in the US, the Lower Columbia Valley of WASHINGTON, the Willamette Valley of OREGON, and the coolest coastal strip of northern CALIFORNIA; the most southern vineyards of CHILE; some elevated vineyards of SOUTH AFRICA; the South Island and southern North Island of NEW ZEALAND; and in Australia, the whole of TASMANIA, small areas of the higher Adelaide hills in SOUTH AUSTRALIA, and southern VICTORIA. Note that ENGLAND and WALES are examples of MARITIME climates with very cool summers, inhibiting RIPENING for many varieties, and may be referred to as very cool climates.

See also CLIMATE AND WINE QUALITY. R.E.S. & G.V.J.

Gladstones, J., *Viticulture and Environment* (1992).

Jackson, D., and Schuster, D., *The Production of Grapes and Wine in Cool Climates* (rev. edn, 1998).

Coonawarra, wine region in the Limestone Coast Zone of SOUTH AUSTRALIA popularly revered for Cabernet Sauvignon, grown on its famous strip of TERRA ROSSA soil. Its cool MEDITERRANEAN climate is very similar to that of Bordeaux; it is slightly warmer and has less growing season rainfall, but Cabernet Sauvignon is normally picked in the second half of April (or, in Bordeaux terms, the second half of October). The name means 'honeysuckle' in the language of the Bindjali First Nations people.

cooperage is a collective noun for wooden containers but has been more traditionally used for both the activities and workplace of coopers, those who make and repair small BARRELS and larger wooden

VATS. At one time all wine or spirit producers of any size would have had their own small cooperage, but today the craft is perpetuated mainly by specialist cooperage businesses. The French term is *tonnellerie*.

History

Until relatively recently, coopers played an important role not only in the wine business but also in myriad aspects of daily life. Almost all containers—buckets, barrels, tanks—were made by coopers from various woods (see BARRELS, history). Barrels were made to hold salted fish, flour, gunpowder, oil, turpentine, salt, sugar, butter, and many other household commodities since they retain liquids safely, keep the elements out, and are easy to manœuvre.

Coopers' guilds were already established by the end of the 9th century; during the Middle Ages, laws relating to apprenticeships and guild memberships were codified throughout Europe (with nepotism already playing its part). At the end of the 18th century, there were approximately 8,000 coopers in Paris alone. It is still possible to meet coopers who are the last in a line of craftspeople dating back to the 17th century. Such skilled workers, who can probably make barrels with handtools alone, may well have served traditional apprenticeships that often involve extensive work in different regions of their own countries as well as abroad.

As Europeans colonized the New World, they inevitably took their coopering skills with them. John Alden, one of the more famous early North American colonists of Plymouth, Massachusetts, was a master cooper, and by 1648 there were enough coopers to form a guild in this New England colony. America's important export trade of STAVES and logs to Europe began slightly later in the 17th century, when the Spanish controlled large parts of what is now the United States.

During the 19th century, coopering remained an important craft, but the advent of metal (and later plastic) containers ultimately reduced coopering to an adjunct of the drinks business. More than one million barrels were made for salted herring in Britain in 1913, for example, but by 1953 the number had dropped to around one-tenth of this figure, and now this business is virtually extinct.

American PROHIBITION had a dramatic impact on the sale of fine wines and spirits and, in turn, on the cooperage business—particularly in the United States but also in the British Isles, where

only those coopers working on beer barrels were unaffected. Before the Second World War, most beer barrels were made of wood and many breweries had their own cooperages, but by the early 1960s wooden barrels had been replaced by metal ones. In much of the wine industry, too, wood was replaced by concrete, stainless steel, and other neutral materials, particularly for larger tanks (see CONTAINERS).

Cooperage today

As wooden barrels are expensive to buy, use, and maintain, they tend to be used only for products whose sale price can justify such a major investment or, in the case of older containers, by those who have inherited them.

Cooperages are found wherever there is a wine or spirits business that needs barrels, notably in America, Scotland, and France but also in Italy, Spain, Portugal, Ireland, eastern Europe, Germany, Australia, and South Africa. They make new vats and barrels (see BARREL MAKING) and/or repair or maintain older barrels and vats (see BARREL MAINTENANCE and BARREL RENEWAL).

There are no serious industry analysts of the contemporary cooperage business, such as there are in the automotive or electronics industries, since it is effectively just a small part of the timber industry. Nor is there any official regulatory or inspection body as there is in the wine trade. Consequently, statistics related to the cooperage industry are little more than educated guesses. Naturally all coopers maintain that their oak is the best wood, entirely hand split and seasoned in the open air, and that their competitors cut corners. In the absence of facts, winemakers have to rely on results rather than rhetoric.

United States The great majority of wooden barrels traded today are made in the American Midwest for the ageing of bourbon whiskey, primarily by two cooperages. No one really knows how many American oak barrels are used in winemaking, but it is likely that more than 100,000 go directly to wineries in the United States alone, and, according to the Associated Cooperage Industries of America, the production rate for both bourbon and wine is increasing.

Nearly all American logs come from privately held forests in the eastern half of the US, notably in Minnesota, Wisconsin, Kentucky, Arkansas, Tennessee, the Virginias, the Carolinas, and Missouri. These logs are purchased by stave-mill operators, some of whom also run cooperages. Cooperage use accounts for about 3% of all American white oak harvested every year. Most American oak is used for furniture, construction, veneer, and pulp.

The logs are cut into appropriate lengths, quarter-sawn, planed, and then sold to cooperages. Customers for American oak staves are found not only in bourbon country but in cooperages in California, Australia, and even Spain, where American oak has until recently been used almost exclusively for wine maturation, most notably in RIOJA and JEREZ, for the historical reasons outlined.

For whiskey to be called bourbon, it must, according to American government regulations that are a blessing to the cooperage business, be aged in a 'new, charred white oak barrel', so large quantities of used whiskey barrels are commercially available, many of them relatively new. Over two million used bourbon barrels are sold each year to Spain, Scotland, Ireland, Japan, Thailand, India, Puerto Rico, Canada, and Taiwan, as well as to producers of other North American spirits. Most of them are used to mature spirits: various brandies, rums, and whiskies. The Scotch whisky industry is a particularly important consumer of American oak, at any one time using approximately 13 million casks in total. In some cases American oak barrels are sent to Jerez en route to Scotland, where some distillers still prefer to use casks infused with sherry flavours as was the norm in the 19th century, when sherry was shipped in cask to British wine merchants, who would then pass on these casks to the

Scotch whisky industry. Now that sherry is no longer shipped in cask, some Scotch whisky distillers in Scotland have their barrels ‘broken in’ in Jerez with sherry.

France The French cooperage business is much smaller than its American counterpart but is much more important to the wine business. According to the Fédération Française de la Tonnellerie, around 658,000 French oak barrels were produced in 2019, two-thirds of which were exported. The domestic market for these barrels is primarily in BORDEAUX, BURGUNDY, and Cognac, where most French cooperages are located. More than 40% of the exported barrels go to the United States. The balance is shipped to 30 other countries, most notably Italy, Spain, Australia, New Zealand, South Africa, Chile, Argentina, and Germany. As well as selling to Bordeaux, Burgundy, Cognac, and Armagnac, French cooperages are also developing new 'export' markets selling to ambitious winemakers in French regions that had abandoned new barrels. The RHÔNE, LANGUEDOC, ROUSSILLON, and SOUTH WEST FRANCE, as well as the LOIRE, have all become important purchasers.

In France about one-third of all forests are owned by local or national government. However, the sale of over 80% of all lots, carefully delineated groups of trees, is administered by the Office National des Forêts (ONF). In September and October, wood auctions are held all over France, but for the buyer of oak destined to be turned into barrels and vats the most important auctions are held in Nevers, Châteauroux, and Moulins.

A potential buyer bids on the trees in a delineated section, which should be at least 100 and preferably well over 120—sometimes 160—years old before providing suitable wood for casks. Buyers have the right to go into the forest, measure the trees, and even bore into them 30 cm/12 in to see how straight is the GRAIN. They must decide how much of each type of wood there is, how it can be used, and, of course, how much they should bid.

As not every tree in an auction lot can be used for STAVES, French cooperages usually work with wood brokers who have other customers. The most valuable part of a tree is that with the tightest and straightest grains, which can be used for panelling. The furniture and construction industries are important customers.

French barrels cost at least double those made of American oak. French logs are much more expensive because they must be hand split rather than machine sawn and demand more expensive drying methods. (see BARREL MAKING). French cooperages also tend to be smaller and less automated than their American counterparts. But the special qualities of French oak ensure that it is the most sought after by modern winemakers and able to command a considerable premium.

As the use of French oak has become more widespread, staves are now shipped all over the world, notably to Australia, Italy, South America, South Africa, America, Spain, and Portugal, where they may be made up into barrels in local cooperages.

No system of AOC limits the period of time French oak barrels may be used for any wine or spirit. Consequently the sale of used French oak barrels is not as organized as that for American barrels. In Burgundy, producers often use most of their new barrels for their grandest appellations, and lesser appellations get proportionately fewer new barrels. In Bordeaux, one proprietor will often own several châteaux and will treat his or her most prestigious property to the luxury of new oak before passing the barrels down the chain to a lowlier property. Alternatively, used barrels are sold to wineries unable to command the sort of price that can support expensive new barrels or where winemakers do not want the taste of new oak. In the New World, used barrels are often traded between wineries. Relatively young ones, especially those used for white wine, are highly valued, but barrels more than ten years old are usually sold to be cut in half for flower planters.

Hungary There are two major cooperages in Hungary, both affiliated to French cooperages, and many smaller ones.

Italy In Italy, a relatively small but lively cooperage industry makes barrels and vats primarily with oak imported from France and Slavonia (eastern Croatia).

Spain Barrels have been important to the Spanish wine and sherry industries for centuries, and the cooper's craft is sustained there. In Jerez, new barrels are spurned for the maturation of fine SHERRY and will probably be used at least three times for FERMENTATION before being used to mature a top-quality OLOROSO. The older a cask, the more expensive it is, and some bodegas boast casks (or butts, as they are usually called here) that are more than 200 years old.

Portugal The demands of the PORT industry, and a ready supply of Portuguese oak, have kept the cooper's craft alive in northern Portugal, such that French coopers have even imported Portuguese barrel makers.

Australia Distance from most of the world's established coopers has inspired the establishment of several cooperages in South Australia. M.C.K.

co-operatives, ventures owned jointly by a number of members and controlled by them democratically, are extremely important as wine producers. They have the advantage for their members of pooling winemaking and marketing resources and costs, giving them negotiating power, and helping to ensure the sustainability of their

members' vineyards. Like individual producers, co-operatives in Europe may be eligible for EU subsidies, for example for investment in buildings and equipment. In most countries they also enjoy the commercial advantage of being able to describe their wines as bottled by the producer, using such reassuring phrases as MIS(E) EN BOUTEILLE *à la propriété* and ERZEUGERABFÜLLUNG more usually associated with much smaller, individually managed wine enterprises. The better co-operatives are becoming increasingly skilled not just at winemaking but also at marketing specific bottlings that look and taste every bit as distinctive as the individually produced competition. Co-operatives have traditionally been at their strongest in areas where wine's selling price is relatively low and where the average size of individual holdings is small, although co-operatives are also quite significant in CHAMPAGNE and there are several in the MÉDOC, for example; and in regions such as Italy's ALTO ADIGE, co-operatives are among the most well-known and highly respected winegrowers. The majority of wine co-operatives were formed in the early 1930s in the immediate aftermath of the Depression. In recent years, there has been notable consolidation, with smaller co-operatives joining together for economies of scale.

France

France's *caves coopératives* (often referred to locally simply as *la cave*) are declining in number and influence, but in 2021 the national total of 570 were still responsible for nearly 60% of all wine produced in France and an annual turnover of €5.2 billion. The average number of members, or *adhérents*, of each co-operative is also declining as holdings are amalgamated, and members have been encouraged to grub up less suitable vineyards by the EU VINE-PULL SCHEME. Co-operatives are a particularly strong force in the LANGUEDOC and ROUSSILLON, in CHAMPAGNE, and in PROVENCE. Co-ops' speciality is IGP wine—they produce more than 60% of the French total (compared with 30% of PDO wine)—but those which have established a reputation for particularly sound AOC wines sold outside their own region include Union CHAMPAGNE, Nicolas Feuillatte, La Chablisienne of CHABLIS, the co-operative at Tain l'HERMITAGE, the Plaimont co-operative organization in GASCONY, and a number of ALSACE co-operatives, notably those of Turckheim and Wolfberger. The average quality of wine made in French co-ops has improved since the early 1990s and France's CRISE VITICOLE, enabling their members to survive when they could not have done so in isolation and today helping them to promote and participate in local WINE TOURISM.

Germany

In GERMANY, wine co-operatives have played an increasingly significant role since 1868, when the first one was formally established in the AHR. As outlined in GERMAN HISTORY, co-operatives offered smallholders the chance to compete in the newly quality-conscious German wine market of the late 19th and early 20th centuries. German has several words for co-operative: *Winzergenossenschaft*, *Winzerverein*, *Winzervereinigung*, *Weingärtnergenossenschaft* or *Weinbauernverband*.

Nearly two in every three German vine-growers today belong to the local co-operative, but, because their vineyards are often a small, part-time activity, together they represent around one-third of the total German area under vine. Two of the 13 wine regions of Germany have a central co-operative cellar which is fed grapes, wine, or must by more localized co-operatives. By 2021, the number of co-operatives in Germany had fallen to 141, of which 84 made wine on the premises. However, the vineyard area processed by the co-ops remains stable.

The co-operative movement is particularly strong and successful in the most southerly region of BADEN, where about 70% of all wine produced is sold under the auspices of the giant central Badischer Winzerkeller at Breisach. This vast enterprise is larger than any winery in France. The Baden co-operatives (71 in total) have been particularly active in transcending the co-operative image of quantity over quality by developing superior, small-volume bottlings of distinctive wines. Co-operatives are also extremely important in the WÜRTTEMBERG region, where there are 34, their central cellar being the Württembergische Weingärtner-Zentralgenossenschaft at Möglingen. They are also important in Germany's four smallest regions, SAALE-UNSTRUT, AHR, HESSISCHE BERGSTRASSE, and SACHSEN. In the MOSEL region, Moselland in Bernkastel processes about 22% of the region's output but also handles winemaking and marketing for three co-

operatives in the Pfalz, Rheinhessen, and Nahe. In the RHEINGAU, the role of co-operative cellars is very much less significant.

Italy

In Italy, the *cantina sociale* is no less important, accounting for about 60% of the country's production. There are nearly 500 co-operatives comprising 148,000 members. EU policies have favoured co-operatives in the past, but, as EU subsidies dwindle, the quality of the wine and the ability to run the co-operative on a commercial basis become increasingly important. One of the most respected Italian co-operatives, in the far north-west, is the Produttori del BARBARESCO, whose origins are 19th-century. The influence of the *cantina sociale* (*Kellereigenossenschaft* in German) is particularly strong in TRENTINO, where 15 co-operatives are responsible for most of the region's production, and in the much smaller ALTO ADIGE, where 12 co-operatives are responsible for 70% of wines produced. There they have the highest revenue per hectare of vines in any Italian province, sell mainly to hotels and restaurants, and are critically important to many other industries, particularly tourism. Girlan, Cantina Terlano, Colterenzio, Kurtatsch, and Cantina Produttori Valle Isarco are all impressive. In the VENETO, co-operatives have also traditionally been responsible for the bulk of production, particularly in Verona, where a large number of producers of Soave and Valpolicella either buy from or supplement their production through purchases from the local co-op.

The co-operative Riunite of EMILIA-ROMAGNA was famous in the early 1980s for engulfing the United States and other markets in a tidal wave of LAMBRUSCO. It is still Italy's leading co-operative by turnover. Castelli del Grevepesa is one of TUSCANY's better co-operatives. Further south, quantity, and not always quality, is the chief characteristic of the co-operatives that proliferate practically wherever the vine is grown, although Cantina di Taburno with Luigi Moio as CONSULTANT is a leading light. The Copertino co-operative in PUGLIA makes a good job of its eponymous red. The islands SARDINIA and SICILY were once dominated by co-operatives, of which Settesoli in Sicily and Santadi in Sardinia are models of quality. Settesoli has

cooperated in the local research institute in CLONAL SELECTION, variety and soil matching, and the conservation of almost extinct INDIGENOUS VARIETIES—all of which have helped to improve and increase wine quality in Sicily.

Spain and Portugal

As in Italy, co-operatives are extremely important in Iberia, where grapes are so often grown alongside other crops. Approximately 60% of each vintage is delivered to one of Spain's 572 wine co-operatives (some of which are groups of co-ops), and 35% of Portugal's crop is received by its 75 co-ops (see PORTUGAL, history).

Although the movement began in the early years of the 20th century, it substantially increased in importance in the 1950s, when the wine market was relatively depressed. One of the earliest wine co-operatives was in Olite in NAVARRA, where the movement was particularly powerful, at one time absorbing as much as 90% of grape production. It wasn't until the 1980s that many Iberian co-operatives even began to consider bottling wine, so much of their produce was sold off either for DISTILLATION or as BULK WINE. Today this figure varies from region to region, but in Galicia, for example, the co-operatives bottle almost their entire production, as they do in Rioja. Co-ops are also very important in Castilla-La Mancha, where they number more than 200 and vary in quality. In most regions, particularly in the north, the trend is towards more bottled wine and better quality. Successful small or mid-sized co-ops include Martín Códax in RÍAS BAIXAS, the Capçanes, Masroig, and Falset co-ops in MONTSANT, Viticultors del PRIORAT, Cooperativa Virgen de la Asunción in RIBERA DEL DUERO, Cuatro Rayas in RUEDA, Mazas Cooperativa in TORO, and Sonsierra Cooperative in RIOJA; larger operations producing quality wines include Cooperativas San Alejandro in CALATAYUD and Grandes Vinos and San Valero in CARIÑENA. In the fortified wine regions of JEREZ, much of the rest of ANDALUCÍA, and the DOURO, co-operatives are less important than the long-standing links between vine-growers and individual wine producers.

Rapid growth of Portugal's export market and the private sector during the 21st century spurred co-operatives to adapt and survive (or fail, as some have, most recently in Portalegre). Higher standards of viticulture, with corresponding increases in grape prices for

members, better viniculture (including the recruitment of talented consultant winemakers, e.g. Anselmo Mendes at Biscoitos), and marketing have resulted in a broader base of quality. Leading examples include the co-operatives of Monção (VINHO VERDE), Penalva (DÃO), Cantanhede (BAIRRADA), Pegões (PENÍNSULA DE SETÚBAL), Borba (ALENTEJO), Adega de COLARES, and Pico and Biscoitos in the AZORES (whose survival ensured the future of these islands' traditional varieties).

Rest of the world

Practically wherever wine is made, co-operatives thrive, though there are now very few in Eastern Europe since the privatization of the state co-operatives. Notable examples include Klet Brda and Klet Krško in Slovenia, and there are a few in Croatia, for example PZ Svirče.

Co-operatives have played a particularly important role in the development of the wine industry in the United States (where the last one closed in 2000), South Africa, and Argentina. In 20th-century South Africa, most growers were members of co-ops, whereas in 2020 there were 45 so-called producer cellars, where resources are pooled, but only a handful of those are regulated as co-operatives. In South America, there are still large and successful co-operatives in both Argentina and Brazil, with smaller ones in southern Chile. In Australia, pressure placed on growers by legal and fiscal constraints, as well as the power of the big BRANDS, make it virtually impossible, or at least uneconomic, to run a co-operative.

Copertino, DOC for rosé and robust red wine made mainly from NEGROAMARO grapes on relatively flat terrain in PUGLIA.

co-pigmentation, a mechanism of colour stabilization, involving the interaction of ANTHOCYANIN pigments with another molecule (co-pigment).

In aqueous media, anthocyanins are present under different forms in equilibrium, including red and violet pigment species and colourless hydrated forms. The latter predominate at mildly acidic PH values such as encountered in plant cell VACUOLES and in wine. However, the anthocyanin pigmented forms stack vertically with other species present in the solution (co-pigments) to form complexes from which water is excluded. This results in enhanced colour intensity due to a shift of the balance from the colourless hydrated forms towards the dehydrated pigment forms involved in these stable complexes. The

role of co-pigmentation in wine colour can be estimated by comparing red colour intensity before and after disruption of co-pigmentation complexes by dilution in a wine-like buffer. Co-pigmentation has been reported to account for 30 to 50% of the colour of young red wines, on the basis of such measurements.

copita, special tulip-shaped glass in which SHERRY has customarily been served in Spain, supposedly designed to maximize the AROMA, though some producers prefer a regular wine GLASS.

copper, a micronutrient required in very small concentrations for healthy vine growth (see VINE NUTRITION). Copper is toxic to plants except in very dilute concentrations. Reports of copper deficiencies in vineyards are rare, probably because of the very small requirements by the vines but also because of the widespread use of FUNGICIDES containing copper. In acid soils, the copper from fungicide sprays can actually reach toxic levels, and some parts of the MÉDOC have been affected by copper toxicity. After the annual application of several kg of copper per ha, as in BORDEAUX MIXTURE, for about a century, the level of copper in the soil can be toxic and vine growth severely stunted. Generous applications of ORGANIC MATTER make the copper less available to the vines, as does the addition of lime, which will help to neutralize the toxic effect of copper by raising the soil PH.

Since brass fittings and pumps are now rarely used in wineries, the problem of copper CASSE has been virtually eliminated. However,

this has caused an increase in SULFIDES in wines, as these would have been removed by the copper added to the wines every time a brass fitting was used. Winemakers now need to consider a small, controlled addition of copper to remove them. Tight-sealing corks or screwcaps will highlight the issue if left untreated. THIOLS are vulnerable to removal by copper, but only if the copper is added in excess. The insoluble copper sulfate is usually then removed through SETTLING or FILTRATION. R.E.S. & M.J.T.

Corbeau. See CHARBONO.

Corbières, largest appellation by volume (averaging 550,000 hl/14,529,463 gal annually) in the LANGUEDOC region of southern France, producing some excitingly dense, herby red wines, a small amount of rosé, and a little increasingly well-made white wine from 10,600 ha/26,193 acres of vineyard in 2016. The terrain here in the Pyrenean foothills (see map under LANGUEDOC) is extremely varied and so hilly that it is difficult to generalize about soil types and TOPOGRAPHY. In recognition of this, the appellation was in the 1990s subdivided into 11 so-called TERROIRS, although not without a certain amount of local dissent. The basic distinctions in this southernmost corner of the Aude *département* are between coastal zones influenced by the Mediterranean, the northern strip on the Montagne d'Alaric (some of which has more in common with MINERVOIS), the westernmost vineyards, which are cooled both by Atlantic influence

and by ELEVATION, and the rugged, mountainous terrain in the south and centre in which the FITOU appellation forms two enclaves.

Vineyards in the south-west of the appellation are as high as 450 m/1,500 ft above sea level, and HARVEST may not take place until well into October; those in the coastal Sigean area can vary enormously in elevation, but the high average temperatures and very low annual rainfall are partly compensated for by the marine influence. One of the most admired terroirs is that of Boutenac in the hills south of Lézignan, which has particularly poor soils on a LIMESTONE base in what is known locally as Corbières' 'golden triangle'. In 2005, Corbières Boutenac was granted its own subappellation for wines that, unusually, must contain 30–50% Carignan and satisfy certain minimum ageing periods.

In AOC Corbières, SYRAH, MOURVÈDRE, GRENACHE NOIR, and LLEDONER PELUT must represent at least half the blend in all red wines, and the once-dominant CARIGNAN may not make up more than half. Some producers particularly value the spice and concentration of wine from old vines, which in Corbières effectively means old Carignan. Warmer parts of Corbières can ripen Mourvèdre on a regular basis. Plantings of CINSAUT, useful along with Syrah for rosé, are more limited here than in neighbouring Minervois. PIQUEPOUL NOIR, TERRET, and GRENACHE GRIS are also allowed in red and rosé Corbières, with some of the white wine grapes allowed in the rosé. White Corbières, a rare but often refreshing dry wine, is made principally from BOURBOULENC, MACABEO, GRENACHE BLANC, MARSANNE, ROUSSANNE, and VERMENTINO, providing an interesting aromatic palette for the increasing number of producers prepared to experiment with superior white winemaking.

M.S.

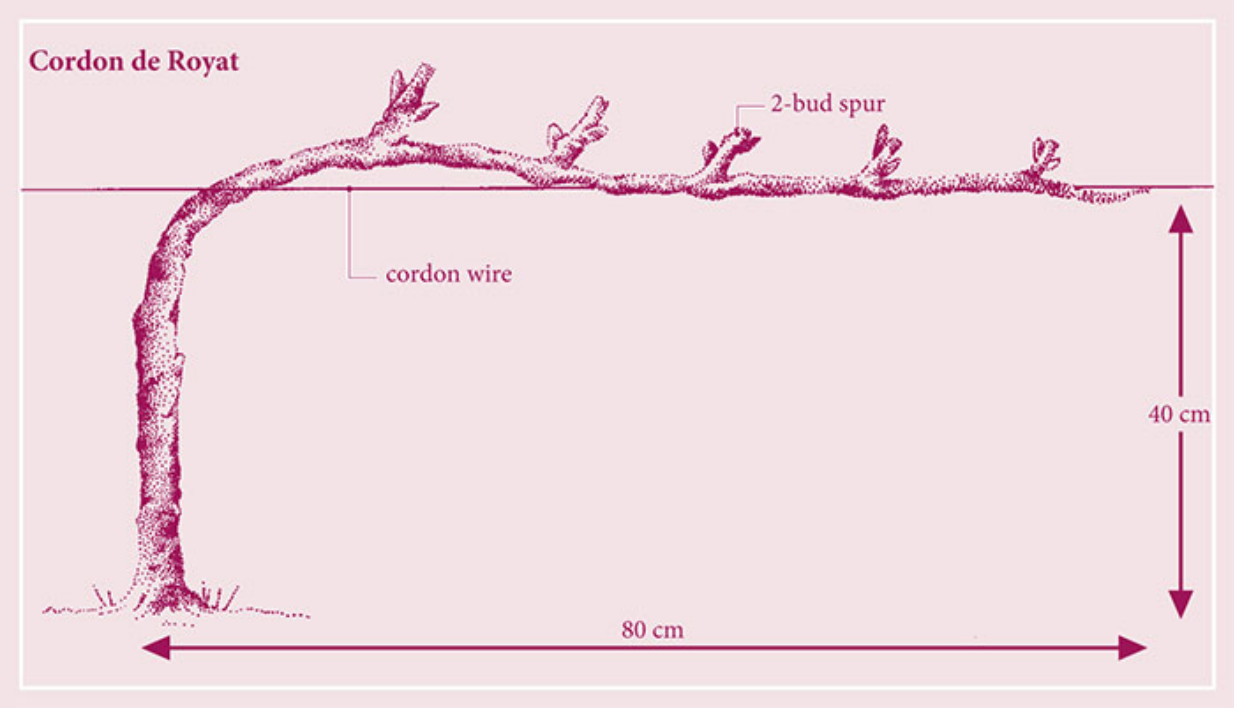
cordon, part of the vine's woody framework, arising from the top of the trunk and on which arms are borne (see diagram under PRUNING). Cordons can be at any angle but are generally trained along horizontal WIRES or, as in some TENDONE trellises, shallowly sloped wires. The most common arrangement is a bilateral cordon in which

two horizontal cordons are arranged in opposite directions from the top of the trunk, but any number of arrangements are possible. The unilateral cordon is common in some parts of Europe. Because of ease of management and MECHANIZATION, SPUR PRUNING using horizontal cordons is being increasingly adopted in New World viticulture. Usually the cordon is trained to its permanent position and remains there, unless it is destroyed by TRUNK DISEASES. See vine-TRAINING SYSTEMS.

B.G.C. & R.E.S.

cordon de Royat, an old form of CORDON TRAINING used in France for wine grapes since the end of the 19th century (see illustration below). The system was proposed by Lefebvre, director of the French agricultural school of Royat. The classic form is a unilateral CORDON on a short trunk (about 30–50 cm/12–20 in), the term 'unilateral' meaning that the cordon is trained only to one side of the trunk and extends mostly from one vine to another. The vines are normally SPUR PRUNED to two-bud spurs. The number of spurs is limited for each variety under AOC laws and set out in the *cahiers des charges*.

R.E.S.



cordon training, a form of VINE TRAINING in which the trunk terminates in a CORDON, and the vine is then typically subjected to SPUR PRUNING. The alternative is HEAD TRAINING, where the vines are usually subjected to CANE PRUNING. The cordon is normally horizontal and can be unilateral (trained only to one side of the trunk) or bilateral (to both sides). See also CORDON DE ROYAT and PRUNING.

R.E.S.

corkage, charge customarily levied in a restaurant for each bottle of wine brought in and consumed on the premises rather than bought from the restaurant's own selection (although see also BYO). The term is derived from the fact that the number of corks pulled represents the number of bottles consumed. There is considerable variation in the amount charged and the grace with which the practice is accepted.

corked, pejorative tasting term for a wine spoiled by a cork stopper contaminated with CORK TAINT. A wine spoiled by cork taint may also be described as corky, and the condition is known as corkiness. This is one of the most serious wine FAULTS as in most cases it irrevocably imbues the wine with such a powerfully off-putting smell that it cannot be drunk with any enjoyment. The unpleasantly, almost mould-like, chemical smell of TCA may also be present in smaller doses that may initially be noticed only by noses particularly sensitive to it or particularly familiar with the wine, but the odour usually intensifies with aeration, and it is difficult for tasters to enjoy a wine once their attention has been drawn to TCA's existence. Even a low level of taint often results in a slight dulling effect on the BOUQUET and palate, and levels well below the threshold of most drinkers' awareness have been shown to suppress fruit characters significantly.

The problem of corkiness was perceived by the wine industry to have increased from the 1980s, which soured relations between the wine and the cork industries and led to a marked increase in the use of alternative CLOSURES, particularly SCREWCAPS. However, cork

producers are investing in new methods that have significantly reduced the incidence of cork taint, giving wine producers renewed confidence in the use of cork as a closure.

It is commonly but erroneously believed that a wine with small fragments of cork floating in it is 'corked'. This may be a SERVING fault but is certainly not a wine fault.

Taber, G., *To Cork or Not to Cork* (2007).

corks, wine-bottle stoppers, without which the appreciation of fine wine, and in particular AGEING, might never have evolved. Cork's unique combination of qualities has made it by far the most popular stopper for wine. In the late 20th century the science of wine production bounded ahead of the science of cork production, to the detriment of relations between the two industries (see CORKED wine), but cork producers have started to catch up in the 21st century.

History

See CLOSURES.

The cork tree

The cork tree, *Quercus suber*, is a relatively young species of OAK and is unusual in that its bark is so thick and resistant that it can be stripped from the trunk and large branches without hurting the tree.

It grows in sandy soils free of chalk and prefers annual rainfalls of 400–800 mm/15–30 in, temperatures which never fall below −5 °C/23 °F, and an ELEVATION of 100–300 m/330–1,000 ft. This effectively restricts cork oaks to the coast of the western Mediterranean, particularly Spain, North Africa, and much of Portugal, where cork plays a significant role in the economy. The cork industry was born in Cataluña but was disrupted by the Spanish Civil War. The commercial stability of Algeria, which still grows more than 10% of the world's cork (though much less than Morocco's 18%), was called into question in the 1960s, so that Portugal is now the centre of the world's cork business, and cork is an important contributor to the Portuguese economy. Portugal's cork forests, centred on the Alentejo, are today the most extensive, their 736,000 ha/1.82 million acres representing 34% of the world's 2.2 million ha of cork trees, significantly assisted in the late 1980s by EU grants.

Spain has the next largest total area planted with cork oaks, about 574,000 ha, mostly in the south and west of the country, from which a high proportion of the cork is shipped across the border for processing in Portugal's more temperate climate (although, in the north-east, Cataluña is still an important supplier of corks, especially to France and particularly to Champagne). So entrenched is the modern cork industry in Portugal—many of the processing centres are located just south of Oporto—that it produces 49% of the world's total output of cork, helped by imports not just from Spain but also from North Africa. Each cork region produces cork with slightly different characteristics. One of Portugal's most prized cork regions is Evora. Although forestry management is important, the most significant determinants of quality occur at the processing stage.

Cork trees, if not a cork industry, also flourish along the west coast of Italy, on Sicily, and Sardinia, as well as on Corsica and along the

Mediterranean coast of France, particularly in Provence, and in Algeria, Tunisia, and to a lesser extent California, but little is made of these plantations commercially.

