The main effect of drying grapes is loss of water and the consequent concentration of sugars. The relationship between water loss and sugar gain is relatively direct so that a water loss of one-third from grapes picked at 12 °BAUMÉ would result in a wine of 16% alcohol (if all the sugar were fermented out). Depending on the wine style desired, the loss of grape weight by evaporation varies between 10 and 60%, with the norm for a PASSITO wine being 35–40%, so the potential alcohol is raised by just over one-third.

Other components behave less predictably. The TOTAL ACIDITY in grapes undergoing a 40% dehydration rises not by 40% but by around 25%. These and other organic substances go through various transformations, resulting in the loss or development of certain aromas in the process. The longer the drying period, the greater the biological change of organic substances and resultant wine quality.

NOBLE ROT may develop on the grapes during dehydration, but it is not desired by most practitioners, particularly those making the drier styles of dried-grape wines such as Amarone. A further problem is insect infestation, particularly of bees, wasps, and hornets.

Crushing or pressing should ideally be as gentle as possible. Gravity may be used to clarify white must; in the case of red wines, stems may be totally or only partially removed.

The MUST of raisined grapes is so concentrated that it slows FERMENTATION, an effect accentuated in cooler climates, especially where the long drying period may mean that the grapes are crushed in midwinter and the ambient temperature is naturally low. In Italy, fermentation may therefore safely take place in wood and may need to be started by heating or by adding specially cultured local YEAST. In traditional areas, the right yeasts have been in the atmosphere for centuries. *Saccharomyces uvarum* begins the job in Valpolicella, according to Masi, while *Saccharomyces bayanus* is able to work at higher temperatures and at the ALCOHOLIC STRENGTH of 16% or more that is necessary for many Amarones.

Some producers allow the fermentation to stop and start for months or even, as in the case of the late Giuseppe Quintarelli, two to three years, allowing Nature to decide how sweet the final wine will be. Most, however, use RACKING and, increasingly, REFRIGERATION to stop fermentation.

The wine is then generally racked off its LEES and the lees sometimes used to enrich normal VALPOLICELLA, the process called RIPASSO. In Tuscany, the so-called GOVERNO process is employed.

Dried-grape wines tend to be particularly high in VOLATILE ACIDS, a direct result of high sugar levels (accentuated if any BOTRYTIZED grapes have been included). The ACETIC ACID of such a wine may well exceed legal levels, sometimes entailing unacceptably high SULFUR DIOXIDE additions. Many argue that high levels of volatile acidity are essential to the quality of such wines, and some maintain that false 'passito' wines can be exposed precisely by improbably low levels of acetic acid.

Dried-grape wines may be divided into two categories: those in which the fresh primary AROMAS are retained; and those in which primary aromas are sacrificed to the development of a more complex ones. The former include most wines based on aromatic varieties such as Muscat, Brachetto, Aleatico, and Riesling, as well as sweet whites where the emphasis is on fruit, such as Recioto di Soave.

These are subjected as far as possible to PROTECTIVE WINEMAKING techniques.

Vin de paille and Vin Santo, with their RANCIO character, are the most notable examples of the OXIDATIVE style. Amarone and Recioto della Valpolicella of the traditional type are also treated oxidatively, the aim being to incorporate in the final tasting experience an evolution of aromas due in some measure to exposure to oxygen. Traditional Amarone and Recioto are, typically, the result of prolonged maceration, deliberately frequent racking, and ageing for years in large, old barrels. Strong, dry Valpolicella Amarone is a notable example, as is Vin Santo with the rancio character encouraged by traditionalists. Since the 1980s, there has been a movement away from such classic styles, however, and modernist Amarone and Recioto producers are aiming for more FRUIT-DRIVEN wines.

Italy produces more dried-grape wine than anywhere else, not least because of the dramatic increase in Amarone production, but experimentation with the technique has spread to Australia, South America, North America, and much of Europe. N.J.B.