The bark of the cork tree is sufficiently thick to yield commercially useful cork from its 25th year, and cork trees are regularly stripped during the summer months, no more than every nine years by Portuguese law. On average, modern husbandry means that each hectare of cork forest yields 230 kg/500 lbs of cork; the older the tree, the more cork it will yield. Although the average life expectancy of a cork tree is about 170 years, there is one tree in the Montijo region south-east of Portugal's capital Lisbon estimated to be about 240 years old which has yielded 1,200 kg of cork from a single stripping. Cork farming, an activity often administered by the state, is an even longer-term undertaking than growing vines, which have an active wine-producing life of around 30 years on average (but see OLD VINES).

The bark micro-structure is unique in that it consists of very small, closely packed, usually 14-sided cells which have undergone a process known as suberinization. This renders it light, elastic, inert, and relatively impermeable to gases and most liquids except particularly strong acids or bases. These qualities and its low conductivity make cork a useful and versatile commodity as an insulator, particularly for the automotive and construction industries, but the principal use for cork is still cork stoppers and, in particular, wine corks.

Cork processing

Modern cork processing follows traditional methods, albeit helped by increasingly sophisticated technology. The strips of cork bark yielded by the annual stripping are stacked and left outside for seasoning (just as oak is in BARREL MAKING) for at least six months. Good drainage and airflow are important at this stage to minimize the risk of TCA development. Still in large strips, the cork is then boiled for about 90 minutes, both to make it more flexible and in an effort to kill off any moulds and other contaminants. This water needs constant replacing or processing to prevent contamination of subsequent batches. The planks are then left to rest in the warehouse of the cork-processing plant for two to three days before being sorted by hand and cut into strips as wide as the length of the final cork stopper. Corks are then punched out of these strips, usually by hand-operated punches but using an increasing degree of mechanization. Machines are more efficient and are now able to scrutinize each strip for impurities. Maximizing yield is a significant factor since only about 40% of all the commercially viable cork harvested is suitable for stoppers. The balance is used for AGGLOMERATE CORKS or other products.

It took four craftsmen two hours to harvest this impressive but still relatively young CORK oak in Estremadura near PORTUGAL's border with Spain. Trees like this, which are never felled, may be harvested dozens of times over their possible 250-year lifespan. © Amorim

Corks are deliberately punched at right angles to the growth of the cork tree, so that any lenticels (occasional knots in the wood) remain transverse and so that the risk of possible leakage due to lenticels is

minimized. The ends of the cork stoppers are then polished to present a smooth surface to the wine.

Various treatments then follow. Bleaching by immersing the corks in a bath of chlorine solution had the twin aims of cosmetic appeal (whitening) and hygiene, but after the discovery that chlorine increases the likelihood of TCA formation and therefore the incidence of CORK TAINT, it was largely superseded by hydrogen peroxide. After complaints from the wine industry in the late 20th century, the major cork producers switched to other sanitizing treatments, with hygiene the main aim, and invested substantially in quality control to reduce TCA incidence. Today cork buyers can request, at additional cost, an analysis of each cork in order to remove any TCA-tainted samples, effectively eliminating the cork-taint problem. (The most fastidious buyers, such as Barbaresco's GAJA, work with several suppliers to spread any risk and also test every batch of corks independently.)

Corks are graded on visual quality (the fewer the markings the higher the grade), branded with the name of the wine producer, and often coated with paraffin, a silicon-based product, or occasionally beeswax to make them easier to extract and reinsert and to ease their passage through BOTTLING equipment.

Finally, corks are sealed into large plastic bags, typically with SULFUR DIOXIDE as a disinfectant, although irradiation and simple holes for aeration are used as respectively more and less sophisticated alternatives. Subsequent storage conditions are critical to minimize mould growth and TCA contamination: ideal is a ventilated, odour-free environment at a temperature of 15–20 °C/59–68 °F in a relative humidity of 50–70%.

The range available

Although the first cork stoppers were tapered, the development of CORKSCREWS made tightly fitting cylindrical corks the norm. Modern corks are available in varying lengths, from 25 to as much as 60 mm (1–2.3 in), according to the AGEING aspirations, or extravagant exhibitionism, of the wine producer. The longer the cork, the longer it is likely to remain an intact and viable stopper (see RECORKING) and, in principle, the lower the OXYGEN TRANSMISSION RATE. However, there is a limit to the length at which cork effectiveness can continue to increase, since most bottlenecks allow only 50–55 mm of cork length to make contact with the glass. There is much less variation in diameter, however, with 24 mm being the norm for a bottleneck with an internal diameter of 18.5 mm, although corks 23 and 26 mm wide are not unknown, depending on the diameter of the necks of BOTTLES used.

The quality of the cork material itself also determines the price and potential life of the stopper. Until the 21st century, the ranking was based solely on visual imperfections. Today, grading includes specific cleaning programmes and fault-testing protocols, as well as assessments of beauty and length. The longest, finest one-piece TCA-tested cork with a guarantee can cost 25–50 times as much as the cheapest, shortest AGGLOMERATE CORK.

T-stopper corks with plastic or wooden tops attached to a natural or agglomerate cork are used for some wines, particularly FORTIFIED WINES and some SWEET WINES, as well as for many spirits.

Corks for SPARKLING WINES—commonly known, with scant regard for appellation laws, as champagne corks—have to be made to very particular specifications. Initially cylindrical, they are much wider than normal corks, about 30 mm, and have to be (half-)driven into the bottleneck, forcing them into a mushroom shape. Champagne corks are held in place, against the force of the pressure of undissolved gas inside the bottle, by a wire muzzle. Because such corks are too wide to be punched whole from the bark of most cork oaks, and to

moderate the cost of such a large cork, champagne corks are usually made from cork agglomerate with one, two, or occasionally three discs of natural cork stuck on to the end which goes into the bottleneck and is in contact with the wine.

Clues from the cork

In general, as corks age they will absorb some wine and lose their resilience and ultimately their capacity to seal against the bottleneck; the narrower and more misshapen a cork extracted from a bottle appears, therefore, the longer it has been there. This is a particularly useful clue to the likely age of a non-vintage sparkling wine, or at least to the time that has elapsed since DISGORGEMENT. It can also provide a clue to the likely age of any other wine which has lost its label or, perhaps in the case of vintage PORT, never had one (although see also RECORKING).

Most fine-wine corks are emblazoned with the name of the wine producer, the cork manufacturer's logo or code, and, sometimes, the vintage. If the vintage year is branded on the ends of a cork, it means the producer opted for fire or laser branding; this is more expensive than the ink that is forbidden on cork ends. Different countries adopt different conventions. On some French corks, for example, you might see MIS EN BOUTEILLE *à la propriété*.

A short agglomerate cork, or a low-grade colmated cork, suggests that the bottler had little regard for the ageing ability of this wine, while a particularly long, one-piece, TCA-tested, unbleached natural cork is indicative at least of ambition or optimism.

If a cork has crystals on the end that has been in contact with the wine (white in the case of a white wine and dyed dark red by a red wine), these are harmless TARTRATES. If a cork seems damp or mouldy at either end, this is not necessarily a sign of any wine fault. Some wine waiters are taught to smell the cork and present it to the customer as an essential part of wine service (see SERVING WINE), but the state of a cork is no sure guide to the state of the wine it stoppered.

For alternatives to corks, see CLOSURES, CROWN CAPS, SCREWCAPS, AGGLOMERATE CORKS, and SYNTHETIC CLOSURES. A.L.W.

Taber, G., *To Cork or Not to Cork* (2007).

corkscrews, wide range of devices for extracting CORKS from the necks of wine BOTTLES.

It might be thought that cork extraction would prove an easy matter with any simple screw device, given the relatively soft, resilient nature of the stopper. However, there have been many hundreds of inventions since the middle of the 18th century with the aim of producing a better, more efficient corkscrew, and as yet none has been accepted as the perfect instrument. In particular, no corkscrew has yet been shown to be infallible with old PORT corks, so PORT TONGS are sometimes employed instead. The extraction operation can vary considerably. Corks vary in length and can also, as they accommodate to the shape of the bottleneck, vary in shape. Furthermore, cork undergoes ageing in old bottles and may partially disintegrate on extraction. The necks of old port bottles, for example, usually have a slightly bulbous form, so that the lower part of the cylindrical cork is weakened where it ballooned out and became cone shaped. Italian wine bottles tend to be narrow at the neck, tightly compressing corks and making them relatively difficult to penetrate.

History

The free-blown, onion-shaped wine bottles (see BOTTLES, history) of the 17th century did not have a standard size of neck. Under these circumstances, tapered corks made a satisfactory stopper, especially as a portion remained proud of the bottle top, facilitating manual removal. The mould-made cylindrical glass bottle which evolved from about 1740 could be BINNED horizontally to keep the cork moist and at the same time to save space. This necessitated a driven cylindrical cork of standard diameter, and the removal of such a cork required a special tool.

Simple corkscrews leave the operator to do the work of screwing the worm (the curly metal bit) into the cork and pulling it out unassisted. Various modifications of handle, shaft, and worm can increase the efficiency of these manœuvres: the handle should be formed to give a good pulling grip; the shaft can be fitted with a metal disc, or button, to obtain more complete contact with the cork; and the worm should be a steel helix 5.7 cm/2.2 in long, be of good open pitch, and have an outer diameter of between 0.8 and 1 cm.

Although it is possible that simple corkscrews were in use by the mid 17th century in England, the earliest extant examples date from the 1690s.

Mechanical corkscrews are designed to reduce the amount of physical effort required during the three manœuvres of piercing, pulling, and disposing of the cork. Mechanical handheld corkscrews can never be used with the rapidity of an efficient wall- or bar-mounted mechanical instrument, although the modern handheld Lever Pull, really a miniature bar-screw in concept, can be used at remarkable speed.

National characteristics

Until fairly recently, the best corkscrews from the points of view of function, design, and quality of workmanship were made in wine-neutral Britain. The two-lever Italian corkscrew with a gimlet-like worm overcame the erstwhile problem of their short, tight corks.

The Germans rarely used anything other than the centre worm and often combined this with an inventive use of springs and ball bearings. In 1882, Karl Wienke of Rostock, Mecklenburg, conceived of using a knife-like handle as a lever. Known affectionately as the waiter's friend, it is still the essential tool of a SOMMELIER worldwide. The development of an articulated lever makes this model even easier to use as the cork is extracted in two stages, keeping it more upright and less likely to break.

The French were keen on nickel plating, contrasting with the bronzed finish of English pieces, as well demonstrated by the lazy tongs models of both countries.

Americans printed the wooden handles with advertisements and became largely preoccupied with self-pullers and other models which used the frame of the corkscrew as a fulcrum and derived from the French *à cage* principle. Screwpull, invented in the 1970s by Herbert Allen, is the culmination of applying this principle using strong modern plastics and a teflon-coated helix. Many other manufacturers today use teflon-coated worms, copying the Screwpull principles.

A two-pronged extractor became jokingly known as the butler's friend, as it enabled the cork to be extracted and replaced without evident damage and, possibly, the wine to be replaced with one less

fine. A more recent development has been The Durand, incorporating a traditional helix within a butler's friend (also known as an Ah-So) and designed especially for old bottles with fragile corks.

B.M.W. & R.N.H.B.

Bibliographical note: Literally dozens of books about corkscrews have been published, with Donald Bull, Ron Maclean, and Ferd Peters particularly prolific authors of them.

cork taint in a wine is often characterized as an off-putting, mouldy, wet-cardboard or wet-dog character. It suppresses fruit and shortens the length of finish of the wine. In its most subtle form, cork taint has a slight dulling effect on the aroma and flavour. At its extreme, it renders a wine quite unapproachable.

Although research results vary, between 3 and 5% of all wines sealed under cork display a musty taint. This is caused by a number of potent organic compounds, the most significant of which is 2,4,6-trichloroanisole or TCA. These taint compounds are metabolic products of fungi naturally present in cork or which have grown in the cork at various processing stages. Initially the occurrence of this taint was ascribed to the washing of cork planks by chlorine-containing bleaches; these have since been replaced by peroxide, but cork taint has remained a problem. It seems that the structure of cork, which is permeated by fine pores (lenticels) to facilitate gas exchange, will always harbour fungi with the potential to produce taint compounds. A study by Duncan, Gibson, and Obradovic has demonstrated the presence of TCA in the bark of cork trees in a Portuguese cork forest. See HALOANISOLES.

Only tiny amounts of TCA are needed to cause a taint problem since its aroma detection threshold in wine is about 3–4 ng/l. Over the past two decades, the major international cork producers have modified their production processes, from storage of the raw material through to the final sorting of the corks. Autoclaving the bark reduced the quantity of TCA by about 85% and is practised by all of the large companies. However, each company has developed proprietary methods that use a combination of pressure and

temperature to drive the TCA out of the corks once they have been punched out. Such methods involve, for example, ozone, vacuum steam, dry steam or extraction using an ethanol bath.

AGGLOMERATE CORKS have also come a long way in reducing levels of TCA. Several of the larger producers guarantee theirs corks to be TCA-free. The greatest changes have been in the sorting and storing procedures of the raw bark as well as fine-tuning the supercritical CO_2 extraction of the TCA and using better-quality plant-based binders to stick the granules together. Some companies are using head-space ionization technology to screen individual corks for volatile TCA so as to eliminate batches with high levels prior to final processing. In many cases, the level of TCA in agglomerate corks is lower than those in the punched corks.

Many cork producers are reporting an increase in sales of natural corks as a result of these improvements. Research has identified the potential contribution of chemicals other than TCA to taint in wine. These include other chloroanisoles such as tetrachloroanisole (TECA) and PCA, as well as alternatives to chloroanisoles. MDMP (see METHOXY-DIMETHYLPYRAZINE) has been identified as a key compound responsible for a 'fungal must' taint in wines that is possibly second only to TCA. TBA (see TRIBROMOANISOLE) also creates musty aromas in wine but is caused by contamination from the winery environment. This tallies with the observation that 'cork taint' can come from sources other than the cork—most notably from wooden structures in wineries that have been chemically treated—though the taint may still be transferred to the wine via the secondary contamination of the cork. But despite a few fairly high-profile instances of winery contamination, it seems that the cork is the culprit in the vast majority of cases. J.A.G. & K.C.

corky bark, virus-like disease and one of the few which can kill vines. It is one of a complex of diseases known as RUGOSE WOOD. Symptoms of the disease resemble those of LEAFROLL VIRUS, in that leaves turn red or yellow and roll downwards in the autumn. Vines infected with corky bark retain their leaves after they would naturally have fallen. It can be transmitted to healthy grapevines by the longtailed mealybug *Pseudococcus longispinus*, which may be regulated by the use of PHEROMONES. There is no control for infected vineyards, and vine removal is the only solution if many vines are infected. R.E.S.

Cornalin, ancient and almost extinct variety from AOSTA that was shown by DNA PROFILING to be identical to HUMAGNE ROUGE in the Swiss Valais. It is therefore an offspring of ROUGE DU PAYS, confusingly renamed Cornalin in the Valais in 1972. J.V.

Cornas, small but dynamic appellation located at the southern end of the Northern RHÔNE making robust red wines that can rival the best of HERMITAGE and CÔTE RÔTIE. The most favourable vineyards are planted on a rumpled, steep, largely east-facing slope that overlooks the village of Cornas, with some notable exceptions such as Reynards

facing south. Much of the vineyard land is terraced, with vines grown on STAKES known as *échalas*. Soils are a SANDY, decomposed GRANITE, planted entirely to Syrah. This is a hot MESOCLIMATE, although more recent plantings have taken advantage of the fresher temperatures on the plateau west of the slope, which rises to 400 m/1,312 ft in ELEVATION.

Until the late 1990s, Cornas had a reputation for making particularly rustic wines, often with an 'animal' side that was probably caused by BRETTANOMYCES. Brett is no longer more of a problem here than it is anywhere else in the Rhône, but the wines have retained a certain wildness of character, with an intense tannic structure. The wines are not as reliably ageworthy as those of HERMITAGE, but some examples can endure 20 to 30 years in bottle. In 2020, 5,243 hl/138,505 gal were made from 155 ha/383 acres, so only marginally more than Hermitage, but Cornas has more land left to plant.

M.C.W.

Cornell University has conducted viticultural research at Cornell AgriTech (formerly the New York State Agricultural Experiment Station) in Geneva, NY, since the 1880s. VINE breeders have released 57 varieties of juice, table, and wine grapes since 1906. As part of the breeding programme, DISEASE-RESISTANT and winter-hardy AMERICAN VINE SPECIES are crossed with VITIS VINIFERA as well as with Asian species of the VITIS genus. Two USDA-ARS units are housed at AgriTech: the Plant Genetic Resources Unit (PGRU) and the Grape Genetics Research Unit (GGRU). The PGRU makes over 1,300 genotypes of cold-hardy *Vitis* germplasm available for grape breeders. Scientists from the GGRU apply genomics and DNA sequencing to identify useful DNA markers (2,000, covering 99% of the genome) to accelerate VINE BREEDING.

The principles of sunlight utilization in grapevine canopies were elucidated by Dr Nelson SHAULIS leading to modern CANOPY MANAGEMENT such as shoot positioning and the GENEVA DOUBLE CURTAIN training system. The modern mechanical grape harvester was also

developed by Shaulis, E. S. Shepardson, and grower Roy Orton. (See MECHANICAL HARVESTING.)

Oenology studies at Cornell began in the 1960s. CAYUGA WHITE, Cornell's first wine grape variety, was released in 1972. More recent releases include CHARDONEL (1990), TRAMINETTE (1996), Valvin Muscat, Noiret, Corot Noir (2006), and Aromella and Arandell (2013). Studies in microbiology, fermentation, flavour chemistry, and wine production are ongoing. Cornell's plant pathologists, grape physiologists, entomologists, extension specialists, and others develop technologies to enhance the quality and TERROIR of New York's grapes and wines and to sustainably control diseases and pests.

Cornell recently instituted undergraduate and one-year master's degrees in OENOLOGY and VITICULTURE, with teaching at Geneva and on the main campus in Ithaca. T.E.M.

Cornifesto, minor dark grape in the DOURO, making light reds and PORTS. A natural ALFROCHEIRO × CAYETANA BLANCA cross.

Corpinnat, a collective EU brand of Catalan sparkling wine registered in 2017 by some of the best former producers of CAVA in reaction to what they considered an erosion of Cava's reputation and standards. Corpinnat wines must come from within a tightly delimited area in PENEDÈS and are subject to stricter regulations such as mandatory hand-harvesting, ORGANIC VITICULTURE, and stringent YIELD limits. Wines must be vinified on the winery premises and age at least 18 months. There were 11 members as of 2022. F.C.

Corrèze, small AOC in SOUTH WEST FRANCE around Brive-la-Gaillarde, yielding a range of white and red wines as well as VINS DE PAILLE. Whites depend on CHENIN BLANC; reds are mainly Cabernet Franc, with Merlot and Cabernet Sauvignon. Wine bearing the DÉNOMINATION

GÉOGRAPHIQUE COMPLÉMENTAIRE Coteaux de la Vézère must be entirely Franc grown on the SLATE soils of south Corrèze. P.S.

Corse is the French name for CORSICA.

Corsica, or Corse in French, is a mountainous Mediterranean island with distinctive, characterful wines. Measuring about 180 km/112 miles long and 80 km wide, it comprises a chain of abrupt mountains rising dramatically above a perimeter of capes, gulfs, and sandy beaches. The island produces many styles of wine, all products of long hours of Mediterranean sunshine, salty breezes, and poor, rocky soils surrounded by the island's signature aromatic shrubland, the *maquis*. Average annual production is 375,500 hl/9.9 million gal with nearly two-thirds of production leaving the island—about 45% to mainland France and 20% exported to Germany, Belgium, and the US.

History

Corsican wine is intimately tied to the island's turbulent history of invasions and occupations, a result of its strategic location in the Mediterranean. Viticulture can be traced back to Phocaean settlement in 565 BCE at modern-day Aléria, on the east coast. The Greeks and then Romans significantly developed viticulture all over the island. Under Genoese rule from the 13th to 18th centuries, Corsican wine took on newfound economic importance, enjoying strong commercial ties with the Italian mainland. It is during this period that grapes such as Sangiovese—known on the island as NIELLUCCIU—are thought to have been introduced to Corsica. After the Genoese signed over the island to France in 1768—one year before the birth of Corsica's most famous son, Napoleon, to a wine-growing family in Ajaccio—viticulture continued to prosper, with local wines being exported around the world.

The wine industry was revolutionized in the 1960s with the repatriation of many French *pieds noirs* from ALGERIA. The returning colonists engaged in widespread planting of high-yielding imported grape varieties and introduced modern techniques aimed at increasing production. Total vineyard area grew fourfold to over 30,000 ha/74,132 acres, producing 2 million hl/53 million gal. This rapid industrialization damaged Corsican wine's image and dealt a major blow to small-scale, traditionally minded farmers.

The 1980s marked a turning point, as EU subsidies led to a campaign of mass uprooting in response to the European WINE LAKE crisis. Coupled with a Corsican cultural movement that placed newfound focus on the island's viticultural heritage, Corsican vineyards began to be restructured with an emphasis on quality. By 2020, vineyards accounted for 5,782 ha/14,287 acres, and varieties once introduced for BULK WINE have been replaced by nobler vines, coinciding with renewed interest in Corsica's wealth of indigenous cultivars.

Geography and climate

With more than 100 peaks over 2,000 m/6,560 ft in elevation, Corsica is essentially a large mountain range sitting in the sea. Its array of valleys and hillsides with varying ELEVATIONS and EXPOSURES to wind and maritime influence results in many diverse MESOCLIMATES. The island is among France's sunniest regions, averaging 2,470–2,885 hours of sunshine annually. Although some parts of the island see significant rainfall, summers are very dry. Colder air from the sea and mountains tempers hot summer days, keeping nights relatively cool and ensuring decent DIURNAL TEMPERATURE RANGE. WIND is extremely influential, with the Cap Corse and Bonifacio averaging only 16 windless days per year. In addition to local sea and land breezes, important winds include the violent mistral from Provence; the libeccio from Gibraltar; the dry, cold tramontane from the Alps; the cool gregale from the Appenines; and the warm sirocco blowing in from the Sahara.

Corsica has four principal soil types: GRANITE across the west and south; SCHIST in the north-east including the Cap Corse, the mountainous finger of land pointing France-wards; pockets of LIMESTONE in Patrimonio and on the island's southern tip around Bonifacio; and ALLUVIAL soils on the flatter east coast.

Viticulture

Vines are typically cultivated in the craggy foothills between mountains and the sea. As in southern France, GOBELET training is traditional, but other systems such as CORDON DE ROYAT and single GUYOT have become more widespread with mechanization. The most common ROOTSTOCK is 110R, chosen for its resistance to drought. The frequent winds help to ward off disease, the main viticultural concerns being summer DROUGHT, DOWNY MILDEW, POWDERY MILDEW, and FLAVESCENCE DORÉE. For AOC wines, IRRIGATION is prohibited, and VINE DENSITY must be at least 4,000 vines per ha (1,600 per acre). in 2021, 22% of vineyards were farmed organically (see ORGANIC VITICULTURE), and BIODYNAMIC VITICULTURE has also taken a foothold.

Vine varieties

Niellucciu (SANGIOVESE), Sciaccarellu (MAMMOLO), and Vermentinu (VERMENTINO) are the most important Corsican varieties, representing nearly 60% of all plantings.

Niellucciu, probably introduced during the period of Genoese occupation, is the most planted variety, accounting for 27% of vineyard area or 1,552 ha/3,835 acres in 2020, much of it in the north of the island, where it thrives on the CALCAREOUS-clay soils of Patrimonio. Niellucciu-based reds are dark and powerful, showing notes of black fruit, licorice, spices, and a savory gaminess. Their firm acidity and grippy tannins provide good ageing potential. It is increasingly used to make bright, crisp rosés as well.

Sciaccarellu (961 ha/2,375 acres) has an affinity for southern Corsica's GRANITE soils, yielding lively, floral reds low in tannin and high in alcohol, with an extravagant perfume of smashed berries, pepper, and wild herbs. It also produces delicate, fresh rosés.

In Corsica, Vermentinu (854 ha/2,110 acres) asserts its status as one of the Mediterranean's finest white grapes. Grown all over the island, it produces fruit-driven quaffers as well as complex, full-bodied wines with the capacity for BOTTLE AGE. These gently floral, dry whites often show hints of lemon, pear, tropical fruits, fresh herbs, honey, and almond, with a subtle bitterness and mouthwatering salinity that make up for their relatively low acidity.

Southern French varieties such as GRENACHE, CINSAUT, and CARIGNAN are well adapted to the climate and can still be found planted alongside their Corsican counterparts, while INTERNATIONAL VARIETIES are increasingly rare. MUSCAT BLANC À PETITS GRAINS (278 ha/687 acres) has long been grown in Corsica, yielding delicately perfumed sweet—and occasionally dry—wines, especially in the north-east.

Recent years have seen the resurgence of Corsica's numerous INDIGENOUS VARIETIES. The CRVI (Centre de Recherche Viticole Insulaire) is engaged in much research and experimentation with these heirloom varieties, some of which have shown real potential in

the face of CLIMATE CHANGE. BIANCU GENTILE, Genovese, Riminese, Codivarta, BARBAROSSA, Carcaghjolu Neru, Minustellu, Morescone, and ALEATICO—to name just a few—are increasingly used.

Vinification

Almost 70% of all Corsican wine is made by CO-OPERATIVES, which, like some of the smaller wineries, took advantage of EU grants available for the installation of modern STAINLESS STEEL tanks and REFRIGERATION equipment, crucial in Corsica's hot climate. Rosés, usually made by direct press, are typically fermented cold in tank with MALOLACTIC CONVERSION blocked. The same is true for white wines, although some growers are using methods such as BARREL FERMENTATION, full malolactic conversion, and SKIN CONTACT to create deeper, more textural whites. Global demand for rosé has led pink wine to reach 70% of production in 2020, much of it produced by co-ops, followed by red (17%) and white (13%).

Red winemaking is relatively traditional; fermentation takes place in steel or CONCRETE tanks, with higher-end cuvées often BARREL-AGED. Some growers are experimenting with alternative vessels including concrete eggs, AMPHORAE, and acacia casks. Additionally, there is a growing contingent of domaines using low-intervention techniques associated with NATURAL WINE such as ambient YEAST fermentation, minimal SULFUR DIOXIDE additions, and bottling without FILTRATION.

Regions

Corsica has nine AOCs: the regional appellation Corse; two cru appellations, Patrimonio and Ajaccio; five village appellations prefixed with 'Corse-' (Calvi, Coteaux du Cap Corse, Figari, Porto Vecchio, Sartène); and one Vin Doux Naturel AOC, Muscat du Cap Corse. AOC wines represent 32% of total production, while ÎLE DE BEAUTÉ, the island's one IGP, accounts for 63%, with the remaining 5% labelled as Vin de France.

Patrimonio is Corsica's first appellation, awarded AOC status in 1968. Patrimonio forms a large amphitheatre of vineyards between the base of the Cap Corse and the Gulf of St-Florent. Just over 400 ha/988 acres of vines are shared between 39 domaines on a matrix of schist and fossil-studded limestone and clay, with occasional incursions of granite. Starring Niellucciu (minimum 90%), the deeply coloured and full-blooded reds make up over 40% of production. Rosés, accounting for one-third of production, are bright, chiselled, herb-scented thirst-quenchers. Patrimonio's whites (100% Vermentinu) are medium- to full-bodied with floral aromas, fleshy fruit, and a fresh mineral backbone. With age, they veer towards notes of petrol, gunflint, and honey. While most producers still use stainless steel or concrete, more and more are experimenting with wood and other vessels with encouraging results. The appellation was France's first to ban the use of synthetic herbicides.

Ajaccio, Corsica's second cru appellation, stretches from its capital city of Ajaccio, on the west coast, to remote inland hillsides to the north and south. Its 17 producers farm a total of 248 ha/613 acres on sandy decomposed granite. Sciaccarellu is the leading grape variety, giving fragrant, crunchy reds scented of wild myrtle and smashed berries. Delicate, floral rosés and whites are also produced. Domaine Abbatucci, a pioneer in biodynamic viticulture on the island, has played a crucial role in the preservation of Corsica's indigenous grapes with its nursery of heirloom varieties dating back to the 1960s.

Corse. This generic AOC is the dominant one on the island, primarily comprising wines from the 'Plaine Orientale', an alluvial zone stretching along the eastern coast from Bastia to Solenzara. Many of the larger estates were established here in the 1960s, its richer, flatter soils being more conducive to mechanization. Rosé dominates, at more than 75% of production. The 1,462 ha/3,613 acres are shared between 22 producers and all four of Corsica's co-ops.

Corse-Coteaux du Cap Corse is a mountainous peninsula in the island's north-east historically renowned for fortified Muscat and Rappu (a rare sweet red made from ALEATICO). However, its rugged schist soils are also conducive to fine white wines. Five domaines here share just 32 ha/79 acres.

Corse-Calvi encompasses 262 ha/647 acres and 11 producers in the north-west. Its granite terroirs range from coastal hillsides to inland plateaus surrounded by mountains, cut off from the Mediterranean's influence. The diversity of wine styles echoes this variety, although the area is notable for citrusy, herbaceous Vermentinu and powerful reds made mostly from Niellucciu, Sciaccarellu, and Grenache.

Corse-Figari comes from 143 ha/353 acres of vines and nine producers in the south-west of the island. Over half of production is red in this particularly hot, rugged, windswept region where granite soils yield robust, spicy wines.

Corse-Porto Vecchio comprises 90 ha/222 vineyard acres and four producers in the far south-east.

Corse-Sartène encompasses 245 ha/605 acres of vineyard and eight domaines in the granitic rolling hills around the eponymous village between Ajaccio and Figari. It is renowned primarily for full-bodied Sciaccarellu-based reds.

Muscat du Cap Corse is a distinctive VIN DOUX NATUREL made by 28 producers from just 39 ha/96 acres of MUSCAT BLANC À PETITS GRAINS grown on the Cap Corse and within the Patrimonio appellation. The grapes ferment partway until MUTAGE with a neutral grape spirit. The resulting wines must be 15–18% alcohol, with at least 90 g/l RESIDUAL SUGAR. Their sun-soaked flavours and delicate scents of maquis herbs, wildflower honey, and candied citrus shine with local desserts and cheeses. A.L.

www.vinsdecorse.com

Cortese, Italian white grape variety most closely associated with south-east PIEMONTE, in the province of Alessandria, where it was first recorded in the early 17th century. No relatives have so far been identified. Total plantings were 2,405 ha/5,943 acres by 2015, and it is the basis of no fewer than nine DOCs. Its most highly regarded wine is GAVI, produced initially to serve the fish restaurants of Genoa and the Ligurian coast. The Cortese dell'Alto Monferrato a few miles west, like the Cortese grown on the Colli Tortonese, rarely achieves the ripeness or winemaking proficiency of Gavi. At its best, the wine is clean and fresh. The use of oak is usually misguided.

Corton and Corton-Charlemagne, respectively the great red and white GRANDS CRUS in and around ALOXE-CORTON in Burgundy's CÔTE D'OR.

Coruche, subregion of TEJO in central, southern Portugal.

Corvina, or Corvina Veronese, the dominant and best grape variety of VALPOLICELLA and BARDOLINO in north-east Italy, producing fruity red wines with a characteristic sour-cherry twist on the finish. Wines from the better Valpolicella producers who reduced yields in the 1980s and 1990s demonstrated that lack of BODY was not an inherent characteristic of Corvina. Since then, it has enjoyed great success as the best variety for AMARONE. Producers such as Allegrini have also illustrated that wines made solely or predominantly from Corvina such as La Poja can be serious, barrel-aged reds. Corvina, sometimes called Cruina, has traditionally been confused with CORVINONE. DNA PROFILING at SAN MICHELE ALL'ADIGE in 2005 supported a parent–offspring relationship with RONDINELLA. Presumably fuelled by the

popularity of Amarone, Italy's total plantings of Corvina Veronese increased substantially in the early 21st century to reach 6,222 ha/15,375 acres by 2015.

Corvinone, red grape variety grown mainly in the VALPOLICELLA zone. It is so similar to CORVINA that it was long mistaken as merely a different CLONE of Corvina, although DNA PROFILING has established that it is a distinct variety. It is now highly regarded as a grape for such DRIED-GRAPE WINES as AMARONE and RECIOTO as its loose bunches and large berries make it particularly suited to DRYING. Total plantings had grown to nearly 1,140 ha/2,817 acres by 2015.

cosecha is Spanish for VINTAGE year.

Costa Rica in Central America has one commercial winery and vineyard, an Israeli-Californian-Costa Rican venture started in 2011. By 2022, 20 ha/49 acres of INTERNATIONAL VARIETIES were planted in the hills above Copey at an ELEVATION of 2,400 m/7,874 ft.