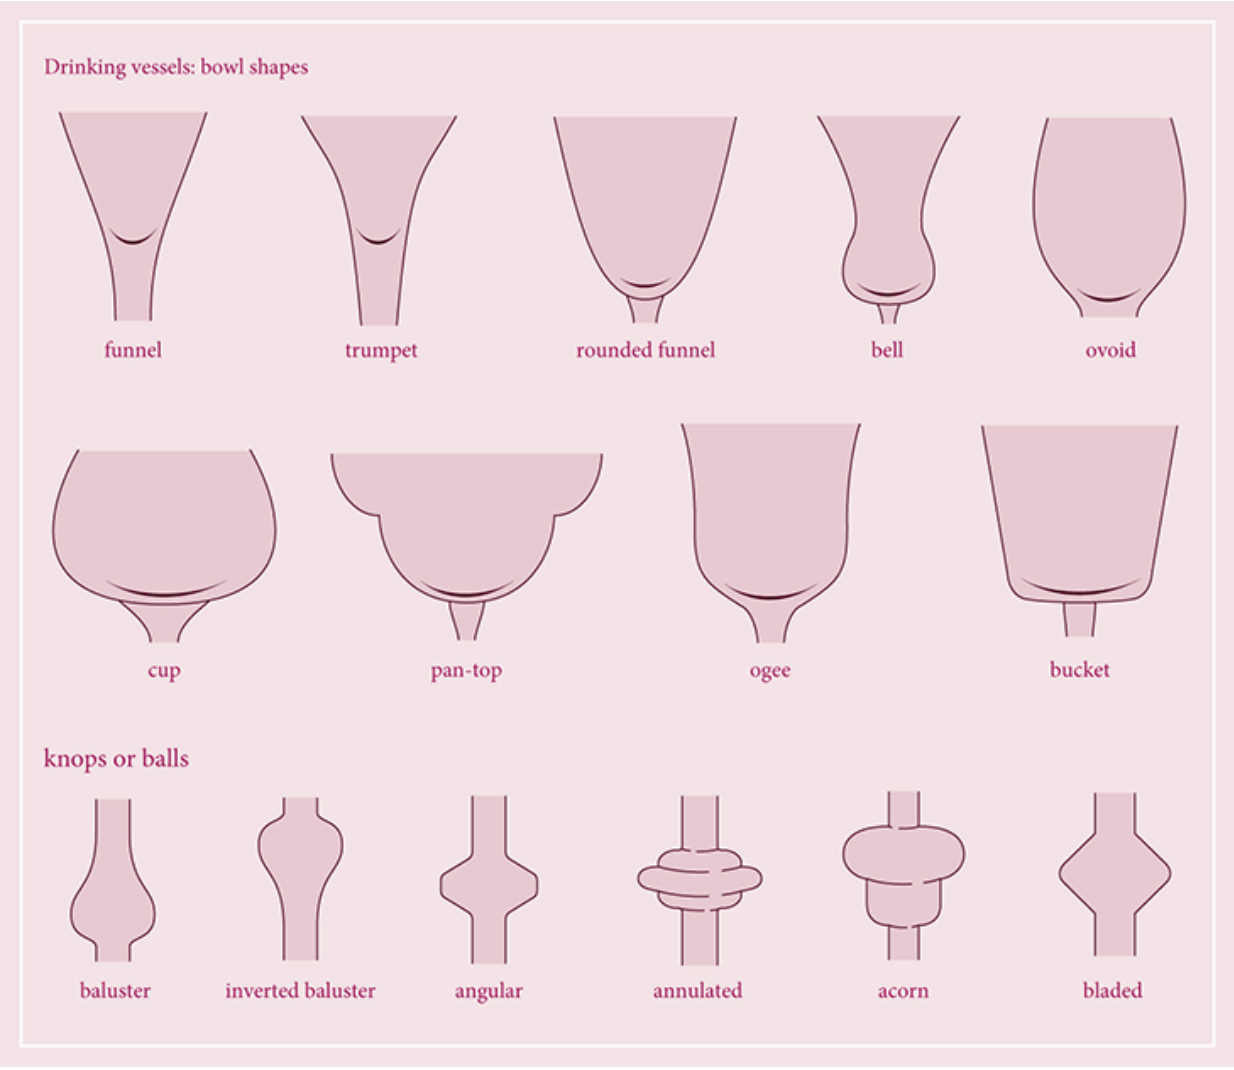
drinking, the activity for which wine was designed, now threatened by rising average ALCOHOLIC STRENGTH. TASTING is different.

drinking vessels. Before the development of glass-making enabled the production of GLASSES (the most common modern wine-drinking vessels), a wide variety of drinking vessels were used for wine. Pottery cups were commonplace, and goblets made of a variety of metals, but even earlier than this wine was sucked through a reed, either from a bowl such as a CRATER or possibly from a hollowed-out gourd or similar vessel provided by Nature. See ancient EGYPT, INDIA, and ARMENIA.



Modern history

The majority of drinking vessels are glass, but—despite its use for thousands of years—glass has not always been available (see GLASS, HISTORY OF). In such times, the principal alternative was silver. There are other occasions when glass was too fragile for a particular environment. Clear drinking glasses were an expensive commodity, beyond the means of most people in the 18th century, but then so was wine—at least in countries where wine was not produced.

Silver was most commonly used for wine-drinking vessels until the Venetian glass industry burgeoned in the 16th century. Although glass became preferred, trade in it was limited; except for exceptional grand occasions and settings, in each country wine was usually consumed from indigenous vessels.

The social history of drinking and eating habits and customs has inevitably played an important part in the history of drinking vessels. FASHIONS change and, for example, the favoured shape for champagne has evolved over the last century from a saucer via a plain tall narrow glass flute to a tulip or regular wine-glass shape. The first introduction of suites of glasses in limited sizes was in the late 18th century, but the designated use for each size can only be conjectural.

It is often observed that many 18th-century drinking glasses are small, but they have to be considered in context. They were not placed on the table for the diner to quaff at will. Rather, they were brought by the footman to each diner when requested and were taken after each draught to await another request. It may be speculated that the larger goblets were used by gentlemen after the servants had been dismissed towards the end of the meal.