Costers del Segre, DOP in north-east Spain in semi-DESERT near the Catalan city of Lerida (see map under SPAIN) and in the lusher mountains bordering the Priorat DOP to the east. The climate is severe, with winter temperatures dipping below freezing in winter and exceeding 35 °C/95 °F in high summer. RAINFALL barely reaches 400 mm/15 in per year. The River Segre, a tributary of the Ebro after which this fragmented DOP is named, is little more than a seasonal stream.

The history of Costers del Segre was initially the history of one estate: Raimat, which covers 3,200 ha/7,900 acres of arid country 15 km/9 miles north-west of Lerida. When Manuel Raventós, owner of CAVA producer Codorníu, first visited the property in 1914, he found infertile salt plains abandoned by farmers. An IRRIGATION artery, the

Canal de Aragón y Cataluña, has since transformed the estate into an oasis, but it took over 50 years of planting cattle fodder, pine trees, and cereals before the soil was fit for vines. Today the Raimat vineyard covers 2,000 ha, which amounts to one-third of the Costers del Segre DOP. Cabernet Sauvignon, Merlot, Pinot Noir, and Chardonnay flourish alongside INDIGENOUS VARIETIES such as Tempranillo, Parellada, and Macabeo.

Of the region's seven subzones—Artesa de Segre, Urgell, Garrigues, Pallars, Raimat, Segrià, and Valls del Riu Corb—Pallars is the most prominent, thanks to pioneer producer Castell d'Encús as well as to ELEVATIONS reaching above 1,100 m/3,609 ft, where the cooler temperatures are seen as an advantage in the face of CLIMATE CHANGE and have even encouraged some producers to plant PINOT NOIR. V. de la S. & F.C.

Costières de Nîmes. Situated in the far south-west of the RHÔNE Valley, this appellation was considered part of the Languedoc by French authorities until 1989, when it was passed to the Rhône. In 2020, 2,844 ha/7,028 acres of vineyard produced 153,380 hl/4,051,871 gal of wine, 43% red, 48% rosé, and 9% white. The growing area can be roughly split into two sections: a northern part whose dominant wind is the mistral, and a southern area, closer to the sea, which is more affected by the dewy marin wind. These sea breezes help to temper afternoon temperatures, making the southern section the cooler of the two; more white varieties are planted here as a result. Soils in both areas are mainly the rounded stones known as *galets roulés* and CLAY. Wines of all colours must be a blend. Grenache is widely planted, but Syrah is the most popular grape for red wines, with Grenache Blanc and Roussanne for whites. M.C.W.

Cot, or Côt, is an important French synonym for the black grape variety of French origin also known as MALBEC and, in CAHORS, Auxerrois.

Côte means ‘slope’ or ‘hill’ in French. *Côtes* is the plural, while *Coteau* (*Coteaux* in plural) means much the same thing but possibly on a smaller scale. Since French vine-growers are great believers in the viticultural merits of hillsides, all of these make suitable wine names. Thus, any index of French wine names contains long lists of Côte, Côtes, and Coteaux de, du, de la, and des various place names, suggesting, often with reason, that the wine comes from the slopes above these places. Some of these prefixes are eventually dropped, however. Côtes de Buzet, for example, was renamed plain BUZET in the late 1980s, and Côtes du Ventoux has become VENTOUX.

For this reason—and to save readers having to remember whether a wine is, for example, a Coteaux de Somewhere or a Coteaux du Somewhere—such an entry would be listed under S for Somewhere, rather than under Coteaux. Their Côte and Côtes counterparts are listed similarly. The only exceptions to this are names in which the Côte, Côtes, or Coteaux are integral. They follow this entry.

Côte des Blancs, area of CHAMPAGNE on east-facing slopes south of Épernay noted for the quality of its Chardonnay grapes.

Côte d’Or, the heart of the BURGUNDY wine region in eastern France in the form of an escarpment supporting a narrow band of vineyards for nearly 50 km/30 miles southwards (and a touch west) from Dijon, capital of the *département* of the same name (see map under BURGUNDY). The name ‘Côte d’Or’ apparently translates directly as ‘golden slope’, evoking its autumnal aspect, but some think it may be an abbreviation of ‘Côte d’Orient’, a reference to the fact that the escarpment on which the vines flourish faces east. Viticulturally it is divided into two sectors: the Côte de NUITS, in which great red wines are made from the Pinot Noir vine; and the Côte de BEAUNE, where the reds are joined by the finest white wines made from Chardonnay.

The Côte d’Or represents the fault line separating the hills of the Morvan from the plain of the Saône, which, in the Jurassic period 195–135 million years BCE, was an inland sea. The predominant rock

is Jurassic LIMESTONE, which favours both Chardonnay and Pinot Noir vine varieties. However, the escarpment features many differing forms of limestone and other rocks. Oolitic limestone, which originated as a precipitation around marine debris of carbonate of lime from the seawater, is usefully porous and provides good DRAINAGE compared with marlstone, which is made up of clay, sand, gravel, and marl, the result of decomposition of older mountains such as the Ardennes.

The escarpment is also broken up by streams—the Vouge in Vougeot, the Meuzin in Nuits-St-Georges, the Rhoin in Savigny, the Dheune and Avant-Dheune further south—running down from the hills eventually to join the Saône, as well as by dry valleys (*combes*) such as the Combe de Lavaux in Gevrey-Chambertin. These breaks vary the orientation of the vineyards: thus Clos-St-Jacques is exposed more to the south than to the east, while much of Corton-Charlemagne actually faces south-west. The streams also affect the composition of the soil by bringing down alluvial deposits.

A cross-section of the Côte reveals topsoil too sparse on the hilltop and too fertile in the plain to produce wine of any quality. The vineyard area begins to the west of the Dijon–Lyons railway line, but only the most basic wines made from ALIGOTÉ and GAMAY are produced here. Approaching the main Dijon–Chagny road, the D974, the vineyards are still on flat, fertile land, but Pinot Noir and Chardonnay are planted to produce BOURGOGNE Rouge and Bourgogne Blanc. These in turn give way to village APPELLATION vineyards; as the ground starts to slope upwards, drainage improves, and the soil is less fertile.

Where the slope becomes more pronounced and clay gives way to stonier topsoil, the vineyards are designated PREMIERS CRUS, reflecting the potential quality of the wines from land which drains well and enjoys greater exposure to the sun. The finest of these vineyards, in certain villages only, are classified as GRANDS CRUS (listed under BURGUNDY). The premier and grand cru vineyards are mainly at elevations of 250–300 m/800–1,000 ft above sea level. Near the top of the slope, where the soil is almost too poor, there is usually a

narrow band of village appellation vineyards providing fine but light wines.

Viticultural practices are relatively constant for both major grape varieties throughout the Côte d'Or. VINE DENSITY is notably high—about 10,000 vines per ha (4,000 per acre)—and vines are trained and pruned chiefly according to the single GUYOT system (although CORDON DE ROYAT is increasingly employed to restrict vigour in younger vines and those on over-productive ROOTSTOCKS). Harvesting is still mostly manual, especially for Pinot Noir. Yields are usually restricted at village level to 50 hl/ha (3 tons/acre) for red wines and 57 hl/ha (3.5 tons/acre) for white, reduced by 2 hl/ha for premiers crus.

There are no set rules for the production of great red burgundy, and every domaine or NÉGOCIANT house revels in its own idiosyncrasies. Principal options include DESTEMMING of the grapes (wholly, partly, or not at all); length of MACERATION period; fermentation TEMPERATURE; length of BARREL AGEING; type of OAK barrels used; and RACKING, FINING, and/or FILTRATION regimes. The better wines of the Côte d'Or are all matured for at least a year, more often 18 months, in 228-l/59-gal oak BARRELS, a proportion of which are usually new.

The qualities of great red burgundy are not easy to judge young, especially since the wine tends to be less deeply coloured than equivalent wines from Bordeaux or the Rhône. When young, a fine burgundy should show a bouquet of soft red fruit, ranging from cherries to plums depending on the vineyard and vigneron; complexity comes with maturity, the fresh fruit components giving way to more evolved aromas, often redolent of truffles or undergrowth (*sous-bois*, according to French palates).

Some wines are weighty, others intensely elegant, but all should have concentration. Style depends in part on the character of the village: GEVREY-CHAMBERTIN, VOUGEOT, NUITS-ST-GEORGES, CORTON, and POMMARD tend to produce robust, long-lived wines; CHAMBOLLE-MUSIGNY, VOSNE-ROMANÉE, and VOLNAY epitomize finesse and elegance.

Within each village, different vineyards display their individual characteristics according to the exact SOIL STRUCTURE, ELEVATION, and TOPOGRAPHY.

Differences in annual WEATHER patterns are crucial in determining quality in the region. Burgundy is at a climatic crossroads, experiencing Atlantic, Mediterranean, and Baltic weather systems. A cool breeze from the north (*la bise*) is ideal to temper anticyclonic conditions in the summer; a southern wind brings heat but also danger; HAIL often results when the warm wind swings round to the west, the wettest direction. This has become an increasing problem in recent years with Volnay badly hailed in 2004, 2008, 2012, 2013, and 2014. Since then, FROST has become a greater scourge, with damage in 2017 and 2019 and more serious episodes in 2016 and 2021.

There is probably greater vintage variation in Burgundy than in any other wine region. In some VINTAGES—2004, 2008, and 2011 for instance, more rarely since—Pinot Noir grapes struggled to ripen fully, although growers who conscientiously restrict yields often produce excellent wines. The 1996 vintage, which produced fine wines for ageing, was unusual in that September sunshine ripened the grapes fully, judging by the sugar levels, yet cool nights maintained the acidity at levels normally associated with an unripe year. In other years, excessive rainfall can either swell the crop to produce dilute wines, as in 1982, 1992, 2000, and to some extent 2017 (red) and 2018 (white), or encourage ROT (as in 1986 and 1994). Most difficult to judge are the hot vintages in which the fruit in the wine is either supported or, sometimes, overwhelmed by TANNINS (as in 1976 and 1983) or can appear ultra-ripe (2003, 2009, and 2018–20). Balance may be best achieved in those vintages where ripeness is only just attained, as in 2002 and 2010. However, the greatest vintages of the past 50 years have been 1978, 1985, 1990, 1999, 2005, and 2015.

Great white burgundy is produced in the Côte de Beaune, notably in the villages of MEURSAULT, PULIGNY-MONTRACHET, and CHASSAGNE-MONTRACHET, along with a small enclave further north yielding the

grand cru Corton-Charlemagne (see ALOXE-CORTON). The soils suited to Chardonnay production tend to be paler in colour than the iron-rich, redder soils on which the Pinot Noir thrives (see SOIL COLOUR). The Chardonnay vine is hardier than the Pinot, the grapes ripen more easily, and the wines require less delicate handling. It is easier to make good white burgundy than good red, but very little great white burgundy is made.

The grapes are pressed (usually without SKIN CONTACT), left to settle, then fermented in oak casks for up to a year (see BARREL FERMENTATION), although those with suitable cellars prefer to keep the wine for a second winter in wood, usually racking the wine into older barrels while retaining the fine LEES. Others keep the wine for six months in tank. In the early months some producers like to stir the lees to nourish the wine (see LEES STIRRING).

Fine white burgundy, when young, is more likely to show the character of the oak in which it has been vinified than the grapes from which it came. Hallmarks of quality are fullness of BODY, balance of ACIDITY, and persistence of flavour. Only after two or more years of bottle age will a fine Meursault or Puligny-Montrachet start to show the quality of the fruit. This will deepen with age and, although vegetal tones may appear, they should not overwhelm the natural elegance of the wine. A village appellation wine should be at its best from three to eight years old, a premier cru from five to ten years, while a grand cru worthy of its status needs a full decade of BOTTLE AGEING (but see also PREMATURE OXIDATION).

For more detail, see under names of individual villages or appellations. See BEAUNE, CÔTE DE and NUITS, CÔTE DE for a full list of the villages in each. To most of the villages and towns in the Côte d'Or was appended the name of their most famous vineyard, typically in the late 19th century. Thus, for example, Vosne became Vosne-Romanée and Puligny became Puligny-Montrachet. J.T.C.M.

Côte Rôtie, one of the most prestigious appellations of the Northern RHÔNE, considered by many to be the equal of HERMITAGE, though very different in style. The name translates as 'roasted slope' but has been until recently a MARGINAL CLIMATE for ripening Syrah, the dominant vine variety. Situated at the northern limit of the northern Rhône growing area close to the village of Ampuis, the appellation comprises a series of steep, terraced hillsides that rise up from the river Rhône to an ELEVATION of around 325 m/1,066 ft. Due to the course of the river, these dramatic vineyards typically face east, south-east, and south, enjoying beneficial exposure to the sun.

This red-only appellation is divided into 73 LIEUX-DITS over three communes. Two of the most well known are the Côte Blonde and the Côte Brune immediately to its north-east. These names derive from the two main soil types in the appellation: Blonde refers to pale yellow GNEISS, Brune to dark brown SCHIST. Somewhat confusingly, since gneiss predominates from Côte Blonde southwards, the entire half of the appellation is sometimes referred to as 'the Côte Blonde'; conversely, it is schist that dominates from Côte Brune northwards, so this side of the appellation is sometimes referred to as 'the Côte Brune'. The gneiss soils contain less CLAY, are relatively free-draining, and produce a lighter-structured, more fragrant style of wine. The heavier schistous soils typically produce a more full-bodied, rounded, structured style of Syrah that is usually somewhat longer-lived. In the far south of the appellation there is also some GRANITE; other minor soil types include pebbly ALLUVIUM and pockets of LOESS. Some vines are trained on wires, but most are trained on one or two stakes known as *échalas* (see TRAINING SYSTEMS).

One peculiarity of the appellation is that up to 20% VIOGNIER is allowed in the wine, although this must be co-planted with the Syrah and CO-FERMENTED. In practice more than 10% is rare, as it can dominate the finished wine. Viognier is more commonly grown towards the south of the appellation, close to neighbouring CONDRIEU. It can add aromatic lift, alcohol, and texture to the red wines. Pure Syrah wines tend to age a little longer—typically up to ten years, the best 20–30 or more.

Vines have been grown here since Romans were settled nearby, as mentioned by PLINY the Elder, among others. After PHYLLOXERA, the appellation was slow to be replanted and until the 1970s was rather moribund. Attention was drawn to the appellation thanks to the meticulous work of Marcel GUIGAL, whose company continues to be a driving force. In 2020, 330 ha/815 acres of vineyards produced 11,467 hl/302,926 gal of wine that was bottled under the appellation.

M.C.W.

Cotnari, appellation (DOC in Romania) most noted internationally for once-famous sweet white wine produced in hilly countryside in the north-eastern Moldovan Hills (see ROMANIA for geographical details). First documented in the 15th century, it once rivalled Hungarian TOKAJI as an elixir of FASHION sought after in the courts of northern Europe.

Cotnari wines are almost all produced by the large former state winery Cotnari SC or its premium off-shoot Casa de Vinuri Cotnari, owned by the second generation of the same families. Both are very protective of the Cotnari name, so it has been difficult for other producers to gain a foothold here. Cotnari wines remain very popular in Romania.

The DOC allows wine to be made from any of four local white grape varieties plus red FETEASCĂ Neagră and pink-skinned Busuioacă de Bohotin. The wines are often vinified from dry to semi-sweet, as single varieties, or as a traditional blend containing a minimum of 30% GRASĂ (which provides the body and sugar). TĂMÂIOASĂ Românească provides its 'frankincense' aromas (and sugar without

losing acidity in the Cotnari MESOCLIMATE), Frâncuşă gives acidity (it must make up at least 30% in a blend, although it can suffer from poor FRUIT SET), and Fetească Albă the aroma. Occasionally, Grasă ripens to very high sugar levels and may be affected by NOBLE ROT. Such wines can be long-lived and impressive—and are released occasionally as 'collection' wines. C.G.

Couchois, Bourgogne, Côtes du, appellation created in 2000 for red wines made from Pinot Noir grown around the town of Couches north-west of the Côte Chalonnaise. See BOURGOGNE.

Couderc Noir, a FRENCH HYBRID of a dark-berried VITIS RUPESTRIS × *Vitis lincecumii* cross and VITIS VINIFERA, is one of several productive but undistinguished hybrids that proliferated in the MIDI in the early 20th century). Although not as popular as VILLARD once was, Couderc Noir was so widely planted that France's total area of Cabernet Sauvignon did not overtake that of Couderc Noir until well into the 1970s. By 2019 total plantings were just 142 ha/351 acres. The wine produced can be aggressively non-*vinifera* in taste.

Coulanges-la-Vineuse, commune near AUXERRE whose name may be appended to that of red, white, and rosé BOURGOGNE.

coulure, French term, also commonly used by English speakers, for one form of poor FRUIT SET in the grapevine. Excessive shedding of OVARIES and young berries results in relatively few berries per bunch, either during or soon after FLOWERING. To a great extent, coulure is a natural and necessary phenomenon, since the vine cannot possibly ripen the crop if all the flowers remained as berries. However, for some varieties in some years, coulure can be excessive and YIELD drastically reduced. This can have a disastrous effect on grape-growers' incomes and can also affect grape supply and wine prices in

certain years. GRENACHE vines are particularly susceptible to coulure, as are MALBEC, CABERNET SAUVIGNON, and MERLOT.

Coulure is caused by an imbalance in the levels of CARBOHYDRATES in vine tissue. Weather conditions around flowering which reduce PHOTOSYNTHESIS—such as periods of cloudy, cold, and wet weather—will cause coulure and can have devastating effects on yield for some varieties. Coulure also happens where the total leaf area, and thus photosynthesis, is limited. Low carbohydrate levels can also be due to competition between INFLORESCENCES and vigorous shoot growth, combined with warm temperatures, which favour RESPIRATION. Very fertile soils, excessive application of FERTILIZERS, especially those high in NITROGEN, vigorous ROOTSTOCKS, and PRUNING too severely (see BALANCED PRUNING) can also cause coulure.

There is little growers can do to prevent coulure. It is not always possible to grow varieties which are not susceptible, as particular varieties may be required by local regulations or for a certain style or blend. CLONAL SELECTION can be effective in reducing susceptibility for varieties such as Merlot and Malbec. Topping shoots (see TRIMMING) during flowering can reduce coulure by temporarily stopping competition for carbohydrates between actively growing SHOOT TIPS and INFLORESCENCES. Later pruning may also help because a delayed BUDBREAK will increase the possibility of warmer weather at flowering. Some chemical GROWTH REGULATORS can reduce coulure by inhibiting shoot growth. A Coulure Index (CI) was defined for the first time in 2009—the higher the numerical value, the greater the expression of the condition. R.E.S. & P.R.D.

Collins, C., and Dry, P. R., 'Response of fruitset and other yield components to shoot topping and 2-chlorethyltrimethyl-ammonium chloride application', *Australian Journal of Grape and Wine Research*, 15 (2009), 256–67.

Iland, P., et al., 'Flowering and fruitset', in *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

Counoise is one of the more rarefied varietal ingredients in red CHÂTEAUNEUF-DU-PAPE, easily confused in the vineyard with the much lesser southern Rhône variety AUBUN, with which it may sometimes be mingled in older vineyards. It is authorized as a supplementary ingredient for most red-wine appellations around the southern Rhône, including LANGUEDOC AOC, but, although VARIETAL southern French versions are made, it is not widely grown outside Châteauneuf-du-Pape. Total French plantings increased in the 1980s to around 900 ha/2,200 acres but in 2019 were only 322 ha.

As a vine, it leafs and ripens late and yields conservatively. As a wine, it is not particularly deeply coloured or alcoholic but adds lift, a peppery note, and lively acidity to a blend. Enthusiasts such as the Perrin family of Ch de Beaucastel typically use about 5% of Counoise in their red Châteauneuf-du-Pape and have disseminated it around California's Central Coast and beyond via their Tablas Creek vine NURSERY there.

counterfeit wine has, alas, become more common as FINE WINE has become more valuable. Wine of all sorts has been subject to ADULTERATION AND FRAUD for centuries, but the escalation in prices of the most sought-after names, the rapid increase in the number of (often inexperienced) COLLECTORS, and the fact that a fine wine may be consumed many years after it was bought combined, in the late 20th and early 21st centuries, to provide irresistible opportunities for fraudsters in general and counterfeiters in particular.

In less developed markets, poor-quality wine may be packaged in a poor copy of a famous wine's BOTTLE, LABEL, and CAPSULE; but usually more sophisticated methods are called for, leading to a new breed of wine CONSULTANT who is expert in, inter alia, precise label design and typeface evolution for the most valuable wines (see AUTHENTICATION). Wines that have been particularly popular with counterfeiters are, of course, the rarest, which means that the likes of PETRUS, DOMAINE DE LA ROMANÉE-CONTI, and Henri Jayer burgundies have appeared at auction unfeasibly often, just as vintages 1961 and 1945 of fine

bordeaux have. A favourite recipe for fake top-vintage Petrus, for example, has been a mixture of off-vintage Petrus with particularly ripe California red. Printers are necessary accomplices for counterfeiters.

The most common counterfeits have included Chx Cheval Blanc 1921 and 1947, Lafite 1787 and 1870, Lafleur 1947 and 1950, Latour à Pomerol 1961, Margaux 1900, and Petrus 1921 and 1947. Among other counterfeits, there have been discoveries of fake 1990 Penfolds Grange and of 1994 and 1995 SASSICAIA, but even mid-priced wines such as Rioja and MOUTON CADET have been victims.

Wine AUCTIONS provide the perfect arena for such frauds, but counterfeit wines have also been sold by retailers and privately. This has led to an increase in interest in each bottle's precise PROVENANCE and calls for some sort of system akin to motor vehicles' logbooks, perhaps using BLOCKCHAIN technology.

Producers of most wines targeted by fraudsters have been taking anti-counterfeit measures such as special invisible marks on various aspects of packaging of this century's vintages, but mature fine wine should be bought only from the most impeccable of sources. Premiums for wines direct from château, domaine, or estate have risen.

Wallace, B., *The Billionaire's Vinegar* (2008).

Steinberger, M., 'A Vintage Crime', *Vanity Fair* (July 2012).

country wines. See HOME WINEMAKING.

coupage, French and EU term for BLENDING. It means literally 'cutting' and retains a slightly pejorative overtone, tending to be reserved for wine blending at its least glamorous, while the French word ASSEMBLAGE is more commonly used for blending different lots of a fine wine. EU regulations prohibit the *coupage* of all sorts of

different wines, including EU with non-EU wines, or WINE WITHOUT GEOGRAPHICAL INDICATION with PDO and PGI wines.

Courbu Blanc, Basque speciality often blended with PETIT MANSENG and GROS MANSENG, distinct from PETIT COURBU. See also HONDARRABI. Courbu Noir is an almost extinct speciality of BÉARN.

courses, wine. See EDUCATION.

court-noué, common French term for FANLEAF DEGENERATION, a virus disease of the vine.

Cova de Beira, large subregion within BEIRA INTERIOR in central Portugal. Wines bearing the name are rarely seen on export markets.

cover crop, a crop of plants other than vines established in the vineyard, typically between the rows, generally to benefit the vineyard soil by increasing ORGANIC MATTER but also for biodiversity (see ECOSYSTEM). Sometimes known as a sward. Cover crops may be sown, or volunteer plants or WEEDS encouraged to grow, as an alternative to bare soil created by TILLAGE. They are normally grown over the summer or winter and mown during the vine-growing season, primarily to avoid water competition, or they may be removed by tillage. Typical sown cover crops are grasses and legumes. The grasses used may be native to the area or specially introduced species such as perennial rye grass, fescue, or bent grasses, although often cereals such as barley or oats are used for autumn sowing. Legumes sown as cover crops to fix atmospheric NITROGEN into the soil include clovers, medics, peas, vetches, and beans. Occasionally, deep-rooted cover crops such as chicory (*Chicorium intybus*) are sown to compete for soil water with over-vigorous vines, especially in deep, fertile soils in high-rainfall areas.

Cover-crop management is more difficult in high-density, narrow-spaced vineyards (see VINE DENSITY).

The most common reason for sowing cover crops is to increase the organic matter in the soil and hence improve its structure and water-holding capacity. This is achieved with species such as cereals and grasses that grow quickly and produce plenty of bulk, which can then be incorporated into the soil by shallow tilling. Cover crops with a deep tap root (such as radish and chicory) or which are hollow-stemmed (such as oats) maintain soil structure by facilitating water infiltration. When a cover crop is slashed, the residues left on the soil surface reduce the amount of EVAPORATION from the topsoil.

Cover crops are also commonly sown to stop SOIL EROSION in areas with storms and are especially useful in sloping vineyards. The roots of the cover crop bind the soil and resist the flowing water. Tall cover crops are also used in newly established vineyards to combat high winds, which can cause damage to young plants. Cover crops also help reduce SOIL COMPACTION.

Another important use of cover crops is to compete with the vines, especially when they are too vigorous, and to encourage earlier RIPENING and improve wine quality. Slight WATER STRESS hastens the ripening process, so cover crops, which compete with the vines for water and nutrients (especially nitrogen), can help to generate this stress in areas of high summer rainfall. Nitrogen from legume cover crops and plenty of soil moisture can lead to excessive vine VIGOUR. Some mowers throw the cover crop clippings under the vines, thus forming a MULCH to reduce evaporation.

Apparently weedy vineyards should not necessarily be dismissed as untidy; they may represent a deliberate ploy to improve wine quality. Deep-rooting crops such as mustard, lucerne (alfalfa), and chicory can be particularly useful to use up subsoil water which more shallow-rooted grasses cannot reach.

Cover crops should be grown with caution. In spring, they make the vineyard more prone to FROST than if the soil is bare. The cover crop may play host to insects which spread diseases such as

FLAVESCENCE DORÉE. If the cover crop is not mown or cultivated in summer it can use excessive amounts of water or nutrients, and the vines can suffer as a result. Because of competition with vines for nitrogen, the use of cover crops can also cause STUCK FERMENTATIONS (although ORGANIC growers claim the reverse is the case). These effects can be offset by close mowing or by killing the cover crop by tilling or HERBICIDES. Cover crops reduce the problems caused by dust from traffic on bare soil alleyways in the vineyard; dust can encourage MITES.

In arid Central Otago, New Zealand, where animal manure is scarce, cover crops sown to supply nitrogen to the vines have been maintained by the installation of a shallow DRIP IRRIGATION line in the mid row. R.E.S. & R.E.W.

Cowra, southernmost region in Australia's Central Ranges Zone in NEW SOUTH WALES, with 932 ha/2,303 acres of vineyards planted in 2020. Warm and dry with cool nights, the region is best known for generous styles of Chardonnay. Reds including Shiraz, Cabernet Sauvignon, and Grenache are also produced. A.R.P.

crater, big, deep bowl with a wide mouth used in ancient GREECE for mixing wine, most often with water. The crater was characteristically 12–18 in (30–45 cm) high and could be either painted pottery or made of bronze. The most remarkable example is the huge bronze

crater, over 5 ft/1.5 m high and probably of Spartan manufacture, which was found at Vix in France (see CELTS). J.J.P.

Crato Branco, Algarve synonym for Portugal's SÍRIA grape.

Cream, the sweetest, darkest style of SHERRY (with the exception of PX, which is even sweeter and darker), created expressly for the sweet-toothed British market by Harveys of Bristol. Bristol Milk was a style of sweet sherry sold successfully in the early 19th century by both Averys and Harveys. The story goes that a lady visitor to the cellars in 1882, on tasting Harveys' new, as-yet-unnamed BRAND of sweet sherry, observed, 'If that is Milk, then this is Cream.' Harveys Bristol Cream was thus named, and it became the most successful branded sherry in the world. This sweet style of sherry is eschewed by the Spaniards, for it is essentially the product of BLENDING not necessarily very distinguished sherries with sweetening and colouring wines. Pale Cream was another highly successful sherry style launched, with huge initial success, by Croft in the 1970s. Most Pale Cream is essentially sweetened FINO, though it may occasionally be the same as Cream but with the colour removed, by CHARCOAL or other treatments. Cream sherries generally have a RESIDUAL SUGAR content that is equivalent to 4.5–6.5 °BAUMÉ.

Crémant, term used as France's shorthand for the country's finest dry sparkling wines made outside Champagne using the traditional method of SPARKLING WINEMAKING. The term was adopted in the late 1980s, when the expression *méthode champenoise* was outlawed by the EU (and replaced by MÉTHODE TRADITIONNELLE). The principal provenances of modern Crémants are Alsace, Bourgogne (Burgundy), Loire, and Limoux. The best sparkling wines of LUXEMBOURG are also called Crémant. Crémant de Saumur and Crémant de Vouvray were the first non-champagne sparkling wines to use the term, and in the mid 1970s the Crémant de Loire appellation was born, soon followed

by Alsace and Bourgogne. Bordeaux and Limoux joined the official Crémant appellations, created under INAO authority, in 1990 and were followed by Die in 1993, Jura in 1995, and Savoie in 2014.

Although grape varieties and TERROIRS vary from region to region, certain strict sparkling winemaking rules are imposed, including WHOLE-BUNCH PRESSING; a maximum yield of 100 l per 150 kg of grapes (the same as CHAMPAGNE prior to 1993); a maximum SULFUR DIOXIDE content of 150 mg/l; and a minimum of 12 months between initial bottling and release.

Crémant d'Alsace

Sparkling winemaking using the TRADITIONAL METHOD in Alsace dates from the late 19th century and in the 1980s became an important commercial activity, representing almost a quarter of the region's output. Only the grape varieties Pinots Blanc, Noir, and Gris, together with the related Auxerrois, and Riesling and such Chardonnay as is planted in Alsace, may be used (i.e. no Gewurztraminer or Chasselas), and any rosé must be made entirely of Pinot Noir. Maximum yields are 80 hl/ha (4.5 tons/acre). The wines are well made, tend to have a particularly fine mousse, high acidity, and to be relatively light in BODY. Only if substantial proportions of Riesling are used do they acquire strong flavour. Production is in the hands of nearly 500 small-scale producers whose blending capability is usually limited. A total of 3,940 ha/9,736 acres were devoted to the wine in 2019.

Crémant de Bordeaux

A small and declining amount of sparkling wine has been made in the BORDEAUX region since the end of the 19th century. Today production is controlled by a handful of companies which have not established a clear style or identity for the white and pink wines.

Crémant de Bourgogne

This appellation, created in 1975, replaced that of Bourgogne Mousseux (now used exclusively for sparkling red burgundy), under which name sparkling burgundy of all colours enjoyed considerable commercial success in the 1950s and 1960s. As of 2021, the appellation is open solely to white and rosé wines made from any grape varieties grown in BURGUNDY, although Gamay may not constitute more than 30% of the blend. RULLY in the Côte Chalonnaise and AUXERRE in the far north of Burgundy are the principal sources of Crémant de Bourgogne (CÔTE D'OR grapes being in general worth considerably more when sold as still wine), and there can be considerable stylistic differences between their produce. Crémant from southern Burgundy can be full and soft, a good-value alternative to bigger styles of champagne, while Crémant made in the north is usually lighter and crisper.

Crémant de Die

Crémant de Die is a dry sparkling wine made by the TRADITIONAL METHOD from at least 55% CLAIRETTE grapes with no more than 10% of the Muscat Blanc that is grown for another of the region's three sparkling wines (see CLAIRETTE DE DIE for more details), and the balance ALIGOTÉ.

Crémant du Jura

Created in 1995, this appellation represents more than 25% of Jura wine production. The wines may be white or rosé from any of the authorized JURA grape varieties, although the white must be at least 70% Chardonnay, Pinot Noir, and Trousseau, and the rosé at least half Poulsard, Trousseau, or Pinot Noir. In practice, few white Crémants du Jura are made from anything other than Chardonnay, although some interesting white blends with Savagnin are available. All but the largest producers have their base wine made sparkling by one of two specialist companies who then return the finished wines to individual producers to market. Whereas the larger Jura wineries tend to make excellent-value Brut or Demi-Sec versions, since the mid 2010s several organic producers have made high-quality Brut Zéro or Nature Crémant du Jura.

Crémant de Limoux

This appellation represents the increasing champenization of the ancient sparkling wines of LIMOUX in a particularly cool, high corner of the southern Languedoc. In 1990, Blanquette de Limoux became an appellation reserved for sparkling wines made principally from the MAUZAC grape grown traditionally in the region. Crémant de Limoux, in contrast, focuses on Chardonnay and Chenin Blanc, with no more than 20% Mauzac allowed. The rosé version must contain at least 15% Pinot Noir. In 2018, a total of 823 ha/2,034 acres were devoted to the wine, a very high proportion of which is made by the CO-OPERATIVE.

Crémant de Loire

Crémant de Loire was created in 1975 and encompasses the Anjou, Saumur, and Touraine regions. Most of the middle Loire's wide palette of grape varieties may be used to produce Crémant, with the sensible exception of Sauvignon Blanc, whose aroma has yet to prove itself an attractive sparkling wine ingredient. GROLLEAU grapes may not represent much of any blend, and in practice CHENIN BLANC is the most common dominant component, clearly distinguishing the flavour of most Crémant de Loire from Crémants made from Pinots and Chardonnay to the east. Levels of winemaking are generally high among the nearly 200 producers (including several important co-operatives and NÉGOCIANTS).