By the mid 19th century, service *à la russe* had become fashionable, with its place settings of cutlery and glasses with which a diner today would be familiar. The ‘new’ arrangement dispensed with the need for a footman for each diner, and it was the cause of the widespread use of long sets of glasses, with each diner having up

to six glasses for different wines, not to mention tumblers and finger bowls.

Glass Drinking vessels in both silver and glass were made by the Romans. The glass-making craft went into decline after the collapse of the Roman Empire; although glass was made in small quantities, it was not until the Renaissance that glass-making gained a prominent place in the decorative arts in VENICE. By the 16th century, Venice was producing fine and elegant drinking glasses. The soda glass was almost colourless and very thin. The often-decorated baluster stems had elements of very narrow section.

Draconian attempts to prevent the secrets of glass-making from leaving Venice were put in place in order that the city should retain its supremacy. However, a few of those with the knowledge did leave, and small factories sprang up all over Europe in consequence. To raise revenue, the English monarch granted glass-making monopolies on payment of a fee, and in 1574 Elizabeth I let a lapsed monopoly fall to Giacomo Verzelini. A few of his glasses, closely following Venetian models, sometimes dated and usually engraved, survive. England and subsequently Britain became the dominant production centre.

In the early 17th century, wood-fired furnaces were outlawed in England, hence the setting up of glass houses in coal-producing areas —Newcastle, Stourbridge, and Bristol. As described in DECANTERS, a major advance in glass technology was made in the 1670s by George Ravenscroft with the introduction of lead and flint glass, and it was this which enabled British glass-makers to hold world supremacy for the ensuing hundred years. However, drinking glasses were still being made in Italy and in large numbers in what is now Germany and the Netherlands throughout the 17th century.

The earliest lead glass was frequently unstable and soon after manufacture developed crizzling: a myriad of short cracks within the glass that gave it a milky effect. Ravenscroft and others in England soon improved the recipe and technique, enabling them to produce glasses of a rich weight and colour, quite unlike the light, pale products of Venice. The soda glass of Venice lent itself to thin and elegant shapes, often embellished with lattice designs in opaque white glass within the form or with coloured elements. The English

lead glass, by contrast, was heavy and with a grey tint, capable of being drawn into bold plastic forms.

The drinking glass can be divided into three parts: the bowl, stem, and foot. Made separately, the parts were put together during the final stages of production. The bowl can take a variety of shapes, each with a name recognized in the large glass-collecting fraternity. Trumpet, ovoid, bell, and bucket are obvious shapes, but rounded funnel, ogee, cup, and pan-top are also illustrated above.

The stem of a wine glass is perhaps the element offering most opportunity for decorative treatment. The stem may be straight or with swellings called knops. The early examples were generally heavily knopped, the main element of the stem often of baluster outline but with other swellings above, below, or both. The knops, like the bowls, have names such as acorn, bladed, baluster, annulated, and ball, all of which are more or less self-descriptive (see diagram).

Beneath the stem is the foot. Most wine glasses have a foot of a flattish conical section, some raising the stem 5 mm/0.25 in or more away from the table, others by three times as much. Most glasses before the mid 18th century have an additional feature called a folded foot. Long before English glass became pre-eminent it was realized that if, when the foot was made, the rim was folded underneath itself, a much sturdier glass was the result. Some glasses have a domed or tiered foot rather than a conical one.

During the 1670s and 1680s, wine glasses followed the Venetian forms, some of which had changed little over 100 years. By the 1690s, the particular qualities of lead glass began to be appreciated and resulted in the manufacture of glasses of substantial weight and a solid form quite distinct from the Venetian tradition. Over the next 20 years, designs were refined to what many consider the zenith of glass-making, characterized by bold, pure, unadorned form. Many glasses were lightened by air bubbles or tears being blown within the stem and occasionally at the base of the bowl, but the form remained substantial. These glasses are referred to as heavy balusters.

The heavy balusters became lighter as time progressed, partly perhaps because of taxation on the weight of glass. The bold designs became more fussy, with increased numbers of elements in the stem, and the stem itself became thinner. The heavy balusters had given way to light balusters and balustroids by the 1730s and 1740s. Some glasses had stems moulded of polygonal section; these are known as Silesian stems. During the 1740s and 1750s many glasses had stems that had inserted in them a series of small bubbles. When twisted and stretched these formed helices of air within the stem, or air twists. By this time, too, it was becoming fashionable for the stems to be straight sided, and folded feet were at the end of their span.

A popular form in the 1760s was the result of twisting opaque white or coloured glass into the stem, instead of air bubbles.

The next phase of glass-making was the facet stem—quite simply the cutting of the stem with shield, diamond, or hexagonal facets. Traditionally air twists have been dated to the 1750s, opaque twists to the 1760s, and facet stems to the 1770s. It seems far more likely in view of the general shape and proportion of these styles that they were made more or less concurrently; whatever the truth, it marked the end of the golden age for British glass collectors. Facet stems continued to be made to the end of the century, with the stems becoming shorter and the overall proportion degenerating.

During the 18th century, there were forms of embellishment other than pure shape. Wheel-engraving produced fine decoration in the 1730s and 1740s, sometimes being delicate bands of flowers and scrolls around the rim, while glasses engraved with Jacobite and Williamite symbolism had their enthusiastic followers. In the 1760s, the enamelled decoration of William and Mary Beilby of Newcastle enjoyed royal and other esteemed patronage, while in the following decade the gilt decoration of James Giles drew its admirers, as did the stipple engraving of David Wolff.

The 19th century saw the fast decline of design, with many drinking glasses cut to match the cut decanters of the period. At this time, too, the idea of having glasses in different sizes and shapes for different drinks was becoming widespread, although this idea was not unknown in the 1780s. By the mid century, glasses could be ordered

in large suites with sizes from goblet to liqueur matching the decanters, claret jugs, and finger bowls. Decoration was either cut or acid-etched and in a variety of patterned styles.

The 20th century saw an interest in antiques, and a large quantity of glass was made, much of it in the Georgian style. For the amateur it can be difficult to distinguish between a Georgian decanter of, say, 1815 and a copy made 100 years later. Wine glasses with green and cranberry-coloured bowls on clear stems also became popular at this time.

Silver During the 16th century and before, glass was a very highly prized commodity, and wine would normally have been consumed from silver or silver-gilt goblets. Early wine cups—often with a cover—were invariably heavily decorated and were considered status symbols. Many that remain are so large that their use must have been communal. Smaller cups for individual use date back to the Middle Ages, but by the 1570s a standard pattern of a wide, shallow bowl on a baluster stem emerged. The making of silver drinking cups appears to have almost stopped by about the 1650s, probably due to the impact of Venetian glass and the subsequent burgeoning of glass-making in England.

There was a revival of silver drinking goblets in the 1780s which lasted for some 25 years. These were usually quite large, having ovoid bowls often made in prevailing styles during the 19th century in small numbers.

Other materials Drinking vessels were made in a variety of other media. Before long-distance maritime trade became frequent, ostrich eggs and coconuts were particularly prized for their exotic rarity and were mounted in silver as cups. At a more basic level, the horns of various animals were used for drinking, and wood was lathe-turned into cups and goblets. Antique cups of pottery and earthenware are also occasionally found. drip irrigation, a form of IRRIGATION in which water is applied literally as drops to each vine from a pressure-reducing plastic device (the dripper) attached to a plastic pipe suspended about 40 cm/10 in above the ground from posts along each vine row. The technique was developed in Israel and Australia in the 1960s and has been widely adopted wherever irrigation is permitted. Drip irrigation has transformed viticulture. Unlike flood irrigation, it allows irrigation of vineyards on undulating land and uses a limited water supply to maximum advantage. The technique requires extensive filtration of irrigation water, and soluble FERTILIZERS can be added directly to it, a process known as FERTIGATION.

Refinements include pressure-compensated drippers to manage a range of TOPOGRAPHIES, burying irrigation lines, or connecting the dripper to a buried emitter, techniques which usefully reduce evaporation from the wet soil surface. Research into the benefits of above- or below-ground systems in Australia and New Zealand has shown contradictory results, but a buried drip system placed mid row allows LEGUMES to be grown and managed by mowing, a convenient source of NITROGEN for organic vineyards (see COVER CROPS).

drones, or unmanned aerial vehicles (UAVs), are proving useful and versatile in the vineyard, for example for measuring vine VIGOUR, temperature, and wind conditions; SPRAYING; potentially monitoring pests and diseases; and deterring BIRDS. They are less expensive than helicopters and conventional aircraft, and they can get much closer to the vines. See also REMOTE SENSING and ROBOTS.

drosophila, an insect pest of grapevines. The names 'fruit fly', 'Mediterranean fruit fly', 'vinegar fly', and 'pomace fly' are all applied to various species of *Drosophila*, in particular *Drosophila melanogaster*. *Drosophila* feed and reproduce in fermenting fruits and can frequently be found in the domestic fruit bowl. The major damage they cause in grapes, with a drastic reduction in wine quality, is the spread of bunch rots, especially SOUR ROT. *Drosophila* multiply rapidly—with a period of only six to eight days for the egg-to-egg reproductive cycle in hot climates—which explains why this fly has been used so much for the study of genetics. They are also a common problem in wineries during vintage, when insects can contaminate wine by spreading harmful bacteria, particularly ACETIC ACID BACTERIA. Maggots may develop in overripe fruit. Control is difficult and includes the destruction of breeding places, such as piles of rejected fruit and pomace.