Crémant de Luxembourg

Luxembourg has a long tradition of sparkling winemaking, and its particularly acid wines were at one time valued as base wines for SEKT. The Crémant de Luxembourg appellation was created in 1991, following the INAO rules laid down for French wines. Permitted grape varieties are Elbling, Pinot Blanc, Rivaner (Müller-Thurgau), Sylvaner, Auxerrois, Chardonnay, Pinot Gris, Gewürztraminer, Muscat Ottonel, and Riesling for white wines, Pinot Noir for rosé.

Crémant de Savoie

This appellation was introduced in 2014, replacing SAVOIE *mousseux* and *pétillant*. Blends should be composed of at least 60% JACQUÈRE and the local ALTESSE, with a minimum of 40% Jacquère (Altesse is optional), supplemented by other permitted Savoie white grapes such as Chasselas or Chardonnay and up to 20% red grapes. SEYSSEL and AYSE have their own appellations for TRADITIONAL METHOD sparkling wines. In 2020 these three sparkling appellations combined accounted for just 5% of Savoie wine production.

Crépy, CRU (formerly a small appellation in its own right) within the eastern French region of SAVOIE above the south shore of Lake Geneva producing generally dull, light, dry white wines from the CHASSELAS grape.

Crete, large island in the south-east of GREECE famous for the Minoan civilization (*c.*2000–1400 BCE). Its wines were most famous in the Middle Ages when the island was known as Candia. In modern times, Crete spent most of the 20th century producing wines to be consumed on the island, but the new millennium witnessed a paradigm shift, with more quality-minded producers who have saved a number of rare but superb varieties from oblivion along the way.

Most vineyards are on the north of the island, protected from hot winds from North Africa by the island's mountain ranges, the tallest of which reach 2,456 m/8,058 ft. The island's most important viticultural centre is the area south of the port city of Heraklion, which includes the PDOs Archanes, Dafnes, and Peza, although ambitious producers are also found around Chania in the west and Sitia in the east. The mountainous landscape gives rise to diverse soils and MESOCLIMATES, which in turn support a plethora of local grape varieties. The pale red LIATIKO, the third most important black grape on the island, ripens very early, sometimes as early as July; its

high sugar content and low tannin levels make it particularly prized for sweet DRIED-GRAPE WINES. Robust red wines are made from the tannic, deep-coloured Mandilari (MANDILARIA), often augmented with the less-tannic and most widely planted red variety KOTSIFALI.

The island's most important local white grape is VILANA, which makes soft, floral white wines, blended with Thrapsathiri for PDO Sitia. Potentially more exciting but far rarer is VIDIANO, a white grape originating in Rethymno making full-bodied whites. There are many other rare vine varieties such as Dafni, Plyto, and even a single plant of Samos Muscat Noir that has been rescued from extinction by observant growers.

Crete also boasts two PDOs dedicated to wines made in a style that harkens back to the wines traded by the Venetians in the Middle Ages: PDO Malvasia Handakas-Candia and PDO Malvasia Sitia. Both are blends of sun-dried grapes, in both fortified and non-fortified variations. Confusingly, the grape variety Malvasia may make up only a small amount of the blend; the bulk must be made up of Assyrtiko, Thrapsathiri, and Liatiko, with Vidiano in Handakas-Candia and Athiri in Sitia. Also allowed is a small amount of MUSCAT BLANC À PETITS GRAINS.

See also MALVASIA, MALMSEY. K.L.

crianza, Spanish term used both to describe the process of AGEING a wine and also for the youngest officially recognized category of a wood-matured wine. A crianza red wine may not be sold until its third (second for whites and rosés) year, and it must have spent a minimum of six months in cask. Crianza white and rosé must be aged for at least 18 months, including six months in wood. In RIOJA and other regions such as RIBERA DEL DUERO, where the term is most commonly used, the wine must have spent at least 12 months in oak BARRICAS. An increasingly frequent, albeit unofficial, category now is semi-crianza, or *roble* (meaning OAK), for wine aged in cask for less time than the crianza minimum. With the term JOVEN fully accepted

for fruity young wines without cask ageing, the slightly derogatory description *sin crianza* had all but disappeared by the late 1990s.

Crimea, important wine-producing peninsula off southern UKRAINE surrounded by the Black Sea. After decades of being controlled by and selling most of its wines in Ukraine, the region was annexed by RUSSIA in 2014.

Grapes were grown here from at least the 4th century BCE. Archaeological evidence includes stone fences, remnants of viticultural plots and wineries, and wine AMPHORAE in the Tauric settlement of Uch-Bash near Inkerman. There have also been wine-related finds in the ancient town of Myrmecium in the east of the Kerch Peninsula. The unearthed tomb of a Scythian chief dated 500 BCE was arranged with an amphora of CHIAN wine at its head.

By the 19th century, Crimea's wines were well regarded among the Russian aristocrats who came to vacation along its south coast. Cyrus REDDING noted in 1833 that 'the Crimea wines are thought the best in the empire'. The wine-loving Count Mikhail Vorontsov, governor-general of that part of Russia which then included the Tauric province, began to build the Alupka Palace and associated winery in the 1820s; it still produces FORTIFIED WINES in quantity. He also laid the foundations for the MAGARACH Institute for wine research. Vorontsov imported a wide range of European grape varieties, as did his successor as principal Crimean wine innovator, Prince Lev Golitsyn. In 1882 Golitsyn established the Novyi Svit (New World) winery, which, inter alia, produced pre-revolutionary Russia's 'Shampanskoye' and continues to make sparkling wine today.

Since then, vineyard plantings have fluctuated wildly, reaching their zenith in 1959 with 152,500 ha/376,836 acres. In 2020 just 18,067 ha remained, spread throughout three winemaking regions: the interior Steppe; the South Coast, specializing in strong, sweet wines made like VINS DOUX NATURELS as well as Kagor (a name inspired by CAHORS), a deep-coloured wine made from MUST heated before fermentation, with MASSANDRA the dominant winery; and the West

Coast, associated with dry varietals produced by small, new-wave operations such as Oleg Repin and Uppa, a winery from sommelier Pavel Shvets.

In addition to international varieties, Crimea's vineyards feature many crosses, such as Bastardo Magarachsky, a cross between BASTARDO and SAPERAVI. There is also renewed interest in INDIGENOUS VARIETIES, particularly Kokur, used primarily for dry, still, and sparkling white wines. O.P.-T.

Criolla Chica is the Argentine name for the Listán Prieto of Spain, the PAÍS of Chile, the MISSION of California, and the Negra Corriente of PERU. It was thought to be descended from the seeds of grapes (presumably well raisined after their voyage under sail across the Atlantic) imported by the Spanish conquistadores possibly as early as the 16th century (see SOUTH AMERICA), but it was in fact introduced as CUTTINGS. Criolla Chica was planted on just 338 ha/835 acres in 2020 and is therefore much less common in Argentina than the other pink-skinned grape varieties CRIOLLA GRANDE and CEREZA. Its wine is generally paler but of a slightly better quality.

Criolla Grande, the fourth most planted vine variety in Argentina after MALBEC, CEREZA, and BONARDA, is a spontaneous Listán Prieto (CRIOLLA CHICA) × MUSCAT OF ALEXANDRIA cross. Although the area planted with this coarse, pink-skinned grape has declined substantially, there were still 13,348 ha/32,984 acres in 2020. Almost all Criolla Grande is in Mendoza province. Criolla Grande is a low-quality CRIOLLA and is lighter-skinned than CRIOLLA CHICA. The two Criollas, along with Cereza and Moscatel Rosada, form the basis of Argentina's declining trade in basic deep-coloured white or pale pink wine sold very cheaply in litre bottles or cardboard cartons.

Criollas, generic name for vine varieties that have been common in SOUTH AMERICA, particularly ARGENTINA, since the arrival of the

conquistadores. They include CEREZA, CRIOLLA CHICA, CRIOLLA GRANDE, various local Moscatels, PEDRO GIMÉNEZ, and various TORRONTÉS.

Criots-Bâtard-Montrachet, great white GRAND CRU in Burgundy's CÔTE D'OR. For more details, see MONTRACHET.

crise viticole, la, widely used phrase for France's wine crisis of 1907 (see LANGUEDOC) and also that of the early 21st century resulting from plummeting wine sales both at home and abroad. Sales stagnation affected not just the Languedoc, with its huge volumes of surplus VIN DE TABLE and VIN DE PAYS and its notoriously militant vignerons, but also AOC wines, notably MUSCADET and to a lesser extent BEAUJOLAIS and the less favoured parts of BORDEAUX.

critics, wine A subgroup of WINE WRITERS who see the assessment of specific wines, often SCORING them, as their principal role.

Crljenak Kaštelanski, 'the red wine grape of Kaštela', a region north of Split in Croatia. It has turned out to be ZINFANDEL and is being planted once more by Croatians. See also TRIBIDRAG.

Croatia, or Hrvatska, is one of the most successful wine producers of the former YUGOSLAVIA on the Balkan peninsula. In recent years Croatia has become hugely popular as a tourist destination with close to 21 million foreign visitors in 2019, vastly outnumbering its resident population of 4.1 million and creating a ready-made market for its wines.

History

Viticulture in this region dates to the ancient Greeks and possibly earlier with the Illyrians. The UNESCO-listed Stari Grad plain on the island of Hvar may be the world's oldest continuously cultivated viticultural site, dating to the 4th century BCE, with its original layout of geometric parcels, or *chora*, divided by stone walls. Grape-growing increased in importance under ROMAN occupation. The land was part of the Ottoman empire from the 15th century and was subsequently part of the Habsburg empire when grape-growing flourished until the arrival of PHYLLOXERA. Under 20th-century socialist rule, wine production became centred on large, collectivized state wineries.

The break-up of Yugoslavia and the brutal wars of independence that followed in the early 1990s had a significant effect on viticulture. In 2020, there were still around 17,000 uncleared landmines in the country. After a late start as an independent nation (compared with neighbours such as SLOVENIA and HUNGARY), Croatia has accelerated the development of a fascinating wine industry based on private wine producers, although it has suffered from the common Balkan problem of fragmented land holdings. In 2020, the country had 26,864 wine entities in its register, with 1,575 wine producers, though only 145 had over 10 ha/25 acres.

Geography and vine varieties

Falling within the latitudes of 46–42° N, Croatia stretches 1,880 km/1,170 miles along the Adriatic coast, with 1,244 islands adding a further 4,398 km of coastline. Within this are 18,759 ha/46,354 acres of vineyard in 2020, spread among 18 PDOs in two categories—*Vrhunsko Vino* (premium quality wines, 11.9% of 2019 harvest) and *Kvalitetno Vino* (quality wines, 72% of 2019 harvest)—plus table wines (*Stolno Vino*). The unusually wide range of climatic influences plus a plethora of grape varieties—Croatia claims to grow around 200 varieties, around 40 identified as indigenous—gives rise to an impressive diversity of wines.

The coastal regions of Istria and Kvarner have a mild climate, with MEDITERRANEAN influences meeting the cold air flowing down from the Alps, and share both climate and cultural influences with both north-east Italy and Slovenia. Iron-rich red soils are widespread. White wines dominate, particularly those made from MALVAZIJA ISTARSKA, Croatia's second most planted variety (1,626 ha in 2020). Most often vinified without oak in a fresh, fruity style, it also responds well to being picked later and vinified, often with extended SKIN CONTACT, in barrels of acacia or oak. Reds are less important in this region, with the most characteristic being TERAN (Terrano), a firm, high-acid variety grown on 237 ha in 2020. The name was the subject of dispute with Slovenia, which has registered 'Teran' as a protected term, but is now allowed provided 'Hrvatska Istra' is clearly specified on the label. Merlot produces some fine wines and is sometimes blended with Teran. The island of Krk's speciality is the delicate white Žlahtina grape. There are three PDOs: Primorska Hrvatska/ Hrvatsko Primorje, Hrvatska Istra, and Muškat Momjanski.

Dalmatia stretches south from Zadar to the country's southern border with MONTENEGRO and includes the important wine-growing islands of Korčula, Hvar, Vis, and Brač. Its often steep and rocky vineyards enjoy sunny summers and are noted for their treasure trove of INDIGENOUS VARIETIES. They produce some of the country's

most full-bodied reds, frequently over 15% alcohol. This is the only Croatian region where reds predominate, especially PLAVAC MALI (Croatia's third most planted grape with 1,427 ha/3,526 acres in 2020). This is the grape responsible for Dingač, the first protected designation in Croatia in 1965, from the seaside terraces of the Pelješac Peninsula. CRLJENAK KAŠTELANSKI, rescued from just nine vines at Kaštela near Split in 2002, was shown by DNA PROFILING to be ZINFANDEL (aka Tribidrag) and also a parent of Plavac Mali, along with Dobričić. It has since been planted much more widely. Babić (314 ha) is another good-quality red wine grape grown on famously stony coastal vineyards near Šibenik and the UNESCO-listed hillsides of Primošten. POŠIP (330 ha) is Dalmatia's most important white wine grape and is producing increasingly exciting wines, especially from Korčula, Hvar, and Brač. Other interesting pale-skinned Dalmatian varieties include Grk, Debit, Vugava, Bogdanuša, Gegić, and Maraština. A traditional sweet wine from dried grapes called Prošek is made on islands such as Hvar and Brač but is subject to legal action in 2021 from Italy's PROSECCO producers, who cite consumer confusion. Dalamatia's PDOs are: Sjeverna Dalmacija, Dalmatinska zagora, Srednja i Južna Dalmacija, Dingač, and Ponikve.

The inland zone of Slavonia and Croatian Danube is the home of Croatia's most important wine grape Graševina (WELSCHRIESLING, planted on 4,525 ha/11,181 acres). This relatively flat region of plains with a few low hills reaches as far north-east as the foothills of the Fruška Gora Range. White grapes predominate, and the long, warm autumns encourage the production of sweet, late-harvest whites. Graševina is often a workhorse grape but arguably reaches its peak around the historic town of Kutjevo and the Golden Valley area, while Traminac (GEWÜRZTRAMINER) can also be notable, especially around Ilok. More recent arrivals of INTERNATIONAL VARIETIES such as Chardonnay and Sauvignon Blanc are proving successful. Reds are led by Frankovka (BLAUFRÄNKISCH), but some promising wines have now been made from Pinot Crni (Pinot Noir), Merlot, and Cabernet Sauvignon. Slavonia is also famous for its OAK, particularly beloved of

Italian producers for their large oak casks (*botti*). PDOs are: Istocna Kontinentalna Hrvatska, Hrvatsko Podunavlje, and Slavonija.

The Croatian Upland region surrounding the capital Zagreb is the coolest zone, with small family vineyards dotted across green hillsides. International white grapes predominate, and some fresh, zesty Sauvignons, crisp Rieslings, and decent Pinot Gris and Pinot Noir, especially in Plešivica, have been produced. Also made are some impressive ICE WINES, increasingly good sparkling wines, and several NATURAL and ORANGE WINES. FURMINT under its local name of Pušipel is impressing in Zagorje-Međimurje in the north, in both still and sparkling versions. It also appears as Moslavac in Moslavina, where the native variety Škrlet is also found for fresh, fruity wines. PDOs are: Zapadna Kontinentalna Hrvatska, Moslavina, Prigorje-Bilogora, Plešivica, Pokuplje, and Zagorje-Međimurje E.M. & C.G.

www.vinacroatia.hr/en/

www.total-croatia-wine.com

Croatina, red grape variety from the borders of the PIEMONTE and LOMBARDY regions of northern Italy. The vine buds and ripens late but yields good quantities of fruity wine with a certain bite, designed to be drunk relatively young. Its common synonym is Bonarda, under which name it is used to make an appetizing VARIETAL red in the OLTREPÒ PAVESE zone of south-west Lombardia. The variety is quite distinct from BONARDA Piemontese. Total plantings of Croatina were 2,678 ha/6,617 acres in 2015.

Croft, port shipper with a particularly long history. Its precursor Phayre and Bradley was established in 1678 and a tercentenary

celebrated in 1978, but the head of the FLADGATE PARTNERSHIP, which acquired Croft in 2021, claims even earlier beginnings. The first Croft, from York, became a partner in 1736, and from 1769 the company was known as Croft and Co. In 1911 the firm was taken over by Gilbey's, and the majority shareholding eventually passed into the hands of the multinational corporation that became Diageo. Port shipper Morgan Brothers was acquired in 1952.

Croft expanded into the SHERRY business in the difficult era of the early 1970s, invading Jerez with energy and one novel idea: an entirely new style of sherry, Pale CREAM, which could offer the beguiling combination of a pale, sophisticated appearance with the reassuring sweetness of a cream. It was such an enormous and much-imitated success that a series of ultra-modern bodegas known as Rancho Croft was needed. Croft's Jerez adventure ended in 2001, when Diageo sold the bodegas to GONZÁLEZ BYASS for €54 million. Some of its best old SOLERAS were acquired by a new, quality-minded company, Tradición.

crop thinning, viticultural practice, known as *éclaircissage* or *vendange verte* (green harvest) in French, which is widely claimed to improve wine quality by encouraging fruit RIPENING. Some bunches are removed from the vine, and those remaining should in theory ripen more quickly with the benefit of improved LEAF TO FRUIT RATIO. Crop thinning is usually carried out by hand and is therefore expensive. MECHANICAL HARVESTERS are occasionally used to thin crops, removing individual berries or parts of bunches.

The YIELD is reduced more or less proportionately to the bunches removed (although the remaining berries may be slightly enlarged), which means that only those growers able to guarantee top prices for their produce can afford the operation. The technique became common in the early 1990s among the better wine producers in Bordeaux, where it had been practised at PETRUS since 1973.

Crop thinning is normally carried out at the start of VERAISON, when it is obvious which bunches are slow to ripen. This is also referred to

as colour thinning. It is cheaper if done earlier, but there is a risk that the remaining bunches will become too tight due to larger berries and so be prone to BOTRYTIS BUNCH ROT. Later bunch removal has more impact on yield, and earlier removal on fruit ripening. Crop thinning is common for varieties with large bunches, such as Merlot, and for Pinot Noir, again especially for CLONES with large bunches.

Thinning is also appropriate when it is obvious that the vintage will be late, decreasing the chance of ripening a large crop, and when yield estimates suggest there is going to be more crop than can probably be ripened, especially in cool climates.

The theory of crop thinning is that the remaining fruit ripens earlier and so has better levels of SUGARS and ANTHOCYANINS for red varieties. However, many studies have shown that these benefits are limited and that crop levels need to be greatly reduced for a small change in GRAPE COMPOSITION. For many vineyards where the yield is in BALANCE with shoot growth and the leaves and fruit are well exposed, there will be little benefit from crop thinning. Some viticulturists believe that thinning may bring more psychological benefit to the grower than physiological benefit to the vine and that thinning is best done on the day of harvest. R.E.S.

Reeve, A., et al. 'Vineyard floor management and cluster thinning inconsistently affect "Pinot Noir" crop load, berry composition, and wine quality', *Hortscience*, 53/3 (2018), 318–28.

Reynier, A., *Manuel de viticulture* (12th edn, 2016).

cross, the result of breeding a new variety by crossing two VINE VARIETIES, or the natural (i.e. spontaneous) crossing of two varieties in the field without human intervention. If the varieties are of the same species, usually the European VITIS VINIFERA species, then the result may also be known as an intraspecific cross—MÜLLER-THURGAU would be one example. Crosses of the same species are different from HYBRIDS, sometimes called interspecific crosses, which contain the genes of more than one species of the VITIS genus.

cross-flow filtration. See FILTRATION.

Crouchen, or Cruchen, white grape variety producing neutral wines in both South Africa and Australia. It originated in the western Pyrenees of France but is no longer grown there in any quantity, thanks to its sensitivity to FUNGAL DISEASES. There are records of its shipment to the Clare Valley in SOUTH AUSTRALIA in 1850, and it was long confused with Sémillon, which Australians were wont to call Riesling. It was therefore known principally as Clare Riesling in Australia until 1976, when AMPELOGRAPHER Paul Truel identified it as this relatively obscure French variety. Just 33 ha/82 acres remained in 2022. The South Africans finally started to name their Crouchen correctly rather than calling it Cape Riesling just as it virtually disappeared from their vineyard statistics, with a 2020 total of 159 ha.

crown caps, small metal caps used on beer and soda bottles, have proved to be a very reliable closure for long-term wine-bottle storage (see Helmut BECKER) and provide an extremely cheap and efficient closure for any sort of liquid. Many wine drinkers find their association with what they regard as less sophisticated drinks unacceptable, particularly in a restaurant, but they have been enjoying a modest renaissance with the PET-NAT category. The crown cap is also used nearly universally for closing SPARKLING WINE bottles during the TIRAGE process; DISGORGING is much more difficult if a cork has to be extracted. Some sparkling wines have been released under crown seal in Australia and California, to minimize the possibility of CORK TAINT.

crown gall, BACTERIAL DISEASE which occurs on over 600 plant species, including vines, particularly when grown where winters are so cold that vines can be damaged (see WINTER FREEZE). High incidence of the disease can make vineyards uneconomic. The

debilitating effects of crown gall following freeze injury is an important limitation to the commercial cultivation of all VITIS VINIFERA varieties in regions or sites subject to very cold winter temperatures. The disease is much less common in cold-tolerant species and HYBRIDS.

Crown gall, also known as black knot, is caused mainly by *Agrobacterium vitis* (occasionally by *Agrobacterium tumefaciens*, the predominant causal agent in other crops). The major symptom is the growth of fleshy galls (tumours) on the lower trunk which can girdle the trunk and cause portions of the vine above to die. The bacterium lives inside nearly all vines and so is routinely spread via propagation and if infected stock is planted, but it causes disease only after injury occurs. Control is difficult. Research in the early 1990s showed that hot-water treatment of dormant CUTTINGS (50 °C/122 °F for 30 minutes) reduces levels of the bacterium, and TISSUE CULTURE can provide total elimination, allowing production of nursery stock free of *Agrobacterium*. Avoiding the pathogen in new plants can significantly reduce the impact of sub-lethal winter-freeze injury to trunks. In the north-eastern United States, growers train the vines with up to five trunks so that there is always a young healthy trunk to replace dead or dying ones, a technique that also helps to manage TRUNK DISEASES. See TRAINING SYSTEMS. W.W.

Wilcox, W. F., et al., *Compendium of Grape Diseases, Disorders, and Pests* (2nd edn, 2015).

Crozes-Hermitage, the northern RHÔNE'S largest appellation, regularly producing more than 13 times as much wine as the much more distinguished vineyards of HERMITAGE which it surrounds, and around 25% more than the similarly priced, and similarly extended, appellation of ST-JOSEPH across the river. Like both these appellations, Crozes-Hermitage is usually red and made exclusively of the SYRAH grape, although just over one-tenth of production is full-bodied dry white wine made from the MARSANNE grape supplemented by

ROUSSANNE. Up to 15% of white grapes may be added to red Crozes at FERMENTATION, though in practice this is extremely rare.

The appellation was originally granted to the village of Crozes to the north of Hermitage in 1937, then it was extended in 1952 to include a further ten communes. The terroir is far from homogeneous, however. The cooler, GRANITIC hillsides to the north of Hermitage (at Gervans, Érôme, and Serves-sur-Rhône) typically produce a lean, fresh style of wine. The Syrah grown on the successive flat GRAVEL and CLAY terraces to the south and east of Hermitage (at Chanos-Curson, Beaumont-Monteux, Pont-de-l'Isère, and La Roche-de-Glun) is relatively rich and generous. The communes of Mercurol and Larnage, with its white kaolin clay, were historically better known for whites and today produce fine examples of both colours. Total vineyard area in production expanded by about one-quarter between 1990 and 2005; by 2020 wine was produced by 1,818 ha/4,492 acres. Around half of this is produced by the high-quality CO-OPERATIVE Cave de Tain. The appellation's best reds can be kept for five years or more (and in good years can happily survive for ten or more), but the average Crozes, red or white, is usually at its best drunk young. M.C.W.

cru, French term for a vineyard, usually reserved for those officially recognized as of superior quality. Such recognition was already known in ancient ROME. In English the word is often translated as 'growth' (*crû* is the past particle of *croître*, 'to grow'). PREMIERS CRUS, for example, are called FIRST GROWTHS in BORDEAUX, according to one of their official CLASSIFICATIONS. A cru that has been 'classified' is a cru classé, or CLASSED GROWTH. In Bordeaux, the term 'cru' is applied to an estate and its vineyards. In BURGUNDY's vineyard hierarchy, on the other hand, it is applied to a vineyard, with 'premier cru' being the level below GRAND CRU. The latter can have a very specific meaning, notably in ALSACE.

The ten top-ranked communes in BEAUJOLAIS are called crus, and their produce is cru beaujolais. The term 'cru' also refers to a DÉNOMINATION GÉOGRAPHIQUE COMPLÉMENTAIRE and may precede the name of the DGC on the label.

In SWITZERLAND, the first two vineyards to be officially awarded grand cru status were the neighbouring Dézaley and Calamin in Vaud.

The term has been enthusiastically adopted in Italy, most recently to refer to superior vineyards that have achieved the status of MGA. The local dialect for a site of the highest quality in PIEMONTE is SORÌ.

cru artisan was recognized by the EU in 1994 as a 'traditional expression' reserved for AOC wines from a particular category of wine estates in the Médoc, Haut-Médoc, Margaux, Moulis, Listrac, St-Julien, Pauillac, and St-Estèphe. A cru artisan is more humble, and generally much smaller, than a CRU BOURGEOIS.

cru bourgeois, a category of red-wine properties, or CRUS, designated bourgeois, or a social stratum below the supposedly aristocratic crus classés, in the MÉDOC region of Bordeaux. While the crus classés represent about 25% of the Médoc's total wine production from 60 estates, the crus bourgeois, from a possible total of more than 250 generally much smaller estates, represent a further 30% or so. The properties can vary, however, from simple smallholdings to others such as Ch Larose-Trintaudon, the largest estate in the Médoc, or Ch Lilian Ladouys of St-Estèphe, which totals 80 ha/198 acres.

The description 'cru bourgeois' has been used orally for several centuries and appeared in an early edition of Cocks et FÉRET in the mid 19th century, but the First World War and then the dire state of the international wine market at the end of the 1920s called for a new impetus. A first CLASSIFICATION of the crus bourgeois of the Médoc was drawn up in 1932, and one can only imagine the difficulties of bestowing this supposed commercial advantage, ranked

into three classes, on a few hundred Médoc wine farmers. Thirty years later, when the Syndicate of Crus Bourgeois set about revitalizing itself, it was discovered that, of the 444 members registered in 1932, more than 300 had been absorbed into other estates or converted their land from viticulture to another crop such as pines instead. The lack of official recognition by the Minister of Agriculture when the list was first drawn up in 1932 was a constant source of difficulty and potential abuse of the title, but the designation 'Cru Bourgeois' was officially recognized in the EU labelling laws of 1979 on condition that its use be codified by the French government.

In 2003 there was an ill-fated attempt to draw up a permanent classification of crus bourgeois properties, but from 2008 cru bourgeois became not an official designation of estates but a self-regulated accolade awarded annually to particular wines on the basis of BLIND TASTING by a professional panel and announced each September two years after the harvest. In 2020 the focus reverted once again to estates, with the introduction of a five-year classification awarded on the basis of a blind tasting of five vintages renewable every five years. Additionally, as of 2025, all crus bourgeois wineries must be farmed under SUSTAINABLE VITICULTURE, achieving at least HVE Level 2 status, with Level 3 reserved for Supérieur and Exceptionnel properties. Thus the number of crus bourgeois varies. In general this category can offer some of Bordeaux's best-value and most accessible wines. They are made mainly from Cabernet Sauvignon grapes but often contain a high proportion of Merlot, usually supplemented by some Cabernet Franc. Some BARREL MATURATION is usually involved in the making of the most highly priced crus bourgeois, even if only a small proportion of new OAK is lavished on this wine category. However, viticulture and winemaking at the best crus bourgeois can be very similar to that practised by the crus classés (even if the selling prices are much lower). The wines are generally ready to drink between four and eight years old, but the best may be aged up to 15 years.

J.R. & J.L.

Cruess, William Vere (1886–1968), biochemist, teacher, and author, was the link between work in wine research and teaching of the pre-PROHIBITION and post-Repeal eras in CALIFORNIA and thus had a central role in the restoration of the California wine industry. Professor of Food Technology at the University of California at Berkeley, Cruess had researched FERMENTATION before Prohibition. In the 'dry years' he studied such things as the production of grape syrup and other VINE PRODUCTS. Immediately upon Repeal he undertook to re-establish viticultural and oenological research at the University of California and did so with remarkable speed and efficiency. His *Principles and Practices of Wine Making* (1934) was the first work for the guidance of commercial winemaking published after Repeal.

Cruet, CRU east of the vermouth town of Chambéry whose name may be added to the eastern French appellation SAVOIE for white wines from the JACQUÈRE variety. Cruet is dominated by the region's largest CO-OPERATIVE. W.L.

crush, mainly American term for the whole HARVEST season, named after one of the first processes in the winery (CRUSHING) rather than what happens in the vineyard.

crusher-destemmer. See DESTEMMER-CRUSHER.

crushing, winemaking operation of breaking open the grape berry so that the juice is more readily available to the YEAST for FERMENTATION. It increases the initial speed of EXTRACTION of colour and flavour components from the skin, and in white-wine production it increases the speed of juice DRAINING but releases juice with higher solids levels compared with WHOLE-BUNCH PRESSING.

Crushing was traditionally done by foot, but this is relatively inefficient and expensive. However, it is said to be more gentle than mechanical crushing and is prized in regions such as the DOURO. It can also useful in small-scale winemaking. Modern crushers generally use intermeshed counter-rotating rollers spaced just far enough apart to pass grape seeds (which can exude bitter TANNINS if smashed). Typically, crusher rollers are attached as an extra stage on destemmers (see DESTEMMING). In practice, the destemmer itself may also result in some degree of grape crushing, as do pumps that might be used to move grapes to a PRESS or fermentation tank. Machine harvesting may also result in a small degree of crushing. S.N.

Nordestgaard, S., 'Gentle or intense grape crushing?', *Australian and New Zealand Grapegrower and Winemaker*, 639 (2017), 77–82.

crust, name for the SEDIMENT that forms in bottle-aged PORT. Crusted port is a style of port created by British shippers in order to provide some of the qualities of vintage port in a shorter time and therefore at a lower price.

cryoextraction, or freeze CONCENTRATION (*cryo* referring to very low temperatures), the winemaking practice of freezing grapes prior to PRESSING first proposed by French OENOLOGIST Serge Chauvet. It replicates the process of leaving grapes to freeze on the vine that is essential to the production of ICE WINE and may be used to reduce dilution, for example to concentrate the juice from BOTRYTIZED grapes in wet vintages when natural conditions do not allow this to happen on the vine. Freshly picked grapes are held overnight at sub-zero temperatures, −5 or −8 °C/15 °F, and then pressed immediately. The freezing point of grape must depends on its concentration of sugars, so only the less concentrated grapes freeze. Pressing the grapes straight out of the cold room therefore yields only the juice of the non-frozen, ripest grapes, whose chemical composition remains

unchanged. The colder the grapes are kept, the less juice is obtained, but it will be the most concentrated from the ripest grapes. In the late 1980s a few SAUTERNES properties experimented with the technique, and it is still used at some CLASSED GROWTHS. Cold rooms at a temperature of around −2 °C may also be used for so-called 'supraextraction', an alternative to MACERATION. Freezing and then thawing the skins releases more FLAVOUR PRECURSORS. V.L. & A.O.

crystals in a bottle of white wine, on the underside of a cork, or on the inside of a vat are harmless deposits. See TARTRATES for a full explanation.

Cserszegi Fűszeres, IRSAI OLIVÉR × TRAMINER cross developed in Hungary in 1960 and widely planted there for basic grapey wines. Plantings totalled 3,999 ha/10,102 acres in 2021, mainly in Kunság.

CSIRO (Commonwealth Scientific and Industrial Research Organization), founded in 1926, is Australia's national science agency and one of the world's largest and most diverse research institutions. Its charter covers research into areas of economic, environmental, and social benefit to AUSTRALIA. Early grapevine research focused on solving immediate problems relating to the adaptation of northern-hemisphere practices, irrigation, and pest and disease control to the new Australian viticultural frontiers.

After the Second World War, CSIRO's viticultural research broadened to include nematology (see NEMATODES), IRRIGATION, hydrology, and basic VINE PHYSIOLOGY. In the 1960s, there was an even greater shift in emphasis to viticultural research. A new laboratory was opened on the Waite Campus in ADELAIDE to accommodate a group of plant physiologists. As well as conducting seminal research into topics including plant hormones, FLOWERING, and FRUIT SET, more applied research stimulated changes in industry practices, such as the introduction of the complementary

management techniques of MINIMAL PRUNING and MECHANICAL HARVESTING.

CSIRO holds Australia's largest collection of grapevine germplasm at Irymple, Victoria, which includes around 680 varieties and many non-VITIS VINIFERA species. VINE BREEDING and selection has yielded a number of new varieties such as TARRANGO, TAMINGA, TYRIAN, CIENNA, and Mystique as well as successful table grapes and RAISINS.

In the 1990s, CSIRO extended its research to encompass computer modelling of vine growth, water and nutrient application, YIELD estimation, DNA PROFILING to identify varieties, and PRECISION VITICULTURE. GENETIC MODIFICATION is an increasingly important avenue of research in viticulture worldwide, and CSIRO achieved the transformation of SULTANA and a range of wine grape varieties in the late 1990s. The genes controlling the production of colour, TANNINS, and FLAVONOLS in berries were also identified.

New CSIRO wine-grape research initiatives include a focus on disease resistance, RIPENING, abiotic stress, and flavour and aroma development in berries, this last aimed at understanding the management and genetics of grape flavour and aroma and links to final wine style.

Results of CSIRO research have given Australian viticulturists access to improved varieties, ROOTSTOCKS resistant to salt and nematodes, and water and nutrient management strategies suited to intra-vineyard variation and different environments. P.B.

Cuba. Attempts have been made to establish commercial vineyards on this tropical Caribbean island since Spanish colonists arrived in the 1500s, but most Cuban wines today rely on imported bulk wine or home-grown fruit.

cultivar, term developed by professional botanists to mean a group of plants sharing common characteristics persisting under cultivation that have either been selected or otherwise genetically manipulated

by humans. According to the rules of plant taxonomy, 'cultivar' would be a more appropriate term than VARIETY, but it does not have a wide following outside professional botanists and horticulturists, except in South Africa where it is widely and generally used. It has a major deficiency in that it has no adjectival form and, therefore, no counterpart to VARIETAL.

cultivation. See TILLAGE.

curettage, *curettage* in French, also known as vine surgery or dendrosurgery, the surgical removal of dead wood to prolong the life of vines affected by TRUNK DISEASES.

> Cholet, C., et al., 'Plant resilience and physiological modifications induced by curettage of Esca-diseased grapevines', *OENO One*, 55/1 (2021).

currants, small, dark, dried grapes (see RAISINS) made from the Greek vine variety KORINTHIAKI, called Zante Currant in Australia and Black Corinth in California.

Currency Creek, a cool MARITIME region in the Fleurieu Zone of SOUTH AUSTRALIA producing BORDEAUX BLENDS (white and red) and Shiraz from 1,032 ha/2,550 acres of vines in 2022.

Curtefranca. See FRANCIACORTA.

custom-crush facility, American term for a winery specializing in vinifying grapes on behalf of many different vine-growers, typically those without their own winemaking equipment. The various wines are kept separate and marketed by the growers under their own labels. Such operations have played an important part in establishing

ambitious new wine producers, as in CALIFORNIA and Long Island in NEW YORK, and indeed whole new wine regions such as Marlborough and Central Otago in NEW ZEALAND, where new or small-scale growers can ill afford to build their own wineries.

Custoza, or Bianco di Custoza, an increasingly ambitious dry white wine produced in the VENETO region of north-east Italy in a wide stretch of territory extending south-west from the city of Verona partially overlapping the BARDOLINO DOC zone on the shores of Lake Garda and immediately south of the lake. The vineyard area planted increased from 1,200 ha in 2011 to 1,400 ha/3,459 acres in 2020, reflecting the wines' growing market value. The blend historically consists of Fernanda (CORTESE), GARGANEGA, and Trebbianello (a local strain of FRIULANO), with Trebbiano Toscano a minor ingredient. The result can be captivating, with Cortese adding perfume and precision, Friulano weight, and Garganega depth. Research in SOIL composition and MESOCLIMATES has resulted in the identification of ten subzones in the DOC, which has led to greater attention in matching varieties to soils. This, in combination with lower yields and modest prices, makes Custoza one of Italy's best-value white wines. W.S.

www.custoza.wine

cut cane, viticultural technique designed to increase the sugar concentration in almost-ripe grapes. The term originated in Australia, where the technique is typically used to produce sweet wines, but it is apparently also used very occasionally for dry red wines in Italy, where it is referred to as *taglio del tralcio*. By cutting the canes almost at the time of HARVEST, water supply to the fruit is halted, and so the berries start to shrivel (as in the production of DRIED-GRAPE WINES). Sugar concentration is elevated as water is lost through the

berry skin, and ACIDITY may also be increased. The technique, resulting in grapes known as PASSERILLÉS in French, was developed to avert rain spoilage of grapes intended for drying. R.E.S.

cuttings, cut lengths of CANES used for vine PROPAGATION. Cuttings are the basis of propagation for commercial grape production, whether as own-rooted plants (see ROOTLINGS) or as SCION varieties for GRAFTED VINES. Both methods are representative of asexual or vegetative propagation, and the progeny are considered as CLONES of the source vines. In commerce, cuttings are cut from dormant vines in lengths of 30–45 cm/12–18 in. Once made, the cuttings are kept cool and moist and planted in a nursery in spring for roots to form at the base and a shoot to grow from the top bud. The plant is now called a rootling. It is typically lifted from the nursery in autumn and planted in its vineyard position the following spring. B.G.C.

cutworms, the larvae of several species of MOTHS, are a serious pest for all sorts of crops worldwide, including grapevines. They hide in the soil or under the vine's bark during the day and emerge to feed and cause damage at night, particularly to the buds. Young vines are particularly prone to damage. Cultural practices, natural enemies, and climatic factors may keep cutworms to tolerable levels, but there are no really effective insecticides.

University of California Agriculture & Natural Resources, UC IPM Pest Management Guidelines: cutworms. www2.ipm.ucanr.edu/agriculture/grape/Cutworms/.

cuve is the French word for a vat or tank. Thus a *cuverie* is the vat hall, typically where fermentation takes place. *Cuves* may be made of any material—wood, concrete or, most likely, stainless steel—and come in many different shapes and sizes. See FERMENTATION VESSEL.

cuve close, French for ‘sealed tank’. See TANK METHOD.

cuvée, French wine term derived from CUVE, with many meanings in different contexts. In general terms it can be used to mean any containerful, or even any lot, of wine, and therefore wine labels often carry relatively meaningless descriptions incorporating the word *cuvée*. *Tête de cuvée*, on the other hand, is occasionally used for the top bottling of a French wine producer.

In CHAMPAGNE and in relation to other traditional-method sparkling wines, *cuvée* is a name for the first and best juice to flow from the press (see SPARKLING WINEMAKING). The blend of base wines assembled for second fermentation in bottle is also known as the *cuvée*. Thus the term is often used in many champagne and sparkling wine names.

Elsewhere, *cuvée* may be used to describe any ambitious blend, particularly of different vine varieties. German speakers often use the term to refer to any sort of blend, preferring it to German *Verschnitt*.

Cyprus, eastern Mediterranean island about 800 km/500 miles east of GREECE and 75 km south of TÜRKIYE. Most wine production is concentrated in the southern Greek part of the island. The few wineries that do exist in the northern Turkish-controlled zone are of little commercial significance. Despite the island’s importance in the ancient wine trade (see below), Cyprus wine languished in terms of quality for most of the 20th century. Investment from the 1990s led to an improvement in production techniques and resulting wines; EU membership in 2004 stimulated even greater changes and restructuring of the industry. However, production dwindled to just 7,613 ha/18,812 acres by 2020. Of these, 583 ha/1,440 acres were new plantings.

History

Wine cultivation and production in Cyprus are believed to date back 5,500–6,000 years. Archaeological evidence including residue from stone press bases and vats confirm winemaking in Cyprus in the Early Bronze Age (2,100–2,000 BCE). Because of its position in the eastern Mediterranean, the island has changed hands many times. In antiquity, domination by various foreign powers alternated with brief periods of independence. In 58 BCE Cyprus became part of the Roman province of Cilicia in Asia Minor. In 668 CE Cyprus was occupied by Arabs; when they were finally expelled in 965, Cyprus became an advance base of the Greek navy. In 1191, during the Third CRUSADE, Richard I, king of England, conquered Cyprus and sold it to the Templars, who soon gave it back to him, whereupon he presented it to the rejected king of Jerusalem, Guy de Lusignan. Guy de Lusignan imposed a feudal system on Cyprus and governed the island as a separate kingdom, which it remained until it became a colony of then-powerful VENICE in 1489.

The Crusaders and Venetian expansionism made the island part of the Latin West, which soon became fond of its wines. The earliest record of Cyprus wine being drunk in the West is dated 1178 when Count Baldwin of Guines offered it to the Archbishop of Reims. The Old French poem *La Bataille des vins* (see MEDIEVAL LITERATURE) awards the palm to *chypre*, Cyprus wine, because it is stronger and sweeter than any wine in western Europe (FORTIFICATION and MUTAGE were as yet unknown). We do not know when the wines of Cyprus first reached the English market, but in the 13th and 14th centuries they, along with other sweet wines from the East and from Italy (see ENGLAND), fetched higher prices than the wines of GASCONY and LA ROCHELLE. The Venetians shipped them from Cyprus to Venice in their galleys, and from Venice they distributed them all over Europe.

The modern Cypriot dessert wine, Commandaria, harks back to the Crusades, when the Knights Hospitallers moved their

headquarters from Acre to Cyprus, where each 'commandery' (manor) made wine. For more details, see COMMANDARIA.

Simon, A. L., *The History of the Wine Trade in England*, 3 vols. (1906–9).

Modern history

Ottoman rule (1571–1878) brought a steep decline in both wine production and the importance of the wine industry, which remained underdeveloped until the middle of the 19th century. The first of the modern wineries, Haggipavlu, was founded in 1844. British administration of the island (1878–1960) saw a revitalization of the industry.

After the Second World War, most of the island's wine exports fell into four categories: large volumes of very basic wine for Eastern Bloc countries; wine intended for industrial uses such as VERMOUTH, SANGRÍA, or, in German-speaking countries, *Glühwein*; GRAPE CONCENTRATE sent to Japan, Central and Eastern Europe, and the United Kingdom, where it was reconstituted and made into BRITISH WINE; and Cyprus FORTIFIED WINE.

This was Cyprus 'sherry'-style wine, medium and medium-sweet, fortified and exported in millions of cases, mainly to Britain. From the 1980s the style died out as fresh white wine became technically possible. Cyprus lost over 70% of its vineyard land in the 1980s and 1990s. Entry into the EU in 2004 put an end to government grape price subsidies, and vineyard land further contracted.

By 2020 the downward trend was beginning to reverse. The big four wineries—KEO, ETKO (Haggipavlu family), SODAP (a CO-OPERATIVE, also known as Kamenterena Winery), and LOEL—had dominated production for decades, but a new generation of winegrowers were busy either buying and replanting vineyards or developing relationships with small landowners in a pursuit of quality- rather than quantity-driven production. In 2020, the Department of Agriculture recorded 3,800 ha/9,390 acres of vines and 116 registered wineries, up from 52 wineries in 2014.

Climate and geography

At latitude 35° N, Cyprus has a typically MEDITERRANEAN climate, with mild winters, hot summers, and precipitation mainly confined to the winter months. However, the island's central mountain massif rises to over 1,700 m/5,577 ft in ELEVATION. Summer temperatures can vary more than 12 °C/54 °F between low- and high-elevation vineyards. Harvest extends from mid July into early November depending on grape type and site elevation.

Rainfall is low, at 500 mm/19 in per annum at lower elevations and 900 mm/35 in for the higher. DRIP IRRIGATION is permitted but rare because of limited water availability and very fragmented, small vineyard holdings.

Most wine vineyards are on the south- and west-facing slopes of the Troodos Mountains, the best at elevations of 500–1,500 m/1,650–4,950 ft. To bring the industry in line with the EU, a CONTROLLED APPELLATION scheme has been developed, with PDOs for Commandaria, Laona Akama, Pitsilia, Vouni Panayia-Ambelitis, Krasochoria Lemesou, Krasochoria Lemesou-Afames, and Krasochoria Lemesou-Laona, although the scheme has so far been little used except for Commandaria. More common are the four PGI regions: Pafos/Paphos, on the western side of the island; Lemesos (Limassol in anglicized form) to its east, stretching from the southern coast up into the Troodos Mountains and encompassing the Commandaria PDO; Larnaca further east along the coast; and Lefkosia, inland and encompassing PDO Pitsilia, where vines grow at elevations as high as 1,450 m/4,757 ft.

Pitsilia and the northern half of Commandaria have igneous soil and subsoil. Elsewhere soils are of sedimentary LIMESTONE with a particularly high active LIME content.

Climatic hazards are restricted to HAIL and, in higher-elevation vineyards, spring and autumn FROST. The lack of humidity means that DOWNY MILDEW is unknown, but growers regularly spray against POWDERY MILDEW. BOTRYTIS is found only in grape bunches that have

previously been attacked by eudemis MOTHS or other INSECTS. Almost all vines are GOBELET trained, except for some non-indigenous varieties supported by TRELLIS SYSTEMS.

Vine varieties

Cyprus has never been invaded by PHYLLOXERA, and its UNGRAFTED VINES are protected by strict QUARANTINE, slowing the introduction of INTERNATIONAL VARIETIES. Save for SYRAH—which, as elsewhere around the Mediterranean, is really at home here—and white varieties Chardonnay, Sémillon, and Sauvignon Blanc, the focus is on native varieties. PALOMINO and MUSCAT OF ALEXANDRIA (called Malaga here), once popular for use in fortified wines, have declined steeply in hectarage. Only Viognier, ASSYRTIKO, and one or two other Greek varieties have arrived recently.

Since 2004, production of the island's largest-production varieties, MAVRO and XYNISTERI, has nosedived, as winegrowers change emphasis from quantity to quality and as well as abandon low-elevation vineyards in preference for cooler altitudes in the face of CLIMATE CHANGE.

Today Xynisteri is the most common white variety in Cypriot vineyards, accounting for 27.5% of the total annual production in 2022, marking the success of white wine sales for summer drinking for the tourist trade. Rosés do well, too.

Although Cyprus does produce serious, long-lived dry red wines, these are only just becoming appreciated. Mavro remains the dominant red wine grape, but more attention to matching grape varieties to MESOCLIMATE has instigated a rediscovery of ancient varieties: MARATHEFTIKO (called Vamvakada in Pitsilia), a feminine variety that needs to be co-planted with a pollinator but has great colour, fine-grained tannins, and black- and red-cherry flavour, now produces nearly a half-million tonnes per year, and the deeper, darker, wilder Lefkada is also increasing in volumes. Yiannoudi, a newly rediscovered sister grape to Maratheftiko, has made its way into commercial production in the last decade. Rediscovered white grapes including Spourtiko (light, apple-y, low alcohol), Promara (riper, more pronounced apple and pear flavours), Morokanella/Kanella (warmer,

more floral), and its cousin Vassilisa (similar but more delicate) are just creeping on to the market.

cytokinins, natural HORMONES in vines produced in the root tips and affecting the growth of other parts of the plant. Cytokinins favour cell multiplication and affect growth and development of SHOOTS and INFLORESCENCES. Fewer cytokinins are produced in dry soils as well as in cold and wet soils, and this appears to be critical for BUDBREAK and early shoot growth.

Czechia officially split from SLOVAKIA in 1993, taking less than one-third of the productive vineyard area, just over 40% of wine production, and around two-thirds of the wine consumption of the original Czechoslovakia. In 2018, the republic counted 18,200 ha/44,500 acres of vines, which fulfils only 60% of the local demand, so very little Czech wine is exported.

About two-fifths of the country's vineyards lie on gentle slopes, usually topped by forests, while the rest are on undulating plains which slope towards the Danube Basin. The republic and its vineyards divide into two distinct regions: the tiny vineyards of PDO BOHEMIA on the banks of the River Labe (Germany's Elbe) in the north; and the larger PDO MORAVIA to the south along the Austrian and Slovakian borders.

In terms of GEOLOGY, both regions are very varied. In BOHEMIA vines are traditionally planted on the warm slopes of the main rivers

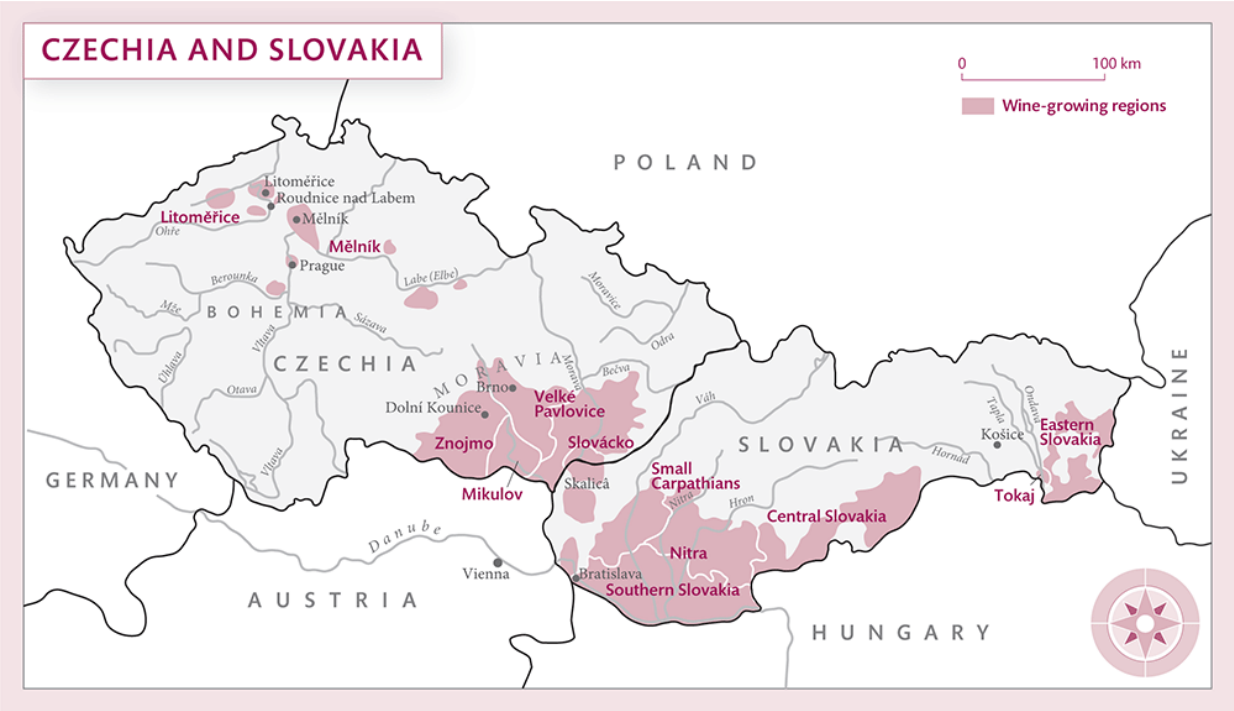
Labe and Vltava. In Prague the subsoil is mostly Silurian and Devonian LIMESTONE with various VOLCANIC components; Mělník and Roudnice are mostly on 'opuka', limestone marl, while in the north around Litoměřice the soil is predominantly alkaline BASALT. Moravia´s most notable terroir is the GRANITE of Brno Massif in Dolní Kounice and the Jurassic limestone of the Pálava Hills. The lower reaches where most vineyards are situated tend towards CLAY and SAND, but the major influences are the relatively low ELEVATION (100–250 m/330–820 ft above sea level) and the CONTINENTAL CLIMATE. Rainfall in Moravia is relatively low, on average 510 mm/20 in annually, which has encouraged the adoption of ORGANIC VITICULTURE. A trend in NATURAL WINE has become significant, too, led by Milan Nestarec.

Because of their position north of the Danube, most of the slopes face south and are protected by higher land in the north. The vines are trained like those of Germany and Austria, mostly using the Rhinehessen pruning system. Nearly 65% is planted to white grapes, particularly Veltlínské Zelené (GRÜNER VELTLINER), MÜLLER-THURGAU, Ryzlink Rýnský (RIESLING), Rulandské Bílé (PINOT BLANC), Ryzlink Vlašský (WELSCHRIESLING), and Rulandské šedé (PINOT GRIS). The aromatic variety Pálava (MÜLLER-THURGAU x Traminer) is on the rise and very promising in both dry and sweet wines. Also notable are wines from Sylvánské zelené (SILVANER), Neuburské (NEUBURGER), and Moravian Muscat (Muscat Ottonel x Prachtraube). Plantings of HYBRIDS such as SOLARIS, Hibernal, and Johanniter have grown, too, especially for organic growers. The country has the world's largest area of Svatovavřinecké (ST-LAURENT) at 1,012 ha/2,500 acres, but the most planted red variety is Frankovka (BLAUFRÄNKISCH), followed by ZWEIGELTREBE, PINOT NOIR, and Modrý Portugal (PORTUGIESER). There are many other interesting dark-skinned varieties, including Czech crossings such as André, Alibernet, Cabernet Moravia, and Neronet.

Wine laws in Czechia are modelled on German wine laws, using as a basis RIPENESS, here measured in °NM (normalized MUST WEIGHT measurement) similar to the KMW scale of Austria although 1 °CNM

denotes 1 kg of sugar per 100 l of grape must while 1 °KMW denotes 1 kg of sugar in 100 kg of must. CHAPTALIZATION is allowed and sometimes practised, although less so given CLIMATE CHANGE. In addition to PDO and PGI classifications, Czech wines may also be classified by VOC (*Víno originální certifikace*), an appellation system based on place and grape varieties. Of the 13 VOCs, the most noteworthy are VOC Znojmo, the oldest, focusing on Sauvignon Blanc, Grüner Veltliner, and Riesling; VOC Pálava (in Mikulov) for Welshriesling on limestone; and VOC Modré Hory (in Velké Pavlovice) for St. Laurent, Bläufrankish, and Blauer Portugieser.

SPARKLING WINE, ICE WINE, and STRAW WINE are also Czech specialities. K.K.



D

DAC, Districtus Austria Controllatus, denotes AUSTRIAN appellations of origin established and regulated by grower-dominated regional wine committees and intended to define and promote a typical style and flavour profile (or multiple profiles, including specified grape varieties) for each of Austria's growing regions. With the approval of the Thermenregion DAC in 2023, all 17 of Austria's winegrowing regions have DACs, listed here alphabetically with each one's inaugural vintage:

CARNUNTUM (2019)
EISENBERG (2009)
KAMPTAL (2008)
KREMSTAL (2007)
LEITHABERG (2008)
MITTELBURGENLAND (2005)
NEUSIEDLERSEE (2011, revised and much expanded from 2020)
ROSALIA (2017)
RUSTER AUSBRUCH (2020)
SÜDSTEIERMARK (2018)
THERMENREGION (2023)
TRAISENTAL (2006)
VULKANLAND STEIERMARK (2018)
WACHAU (2020)
WAGRAM (2002)
WEINVIERTEL (2002)
WESTSTEIERMARK (2018)
Wiener Gemischter Satz (2013; see WIEN)

A potential revision of the DAC governing Wien to encompass that region's wines from Grüner Veltliner and Riesling is under discussion.

The capital letters DAC appear on labels in immediate conjunction with the relevant name. In some instances, a separate DAC Reserve tier is legislated. D.S.

Dão, REGIÃO DEMARCADA since 1908, this DOC in north-central Portugal produces some of the country's most elegant, mineral wines (see map under PORTUGAL). Locked in on three sides by granite mountains and sheltered from the Atlantic, Dão benefits from long, warm summers and abundant winter rainfall (which supports the pine forests whose resin notes can be detected in mature Dão wines, especially reds, but also those made from ENCRUZADO). GRANITIC sandy soils are well drained (sometimes too well drained—WATER STRESS can prejudice ripening in the lead-up to harvest). Small and scattered, the vineyards (which cumulatively occupy just 3.5% of the DOC's footprint) are stocked with a wealth of INDIGENOUS VARIETIES, including Portugal's flagship red grape TOURIGA NACIONAL which is thought to have originated here. For much of the second half of the 20th century, however, the wines rarely lived up to expectations, a consequence of heavy-handed government intervention since the 1940s.

In an attempt to impose some form of organization on the highly fragmented, largely subsistence economy in the north of Portugal, the Salazar government introduced a programme of co-operativization. Ten CO-OPERATIVES were built in Dão between 1954 and 1971, and the authorities gave them the exclusive right to buy grapes. Private firms were effectively restricted to purchasing ready-made wine. Wines became ever more standardized and, as co-operatives were poorly equipped and paid scant attention to HYGIENE, standards fell. This monopolistic legislation was felt to be incompatible with Portugal's membership of the EU, and the law institutionalizing Dão's co-operatives was overturned in 1989. Some enterprising initiatives followed, led by SOGRAPE, which built a modern

winery in the heart of the region, and an influential band of single estates whose ever-rising numbers have consolidated Dão's revival of fortunes. A 21st-century wave of newcomers counts notable Douro producers and NATURAL WINE enthusiasts among its number. Just five co-operatives remain.

About 80% of Dão wines are red, thanks to the modern era's introduction of planting varietally blocked vineyards (traditional vineyards comprised FIELD BLENDS). Touriga Nacional, Tinta Roriz (TEMPRANILLO), Jaen (MENCÍA), and ALFROCHEIRO Preto have become the mainstay of the region's leading wines, although efforts are underway to revive some of its more obscure varieties. Although tannins are accentuated by the high acidity in the region's wines, modern reds are much less austere and tannic than in the past when many wines suffered from excessive MACERATION with stalks and protracted ageing in old CASKS or CONCRETE tanks. New French OAK and overripeness can mar TERROIR expression, but the pendulum (in some quarters at least) is swinging back in favour of greater restraint.

White wines improved markedly in the early 21st century, becoming fruitier without sacrificing varietal complexity or the region's hallmark freshness. Encruzado is without doubt the jewel in the crown, making ageworthy VARIETAL wines that may be crisp and fragrant or more Burgundian if BARREL FERMENTATION is employed. Encruzado may also be blended with less structured varieties such as MALVASIA Fina and BICAL, known here as Borrado das Moscas. The VINHO REGIONAL is Terras do Dão. S.A.

DAP. See DIAMMONIUM PHOSPHATE.

Davis, the usual abbreviation in the wine world for the influential wine-related faculties of the University of California at Davis, a small city 70 miles north-east of San Francisco in California's Central Valley. Although the university is known throughout the world as a centre for research and instruction in agriculture, it began as the home of the University Farm established in 1906.

Until the late 19th century, grape-growing and winemaking in California had been relatively haphazard, with numerous problems generally unrecognized. An act of the state legislature in 1880 directed the nascent University of California to start research and teaching in VITICULTURE and OENOLOGY. The fact that Berkeley, the original site of the university, was too cold and foggy for grape-growing encouraged the establishment of the farm in the warm, inland climate of Davis.

The then Professor of Agriculture, Eugene Hilgard, soon recognized that grafting VITIS INIFERA SCIONS on to hybrid ROOTSTOCKS was the only practical solution to the world's PHYLLOXERA epidemic. He also recognized the importance of matching vine variety to soil and climate for fine-wine production. Hilgard established early co-operation between ACADEME and practitioners.

PROHIBITION brought a temporary hiatus in Davis's wine-related activities, though the study of viticulture continued. The department moved to Davis shortly after the end of Prohibition; in 1959 UC Davis was declared an independent general campus, no longer a branch of UC Berkeley. The university hired a powerful group of academics, including the late Albert J. WINKLER, famous for his DEGREE DAY/heat-summation method of CLIMATE CLASSIFICATION; Harold P. Olmo, breeder of NEW VARIETIES; and well-known oenologist Maynard A. AMERINE. The department was and still is responsible for the development of assays and technologies routinely employed in wineries internationally, along with a curriculum used throughout the world.

Current research efforts are dedicated to understanding the impact of viticultural practices such as REGULATED DEFICIT IRRIGATION, YIELD, clonal variation, and SITE SELECTION on wine composition and perceived quality. In addition, novel molecular and genetic technologies have been developed and applied for the improvement of both scion and rootstock varieties with the aim of producing vines less susceptible to pests and diseases and increasing understanding of grape berry maturation and flavour and aroma development. Genomics technologies have been used to further understand the YEAST and bacterial fermentations of wine, to profile the presence and persistence of both wild and spoilage flora, and to map winery and vineyard microbes (see SOIL BIOTA) and their impact on grape and wine quality. The department is similarly engaged in profiling the key chemical components responsible for wine aroma and flavour, as well as linking the development and evolution of these components to vineyard practices, using consumers and professionals for sensory evaluation. The department is also playing an important role in defining the bioactive compounds of wines responsible for the health benefits of moderate consumption (see HEALTH). Sophisticated tools for the ANALYSIS of wine chemistry, aroma, flavour, and ageability are also being pioneered and applied to the investigation of wine composition. Consumer-preference profiling is being exploited to better understand the phenomenon of preference. Work on vine-variety identification using DNA PROFILING continues along with the breeding of new varieties resistant to various pests and diseases and those that are DROUGHT- and salt-tolerant, as well as researching solutions to help the industry survive recent and potential future WILDFIRES.

The department's new facilities, opened in 2008, have ushered in a new era of teaching, research, and SUSTAINABILITY. The teaching and research winery, opened in 2013, is the most advanced and sustainable in the world. The Davis campus also houses the FOUNDATION PLANT SERVICES.

Davis continues to be one of the principal centres for teaching and research in viticulture and oenology, and it has trained numerous winemakers from around the world. It has become synonymous with a scientific approach to wine production and understanding wine quality as opposed to one informed solely by TRADITION and observation. K.L.B.

day–night temperature difference. See DIURNAL TEMPERATURE RANGE.

deacidification, winemaking process of decreasing the excessive ACIDITY of MUST, grape juice or wine made in cold wine regions or, in particularly cool years, in TEMPERATE wine regions. A number of techniques have been developed and are usually strictly governed by local regulations.

MALOLACTIC CONVERSION is a way of lowering acidity biologically, but it is difficult to persuade LACTIC ACID BACTERIA to work in very acid conditions.

Winemakers may choose not to use biological methods for reducing acidity because malolactic conversion can introduce other flavours and reduce the fruitiness of a wine. There are other forms of deacidification which rely on chemical processes, notably adding compounds to must, juice or wine that will eliminate acidity as CARBON DIOXIDE and insoluble solids that can be filtered or settle out. Potassium bicarbonate and calcium carbonate are commonly used. In some very cool regions, where grapes have higher MALIC ACID levels, the addition of calcium carbonate can lead to an imbalance in the proportion of malic acid to TARTARIC ACID. Double-salt deacidification resolves this by reducing both the malic and tartaric acids in the juice. Other methods include REVERSE OSMOSIS and ELECTRODIALYSIS.

Deacidifications are most effective after fermentation, partly because alcohol decreases the solubility of cream of tartar, thereby

reducing some of the must acidity, and fermentation itself produces a better mix of flavour by-products in the more acid solution.

Deacidification is not the commonplace procedure that ACIDIFICATION is in warmer regions. It is practised in northern Germany, Luxembourg, Burgundy, the United Kingdom, Canada, New York State, Tasmania, and New Zealand's South Island in certain years but is becoming less common as a result of CLIMATE CHANGE.

M.J.T.

dead arm or dying arm, common names for several fungal diseases in vine wood that cause cankers and dieback. See TRUNK DISEASES, EUTYPA DIEBACK, PHOMOPSIS, and BOTRYOSPHAERIA DIEBACK.

dead fruit. See OVERRIPENESS.

de-alcoholization. See ALCOHOL REDUCTION.

de-alcoholized wine, one that has undergone ALCOHOL REDUCTION, or de-alcoholization, to produce a wine with an ALCOHOLIC STRENGTH below 0.5% in an attempt to provide a drink that tastes like wine but has none of the negative implications for HEALTH and has fewer calories than regular wine. Such wines fall within the increasingly popular NOLO category. The process of removing alcohol from wine makes it less microbiologically stable and FILTRATION more difficult. There has been a lively debate in some traditional wine-producing countries over whether such products should be entitled to use the word 'wine' in their name. The EU resolved this by creating a formal legal category for 'de-alcoholized wine' in 2021, taking effect in 2023. The same term is regulated in the US, with 'alcohol-removed' an accepted alternative. Other countries may use different terminology, for example NON-ALCOHOLIC WINE or 'alcohol-free wine'. See also PARTIALLY DE-ALCOHOLIZED WINE.

Schneider, I., and Marzolph, F., 'Alcohol-free wine presents challenges in filtration and quality assurance', *Wine Industry Advisor* (June 2022).