While *Drosophila melanogaster* is an inconvenience, the Spotted Wing Drosophila (*Drosophila suzukii*) is an acknowledged pest which is causing concern in many vineyard and fruit-growing regions. This small insect has been known in Japan as a pest of soft-skinned fruits such as strawberries, cherries, and grapes since the early 1900s. It was first noted in North America on California strawberries in 2008 and has now spread north to Oregon and British Columbia, south to Mexico, and as far east as Quebec by 2013. The insect was first reported in Spain in 2008, and by 2012 had been reported in 11 countries, causing severe problems in several European regions in 2014. The main cause for concern is that the female has a strong, serrated ovipositor, enabling her to lay eggs in ripening fruit. Eggs hatch in a day, and maggots feed inside the fruit with no visible sign of their presence from the outside, making it difficult to eliminate the grapes from the harvest. R.E.S.

drought, a severe and prolonged deficit of RAINFALL, compared with that normally received. Its implications for viticulture depend on the region and its normal climate. In cool and wet viticultural regions, drought years often produce the best vintages, especially of red wines. This is because excessive vegetative growth, or excess VIGOUR, is arrested; YIELDS are limited; BERRY SIZE may remain small with purported benefits for wine quality; and sunshine and warmth are greater than average. Such effects are well known in Europe and New Zealand.

However, severe WATER STRESS reduces yield and negatively affects the vine's ability to ripen grapes. It is almost always detrimental to

wine quality, especially if it occurs during ripening.

Most dry viticultural climates are regularly warm and sunny enough, and drought is nearly always detrimental: whether directly, in the case of DRY-FARMED vineyards, or indirectly via a lack and/or reduced quality of IRRIGATION water. California suffered a periodic drought from 2011 to 2017 and again in 2020, with more than half of California suffering 'extreme drought' in 2021, causing stresses on underground water reserves and leading to devastating WILDFIRES. Australia also suffered drought and irrigation water restrictions, as well as bushfires, earlier in the 21st century and again in 2017–19. These phenomena are increasingly associated with CLIMATE CHANGE. Drought in such climates reduces growth and yield, and if very severe they can disrupt the ripening process more or less completely. In desert regions, drought is the norm, and commercial viticulture may survive only if sufficient irrigation is available.

Drouhin, Joseph , one of the most respected grower-merchants in Burgundy. Founded in 1880, the firm is based above historic cellars in the city of Beaune, dating from the 13th century. Joseph's son Maurice, who took over control of the firm in 1918, built up its reputation for quality and acquired a number of important vineyard holdings, starting with the Clos des Mouches (see BEAUNE). After the Second World War, exports of Joseph Drouhin wines increased considerably.

Robert Drouhin took over control of the house in 1957 and made many significant vineyard acquisitions, particularly on the Côte de NUITS, including Musigny, Griotte-Chambertin, Bonnes Mares, and Grands Échezeaux. An outpost in CHABLIS was established as long ago as 1968, with holdings in several GRANDS CRUS and PREMIERS CRUS. In 2020 the firm's holdings (all organically cultivated, with biodynamic practices) totalled 79.92 ha/197.49 acres. Drouhin also vinifies and distributes wines from the Laguiche family domaines, including Le Montrachet.

At 12,500 plants per ha its VINE DENSITY is one of the highest in Burgundy (where the average is 10,000). Drouhin was one of the first firms to investigate and embrace the fundamentals of modern winemaking, although many traditional techniques are also used. The clean, rigorous wines are never among Burgundy's richest but are serious expressions of each appellation. Today the firm is run by Robert's children Philippe, Véronique, Laurent, and Frédéric, together with Véronique's eldest daughter Laurène.

Somewhat ironically in view of Maurice's stated aim that Joseph Drouhin should concentrate on burgundy exclusively, Robert Drouhin was the first Burgundian to make a significant investment in a wine region outside France. Domaine Drouhin Oregon, established in 1987, owns 100 ha/250 acres of vines in production in Oregon's Dundee Hills. Roserock vineyard in the Eola-Amity Hills was acquired in 2013. These Oregon wines are vinified by Véronique Drouhin.

drunkenness and its history is inextricably entwined with that of wine, since one of the chief reasons wine has been cherished, and prohibited, is its property to intoxicate. Excessive wine drinking has therefore always had moral or religious connotations, beginning with the 'shameful' intoxication of Noah after the Flood (see BIBLE).

Varying definitions of what constitutes excessive drinking have prevailed at different times and in different societies, with opinions sometimes diverging within that same society. It is also important to note that drinking has always accompanied festivity and ritual and that societies have developed rules to contain it. The fear that these rules may be violated and society threatened is therefore apparent at almost every stage in the history of drunkenness.

Wine drinking is first documented in the ancient civilizations of the Middle East; the same is true of drunkenness (see SUMER and ancient EGYPT). An early Mesopotamian tablet describes a man drunk from strong wine: 'he forgets his words and his speech becomes confused, his mind wanders and his eyes have a set expression'. The suggested hangover cure includes liquorice, beans, and wine, to be administered before sunrise and before he has been kissed. The

request of an Egyptian woman living in the 17th Dynasty may have been typical: 'Give me 18 cups of wine, behold I should love drunkenness.' Other races were quick to point the finger of over-indulgence at the Egyptians.