Debina, the sprightly white grape variety that is solely responsible for the lightly sparkling white wines of Zítsa in Epirus high in north-west GREECE near the Albanian border but also used to produce still whites and ORANGE WINES. At these ELEVATIONS (600–700 m/1,968–2,297 ft) acidity levels remain high.

débourbage, French term for SETTLING out solids from MUST.

decanters, vessels, usually glass and stoppered, into which wine is poured during DECANTING.

The decanter as we know it today has changed form very little in the last 250 years, in that it is a handleless clear glass bottle with a capacity of about a litre and, normally, a stopper. Stopperless decanters are known as carafes. The shape and the decoration have changed in line with fashion and as technology has allowed. Since the capacity is noticeably more than that of a standard 75-cl/27-fl oz bottle, it allows the wine to 'breathe' and develop (see AERATION).

History

The decanter's origins lie with the Roman serving bottle, which was typically square. Some Roman glass bottles may have been used for serving wine, but the Romans also used silver. After the collapse of the Roman Empire, glass production went into a sharp decline until the revival of the glass trade in Renaissance Italy. By the 16th century, Venice had emerged as the principal centre of glass-making.

While the glass trade was expanding, other developments were afoot. Popular throughout northern Europe during the 16th and early 17th centuries were bulbous earthenware jugs with flat, small handles and short, narrow necks.

A more sophisticated finish, sometimes employed, was a salt glaze which produced a textured surface not unlike orange peel. In addition, Chinese porcelain jugs were being imported for the most sophisticated of tastes, while some preferred their wine served in carved rock crystal. Whether the jug was salt glaze, tigerware, porcelain, or crystal, all the better-quality pieces were given silver or silver-gilt mounts. For the grandest, gold was used.

Throughout the medieval period and well beyond, pouring vessels were also made in bronze and silver, but these media often gave way to glass once a centre of production became established in a country. The new glass serving vessels represented the latest in fashion and technology and were quickly adopted by society. For almost a century, England—which was an important wine market—relied on imports until George Ravenscroft and others started producing glass using lead oxide as a flux in the 1670s. This, together with his flint glass, allowed the production of usable jugs and glasses. His developments gave Britain a lead that lasted for about 100 years.

Contemporary with the jug, decanters were also made which took the same form as bottles but with a much greater sophistication of material, decoration, and workmanship.

With the exception of very early decanter jugs, decanters first acquired stoppers in the 1730s.

In the early 19th century, the introduction of steam-driven cutting tools and better lighting from oil lamps produced a fashion for profusely cut decanters, although plain ones continued to be made too. From the 1820s a wide variety of shapes and patterns gained favour at the expense of a well-defined progression of design, and many of these are now considered desirable antiques.

The 1840s saw the return of the 'shaft and globe' shape that had been popular a century before. This form continued in fashion until the 20th century, gradually changing in proportion and weight of cutting. The 1870s saw acid-etched decoration of machine precision and other applications of mechanical and chemical technology which enabled decanters to be made in a variety of complex patterns. Some decanters from this time were raised on a foot, a new idea that remained popular for the remainder of the century.

Decanters were not the only vessels from which wine was served. Jugs were made in silver throughout the 18th century. Glass CLARET jugs were made during the 19th century and followed the pattern of decanters, the only difference being the addition of a handle and a modified rim to form a pouring lip.

Claret jugs of glass mounted with silver, silver plate, or gilt became popular from about 1835. One favoured design, incorporating a globular body with a wide neck, closely imitated the jugs of the late 16th century.

The Arts and Crafts movement influenced some designs for claret jugs, as did art nouveau and late 19th century interest in Japanese forms. Novelty jugs would also be made in the form of a duck, walrus, seal, or some other animal, with the body in glass and the head in silver or silver plate. All these forms were prevalent in the closing 30 years of the 19th century.

While it is not possible to describe every sort of decanter, there is one type which should not pass unmentioned. It has a conical body, giving it a very wide base, and it usually has neck rings. Many are plain but some have cut decoration. Plain or decorated with cutting, all are considerably heavier than their standard counterparts. Originally called 'rodneys', today they are known as ship's decanters.

Butler, R., *Great British Wine Accessories 1550–1900* (2009).

McConnell, A., *The Decanter: An Illustrated History of Glass from 1650* (2004).

Modern decanters

Any container—a simple jug, for example—can be used as a vessel for wine, so long as it is made of an inert material and can hold at least the contents of a bottle while, ideally, leaving a considerable surface area in contact with air. Some decanters, notably one designed in the late 1980s by the Ch LATOUR management, are shaped so that a bottle exactly fills them to their maximum width, thereby maximizing the potential for AERATION. Some decanters are designed specifically for magnums, or double-sized bottles. Others have handles, all manner of different shapes, engravings, shadings, or designs, including one to ensure circulation with a semi-spherical base that cannot be laid to rest other than in a special cradle by the host's elbow (see PASSING THE PORT). Wine need not be served from clear glass, or even glass at all, but most wine's COLOUR (whites as much as reds) can give great aesthetic and anticipatory pleasure.

See LEAD for details of the limited extent to which this toxic element may be leached from different sorts of decanters.

decanting, optional and controversial step in SERVING wine, involving pouring wine out of its bottle into another container called a DECANTER.

Reasons for decanting

The most obvious reason for decanting a wine is to separate it from any SEDIMENT that has formed in the bottle which not only looks unappetizing in the glass but usually tastes bitter and/or ASTRINGENT. Before winemakers mastered the art of CLARIFICATION, this was necessary for all wines. Today such a justification of the decanting process effectively limits it to those wines outlined in AGEING as capable of development in bottle, in most of which some solids are precipitated as part of the maturation process. Vintage and crusted PORTS in particular always throw a heavy deposit (since they are bottled so early in their evolution), as do red wines made with no or minimal FILTRATION. It is rare for inexpensive, everyday TABLE WINES to throw a deposit, and most large retailers insist on a level of filtration that makes a deposit unlikely (although not unknown in older, higher-quality reds). To check whether a wine bottle contains any sediment, stand it upright for an hour or more and then carefully hold it up to the light for inspection at the base (although some BOTTLES are too dark for this exercise to be effective).

Another traditional but disputed reason for decanting is to promote AERATION and therefore encourage the development of the wine's BOUQUET. Authorities as scientifically respectable as the late Professor Émile PEYNAUD argued that this is oenologically indefensible: that the action of OXYGEN dissolved in a sound wine when ready to serve is usually detrimental and that the longer it is prolonged (i.e. the longer before serving a wine is decanted), the more diffuse its aroma and the less marked its sensory attributes. His advice was to decant only wines with a sediment and then only just before serving. If they need aeration because of some wine FAULT such as REDUCTION or MERCAPTANS, then the taster can simply aerate the wine by agitating it in the glass. Peynaud's argument was that from the moment the wine is fully exposed to air (which happens when it is poured, but not to any significant extent during so-called BREATHING)

some of its sensory impressions may be lost, and so decanting immediately before serving gives the taster maximum control.

It is certainly wise advice to decant fully mature wines only just before serving, since some are so fragile that they can withstand oxygen for only a few minutes before succumbing to OXIDATION. And it is also true that the aeration process of an individual glass of wine can be controlled by the person drinking out of it. However, there are certain types of young wines, ultra-traditional BAROLO most obviously, which may not have been included in Professor Peynaud's experiments with decanting regimes but which can be so concentrated and tannic in youth that to lose some of their initial sensory impressions is a positive benefit.

There is also the very practical fact that many hosts find it more convenient to decant before a meal is served rather than in the middle of it. There are also people who enjoy the sight of (perhaps both red and white) wine in a decanter so much that they are prepared to sacrifice the potential reduction in gustatory impact.

How to decant

Some authorities argue that bottles that have been stored horizontally should be disturbed as little as possible before being decanted, so it is best to transfer them to either a DECANTING CRADLE or a (much more expensive) decanting machine. The alternative and more common method involves standing the bottle upright for as long as possible before opening, certainly a few hours for wines which have a great deal of sediment, to allow the sediment to fall through the wine to the base of the bottle. Whichever method is used, ensure that the decanter looks and smells absolutely clean, and find a strong light source against which the bottle can be held (a candle, flashlight, desk light, or unshaded table lamp will do). After opening the bottle as gently as possible and wiping the lip of the bottle clean to avoid any possible contamination, particularly if the CAPSULE is old enough to contain LEAD, steadily pour the contents of the bottle into the decanter watching the lower shoulder of the bottle with the light source behind it. The sediment should eventually collect in the shoulder, and the pouring action can be halted as soon as any sediment starts to spill into the bottleneck.

To extract maximum volume of liquid from a bottle with sediment, or if there is no time to let all the sediment fall to the bottom of the bottle, or if a cork collapses into fragments in the bottle during extraction, the wine can be filtered into the decanter through clean fabric such as muslin, a paper coffee filter, or a special inert wine filter.

Peynaud, É., *Le Goût du Vin* (1983), translated by M. Schuster as *The Taste of Wine* (2nd edn, 1996).

decanting cradles, bottle carriers, usually made of wicker or metal, which keep the bottle at a perpetually inclined angle with the bottleneck only slightly higher than the base of the bottle, so that the SEDIMENT does not have to fall through the wine to the base of the bottle between STORING horizontally and pouring.

Special decanting machines have also been constructed, designed to pour wine gently out of a bottle held horizontally so that the deposit hardly moves at all.

De Chaunac (Seibel 9549), early-ripening, productive, disease-resistant, dark-skinned FRENCH HYBRID grown for a wide range of wine styles in NEW YORK's Finger Lakes region and in Ontario in CANADA.

defoliation, loss of leaves of a vine, can be caused by various agents. If extensive and badly timed, it adversely affects fruit RIPENING and wine quality, although the precise effects depend on the time of the year. Defoliation is, of course, a natural process and happens at the end of each growing season in the autumn. Normally it is caused by the first FROST, but it may also be through mechanical damage or merely senescence due to shorter days and lower temperatures. By this time the vines have lost most of the green colour from their leaves and are no longer effective at PHOTOSYNTHESIS. Providing the vine's reserves of CARBOHYDRATES are topped up by late-season photosynthesis, there is no negative effect of defoliation.

However, defoliation can occur at any time of the growing season due to climate, disease, or pests. Frosts at any time in the growing season can partially or totally defoliate vines, as can HAIL. A mild hailstorm may simply tear some leaves, but a severe hailstorm will rip off all the leaves and cut green shoots back to their thick basal stubs. FUNGAL DISEASES such as DOWNY MILDEW can also cause defoliation if left unchecked. Similarly, insect pests such as the WESTERN GRAPELEAF SKELETONIZER and GRASSHOPPERS, as well as grazing ANIMALS, can defoliate entire vines.

The vine responds to defoliation by producing new leaves on lateral shoots. However, this new growth will depend on stored carbohydrate reserves of the vine for a month or so, and so will weaken the vine until the new leaves are able to produce carbohydrates by photosynthesis and build up reserves again. While

vigorous vines may be able to recover from a single defoliation, repeated defoliation can weaken the vine perhaps to the point of death.

Defoliation will have an impact on fruit growth and ripening. A low LEAF TO FRUIT RATIO causes a reduction in levels of fruit sugars (see SUGAR IN GRAPES) as well as in PHENOLICS, with an adverse effect on colour and flavour of the resultant wine. However, the vine can compensate for a lower-than-ideal leaf area by automatically increasing the rate of photosynthesis, so that practices such as LEAF REMOVAL and TRIMMING do not normally cause negative effects. Good-quality wine can be made only from vines with a sufficient area of healthy leaves exposed to sunlight. R.E.S.

dégorgement, French term for the DISGORGEMENT operations at the end of the traditional method of SPARKLING WINEMAKING.

degree, the ALCOHOLIC STRENGTH of a wine, identical to the wine's percentage of ETHANOL by volume. This was traditionally regarded as the most vital statistic of all for everyday French VIN DE TABLE, whose price was generally quoted per *degré/hecto*, as though its only important characteristics were its potency and volume—perhaps with some justification since, at this quality level, wines with low alcohol levels tended to have been over-produced and to be low in fruit and concentration.

degree days, unit devised to measure the TEMPERATURE component of climate. See CLIMATE CLASSIFICATION for more details.

dehydration, winemaking process used in the production of DRIED-GRAPE WINES—and a frequent consequence of extended HANG TIME. The dehydration process transforms grapes into RAISINS and has

to be arrested before completion if appetizing wines are to be made from the results.

Dekkera. See BRETTANOMYCES.

Delaware, dark-pink-skinned VITIS LABRUSCA × *Vitis aestivalis* vine variety that is quite popular in NEW YORK and, for reasons that are now obscure, also planted in JAPAN and KOREA. Its early ripening is presumably an advantage in Japan's damp autumns. The wine is not as markedly FOXY as that of its great New York rival CONCORD. It was first propagated in Delaware, Ohio, in 1849.

délestage. See RACK AND RETURN.

delimitation, geographical. The central purpose of geographical delimitation of a wine area, typically into a CONTROLLED APPELLATION, is to establish a distinctive identity for the wines produced within it and provide a means whereby the provenance of those wines can be guaranteed. It is based primarily upon the assumption that different environments give rise to wines of different character (see TERROIR), but it is also increasingly used as a means to market wines from specific places.

Since classical antiquity, wines from certain regions tended to be called after the area of their production, with many gaining particularly high reputations (FALERNIAN, for example, in ancient Rome), but the first legal vineyard delimitation may well have been that of CHIANTI, Pomino, and CARMIGNANO in 1716 by Cosimo III de' Medici, Grand Duke of Tuscany, in a document which further states that penalties will be incurred if any wine makes a false claim to be from those demarcated regions. The DOURO Valley of northern

Portugal was famously first delimited in 1756, associated with the establishment of the Companhia Geral da Agricultura das Vinhas do Alto Douro. During the 18th century, there had been many disputes over the sources and qualities of wines exported from Oporto (see PORT), as well as conflicts between foreign wine shippers and the Portuguese growers; the formation of the Companhia Geral, with its strictly defined areas of operation, was designed to remedy the situation. At the heart of this legislation was the establishment of a specific area in the upper Douro Valley from which farmers were able to obtain higher prices for their wines compared with those produced elsewhere.

During the 18th century in other parts of Europe, CLASSIFICATIONS of the different qualities of wine were becoming increasingly common. Thomas JEFFERSON, for example, commented on the various categories of wines from Bordeaux and Burgundy in 1787. In the 19th century, more formal classifications emerged, with the most famous of these being the classification of the wines of the MÉDOC and Lavalle's classification of the wines of the CÔTE D'OR, both of which date from 1855. By the early 20th century, in the wake of the devastation caused by POWDERY MILDEW and PHYLLOXERA, there were two fundamental problems facing the wine industry: ADULTERATION AND FRAUD. Many wines contained a range of ADDITIVES designed to mask their flavour; and wine purporting to come from a respected source frequently contained wines from elsewhere. In order to overcome these problems, groups of growers, such as those in Chablis and Bordeaux, decided to form their own associations to guarantee the origin of their wines. National governments then began to concern themselves more formally with the geographical delimitation of areas of wine production, with the French taking a first step in 1905 towards the creation of a national system of wine control based on the delimitation of areas of origin. Through further laws, most notably those of 1919 and 1927, this eventually culminated in 1935 in the law creating the *appellations d'origine contrôlées* (see AOC).

Numerous systems were also developed in other countries. In GERMANY, for example, the German wine law of 1930 included the use of vineyard names, although the perceived quality of Germany's wines was long based not primarily on geography but on MUST WEIGHTS.

Italian wine laws also include an element of geographical delimitation, as represented in the creation of the *denominazione di origine controllata* (DOC) system in 1963 and more recently in the 1992 legislation with its specific reference to Indicazione Geografica Tipica (IGT).

The precise practical methods of geographical demarcation vary from country to country but are usually based on the compilation of a detailed vineyard register and include varying degrees of political intrigue (see, for example, ROMAGNA ALBANA). Producers wishing to gain a certain status must satisfy regional and national committees as to the quality, origin, and distinction of their wines. One of the most rigorous systems of geographical delimitation is that adopted in France under INAO auspices, which requires that commissions of inquiry examine the relationships between such factors as GEOLOGY, SOILS, TOPOGRAPHY, DRAINAGE, slope, ASPECT, and wine quality. In BURGUNDY, for example, the geological origin of the soils is a determining factor in differentiating the GRAND CRU vineyards.

The central feature of geographical delimitation as it applies to wine is not just that it is intended to lead to improvements in wine quality, thus enabling the wines to be sold at a higher price, but also that it is a legislative procedure whereby a privileged monopolistic position is created for producers within a demarcated area. Whether a given vineyard falls within or outside the legal boundary of a delimited wine region can have important commercial consequences, which is why the much more recent demarcation of America's AVAs, South Africa's WINE OF ORIGIN, and some of AUSTRALIA's even newer GIs (see GEOGRAPHICAL INDICATION)—many of them based more on political than geographical boundaries—can be such a contentious process.

The creation of geographically delimited areas remains highly controversial. P.T.H.U. & J.R.

Delle Venezie, with over 28,000 ha/69,189 acres, is Europe's, and probably the world's, largest denomination devoted to a single grape variety, PINOT GRIGIO. In 2020, 45% of the variety's total global production came from this area alone. With 200 million bottles produced annually, the majority sold abroad, Pinot Grigio delle Venezie has come to stand for a style: fresh, easy, often neutral, and low-priced.

Before its elevation to DOC in 2017, delle Venezie was an IGT allowing for a host of single varieties from the area encompassing FRIULI Venezia Giulia, VENETO, and TRENTINO. Subsequently the IGT was renamed Trevenezie and strictly excluded Pinot Grigio, which became the sole permitted variety of the DOC covering the same area.

The impetus for the change is the loose production regulations of IGTs, which allows for little control, opening up the potential for fraud, such as wines labelled as Pinot Grigio but with little or none of the variety in the bottle. The Delle Venezie DOC was created to increase overall quality, stop prices declining, and create an identity for the variety in Italy's north-west, where it has traditionally been grown.

The recently founded Consorzio delle Venezie tries to draw attention to the fact that Pinot Grigio is not a white but a red variety, traditionally and historically fermented on the skins, resulting in a

wine with a light pink-copper hue, called *ramato*, or coppery. With the rise in popularity of so-called NATURAL WINES, this archaic style might become fashionable. W.S.

demi-muid. See BARREL TYPES.

demi-sec, French term meaning 'medium dry' (see SWEETNESS). In practice, the term is used particularly for Chenin Blanc wines in ANJOU-Saumur and TOURAINE. See DOSAGE for official EU sugar levels in SPARKLING WINES.

Denmark . With its far northern LATITUDE, Denmark has a very MARGINAL CLIMATE for winegrowing. CLIMATE CHANGE has helped in the development of a wine industry, as have NEW VARIETIES (HYBRIDS or DISEASE-RESISTANT VARIETIES) such as SOLARIS and Rondo. The country's first commercial vintage was 2001, a year after gaining EU recognition; by 2020 there were around 100 commercial producers, many very small-scale, farming roughly 125 ha/309 acres of vines. Wine is produced in most parts of Denmark and from the country's four PGIs: Jutland, Funen, Zealand, and Bornholm. The country's largest producer, Dyrehøj Vingård, is located in Røsnæs, in the north-western corner of Zealand, where the climate is drier and sunnier than the Danish average. In 2018 Denmark was granted its first (and Europe's most northerly) Protected Designation of Origin (PDO), Dons in East Jutland, for sparkling wines only; Skærsøgaard is its first winery.

A recent speciality of Denmark is fruit wines. Frederiksdal on Lolland are well known for their cherry wines, and Andersen Winery in East Jutland produces sparkling wines from apples, rhubarb, and other fruits.

For the Australian wine region called Denmark, see WESTERN AUSTRALIA. P.L.L.

Denominação de Origem Controlada, the name of a CONTROLLED APPELLATION in PORTUGAL, which replaced the earlier Região Demarcarda when Portuguese wine laws were revised for EU entry. For more details, see DOC.

Denominación de Origen, Spanish CONTROLLED APPELLATION. See DO.

Denominación de Origen Calificada, Spain's superior CONTROLLED APPELLATION. See DOCA.

dénomination géographique complémentaire (DGC), meaning 'complementary geographical denomination', bureaucratic French term for a 'subappellation' or a noted subzone within a CONTROLLED APPELLATION, typically a COMMUNE, whose name can be appended to that of an AOC on a wine label, for example Ayze (Savoie Ayze) or Lugny (Mâcon Lugny).

See also CRU and MGA.

Denominazione di Origine Controllata. See DOC.

Denominazione di Origine Controllata e Garantita. See DOCG.

density, a measurement of the concentration of matter in units of mass per unit volume. In wine it is usually expressed as g/cc, and

occasionally as g/ml, at 20 °C/68 °F (which must be specified since wine's mass per unit volume decreases as its temperature increases). Wine is an interesting mixture because it contains dissolved solids (SUGARS, ACIDS, PHENOLICS, and MINERAL salts) which increase its density above that of pure water, but it also contains ALCOHOL, which is less dense than water. The result is that very dry wines can have densities near 0.9 g/cc while very sweet wines that are low in alcohol (such as some Italian MOSCATO, for example) can have densities around 1.03 g/cc.

A term closely related to density, and used in technical wine ANALYSIS, is specific gravity. The specific gravity is the ratio of the weight or mass of a volume of a liquid to the weight of an equal volume of water. It is thus a pure or unitless number which differs only slightly from density, according to temperature (since the density of water is only exactly 1 g/cc at a temperature of 3.98 °C).

Wine densities are also frequently reported in terms of one of the traditional scales used for measuring the sugar-solution concentrations (see BALLING, BAUMÉ, BRIX, OECHSLE), which also measure wine density but in units other than g/cc. These scales all use different units (see MUST WEIGHT for equivalencies), with Oechsle bearing the most obvious relationship to specific gravity: a MUST with the specific gravity of 1.070, for example, is said to measure 70 °Oechsle. Density is usually measured with a HYDROMETER or mustimeter; while a range of alternative electronic density meters are available, hydrometers are the instrumental standard for this measurement. A.D.W.

deposit. See BOTTLE DEPOSIT and SEDIMENT.

Derenoncourt, Stéphane (1963–), influential, self-taught, now international winemaking CONSULTANT based on Bordeaux's right bank. Originally from the far north of France, he first picked grapes in Fronsac in 1982 and continued as a lowly vineyard worker. He did not make wine until 1990, at Ch Pavie Macquin, and claims that his

winemaking philosophy is informed by his experiences in the vineyard, by expressing TERROIR, and by Burgundian sensibilities.

In 1999 with his wife Christine he acquired Domaine de l'A, an estate in CASTILLON. With a team of eight qualified oenologists he advises around 140 estates from vine to wine. About 60 of these estates are on Bordeaux's RIGHT BANK, 30 on the LEFT BANK, and 25 elsewhere in France. Others are in Spain, Portugal, Italy, Austria, Greece, Turkey, Ukraine, Morocco, Lebanon, Syria, Virginia, and California (Inglenook).

derived pigments. See ANTHOCYANINS.

desert, an arid, treeless region. True deserts are not conducive to growing grapes for wine, even where IRRIGATION water is available. Low HUMIDITY and extreme temperature ranges place stresses on the vine which usually preclude good grape quality. With irrigation they can still be very suitable for TABLE GRAPES, especially early-maturing varieties, and for RAISINS, but wine grapes seldom rise above mediocre quality. See CLIMATE AND WINE QUALITY.

Some near-desert regions used extensively for viticulture include the SAN JOAQUIN VALLEY of California; the southern reaches of the Okanagan Valley in BRITISH COLUMBIA; ARGENTINA's Mendoza region; the Bekaa Valley of LEBANON; parts of ISRAEL; AZERBAIJAN on the west coast of the Caspian Sea; parts of northern CHINA; the lower Murray Valley of SOUTH AUSTRALIA and VICTORIA; and the Little Karoo of SOUTH AFRICA. J.G.

dessert wines usually mean SWEET WINES, but according to American regulations any wine between 14 and 24% alcohol is designated a dessert wine, even if dry and unfortified, and attracts a higher tax rate.

DGB, major South African wine producer formed in 1990 by the merger of Douglas Green of Paarl and Union Wines. Important brands include Boschendal, Bellingham, Franschhoek Cellars, and The Old Road Wine Co. Operating only in the bottled wine sector, it accounts for 10% of South African packaged wine exports and 12% share by value of local bottled wine sales. The DGB sourcing model is a combination of three owned vineyards, one rented farm, and 59 managed contract estates totalling 400 selected vineyard blocks.

M.F.

destalking. See DESTEMMING.

destemmer-crusher, common combination of winemaking equipment which carries out the operations of both DESTEMMING and CRUSHING, in that order. Historically, crusher-rollers sometimes preceded the destemmer and 'crusher-destemmer' was a better description, but that configuration is now rare (except in small-scale winemaking).

S.N.

destemming, the winemaking operation of removing the STEMS, or stalks, from bunches of grapes. It usually takes place immediately before CRUSHING. Grape stems contain TANNINS, which can be leached into the wine during FERMENTATION, making the wine taste HERBACEOUS and/or ASTRINGENT, depending on the variety and how ripe the stems are. Destemming saves space in fermenters and presses, but the inclusion of stems can help dissipate the heat of fermentation and make pressing easier by providing structure to the press cake.

While most grapes are now destemmed, this was not the case historically, and there remain high-profile exceptions to destemming, such as WHOLE-BUNCH PRESSING in CHAMPAGNE, black grapes used for CARBONIC MACERATION in BEAUJOLAIS, and WHOLE-BUNCH FERMENTATION in BURGUNDY and parts of the RHÔNE. Destemming also very slightly increases the resultant colour and ALCOHOLIC STRENGTH because stems, if included, may adsorb pigments and absorb alcohol.

Destemming machines, or destemmers, most commonly employ a rotating shaft with paddles that convey and remove the stems from the grapes inside a perforated cylinder. The cylinder has holes that allow grapes but not most stems to fall through; it usually also rotates, just at a slower speed than the paddles. Some newer destemmers work by shaking the grapes from the stems rather than by rotary movement, which can be a more gentle process. Destemmers with oscillating cups rather than a rotating shaft are particularly effective in excluding the stems. Often the destemmer is accompanied by a set of crusher rollers (that can be bypassed if desired), and the combined device is known as a DESTEMMER-CRUSHER.

Destemming can now also often be performed on machine harvesters. MECHANICAL HARVESTING has always resulted in partial destemming as some grapes are shaken from the vine without their stems, but the complete destemming of grapes on machine-harvesters is a newer phenomenon. It is sometimes accompanied by an on-harvester mechanical SORTING system.

A very few producers destem by hand, thereby keeping the berries whole. The gentler handling is very time-consuming, but proponents believe it results in improved wine quality. S.N.

desuckering, the common viticultural practice of removing unwanted young shoots, known as suckers or WATER SHOOTS, that grow from latent buds. On the vine TRUNK, suckers grow mostly on the lower part, from either the ROOTSTOCK or SCION, and in the HEAD of the vine. Varieties differ in their production of water shoots; GEWÜRZTRAMINER, for example, produces many. The operation is carried out in spring, several weeks after BUDBREAK, when the water shoots are 10–15 cm/4–6 in long. The work is relatively tiresome, as for many vineyards the shoots can be near the ground, although shoots can be removed from trunks mechanically by mounting on the front of a tractor a rotating cylinder with rubber straps attached. HERBICIDES are also used. If the vine is thought to be infected with

TRUNK DISEASE, some suckers should be retained as part of the process of TRUNK RENEWAL.

When desuckering is carried out on CORDON-trained vines, it may be termed SHOOT THINNING. R.E.S.

Deutsche means 'German', thus Deutscher Wein is what appears on the labels of Germany's WINE WITHOUT GEOGRAPHICAL INDICATION (once called Tafelwein); Deutscher Sekt is a SEKT or sparkling wine made in Germany from German fruit; and the Deutsche Weinstrasse is a famous wine route through Germany's PFALZ region.

dew, water which condenses on objects, such as leaves, when the air in immediate contact with them is cooled below dew point, the temperature at which the air becomes fully saturated by its current content of water vapour (see HUMIDITY). Dew contributes little directly to the water supply of the vine. However, the latent heat of vaporization that is released during condensation plays a positive role by slowing night-time temperature drop. The risk of FROST is appreciably reduced when the air contains enough water vapour to result in dew.

Dew has a major (mostly unfavourable) impact on the incidence of VINE DISEASES. It provides the necessary conditions for spore germination and the establishment of several fungal-disease organisms, most notably those for DOWNY MILDEW, BLACK ROT, and the malevolent form of botrytis bunch rot, GREY ROT, even in the absence of wetting rain.

See CLIMATE AND WINE QUALITY and TOPOGRAPHY. J.G.

DGC. See DÉNOMINATION GÉOGRAPHIQUE COMPLÉMENTAIRE.

diacetyl, a product of MALOLACTIC CONVERSION with a powerful butterscotch or butter aroma. The ability to detect diacetyl depends

on its concentration and the wine type and style. The perception threshold varies from 0.2 mg/l for Chardonnay to 0.9 mg/l for Pinot Noir to 2.8 mg/l for Cabernet Sauvignon. At low concentrations, it may be perceived as nutty or toasty and add desirable complexity. In excess, as was once common in NEW WORLD Chardonnays, it is perceived as distractingly obvious butteriness, masking fruit flavours. The amount of diacetyl produced depends on the bacterial strain and the rate of progress of the malolactic conversion as well as temperature, oxygen availability, the wine's pH, SULFUR DIOXIDE content, and, importantly, CITRIC ACID concentrations. P.J.W.

Bartowsky, E. J., and Henschke, P. A., 'The "buttery" attribute of wine—diacetyl—desirability, spoilage and beyond', *International Journal of Food Microbiology*, 96 (2004), 235–52.

Diageo, the world's largest alcoholic drinks company, is now very, very much more interested in spirits than wine—and in BRANDS above all else. Its London fine-wine merchant Justerini & Brooks is somewhat anomalous but earns a Royal Warrant.

diammonium phosphate, or DAP, common YEAST nutrient added during FERMENTATION. Research has shown that it not only encourages fermentation but that appropriate addition may also result in the production of complex compounds and ESTERS that make wines taste more fruity and floral. The current EU limit is 1 g/l, and 0.3 g/l for the second fermentation of SPARKLING WINE.

Torrea, D., et al., 'Comparison of inorganic and organic nitrogen supplementation of grape juice—effect on volatile composition and aroma profile of a Chardonnay wine fermented with *Saccharomyces cerevisiae* yeast', *Food Chemistry*, 127 (2011), 1072–83.

Diamond Mountain, California AVA on the north-western edge of the NAPA Valley.

diatomaceous earth (DE), once widely used in FILTRATION, is a naturally occurring, highly porous, chalky textured sedimentary rock made mainly of silica and consisting of fossilized remains of diatoms, a type of hard-shelled algae. It is also known as Kieselguhr. Because of increasing concerns about potential health hazards and safe disposal of used DE, it is now frequently replaced by cross-flow filtration.

Die, town between the RHÔNE Valley and the Alps (see map under FRANCE) whose name features in the Clairette de Die and Crémant de Die sparkling-wine appellations and Coteaux de Die, a light, still, dry white wine made from CLAIRETTE grapes. According to PLINY, the local tribe in Roman times, the Voconces, made a sparkling sweet wine and practised an early form of TEMPERATURE CONTROL by plunging barrels full of fermenting must into the river. Most wines are sparkling, and many of them are sweet and grapey. For more information, see CLAIRETTE DE DIE, CRÉMANT, and CHÂTILLON-EN-DIOIS.

diet, wine as part of. Some medical research suggests that wine may be drunk for dietary reasons. Wine contains various VITAMINS and MINERALS but in such small concentrations that, for them to make any sufficient contribution to the human diet, excessive amounts of ALCOHOL would also have to be ingested. 'Moderate' wine consumption has been shown to have a beneficial effect for several medical conditions, however, and wine consumption clearly plays a part in the much-vaunted Mediterranean diet (see HEALTH).

No wine is 'slimming', but dry DE-ALCOHOLIZED WINE is usually lower in calories than most.

In Mediterranean countries, before there was a ready supply of safe drinking WATER it was natural to drink wine because it was abundant and relatively cheap. But wine forms part of our diet for reasons beyond necessity or ease of access.

The concept of maintaining good health through diet can be traced back to ancient GREECE and the Greek Hippocrates, in particular, although wine was included in the dietary laws of Moses 1,000 years earlier.

As late as the 1860s, doctors were still matching wines to lifestyles, as they would be termed today. For example, Dr Robert Druitt suggested CLARET 'for children, for literary persons, and for all those whose occupations are chiefly carried on indoors'. The fuller-bodied wines of BURGUNDY, the MIDI, and GREECE he considered better suited to manual workers. H.B. & J.R.

Newman, C., *The White Wine Diet* (2004).