Sources show that drunkenness was both tolerated and at times denounced in these ancient civilizations. Although wine played a part in all their religions, the voice of disapproval most frequently heard was clerical. The ancient Jews also displayed a somewhat equivocal attitude towards wine drinking. The Old Testament contains many warnings against drunkenness alongside mentions of the positive benefits of temperate wine drinking. Some Jewish religious sects, such as the Nazarenes, chose to abstain altogether.

Society in ancient GREECE also showed a marked ambiguity in attitudes towards wine drinking. On the one hand, strict guidelines were laid down to curb any excess. Plato advised no wine before the age of 18 and moderation until 30. The all-male drinking party known as the SYMPOSIUM was, when properly observed, a strictly controlled ritual of drinking combined with poetry, entertainment, and debate. The aim was pleasant intoxication without loss of reason. See HERODOTUS for some more details.

On the other hand, some Greek wine drinkers drank specifically to lose their reason. The worshippers of the wine god DIONYSUS deliberately became intoxicated; indeed this was, in their eyes, a fundamental point of their religion. The authorities took fright at their wild behaviour, identifying drunkenness with a breakdown in social order. Despite attempts to ban the cult, its popularity continued into the Roman era, but attitudes towards drunkenness shifted somewhat afterwards. The Christian Church, while hallowing wine as a sacrament (see EUCHARIST), sought to dissociate itself from the riotous habits and heavy drinking of earlier religions. Behaviour reminiscent of the Dionysiac cult was met with excommunication. When St Bernard developed the Cistercian order in Burgundy he originally intended abstinence for his brethren; this was soon dropped. Monks earned a reputation for excessive drinking in the Middle Ages, but

this reflected their dominance in winegrowing as much as in wine consumption (see MONKS AND MONASTERIES).

There were periods in ancient INDIA when drunkenness was considered a desirable state. Drunkards in the Middle East faced a formidable obstacle, however, in Muhammad's total prohibition on wine (see ISLAM). Wine drinking did not cease because of it but had to be covert. Drinking among the upper classes of Persian society, for example, took place at secret parties reminiscent of Greek symposia, with their strictly ritualized etiquette and emphasis on poetry and discussion (see ARAB POETS).

Meanwhile in Europe the scope for drunkenness was considerably increased with the discovery of DISTILLATION in the 12th century. Intoxication reached new heights as demand for this new liquor spread across the continent. The Dutch and Germans gained reputations throughout Europe for their drunkenness. In 17th-century Holland, drinking hours were applied to keep drinking in check. In Britain, too, drunkenness on the streets was increasingly blamed on spirits. By the 18th century wine was relatively expensive, and only the middle and upper classes could afford this route to drunkenness.

The Victorians were not the first to confront the problem of drunkenness, but they put it on a new footing. Alcoholism was defined as a disease in the mid 19th century and came to be identified with degeneracy of race. In Britain, wine was not seen as the main culprit—indeed it was seen by many, including Prime Minister Gladstone, as the remedy against drunkenness. The new catchword was 'temperance', and, while in the minds of some this meant the encouragement of moderate wine drinking to combat the medical and social ills of addiction to spirits, to a growing band of (often religiously inspired) campaigners it denoted complete abstinence. The governments of Britain and the United States adopted differing interpretations. Gladstone lowered the duty on light TABLE WINES to improve the health and morals of the British, while American states gradually voted themselves 'dry', culminating in full-blown PROHIBITION, which came into force in 1920. Drupeggio, name for the high-acid CANAIOLO Bianco that adds interest, with Trebbiano grapes, to Grechetto, Malvasia, and Verdello, in the ORVIETO wine of central Italy. Total plantings had fallen to 81 ha/200 acres by 2015.

dry, adjective often applied to wines, usually to describe those in which there is no perceptible SWEETNESS. Such wines may have as much as 10 g/l of RESIDUAL SUGAR, or even more in wines with particularly high ACIDITY (which tends to counterbalance sweetness), but in general the level is under 2 g/l. In this sense, virtually all but the most commercial red wines are dry, while white, rosé, sparkling, and fortified wines can vary considerably between bone dry, dry, medium dry, medium sweet, and sweet.

Some wines, particularly reds, are said to have a 'dry finish' if they are especially ASTRINGENT.

For the technical definition of 'dry' as laid down in EU labelling regulations, see SWEETNESS.

Dry Creek Valley, California wine region and AVA north-west of Healdsburg. See SONOMA.

dry extract. See EXTRACT.

dry-farmed vineyards rely entirely on natural RAINFALL and are sometimes referred to as rain-fed.

There can be little doubt that some European areas with both moderate rainfall and MEDITERRANEAN CLIMATES, now practising dry farming, could in many circumstances improve their YIELD and wine quality if limited IRRIGATION were allowed. Excessive WATER STRESS causes loss of PHOTOSYNTHESIS and eventually of the leaves themselves, and it can seriously prejudice normal RIPENING.

On the other hand, even in NEW WORLD regions where irrigation is widely practised, dry-farmed vineyards are often prized for the quality of their fruit, for which some wineries will pay a premium, thereby allowing such vineyards to remain economical. As WATER shortages become more prevalent with CLIMATE CHANGE, dry-farmed vines are likely to become more common, at least in regions of moderate rainfall, as will the use of irrigation. Dubourdieu, a father and son of particular importance in the history of white winemaking in BORDEAUX. The father Pierre (1923–2021), owner—with son Denis—of Ch Doisy-Daëne in BARSAC, produced the first dry white wine in the SAUTERNES area, and it is still made today. He was also instrumental in helping the Vaslin company improve the action of their grape PRESSES, and he was clearly an inspiration to his son Denis, co-oenology editor of the 4th edition of this book, with whom he worked on many experiments.

Denis Dubourdieu (1949–2016) was a research scientist at BORDEAUX University and owner and winemaker at Ch Reynon in CADILLAC CÔTES DE BORDEAUX, Clos Floridène and Ch Haura in the Graves, and Ch Doisy-Daëne and Ch Cantegril in Barsac. In 2014 he bought Ch Doisy-Dubroca, a small classified estate next to Doisy-

Daëne. He was also, with his associates Dr Valérie Lavigne and Christophe Olivier, an international CONSULTANT in OENOLOGY.

He and his research team have been a significant influence on white winemaking, not just in Bordeaux but throughout France and abroad. His early areas of research were into the nature of *Botrytis cinerea* and in particular NOBLE ROT; earlier picking dates to enhance the AROMA of wines made from aromatic white grape varieties; and the influence of fermentation TEMPERATURES and selected YEAST on white wines. Later he investigated FLAVOUR COMPOUNDS in grape pulp and skins, identification of which can assist in the matching of vine varieties to soils and in aspects of vinification strategy such as picking dates, fermentation temperatures, and—a favourite research area of his—the extent of pre-fermentation maceration (see SKIN CONTACT). In particular, he elucidated the chemical nature of the varietal aromas of SAUVIGNON BLANC wines and their odourless precursors located in the grapes; he also demonstrated for the first time that yeast metabolism is involved in the transformation of FLAVOUR PRECURSORS into wine aromas. He also clarified the significant REDUCTIVE and FINING properties of yeast LEES during BARREL FERMENTATION and BARREL AGEING, rationalizing the ancient practice of BÂTONNAGE and also explaining why white wines fermented and aged in barrel are less oaky, oxidized, and astringent than those put into barrel only after fermentation and without lees. Denis Dubourdieu and co-researchers also studied the aroma compounds associated with oak BARRELS; they identified furan-methanthiol as the molecule responsible for the 'toasty' flavour of wines aged in oak. They also extensively investigated various off-odours in wines: those associated with REDUCTION, OXIDATION (including PREMATURE OXIDATION); GRASSY aromas due to ISOBUTYL-METHOXYPYRAZINES; and the ethylphenols associated with BRETTANOMYCES contamination. Most importantly for wine enthusiasts, his explanations of many of the phenomena of vinification have helped winemakers exploit them on a practical level.

Ducellier, name associated with a special fermentation vat designed to extract, without electricity, maximum colour and TANNINS even in short fermentation periods. The system was devised for winemaking in ALGERIA but is now most commonly used to make PORT. See AUTOVINIFICATION.

Duché d'Uzès. In 2020, this region west of the central Côtes du RHÔNE growing area encompassed 317 ha/783 acres. Given its size, relatively little wine is currently bottled under the AOC. The production is 55% red, 16% rosé, and 29% white. Red wines are majority Syrah with Grenache; rosés are majority Grenache with Syrah; whites are majority Viognier with Grenache Blanc. M.C.W.

dulce, Spanish for 'sweet'. See SWEETNESS and, for official EU sugar levels, DOSAGE.

Dundee Hills is a wine region and AVA in the WILLAMETTE VALLEY of Oregon. It is often referred to as 'the Red Hills of Dundee' for its ruddy-coloured VOLCANIC clay soils.

Dunkelfelder, dark-skinned GERMAN CROSS notable mainly for the depth of its colour, a useful commodity in Germany's blending vats. Originally said to be a Blauer Portugieser × Teinturier cross, DNA PROFILING has shown it to be Madeleine Angevine × TEINTURIER. It is popular with growers if not consumers. German plantings totalled 206 ha/509 acres in 2019, mostly in the Pfalz. It is also grown to a limited extent in Switzerland and England. J.V.

Duras is perhaps the oldest vine variety still used in the once-famous red wines of GAILLAC. Its presence distinguishes them from the complex mosaic of other blending permutations that comprise the reds of SOUTH WEST FRANCE. It is not grown in the Côtes de Duras, nor anywhere else in any significant amount outside the Tarn *département*, where Gaillac is the chief appellation. In the Tarn, however, like its blending partner FER, it steadily gained ground thanks to Gaillac's powerful internal lobby against incoming INTERNATIONAL VARIETIES. But total plantings have started to decline once again, down from a peak of more than 1,000 ha/2,471 acres in 2008 to 781 ha/1,930 acres in 2019. The wine is deeply coloured, full-bodied, and lively. VARIETAL Duras wines produced in Gaillac show particularly good structure and acidity, eloquently demonstrating a marriage of CÉPAGE to TERROIR well worth defending. DNA PROFILING has shown that it is a natural CROSS of TRESSOT × SAVAGNIN.