Dijon, capital of BURGUNDY and the focus of the region's vinous ACADEME, the Institut Universitaire de la Vigne et du Vin (IUVV) Jules Guyot in the Université de Bourgogne. In 1856 the scholar Claude Ladrey, friend of Louis PASTEUR, started a course in Dijon that applied chemistry to VITICULTURE and OENOLOGY. In 1901, the institute was founded, awarding its first higher diploma in oenological studies in 1909. Endowed with an experimental vineyard in MARSANNAY (3.6 ha/9 acres) since 1917, the institute is now internationally recognized for teaching and research in both viticulture and oenology.

Dijon offers the fifth-year Diplôme National d'Oenologue; two master's degrees (Vine, Wine, Terroir and Fermentation Processes for the Food Industry); three bachelor's degrees (Vine Science, Marketing of Wine and Oenotourism, and Strategic Management of the Vitivinicultural Operation); and three university diplomas in continuing education (Practical Oenology, Wine, Culture and Oenotourism, and Learn and Understand Wine Tasting). Research concentrates on five main areas: grapevine immunity, the impact of CLIMATE CHANGE, microbiology, physical chemistry, and sensory

analysis. The UNESCO chair of Culture and Traditions of Wine and the Burgundy Vine and Wine cluster are hosted at the IUVV Jules Guyot. Humanities and Social Sciences also contribute to the research advances in vitculture and wine at the university.

Certain CLONES of CHARDONNAY and PINOT NOIR clones such as 115 and 777, imported from Burgundy, are sometimes known as Dijon clones. R.D.G.

iuvv.u-bourgogne.fr

Dimyat, also spelt Dimiat, BULGARIA's widely planted white INDIGENOUS VARIETY whose total area stood at 7,914 ha/9,556 acres in 2021, a considerable increase over the previous decade. It is grown mainly in the east and south of Bulgaria, where it is regarded as a producer of perfumed everyday whites of varying levels of sweetness but usefully dependable quality. The vines yield copper-coloured grapes in great quantity. The wines should be consumed young and cool. DNA PROFILING has shown Dimyat to be the offspring of GOUAIS BLANC and Coarnă Albă and to be a parent of CABERNET SEVERNY and others. It is the same as Serbia's SMEDEREVKA.

dining clubs, private societies of like-minded individuals who meet over meals. A high proportion of what are called dining clubs are in fact wining clubs, devoted to the consumption and discussion of fine wines. See also SAINTSBURY.

Dionysus, the classical god of wine, for whom 'Bacchus' was the more common name among the Romans. However, grapes and vines are not his only attributes, and neither is wine the only aspect of his cult.

Although some scholars have argued that wine is a secondary element in his cult and that the god Dionysus was a late importation

from the East, he is a wine god, an Olympian, and an important influence on ancient GREECE. The earliest festival known to be devoted to Dionysus, the three-day feast of the Anthesteria, is a wine festival. It gives its name to the spring month of Anthesterion and celebrates the broaching of the new wine (the wine of the most recent vintage, which was always kept until the next spring). Clay tablets dating from the late Bronze Age (*c.*1200 BCE) connect Dionysus with wine and thus provide further evidence for the early cult of Dionysus as a wine god.

Dionysus has been taken to be a non-Greek because he is a god of epiphanies. He appears suddenly, from outside, to strike people with madness, most famously represented in Euripides' tragedy *The Bacchae* (probably written shortly after 408 BCE), about Dionysiac frenzy. Although the play praises Dionysus for his gift of wine which lessens the cares of mortals, the madness that he brings is not the result of excessive consumption of wine.

The essence of the cult of Dionysus is the surrender of personal identity. Hence one of Dionysus' symbols is the mask, and he is often depicted in vase paintings of drinking ceremonies as a mask set up on a column draped in cloth. His other attributes are the thyrsus, a tall stick with a bunch of ivy leaves on top—ivy because it is evergreen and produces its berries in the winter, when the mountain ritual takes place and the vine is bare. He is also depicted with grapes or a wine cup; often he takes on an effeminate appearance with long flowing locks. He is frequently equated (especially by HERODOTUS in the 5th century BCE) with the Egyptian god Osiris.

One well-known myth about Dionysus concerns the invention of wine. Dionysus discloses the secret of winemaking to the peasant Icarius and his daughter Erigone, with whom he had lodged as a guest, in return for their hospitality. Obedient to the god's command to teach the art to other people, Icarius shares his wine with a group of shepherds. At first they enjoy this delicious new drink, but as the unaccustomed wine overwhelms them they begin to suspect Icarius of having poisoned them. So they turn on him and batter him to death with their clubs. For a time his body cannot be found, but

eventually Icarius' faithful dog Moera leads Erigone to the spot where he lies buried. Erigone hangs herself in despair. However, in death they receive their due rewards: Icarius becomes the star Boötes, his daughter the constellation Virgo, and Moera becomes Canis, or Sirius, the dog star. Boötes, also known in Greek as 'the grape-gatherer', rises in the autumn, at the time of the vintage, and in the warm climate of Greece the vintage may well have taken place some time before the autumnal equinox, still under the constellation of Virgo. It is also interesting to note that PLINY the Elder recommends the rising of the dog star, 2 August, as the day when wine jars should receive their inside coating of RESIN to make them airtight in readiness for the vintage.

Dionysus is a god who strives against reason, calm, and order. As such he is a god of the people, dangerous and subversive to those in authority. His cult attracts further suspicion because it is surrounded by secrecy.

Gradually Dionysiac orgies appear to have become orgies in the modern sense, and among the Romans the cult of Dionysus was a disreputable affair. Livy gives a lurid account of the banning of the Bacchanalia, but it should not be forgotten that Livy was a historian of conservative tendencies, an admirer of Augustus, who lamented what he considered to be the recent slide into luxury and immorality. Bacchus certainly played little part in the official religion of ancient ROME; he was too dangerous a god. Among the Romans he survives in a sanitized version: jolly Bacchus the wine god, giver of wine and bringer of joy, who makes sorrow bearable. Satyrs and nymphs gambol about him harmlessly, and Silenus is a cheerful old soak. This is the Bacchus that survived into the Renaissance, familiar from the pictures of Titian and his contemporaries. The Romans reduced the complex god of the Greeks to little more than wine personified.

direct producer, term used for a group of vines, also known as FRENCH HYBRIDS, bred from the late 19th century onwards in an effort to combine the pest and disease resistance of AMERICAN VINE SPECIES with the desirable fruit characters of the European VITIS VINIFERA species. They are called direct producers, and sometimes hybrid direct producers, or HDPs, because, unlike *vinifera* VINE VARIETIES, they do not need GRAFTING on to PHYLLOXERA-tolerant ROOTSTOCKS. They are not all sufficiently phylloxera-tolerant, however, and added soil stresses such as DROUGHT or WEEDS can see them weakened by phylloxera. R.E.S.

direct shipping, cause célèbre in the US, which banned shipping of wine direct from winery to consumer until a seminal Supreme Court decision in 2005 liberalized direct shipments into some states yet allowed others to keep their borders closed to wine shipments from out of state. See UNITED STATES, regulations, for more detail of this bypassing of the notorious THREE-TIER SYSTEM.

disease-resistant varieties, semantically expedient term for grapevines introduced by the German Bundessortenamt (Plant Variety Rights Office) in 1995 that were bred specifically to produce wines that taste like those made from VITIS VINIFERA yet meet consumer demands for reductions in AGROCHEMICAL use by incorporating some non-*vinifera* genes for resistance to various common VINE DISEASES. The term replaces the previously pejorative terms 'HYBRIDS' or 'interspecific hybrids' for some of their most promising results of VINE

BREEDING and acknowledges the substantial progress achieved in recent decades. The German term is *Pilzwiderstandsfähige Rebsorten*, often abbreviated to PiWi.

There had been substantial bias against such new varieties, especially those including genes from AMERICAN VINE SPECIES, because of historical associations with poor wine quality and FOXY flavours. The bureaucratic hurdle of the EU's former ban on non-*vinifera* vines for QUALITY WINE (designed initially to exclude the earlier AMERICAN HYBRIDS and FRENCH HYBRIDS, though lifted in 2021) was bypassed by classifying these new disease-resistant varieties as *Vitis vinifera* subspecies *vinifera*.

PHOENIX, the product of BACCHUS and VILLARD Blanc, was the first variety so registered (in 1992), and other German-bred varieties such as REGENT, Merzling, RONDO, Bronner, Johanniter, Prinzipal, Saphira, and SOLARIS have followed, all registered as *Vitis vinifera*. Thanks to this creative taxonomy, which is based on morphological characteristics, these disease-resistant varieties can be grown for quality-wine production, though they still have to be registered for such in any given EU region. The Swiss are very proud of their new variety DIVICO. Five new PIERCE'S DISEASE-resistant varieties (whites Ambulo Blanc and Caminante Blanc and reds Camminare Noir, Errante Noir, and Paseante Noir) were released from the UC DAVIS grape-breeding programme in 2019. INRAE's ResDur programme in France has resulted in the release of several new varieties resistant to POWDERY MILDEW and DOWNY MILDEW (see NEW VARIETIES).

diseases, vine. See VINE DISEASES and individual diseases.

disgorgement, or dégorgement in French, an integral stage in the TRADITIONAL METHOD of sparkling winemaking entailing the removal of a pellet of frozen sediment from the neck of each bottle. For more detail and alternative techniques, see SPARKLING WINEMAKING.

Distell, dominant wine and spirits producer in the SOUTH AFRICAN market and the ninth largest wine company by volume in the world, acquired by brewers Heineken in 2021. Formed in 2000 from the merger of Stellenbosch Farmers Winery and Distillers Corporation, it focuses on such commercial brands as Chateau Libertas, Grand Mousseux, and Tassenberg and had reduced its vineyard holdings to 620 ha/1,532 acres by 2021.

It enjoys 40% by value of the country's domestic wine business and over 80% of the domestic brandy trade but only around 17% of wine exports. M.F.

distillation, the separation of the constituents of a liquid mixture by partial vaporization of the mixture and the separate recovery of the vapour and the residue. When applied to wine (or any other fermented liquid), the result is a considerably stronger alcoholic liquid: brandy in the case of wine and other fermented fruit juices; calvados in the case of certain apples from northern France; and whisky in the case of fermented barley.

distillation, compulsory. In an effort to curb, and dispose of, SURPLUS wine production, the EU authorities instituted a system in 1982 whereby any wine produced over a certain limit should

theoretically be compulsorily bought, at a standard and not-too-attractive price, and distilled into industrial ALCOHOL (resulting, perhaps inevitably, in an alcohol surplus). Average annual quantities distilled under this scheme in the 1980s were well over 30 million hl/790 million gal, or about one-fifth of total European production. In 1993 the European Commission admitted that the scheme had done little to curb over-production; it announced stricter measures designed to offer less financial support to over-producers and to curb abuse of the system. Between 1993 and 1996, the amount distilled was reduced to about 10% of production, but the Commission decided to crack down. In 1998 it introduced a 'crisis distillation' measure which was intended to deal only with exceptional cases of market disturbance and serious quality problems but continued to play an important part in the European wine market. Following further reforms of the common market organization (CMO) for wine in 1999, distillation was 'no longer an obligatory measure in the event of serious wine market crises', and it could be applied to QUALITY WINE. An EU report published in 2002 concluded that distillation was not an efficient way of eliminating structural surpluses and suggested alternative measures such as paying growers a premium for CROP THINNING. Compulsory distillation was finally phased out in 2013 as a result of the wide-ranging 2008 reforms to the CMO. However, in 2014 Spain decided to distil 4 million hl (106 million gallons) to try to balance its own surplus.

The arrival of COVID-19 in 2020 and the associated closures and restrictions imposed on the hospitality sector to restrict its spread represented a grave threat to the EU wine sector. In order to preserve producers' incomes and avoid a massive surplus of unsold wine, the EU introduced support measures including allowing member states to once again fund crisis distillation—a measure that was enthusiastically taken up by some members. J.E.H & J.P.H.B.

diurnal temperature range, or **diurnal temperature variation**, the range in temperatures from the high during the day to the low during the night, also called thermal amplitude or diurnal

swing. It is mainly influenced by the HUMIDITY of a region: lower humidity produces higher daytime temperatures and lower night-time temperatures, while regions with higher humidity see lower daytime temperatures and higher night-time temperatures. Regions at higher ELEVATIONS also experience greater diurnal temperature ranges. A high diurnal temperature range is often considered most important during RIPENING because moderately high daytime temperatures foster sugar development, while cool nights slow down maturation, preserve aromas, and retain ACIDITY in the grapes, resulting in greater freshness in the wines.

See also TEMPERATURE VARIABILITY. J.V.G.

Divico, red grapevine HYBRID created at CHANGINS by Jean-Laurent Spring from GAMARET and Bronner, released in 2013 and spreading quickly in Switzerland (66 ha/163 acres in 2020) thanks in part to its resistance to the major FUNGAL DISEASES. Wines typically have fine tannins, aromas of blueberries, and a slightly bitter finish. J.V.

divided canopy, group of vine-TRAINING SYSTEMS which involve separation of a leaf CANOPY into two or more subcanopies, sometimes called curtains. The expression was popularized by Professor Nelson SHAULIS in the 1960s and 1970s as part of his pioneering promotion of CANOPY MANAGEMENT. One of the most important divided-canopy training systems is the GENEVA DOUBLE CURTAIN developed by Shaulis. The LYRE, SCOTT HENRY, and SMART-DYSON are more recent developments. The advantage of canopy division is that it increases the surface area of the canopy that is exposed to SUNLIGHT, while reducing canopy SHADE. Both yield and wine quality can increase as a result. R.E.S.

DMDC (dimethyl dicarbonate), often known by its US trade name Velcorin, is a sterilant used to eliminate the risk of microbial spoilage.

For red wines, it is particularly useful in preventing BRETTANOMYCES growth in bottle. For other wines with some RESIDUAL SUGAR, it is used more generally for microbial stability. DMDC is short-lived in wine and works by deactivating ENZYMES in the spoilage microorganism to rapidly kill cells, even at low concentrations (<50 mg/l for *Brettanomyces* in wine). Any remaining DMDC breaks down in the wine within 1–2 days, to produce small amounts of CARBON DIOXIDE and METHANOL. This PROCESSING AID is currently approved in the United States, South Africa, Australia, and New Zealand for use in the production of dry wines and in the EU for wines with at least 5 g/l residual sugar. The maximum limit in the EU, the US, and Australia, also recommended by the OIV, is 200 mg/l. While it was originally developed for commercial wines, it has been accepted more widely for higher-quality wines. J.E.H. & A.B.

DNA profiling, also known as DNA typing, DNA fingerprinting, or DNA testing, allows the unequivocal identification of any living individual. This technique was developed in 1985 in forensic science to confound criminals; it was first applied to grape CULTIVARS in 1993 by Australian researchers. Since a grape variety is made of CLONES reproduced asexually by VEGETATIVE PROPAGATION, it is genetically comparable to a human individual. The identification technique is based on small pieces of variable DNA called molecular markers, the most successful using repetitive pieces of DNA called microsatellites. They exist in any living organism, and their length varies from one individual to another. Analysis of 8 to 12 microsatellites is enough to obtain a unique 'genetic identity card', looking like a supermarket barcode, for every variety. This technique, for which data exchanges between laboratories is relatively easy, allowed, for example, identification of the enigmatic PETITE SIRAH in California and solved the long-standing mystery of ZINFANDEL's identity.

DNA profiling technique complements classical AMPELOGRAPHY and offers the advantage of unambiguously identifying grape varieties (as well as ROOTSTOCKS) from any part of the plant, (except seeds, which

are already progenies), independently of the factors potentially influencing the vine's morphology that can mislead ampelographers, such as environmental conditions (e.g. DROUGHT), the development stage (e.g. woody canes used for trading, often impossible to identify visually) or sanitary state (e.g. viruses). There are between 5,000 and 10,000 grape cultivars in the world, for which about 24,000 names have been recorded; thus the same grape often has several names (synonyms) in different regions. Inversely, the same name can be used for several distinct varieties (homonyms). DNA profiling can be very helpful in correcting misnomers and detecting synonyms (e.g. Zinfandel and Primitivo) and homonyms (e.g. the REFOSCO group), and thus it is useful in managing important ampelographic collections. The development of affordable whole-genome sequencing and SNV (single-nucleotide variation) genotyping techniques allowed the discrimination of clones (in this case of Nebbiolo) for the first time in 2017, opening the door for future research.

Microsatellites follow the laws of heredity: half of them come from the mother and half of them come from the father. Much like paternity testing in humans, by looking at a high number of microsatellites (30 to 50) it is possible with DNA profiling to reconstruct the parentage of a variety when both parents are still available. Researchers Carole Meredith and John Bowers at DAVIS were the first to uncover an unexpected parentage in 1997 when they surprised the whole wine world by announcing that CABERNET SAUVIGNON is the result of a (probably spontaneous) CROSS between Cabernet Franc and Sauvignon Blanc. Later on, in collaboration with Jean-Michel Boursiquot at MONTPELLIER, they revealed additional unexpected parentages such as those of CHARDONNAY and GAMAY (both in 1999) and SYRAH (in 2000). Many additional parentages have since been discovered by these and other scientists around the world, including those of SANGIOVESE, MERLOT, and TEMPRANILLO.

DNA profiling has also been used to correctly ascertain the varietal identity of fresh and dried grapes as well as the varietal origin of FREE-RUN juice.

Through DNA profiling, parent–offspring pairs can also be determined when one parent is missing, though it is impossible to infer the direction of the relationship. Pedigree reconstruction makes available unprecedented information about history and migrations of grape cultivars, providing a better understanding of the genetic events that led to today's range of cultivars. The largest pedigree that appears in Robinson, Harding, and Vouillamoz's *Wine Grapes* groups no fewer than 156 European wine grape varieties that are linked by parent–offspring relationships.

However, the 'holy grail' of reconstructing the exhaustive genealogical tree of all existing cultivars will almost certainly never be attained, since many parents have disappeared because of FROST, pests (e.g. PHYLLOXERA), or lack of interest. J.V.

DO stands for Denominación de Origen, the name of Spain's PDO denomination, which is now widely called DOP, Denominación de Origen Protegida.

doble pasta, dark, full-bodied Spanish wine produced by running off a proportion of fermenting must after two days and adding more crushed grapes to refill the vat. The ratio of skin to pulp is effectively

doubled, producing wines with a deep, black colour and very high levels of TANNIN. Doble pasta wines have traditionally been made in JUMILLA, YECLA, UTIEL-REQUENA, MANCHUELA, and ALICANTE, where they are used for blending, but they are being superseded by GRAPE CONCENTRATE. R.J.M.

DOC, initials which stand for Denominação de Origem Controlada in PORTUGAL and Denominazione di Origine Controllata in ITALY, those countries' PDO denomination for superior wines.

A DOC system has also been in operation in ROMANIA since 1975.

Denominação de Origem Controlada

In Portugal, DOC stands for Denominação de Origem Controlada. An alternative term, Denominação de Origem Protegida (DOP), is also available, having been introduced after the EU wine market reforms of 2008. On joining the EU in 1986, Portugal undertook revision of its wine laws to bring them into line with those of other European countries, most notably France. Each of the regions which had already been designated a REGIÃO DEMARCADA (RD) in earlier legislation (BUCELAS, CARCAVELOS, COLARES, DÃO, MADEIRA, SETÚBAL, VINHO VERDE, BAIRRADA, and DOURO) were subsequently designated as DOCs. The system equates roughly with the French AOC and sets out permitted grape varieties, maximum yields, periods of ageing in BULK and bottle, and analytical standards for specified types of wine. Samples must be submitted to the local body controlling that region's wine industry, who grant numbered seals of origin to producers whose wines have satisfied the regulations.

See VINHO REGIONAL (VR) for the denomination below DOC/DOP.

Denominazione di Origine Controllata

Italy's PDO denomination has had a chequered history. Italian wine was first regulated systematically in 1963 in an effort to bring Italy's wine laws into line with those of fellow EU founding nation France. A few of Italy's most famous wines had already been given legal recognition and protection in the 1930s, but this new system was designed to be much more comprehensive and modelled on France's AOC. This meant that individual production zones were DELIMITED; permitted VINE VARIETIES specified, often with specific percentages; levels of ALCOHOL, TOTAL ACIDITY, and EXTRACT were established; and limits, often very generously, placed on YIELDS. Viticultural and winemaking practices were regulated, albeit often in the haziest of terms: 'in conformity with existing practices' or 'so as to not change the nature of the wine' are frequent phrases in the DOC rules. As in the case of the French archetype, this system was set up to protect wine regions against COUNTERFEIT products and imitations, but it has often seemed more concerned with enshrining in law existing practice than in optimizing QUALITY IN WINE, a consequence of forcing Italy's radically different situation into a foreign model.

Towards the end of the 1970s, ambitious producers, particularly those in the CHIANTI CLASSICO zone, became disillusioned with DOC rules which required them to include white wine grapes in their red wines and began to label their best wines with the lowest category VINO DA TAVOLA (see SUPERTUSCANS). See also DOCG, a category designed to be superior to DOC.

In an attempt to correct this confusing situation, the DOC system was overhauled in 1992. Its main innovations were to allow DOC zones to be broken down into subzones, townships, hamlets, microzones, individual estates, and vineyards and to give the entire structure a vertical and hierarchical basis; the smaller the geographical unit, the stricter the production limits and criteria. Producers wishing to use a single-vineyard name for their DOC and DOCG wines had to register their vineyard and define its extent with

the authorities, a reform aimed at curbing the multiplication of invented single-vineyard names (following the Italian FASHION for individual CRUS) with no real territorial basis. While many of these reforms were sensible and well-intentioned, the excessively generous yields of most DOCs were rarely curbed.

The perceived lack of flexibility in permitted grape varieties was also reversed when all but a handful of DOC regulations expanded to allow a broad range of grape varieties, almost always INTERNATIONAL VARIETIES. Perversely, this altered some of Italy's most distinctive wines beyond recognition (see BRUNELLO DI MONTALCINO, for example). This liberalization and GLOBALIZATION came at a time when interest in INDIGENOUS VARIETIES and authentic, TERROIR-driven Italian wine began to grow rapidly.

In the past the failure of the DOC system was evidenced by the fact that by the 1990s DOC wine represented only one-third of the potential production of vineyards designated DOC. While in the last decade Italian wine production overall has declined, 45% of all Italian wine was DOC in 2020, and there were 331 DOCs, 76 DOCGs, and 118 IGTs. The introduction of the EU reforms to the common market organization (CMO) for wine, which came into force in 2008, required all EU member states to register all denominations by the end of 2011; after that date, any changes would need to be approved by the EU rather than by individual member states. This prompted Italy to rush to create and elevate DOCs, resulting in some that exist on paper only or were created purely out of commercial opportunism, such as DOCs Venezia (see VENICE) and ROMA. W.S.

Belfrage, N., *Life Beyond Lambrusco: Understanding Italian Fine Wine* (1985), 44–51.

DOCa, Denominación de Origen Calificada, is a step up from DO/DOP in SPAIN, reserved for regions complying with certain conditions including above-average grape prices and stringent quality controls.

RIOJA was the first Spanish region to be awarded DOCa status, in 1991, followed by PRIORAT in 2000.

doce, Portuguese for 'sweet'. See SWEETNESS and, for official EU sugar levels, DOSAGE.

DOCG stands for Denominazione di Origine Controllata e Garantita, a legal category established in ITALY in 1963 for its highest-quality wines, at the same time as its DOC was created as an Italian version of the French AOC system. The express purpose of this category was to identify and reward the finest Italian wines, which were to be 'guaranteed' (the G) and not merely 'controlled'. The 'guarantee' consists of a laboratory analysis of, among other aspects, the wine's minimum extract, as well as a panel tasting.

If the DOC system did not enjoy general credibility because it was eventually applied liberally and with little rigour, the DOCG title, in contrast, was conferred with admirable parsimony in its first years of existence. It was not even used until 1980; by 1992, when the DOC system was overhauled by law 164, only 11 wines had been deemed worthy of receiving the honour. The first five DOCGs to be conferred were BAROLO, BARBARESCO, CHIANTI, BRUNELLO DI MONTALCINO, and VINO NOBILE DI MONTEPULCIANO, the last of which was the first to be elevated, after having applied as early as 1969. The awarding of DOCG status to ROMAGNA ALBANA in 1986, however, was widely regarded as political in inspiration—a violation of both the letter and spirit of law 930 and, as such, a threat to the viability of the DOCG category itself. It met with such criticism that it was hoped the backlash would have prevented repetition of such an episode.

The authorities nevertheless found themselves in a similar situation with the approval of DOCG for SOAVE, which, while merited in part of the zone, turned into a series of political compromises rather than a coherent attempt to define that which represents the best of Soave. By 2021 there were 76 DOCG wines, many created

since the EU reforms of 2008. Several of the new DOCGs make sense, such as Amarone della Valpolicella, but many are likely to create confusion or trigger incredulity, notably elevations of Superiore or Riserva versions within an existing DOC, such as Bardolino Superiore and Verdicchio dei Castelli di Jesi Riserva, since these suffixes have so far proved unable to guarantee superior quality. In the past, the greatest successes of DOCG have been to decrease YIELDS and promote an image of quality, but the all-too-frequent cases in which the elevation has not involved stricter production rules has diluted their significance. W.S.

doctors of medicine through the ages have displayed an uncommon affection for wine, and not just because of wine's uses as a MEDICINE and beneficial effects on HEALTH. Doctors have long been enthusiastic wine consumers (see Alexander HENDERSON, for example), collectors, and, more recently, producers. There are numerous examples of vineyard owners who combine viticulture with practising medicine. Docteur Peste's slice of the CORTON vineyard is sold each year in the HOSPICES DE BEAUNE auction, itself a medical charity, for example. The MOSEL in Germany has an example of what might be called double-doctoring, in that the producer Dr Thanisch owns a portion of the world-famous Doctor, or Doktor, vineyard of Bernkastel.

Particularly strong medical connections can be traced in the history of AUSTRALIAN wine. During the transport of convicts and subsequent migrant trade of the 19th century, doctors became accustomed to using wine as medicine, and many established their own vineyards on settling in Australia. More than 160 such cases can be cited, including the founders of what were long Australia's three largest wine companies—Hardys, Lindemans, and Penfolds—as well as those of labels such as Angove, Houghton, Stanley, and Minchinbury. Australia was founded in the rum age, developed in the beer age, and is now maturing in the wine age.

See also LITERATURE OF WINE. J.R. & P.A.N.

Norrie, P. A., 'Australia's three leading wine doctors', *Journal of Medical Biography*, 3 (1995), 218–24.

Dogliani, DOCG immediately south of BAROLO in Italy's Piemonte region devoted to DOLCETTO, but under threat of being largely replaced with the much more profitable NEBBIOLO for the production of LANGHE Nebbiolo. W.S.

dolce, Italian for 'sweet'. See SWEETNESS and, for official EU sugar levels, DOSAGE.

Dolceacqua, or Rossese di Dolceacqua, wine from the north-western coast of Italy. For more details, see ROSSESE and LIGURIA.

Dolcetto, an early-ripening, deep-coloured, low-acid red grape variety cultivated almost exclusively in the provinces of Cuneo and Alessandria in the north-west Italian region of PIEMONTE. The wines produced are soft, round, fruity, and fragrant with flavours of liquorice and almonds. Most are designed to be drunk in their first two or three years, although well-made bottles of Dolcetto d'Alba and Dolcetto d'Ovada can easily last at least five years. Dolcetto therefore plays an important role in the economy of various estates, providing a product which can be marketed early while the wines based on BARBERA or, particularly, NEBBIOLO grapes demand extended ageing in cask and bottle. Unlike Barbera, Dolcetto is rarely blended with other varieties, chiefly because it is so rarely planted outside VARIETALLY-minded Piemonte.

As a precocious ripener, ripening up to four weeks before the majestic Nebbiolo, Dolcetto also permits growers to exploit either higher or less favourably exposed vineyard sites and thus maximize the return on their holdings. In the precious BAROLO and BARBARESCO zones, for example, Dolcetto is rarely planted on a south-facing site unless the vineyard is too high to ripen Nebbiolo reliably. And in the

zones of Dogliani, Diano d'Alba, and Ovada, Dolcetto is planted where other varieties may not ripen at all. There is a consensus among growers in the Dolcetto d'Alba DOC, source of much of the finest Dolcetto, that the variety prefers the characteristic white MARLS of the right bank of the Tanaro and cannot give maximum results in heavier soils.

The grape is relatively easy to cultivate, apart from its susceptibility to FUNGAL DISEASES and a tendency to drop its bunches in the cold mornings of late September; but it is far from easy to vinify. While low in ACIDITY, relative to Barbera at least, and therefore *dolce* (sweet) to the Piemontese palate, Dolcetto ('little sweet one') does have significant TANNINS, which producers have learned to soften with shorter fermentations. So rich are the skins of Dolcetto in ANTHOCYANINS that even the shortest fermentation rarely compromises the deep ruby and purple tones of the wine. Like Barbera, it is prone to REDUCTION. Because it is generally vinified early and fast (to make way for Barbera and Nebbiolo in the winery), most Dolcetto is made to be drunk early without ceremony, but Dolcetto d'Ovada DOCG has been associated with fine, elegant Dolcettos that are worth ageing, while Dogliani or Dolcetto di Dogliani DOCG produces truly exceptional, ageworthy, and complex wines radically different from the many uninspiring but cheaper Dolcettos.

There are seven Dolcetto DOCs in Piemonte: Acqui, ALBA, ASTI (where little is planted, GRIGNOLINO being the young wine of choice), Diano d'Alba, Dogliani, Langhe Monregalesi, and Ovada. Alba, Ovada, and Dogliani are quantitatively the most significant, while the Langhe Monregalesi is a barely extant curiosity.

Ormeasco is LIGURIA's version of Dolcetto and is therefore the southernmost extent of Dolcetto territory in Italy. It grows just on the Ligurian side of the mountains that separate Piemonte from Liguria. In 2015, there were 4,381 ha/10,826 acres of Dolcetto planted in Italy. In 2020, DNA PROFILING suggested that Dolcetto was a Dolcetto Bianco × Moissan CROSS.

A fashion for Italian wine and food has spread Dolcetto to the US, Australia, and New Zealand.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Dôle. See SWITZERLAND.

dolium, a large earthenware vessel used in the ancient Roman period. Sometimes with a capacity of several thousand litres, they were often wholly or partly buried in the floor of a barn to create a stable temperature environment for FERMENTATION and provide storage for the wine until it was transferred to AMPHORAE (see also QVEVRI). Recently, at least ten Roman wrecks have been discovered in the western Mediterranean in which the cargo space was largely taken up by a number of *dolia*, thus creating the ancient equivalent of a tanker for the transport of BULK WINE. All these ships probably originated at Minturnae, the port on the west coast of Italy which was the outlet for MASSIC and FALERNIAN. This 1st-century CE experiment seems to have been short-lived, probably because of the inherent instability of such ships. J.J.P.

Hesnard, A., 'Entrepôts et navire à dolia: l'invention du transport de vin en vrac', in Meeks, D., and Garcia, D. (eds.), *Techniques et Économies Antique et Médiévales: Le Temps de l'Innovation* (1997), 130–1.

domaine, French word for an estate, typically a vine-growing and winemaking estate in BURGUNDY.

domaine bottling, the relatively recent practice of BOTTLING the produce of a DOMAINE on the property which produced it (although bottling at least in the region of production was advocated as early as 1728; see LITERATURE OF WINE). Such wines are described as domaine

bottled, or *mis(e) en bouteille au domaine* in French. It is the BURGUNDY equivalent of Bordeaux's CHÂTEAU BOTTLING. Domaine bottling began in the economic crisis years of the early 1930s. but it was not until energetic foreign wine MERCHANTS such as Frank SCHOONMAKER and Alexis LICHINE visited Burgundy in the second half of the 20th century that the better individual producers were encouraged, and in many cases subsidized, to bottle their own production, typically with the help of mobile BOTTLING lines. The movement gathered pace in the 1980s and 1990s and is now seen as standard. However, many domaines also now produce some NÉGOCIANT bottlings, and most of the classic négociants are concentrating more on wines from their own vineyards, so that in either case the small print of BOTTLING INFORMATION may provide the only clue to the original provenance of the grapes: if the label states *mis(e) en bouteille au domaine*, then the wine is made from fruit grown in their own vineyards. Otherwise the label is more likely to note *mis(e) en bouteille par*…followed by the producer's name.

See also ESTATE BOTTLED.

Domaine de la Romanée-Conti, the most prestigious wine estate in Burgundy, based in Vosne-Romanée. 'The Domaine', as it is frequently called, is co-owned by the de Villaine and LEROY families and produces mainly GRAND CRU wines: two whites, Le MONTRACHET and Corton-Charlemagne, and seven reds, Romanée-Conti and La Tâche (both MONOPOLES of the domaine), Richebourg, Romanée-St-Vivant, Échezeaux, Grands Échezeaux, and Corton. For more details of individual wines, see VOSNE-ROMANÉE, ÉCHEZEAUX, and ALOXE-CORTON. The Domaine is the exception to the law according to which no estate in Burgundy may be named after a specific vineyard. Its wines are notable for their richness, subtlety, and longevity.

History

What is now Romanée-Conti was identified by the monks of St-Vivant as Le Cloux des Cinq Journaux in 1512 and sold off, as Le Cros de Cloux, in 1584 to Claude Cousin. His nephew and heir Germain Danton sold again to Jacques Vénot in 1621. Vénot's daughter married a Croonembourg, whose family retained the vineyard, now known as La Romanée (first mentioned in 1651), for four generations until it was sold to the Prince de Conti in 1760. The title Romanée-Conti was not used, however, until after dispossession by the revolutionaries and its sale by auction in 1794.

Romanée-Conti was bought by Julien Ouvard in 1819 and sold by his heirs to Jacques-Marie Duvault-Blochet 50 years later. Duvault-Blochet's eventual heirs were the de Villaine family. In 1911, Edmond Guidon de Villaine became director of what was now known as the Domaine de la Romanée-Conti, selling a half-share in 1942 to his friend Henri Leroy.

Over the years, Duvault-Blochet built up major vineyard ownership including part of Échezeaux, Grands Échezeaux, Richebourg, and the section of La Tâche known as Les Gaudichots. In 1933, the rest of La Tâche was bought from the Liger-Belair family, making a monopoly, and a small holding of Le Montrachet (0.67 ha/1.6 acres) was added in three slices between 1963 and 1980. The Domaine entered into a long-term contract to farm and produce the wines of Domaine Marey-Monge's holding of Romanée-St-Vivant before eventually buying the land in 1988. This was financed by temporarily selling part of their Échezeaux vineyards and a slice of Grands Échezeaux, although they continued to farm the land and bottle the wines. From 2009 the Domaine has also made a Corton, having leased three vineyards there from the estate of Prince Florent de Mérode. The produce of further vineyards owned by the Domaine in Vosne-Romanée and Bâtard-Montrachet is sold in BULK or kept for domestic consumption. In 2018 the Domaine was offered and accepted to lease four large PARCELS of Corton-Charlemagne, the first vintage being 2019.

Today the Domaine continues to be owned jointly by the de Villaine and Leroy/Roch families. Perrine Fenal, daughter of Lalou Bize-LEROY, represents the latter; Bertrand de Villaine, who took over as co-director from his uncle Aubert de Villaine in 2022, the former.

domestic wine production. See HOME WINEMAKING.

Domina, modern red CROSS of PORTUGIESER × SPÄTBURGUNDER (Pinot Noir) that combines the productivity of the first with the ripeness, tannins, and colour of the second, if not its finesse and fruit. The total vineyard area in Germany, mainly Franken, was 354 ha/875 acres in 2020.

Domitian , Roman emperor (81–96 CE) who, in the words of the eulogy by the contemporary poet Statius (*Silvae* 4. 3. 11–12), restored 'to chaste Ceres the acres which had so long been denied her and lands made sober'. By a famous edict, possibly from 92 CE, Domitian banned the planting of new vineyards in Italy and ordered the destruction of at least half of the vineyards in the provinces (Suetonius, *Domitian* 7). He may also have sought to ban the planting within cities of small vineyards, of the sort which have been found at POMPEII. His purpose was not, as some have supposed, an attempt to protect the price of Italian wine at a time of general over-production; rather, it was a heavy-handed attempt to divert investment into the production of cereals, the supply of which was a perennial problem for the large cities of the Roman Empire. There was no way that Domitian could enforce such a ban, and, following the protests which we know came from Asia, he did not persist with the measure. Hence the much later efforts of the Emperor Probus (276–82 CE) to encourage the planting of vineyards should not be

taken as a sign that the ban lasted for centuries, as has often been thought. J.J.P.

Dom Pérignon. See PÉRIGNON, DOM.

Doña Blanca, also known as Valenciana, Cigüente, Malvasía Castellana, and Moza Fresca, variety grown in north-west Spain, particularly in Monterrei, Bierzo, and to a much lesser extent Valdeorras, where it is known as Valenciana. DNA PROFILING has shown that it is identical to the Portuguese variety SÍRIA. In 2020 there were 1,947 ha/4,811 acres planted in Spain.

Dona Branca, soft, northern Portuguese white wine grape planted on 24 ha/59 acres in 2020.

Donnaz, or Donnas, red wine based on NEBBIOLO grapes made in Italy's Valle d'AOSTA.

DOP, or Denominación de Origen Protegida, previously known as DO (which is still widely used), the mainstay of Spain's wine quality control system and equivalent to PDO. The EU's denomination reforms implemented in Spain in 2010 have been followed by some of the more recent Spanish appellations, but both DO and DOP are permitted on labels.

Each region awarded DO/DOP status is governed by a CONSEJO REGULADOR made up of representatives of the regional government (or the Ministry of Agriculture in the three multiregional appellations Rioja, Jumilla, and Cava), vine-growers, winemakers, and merchants who earn their livelihoods in the region. These regional governments decide on the boundaries of the region, permitted VINE VARIETIES, maximum YIELDS, limits of ALCOHOLIC STRENGTH, and any other limitations pertaining to the zone. Back labels or neck seals are

granted by the Consejo to certify that a wine meets the standards laid out in the DOP regulations. A superior category, Denominación de Origen Calificada (see DOCA), was created in 1991.

Spanish wine law has been subject to some criticism as the list of regions promoted to DOP status continues to lengthen (see also PORTUGAL). By 2022 there were 101 DOPs, including the 24 VINOS DE PAGO (no fewer than 11 DOPs in the CANARY ISLANDS alone). The system has most often helped the newer, lesser-known DOPs improve quality levels to no small degree, but some older, well-known Consejos Reguladores continue to uphold certain local quirks, which may sometimes stifle enterprise and initiative among growers and winemakers, as INAO has been known to do in France.

See also the additional Spanish denomination VINO DE CALIDAD.

In Portugal DOP stands for Denominação de Origem Protegida, a term which may eventually replace DOC.

V. de la S. & F.C.

DOQ, or Denominaciò d'Origen Qualificada, the Catalan equivalent of DOCA.

Dordogne, river in SOUTH WEST FRANCE which rises on the Massif Central south-west of Clermont-Ferrand, flows through the Corrèze *département* (whence the merchants of LIBOURNE came), flows through BERGERAC and related appellations, and runs into the GIRONDE to form the more northerly of the two 'seas' referred to in the name of ENTRE-DEUX-MERS, with ST-ÉMILION, POMEROL, FRONSAC, and finally BOURG on its right bank.

dormancy, sleep, the normal state of vines in winter. Grapevine BUDS have three defined stages of dormancy: conditional, organic, and enforced. Dormancy nominally starts with autumn LEAF FALL, although buds are in a state of organic dormancy from VERAISON onwards. PRUNING is carried out when the vines are dormant, and

buds and CUTTINGS taken from the vines at this time are used in PROPAGATION. The first sign that enforced dormancy is ending and BUDBREAK is imminent is BLEEDING, when the vines begin to drip water from pruning cuts. R.E.S.

Iland, P., et al., 'Climate and the vine', in *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

Dornfelder, the most popular German CROSS, bred in 1956 by August Herold, who had unwisely already assigned his name to one of its parents, the lesser HEROLDREBE, and so Dornfelder owes its name to the 19th-century founder of the Württemberg viticultural school. A HELFENSTEINER × Heroldrebe cross, Dornfelder incorporates every important red-wine vine grown in Germany somewhere in its genealogy and happily seems to have inherited many more of their good points than their bad.

The wine is notable for its depth of colour (useful in a country where pigments are at a premium), its good acidity, and, in some cases, its ability to benefit from BARRIQUE ageing and even to develop in bottle. Producing wines that are velvety textured, slightly floral, and sometimes with just a hint of sweetness, Dornfelder is easier to grow than Spätburgunder, has much better resistance to ROT than Portugieser, stronger stalks than Trollinger, better ripeness levels than either, earlier ripening than Lemberger (Blaufränkisch), and a YIELD that can easily reach 120 hl/ha (6.8 tons/acre) (although quality-conscious producers are careful to restrict productivity). It is hardly surprising that it continues to do well in most German wine regions, especially Rheinhessen and the Pfalz, where results are particularly appetizing. Germany's total plantings stood at 7,332 ha/18,118 acres in 2020 but appear to be slowing.

dosage, the final addition to a SPARKLING WINE which may top up a bottle in the case of TRADITIONAL METHOD wines and also determines the sweetness, or RESIDUAL SUGAR, of the finished wine. In French this

addition is called the *liqueur d'expédition*, in Spanish *licor de expedición*, and in Italian *sciroppo di dosaggio*. In traditional-method wines, it usually comprises a mixture of wine and sugar syrup. Champagne is naturally so high in ACIDITY that even wines with relatively high residual sugar can taste bone dry. BOTTLE AGE or extended AUTOLYSIS are excellent substitutes for dosage, however, and, in general, the older the wine, the lower the necessary dosage to produce a BALANCED wine, and vice versa. The 21st century has seen a fashion for champagnes made with no, or zero, dosage. The table gives the legal classification of sweetness levels for sparkling wine and champagne within the EU. This information must be included on the label.

EU classification of sweetness levels for champagne and sparkling wine

RS g/l	Example descriptions
< 3 with no sugar added after the second fermentation	brut nature/naturherb/bruto natural/pas dosé/zéro dosage
0–6	extra brut/extra herb/extra bruto
< 12	brut/herb/bruto
12–17	extra dry/extra trocken/extra seco/extra sec
17–32	sec/trocken/secco or asciutto/dry/seco
32–50	demi-sec/halbtrocken/abboccato/medium dry/semi seco
> 50	doux/mild/dolce/sweet/dulce

double pruning, a time-consuming viticultural technique in which the vines are pruned twice, which alters the timing of vine development (see PHENOLOGY). Double pruning may be carried out for one of two reasons: to delay BUDBREAK and hence reduce FROST hazard in COOL CLIMATES; or to delay harvest and hence potentially increase wine quality in hot regions.

Early winter pruning encourages earlier budbreak, increasing the risk of frost injury in cool, frost-prone climates, but if an initial pruning is light, leaving many buds, budbreak of basal buds is delayed and a second, more complete, pruning can then be done after the danger of frost has passed.

Double pruning in hot climates entails pruning the vines normally in winter and then again in early summer just after FLOWERING. This delays fruit ripening from the heat of midsummer to the cooler conditions of autumn. It reduces yields but can substantially improve wine quality. R.E.S.

Douce Noire, what CHARBONO is called in its Savoie home.

Douro, Portuguese DOC named after the river which rises as the Duero in Spain (see RIBERA DEL DUERO) before turning south to form the frontier with PORTUGAL, then weaving west, where it cleaves through the GRANITE mountains of northern Portugal before finally slipping past Oporto into the Atlantic swell (see maps under PORTUGAL and SPAIN).

First demarcated in 1756, making it one of the world's oldest delimited wine regions (see DELIMITATION and PORTUGAL, history), the Douro Valley's since-modified irregular outline corresponds closely with an outcrop of pre-Cambrian SCHIST, which is hemmed in by GRANITE. For over two centuries, the demarcation applied only to the FORTIFIED wine PORT, which usurped the position of 'blackstrap' table wines that dominated Douro production until the latter part of the 18th century. That changed in 1979, when the DOC was extended to include unfortified TABLE WINE. The first glimmer of the region's true potential for table wines appeared decades earlier, when port shippers FERREIRA launched Barca Velha 1952, a red wine from the Douro Superior, upstream of the port heartland. Making TABLE WINES did not take hold, however, until the 1990s, following Portugal's accession to the EU. This provided invaluable funds for research and

new equipment. It also led to the demise of the port shippers' de facto monopoly over exports, enabling estates to make and sell their own wine. In the spirit of Barca Velha, early efforts focused on ambitious, upmarket reds. But this century has seen the emergence of many a mid-priced and even entry-level Douro table wine as the number of port shippers and independent wine farms (*quintas*) making table wine has mushroomed. While quality is correspondingly more variable, the Douro still produces some of Portugal's most consistent red wines. Today production sometimes exceeds that of port and is expected to grow.

The Douro's unfortified wines can be made from a single variety or, more typically, a blend of as many as 50 of the region's 100-plus approved INDIGENOUS VARIETIES, which are similar to those used for port. Should winemakers stray from the approved list (a miniscule amount of well-known French varieties are planted), wines are labelled Vinho Regional DURIENSE. The region's varietal versatility reflects the sheer diversity of the world's largest mountain vineyard (as of 2020, of about 250,000 ha/617,763 acres, 43,708 ha/108,005 acres were under vine). Divided into three subregions (the westernmost Baixo or Lower Corgo, Cima or Upper Corgo, and the Douro Superior/Upper Douro, which reaches the Spanish border), in general terms it is progressively warmer and drier towards the east. However, since the steep, schistous slopes extend from around 150 m/492 ft to a substantially cooler 900 m/2,953 ft in ELEVATION and face every which way (the Douro DOC tracks not only a 100-km/62-mile stretch of the River Douro but also the valleys of its tributaries), there is many an exception. The first decade of this century saw a sharper focus on taut, mineral white wines sourced from elevated sites and the 'Altos' (peripheral highlands), some located on GRANITE soils, including the Planalto (i.e. plateau) de Alijó, which is a key source of fortified MOSCATEL do Douro (a DOC) and one of Portugal's premier ESPUMANTE brands, Vértice). Earlier picking, the use of older and larger oak barrels, and elevation also result in greater freshness and restraint among the better reds. The quest for individuation and concerns about CLIMATE CHANGE have led some to question 1970s

viticultural studies whose outcome was a shift away from the tradition of field blends towards varietally homogeneous plantings of the supposedly superior red-wine varieties TOURIGA NACIONAL, TINTA RORIZ, TOURIGA FRANCA, TINTA BARROCA, and TINTO CÃO—five were even mandatory for new vineyards planted under the 1982 Trás-os-Montes Integrated Rural Development Project (which encouraged the restructuring of over 3,700 ha of abandoned vineyards). In the 2020s, traditional red-wine varieties that are returning to favour on account of their freshness or lighter body include TINTA FRANCISCA, Donzelinho Tinto, Touriga Brasileira, Folgasão, Tinta Amarela (TRINCADEIRA), Cornifesto, SOUSÃO, RUFETE, BASTARDO, and Malvasia Preta. For whites (mostly from old field blends), key varieties include RABIGATO, CÓDEGA DO LARINHO, VIOSINHO, GOUVEIO, MALVASIA Fina, Donzelinho Branco, and ARINTO. In 2017, ALVARINHO was accorded Douro DOC status. S.A.

Douro bake, traditional expression for the character imparted to wines, especially PORT, matured in the hot, dry climate of the DOURO Valley (rather than the much cooler, damper atmosphere of VILA NOVA DE GAIA, where port has traditionally been matured by the shippers). Some wines matured in the Douro seem to develop faster with greater evaporation, losing colour, browning, and sometimes

acquiring a slightly sweet, caramelized flavour—although poor and sometimes unhygienic storage conditions often have a greater impact on wine quality than does the climate. Many reputable shippers successfully age large stocks of port in the Douro, usually in air-conditioned lodges. R.J.M.

doux, French for 'sweet'. See SWEETNESS and, for official EU sugar levels, DOSAGE.

Dow, important port shipper. See SYMINGTONS.

downy mildew, one of the most economically significant diseases affecting vines, often called peronospora in parts of Europe, and *mildiou* in France. It is a particular problem in regions with warm, humid springs and summers such as many wine regions in northern Europe. Typically (and in this book) referred to as a FUNGAL DISEASE, downy mildew is not in fact caused by a fungus but by *Plasmopara viticola*, a related organism termed a peronosporomycete. This organism is indigenous to eastern North America, and so some species of native AMERICAN VINES such as *Vitis cordifolia, Vitis rupestris*, and *Vitis rotundifolia* are relatively resistant. Commercially important varieties of VITIS VINIFERA, however, are highly susceptible.

The disease caused havoc in the vineyards of Europe when it was accidentally introduced before 1878, probably on American vines imported as grafting stock to combat PHYLLOXERA. By 1882 the disease had spread throughout France. The famous BORDEAUX MIXTURE was first used as a preventive spray to control this disease.

Downy mildew is now widespread around the world, but a few areas with low spring and summer rainfall are essentially free of it, including Afghanistan, northern Chile, Egypt, and Western Australia. It has occurred spasmodically in California and southern Chile.

The disease attacks all green parts of the vine, and young leaves are particularly susceptible. Severely affected leaves will drop off,

reducing PHOTOSYNTHESIS and thus delaying fruit RIPENING. Levels of fruit SUGARS, vine reserves of CARBOHYDRATES, and ANTHOCYANINS are typically depressed. BUDBREAK and early SHOOT growth can be delayed the following spring. Severe infections result in pale, puny reds and weak whites.

The symptoms of the disease are described quite aptly by the name. Leaves show patches of dense, white cottony growth on the undersurface. The earliest stage is the so-called 'oil spot', easily seen on the upper leaf surface when it is held up against the light. PETIOLES, TENDRILS, young INFLORESCENCES, and developing berries are also affected. The organism spends the winter in fallen leaves and can sometimes survive in the buds. Spores germinate in the spring when temperatures reach 11 °C/52 °F, and they are spread to the vine by rainsplash from the soil. Spores are further spread and germinated with high humidity (95–100% relative humidity), warm temperatures (18–22 °C), and moisture. The most severe epidemics of the disease occur with frequent rainstorms and warm weather. The low yields of French vintages such as 1886, 1910, 1915, 1930, 1932, 1948, 1957, 1969, and 2021, produced after wet growing seasons, were probably at least partly due to downy mildew.

There are two principal protection approaches. The first and most common is to use protective sprays which are often based on COPPER. However, the protection lasts for only ten days or so, especially when the shoots are growing rapidly in early spring. Curative fungicides which act against established infections became available in the early 1990s, but these are more expensive. A modern approach is to install a VINEYARD WEATHER STATION which can predict outbreaks by measuring the weather and facilitate more timely SPRAYING.

An alternative but generally less popular approach to the control of this disease is to plant DISEASE-RESISTANT VARIETIES. European vine breeders, especially at GEISENHEIM and Geilweilerhof in Germany, have been particularly successful in developing varieties which require no, or less, spraying against downy mildew, with native American vines contributing the resistant genes. Increased environmental awareness

will encourage their use, but there is consumer resistance to NEW VARIETIES. R.E.S.

Goode, J., *Wine Science: The Application of Science in Wine* (3rd edn, 2021).

Wilcox, W. F., et al., *Compendium of Grape Diseases, Disorders, and Pests* (2nd edn, 2015).

drainage, free movement of water through the SOIL PROFILE or across the land surface; or alternatively, the removal of surplus water by artificial means. The importance of good soil drainage for viticulture and wine quality cannot be overstated. For a detailed discussion, see Seguin. See also TERROIR and SOIL AND WINE QUALITY.

All good vineyard soils are well drained, whether naturally or by artificial drainage. Permanent waterlogging or prolonged waterlogging after the start of spring growth is lethal to vine roots. Even marginal waterlogging can be harmful, causing restriction of root and soil microbial activity and the consequent starvation of the vine for nutrients and root-produced growth substances (see CYTOKININ). Soils that are cold and wet at the time of FLOWERING are a major factor in poor berry setting, or COULURE. However, if waterlogging is temporary and the soil dries out at or just after flowering, with mild WATER STRESS before VERAISON, it is still possible to produce fine wines, especially on ALLUVIAL soils when SAND or GRAVEL is layered over finer sediment. Such waterlogging may reduce root depth but will not necessarily affect eventual wine quality.

Waterlogging confined to the SUBSOIL can still be a serious disadvantage, through killing or inactivation of the deeper roots. This can result in a vine with only a shallow effective root system, readily subject both to later DROUGHT (after the surface moisture has evaporated or been used) and to excessive water uptake following rains during ripening. Seguin argues that such irregularity in the supply of SOIL WATER can be seriously detrimental to wine quality. Subsoils that are regularly waterlogged can be identified by their

bleached, blue-grey colour (see SOIL COLOUR), while well-drained subsoils are usually yellow, brown or reddish, and mottled subsoils indicate intermittent waterlogging.

As a broad rule, light-textured and stony soils drain freely, while tight or heavy CLAY soils (see SOIL TEXTURE) restrict drainage. Subsoils composed of the latter type can result in water tables 'perched' on top of them. These develop most commonly on gradients, where seepage of water down the slope through the surface soil is interrupted by barriers of rock or of clay reaching or approaching the surface.

However, even heavy soils and subsoils can drain adequately if they have good crumb structure (see SOIL STRUCTURE). This depends on their chemical nature, including sufficient contents of CALCIUM and, in the upper layers, ORGANIC MATTER. Unstructured soils can easily pack down to form impermeable hardpans below the surface when subjected to trampling or wheeled traffic (see SOIL COMPACTION). Vineyards are commonly RIPPED before planting to facilitate drainage (see RIPPING).

Several other management factors can influence soil drainage. Deeply tap-rooted COVER CROPS, such as mustard or lupins, can help to create and maintain vertical channels which allow water to infiltrate freely into the deeper soil layers. The maintenance of an organic surface MULCH, whether applied or originating naturally from cover crops, attains the same effect through encouraging EARTHWORM activity. These useful creatures also help to distribute surface organic matter and nutrients through the soil profile. Finally, the application of LIME or gypsum can help on some acid soils, by improving their crumb structure and permeability.

Artificial drainage, where required, can be of several types according to situation and need. Webber and Jones describe them in detail. All forms of artificial soil drainage are expensive, but, on otherwise valuable land for producing high-value grapes, they can be essential. Drainage did, after all, transform the Médoc from a marsh

to one of the world's most admired wine regions (see BORDEAUX, history). J.G. & C.v.L.

Seguin, G., ' "Terroirs" and pedology of wine growing', *Experientia*, 42 (1986), 861–72.

Webber, R. T. J., and Jones, L. D., 'Drainage and soil salinity', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

draining. In WHITE WINEMAKING the operation usually takes place just after CRUSHING, although some winemakers choose to move crushed fruit straight to the PRESS. Any juice run off without pressing is called drainings. The FREE-RUN juice is drained off the grape skins in a draining tank or draining vat, many of which incorporate special design features to assist the separation of liquids from solids. Similarly, in red-wine fermentation, the red wine run off the skins may also be called drainings.

DRC, famous initials in the world of fine wine, standing for the DOMAINE DE LA ROMANÉE-CONTI.

dried grapes. See RAISINS.

dried-grape wines, varied and growing category of generally intense, complex, often sweet wines made from partially raisined grapes. The production technique, involving either leaving the grapes to raisin on the vine or picking and then drying them by various methods, is associated with most of the celebrated wines of antiquity. This early CONCENTRATION technique continues one of the oldest traditions in the gastronomic world.

In the classical world this winemaking style may well have evolved because of problems of wine conservation, particularly for wines traded and consumed outside their area of origin, semi-dried grapes

naturally resulting in sweeter, stronger, and therefore more stable wines. (BOTRYTIZED wines and the technique of FORTIFICATION were developed many centuries later.) The dried-grape tradition has proved particularly resilient close to its origins, notably in Italy.

Ancient history

The technique of twisting the stems of grape bunches to deprive them of sap and leaving them to raisin on the vine may have originated in CRETE, but vinification techniques for dried grapes were perfected in ancient GREECE. The ancient Greeks also learned from other inhabitants of the eastern Mediterranean, particularly the Hittites of Anatolia. The first description of how to make wine from dried grapes is provided by HESIOD, in the 8th century BCE. His *Works and Days* describes how grapes should be dried in the sun 'for ten days and nights' and then in the shade for a further five, before fermenting the wine in jars.

Such methods were responsible for the famous wines of the islands (Chios, Lesbos, and Thasos) which were so highly prized by HOMER and succeeding writers. These wines were often noted as being at their best after many years' maturation, when they had 'lost their teeth': clear evidence of the longevity which only dried-grape wines could provide before the invention of stoppered bottles. Sealed AMPHORAE may have been relatively airtight containers, but long journeys in Mediterranean heat demanded exceptionally robust wines.

Coincidental with the rise of the Greek city states was the emergence of the most adventurous traders of the Mediterranean, those of PHOENICIA. They exported the wines of Lebanon (and the winemaking practices of CANAAN) along the littorals of North Africa and to Spain, Sardinia, and Sicily. One of their colonies was CARTHAGE, founded in 814 BCE, where in about 500 BCE Mago wrote his seminal work on agriculture, now known only in the extensive quotations which survive in the works of succeeding classical authors, notably the Roman COLUMELLA. Redding quotes Mago in the following passage, which summarizes the Graeco-Roman understanding of dried-grape vinification:

> Let the bunches of grapes quite ripe, and scorched or shrivelled in the sun, when the bad and faulty ones are picked out, be spread

> upon a frame resting on stakes or forks and covered with a layer of reeds. Place them in the sun but protect them from the dew at night. When they are dry (sufficiently shrivelled) pluck the grapes from the stalks, throw them into a cask and make the first must. If they have been well drained, put them, at the end of six days, into a vessel, and press them for the first wine. A second time let them be pounded (or trodden) and pressed, adding cold must to the pressing. This second wine is to be placed in a pitched vessel, lest it become sour. After it has remained twenty or thirty days, and fermented, rack it into another vessel and stopping it close immediately, cover it with a skin.

Other writers in ancient ROME such as CATO, PLINY, HORACE, and VIRGIL add other details (such as storing these wines in the rafters, as with modern Tuscan VIN SANTO), but in general they repeat the principles laid down by their Mediterranean forebears.

The Romans, like the Greeks, planted vineyards wherever they went—in Spain, France, Germany, and central Europe, perhaps even in England. Only in the last would the climate have been too austere for the production of *passum* (PASSITO) wines; elsewhere the practice became embedded in the complex strata of vinicultural history, a rich seam of vinous tradition to be mined in later centuries, after the long upheavals which followed the collapse of the Roman Empire.

Evolution since the Middle Ages

Italy The *vinum reticum* of Verona praised by Pliny was presumably the ancestor of today's RECIOTO and AMARONE. It was relatively common for wines to be made from grapes dried on the vine cut off from the flow of sap by having their stems twisted, or *torcolato*. (This Venetian word is found in the name of a modern white Recioto made in Veneto's BREGANZE from partially dried VESPAIOLA grapes, alluding to the way the grapes are twisted around ropes to dry or are basket-pressed. Similarly, the Italian equivalent *torchiato* is heard in today's Torchiato di Fregona, a sweet wine made in Treviso.) The dried-grape tradition was presumably enhanced in 1204 when Venice conquered Crete, the stronghold of this classical heritage. The result seems to have been a revival of dried-grape winemaking throughout the growing Venetian empire, not just in Veneto but on the islands and coast of what is now SLOVENIA and CROATIA.

In early 14th century PIEMONTE, such wines were in great demand; they are mentioned again in the mid 17th century, but the tradition survives only as a curiosity today. In TUSCANY, however, VIN SANTO survives as an apparently unbroken tradition, practised by most of the best estates. Versions exist in other parts of Italy, notably in TRENTINO. Other survivals include the VERDUZZO of Ramandolo, the generally overrated PICOLIT of FRIULI, the remarkable Rosenmuskateller of TRENTINO-ALTO ADIGE, SFORZATO or Sfursat of VALTELLINA, ALBANA passito from Romagna, and SAGRANTINO passito from Umbria. In the south and islands, examples of this renascent tradition include a range of wines based on raisined MOSCATO, ALEATICO, MALVASIA, and Nasco grapes, not to mention Vecchio Samperi, the rare unfortified wine in the style of MARSALA from de Bartoli. Perhaps the best-known example of passito wine in southern Italy today is Vallone's Amarone-like Graticciaia, dried not three months under the winery roof but about ten days under the Puglian sun, still hot immediately after the grape harvest. And the island of Pantelleria is famous for a wine made from dried Moscato grapes.

Elsewhere It is clear from REDDING that dried-grape wines were much more common in early 19th century France than today. He mentions the VIN DE PAILLE of Alsace, two types from Argentat in the Corrèze (way upriver of modern BERGERAC), one of them slightly sparkling, and what sounds like a magnificent example from the SCIACCARELLU grape made at Sartène in CORSICA. He also makes clear that MUSCAT DE RIVESALTES was then a true raisin wine, often the result of twisting grape stems on the vine, and not, as now, a fortified blend. In contemporary France, the tradition survives only in the *vins de paille* of Hermitage and the Jura, made as curiosities by a small number of producers in each region, in quantities so tiny that they rarely reach the market.

In Spain, the classical traditions continued in muted form through the Muslim occupation and were revived thereafter. The most notable surviving derivatives are the Andalusian specialities SHERRY, MONTILLA, and MÁLAGA, whose richer styles have always been made with semi-dried grapes, but these are not pure dried-grape wines because most (although not Telmo Rodriguez' Molino Réal Málaga) are now fortified. Elsewhere in Spain the tradition is almost extinct.

Surprisingly few dried-grape wines can be found in Greece today. The rich wines of Sámos date from the replanting of the island's vineyards in the 16th century, but those of SANTORINI are descendants of the classical prototypes, as is the COMMANDARIA of Cyprus.

There are records of straw wine (*Strohwein*) being made in FRANKEN in Germany; a rich red dried-grape wine just over the border in Switzerland from Italy's VALTELLINA; a 'green' wine of remarkable strength produced near Cotnar on the borders of Moldova and Romania (see COTNARI); and of course the rather special case of TOKAJI in Hungary. The last survives, as does *Strohwein* in Austria, Switzerland, and Germany, although the term *Strohwein* is protected in the first two and thus prohibited in the third; most of the others have vanished. The only notable additions to the once splendid roll-

call of wines from the old Austro-Hungarian empire are a few straw wines and reed wines from AUSTRIA.

Redding mentions Shahoni, the 'royal grape' of the province of Cashbin in Persia, claiming that 'the grapes are kept over the winter, and remain on the vine a good deal of the time in linen bags', and also lists from Argentina a 'sweet wine, resembling Malaga, made at Mendoza at the foot of the Andes, on their eastern side' as well as the famous CONSTANTIA from South Africa, now revived. In modern times there have also been experiments with dried-grape wines in California and Australia (see CUT CANE). S.P.D.L.

Modern production techniques

Grapes with maximum EXTRACT and SUGARS are required, which normally entails restricting YIELDS. Such grapes may be picked either before, at, or after full RIPENESS. Twisting the stalk was once practised in the Veneto, but most growers now prefer to dry their grapes off the vine.

Those who pick slightly before full maturation claim there is less risk of ROT, thicker skins, enhanced resistance during drying, and higher acidity, all of which favour aroma, freshness, balance, and longevity—and concentrate the grapes which remain on the vine.

Only the ripest, healthiest grapes are generally picked, which today means a pre-selection by experienced pickers. Healthy grapes are vital since any incipient mould or rot soon spreads during the drying process. Skins must remain intact, to which end the grapes may well be laid in small trays for transport to the winery. The bunches should be *spargolo*, loose rather than compact, so that air circulates around the individual berries during the all-important drying process.

Sun drying is still practised in places such as the Sicilian island of PANTELLERIA off Tunisia, in southern PUGLIA, and on the Greek island of SANTORINI. The process can be many times faster than drying under cover, but this can result in excessive colour, caramelized flavours, and loss of aroma, bypassing some of the microbiological transformations which are the essence of fine dried-grape wine.

Most grape drying for commercial purposes happens in a winery loft, where windows may be opened to let in plenty of air (essential against the development of rot and mould). Bunches are hung up vertically (on hooks or on long strings) or are laid out horizontally on neutral, bone-dry materials. Straw is rarely used because of its attractions for mice. Wire mesh, nylon nets, and wooden or plastic fruit boxes were 20th-century developments; more traditional cane and rush mats and bamboo racks remain popular in much of Italy. Today, in zones where dried grapes constitute an important factor in

the local wine economy, purpose-built grape-drying plants have been created complete with temperature control and wind machines.

The duration of the drying process is dictated by the grape variety, the type of wine required, and microclimatic conditions during drying. Sugar-rich Greek grape varieties such as MUSCAT, ALEATICO, and MALVASIA require less time than more northern varieties. Three weeks may suffice for a Muscat, whereas a Veronese variety such as GARGANEGA for a white RECIOTO or CORVINA, CORVINONE or RONDINELLA for a red Recioto or Amarone will need three to four months—in some cases, for Recioto, even up to six months. Ideal conditions include considerable currents of dry air, and humidity is such a problem in some valley sites that drying facilities are being moved to higher elevations. Excessive heat is generally regarded as negative, as is excessive cold.