Duras, Côtes de, red and white wine AOC (since 1937) of SOUTH WEST FRANCE, bounded by Côtes du MARMANDAIS to the south, BERGERAC to the north, and ENTRE-DEUX-MERS to the west. The town of Duras, with its impressive castle, marks the eastern extremity of the Entre-Deux-Mers plateau, and the 1,943 ha/4,857 acres of vines are planted either on LIMESTONE hilltops or on slightly more sheltered limestone and CLAY slopes.

The vine varieties are essentially those of BORDEAUX, and a specifically Duras character in the red wines is difficult to discern

(although winemaking techniques such as BARREL MATURATION are increasingly employed). White Côtes de Duras can display originality, however, in fresh, dry Sauvignons and the sweet or MOELLEUX wines usually produced from Sémillon and MUSCADELLE.

The district has become a hotbed of ORGANIC and BIODYNAMIC VITICULTURE among the smaller producers, while the energetic CO-OPERATIVE of Landerrout-Duras is responsible for about half of the region's wines. P.S.

Durbanville, an important ward in the Coastal Region in SOUTH AFRICA, part of the Tygerberg district.

Durella, tart, white grape of the VENETO producing both sparkling and sweet wines.

Dureza, scarcely cultivated Ardèche dark-berried vine variety famous chiefly as a parent of Syrah, with MONDEUSE BLANCHE, and as a possible half-sibling of AGLIANICO.

Duriense, Portuguese VINHO REGIONAL whose boundaries correspond to the DOURO region, but producers may use a much wider range of grape varieties. As a result, a handful of credible examples of Pinot Noir, Syrah, Petit Verdot, Malbec, Sauvignon Blanc, Riesling, and Chardonnay bear witness to the Duriense's great diversity of TERROIR. S.A.

Durif is a well-travelled black grape variety, revealed in 1999 as probably a CROSS of PELOURSIN with SYRAH, propagated by a Dr Durif in south-eastern France in the 1880s. Today it has almost disappeared from France, but it is still cultivated in both North and South America as the dominant proportion of all vines called PETITE SIRAH.

As Durif, it was long grown in Australia's RUTHERGLEN, making a prodigiously inky, alcoholic wine of surprising quality. In the late 1990s and early 2000s, it was enthusiastically planted by RIVERINA growers who valued the way it retains deep colour and strong flavour even when heavily cropped. They were responsible for over half the national total of 625 ha/1,544 acres in 2015.

dusting, a vineyard practice designed to apply AGROCHEMICALS in dry powder form. Typical of such operations is the application of finely ground elemental SULFUR dust to control the fungal disease POWDERY MILDEW. Most vineyard agrochemicals are applied by SPRAYING, using a liquid formulation with water as the carrier. R.E.S.

Dutch East India Company, powerful trading organization which played a seminal part in the wine history of SOUTH AFRICA. Founded in March 1602 by the amalgamation of four Holland and two Zeeland companies which had been set up between 1596 and 1602 to conduct trade in East Asia, the General United Chartered East-India Company in the United Netherlands (Vereenigde Oost-Indische Compagnie: VOC) dominated European trade with the Orient for the rest of the 17th century, with counters and outposts strung out along the extended sea routes which linked the Netherlands with southern Africa, India, Ceylon, Sumatra, Java, Borneo, and Japan. Apart from its participation in the bulk transport of FORTIFIED WINES such as MADEIRA and spirits to the ends of its seaborne empire, it played a vital part in the Dutch penetration of southern Africa and in the establishment of viticulture on the Cape of Good Hope. See SOUTH AFRICA, history. A.J.D.

Dutchess, white AMERICAN HYBRID based on VITIS LABRUSCA, *Vitis aestivalis*, and VITIS VINIFERA grown with limited success in New York State. Created in 1868 by Andrew Jackson Caywood in Poughkeepsie, New York.

Dutch wine trade, a major influence on the history of international trade in wine. By the middle years of the 17th century, the Dutch republic had achieved a dominant position in the world trade in wines and spirits (and much else besides)—greater, even, than that of ENGLAND, whose Navigation Acts of the 1650s were directed specifically at Dutch freight. John Locke recorded in 1678 that the Dutch conducted more trade through BORDEAUX than England. Amsterdam, Rotterdam, and Dordrecht were world emporia. Its geographical position, at the estuaries of three great RIVERS, Schelde (Scheldt), Maas (Meuse), and Rhine, made it a natural point of convergence for river-based traffic; its wealthy bourgeoisie created a consumer demand distributed throughout the region, in addition to that of the nobility; and, lastly, its relative proximity to long-established and highly productive winegrowing areas enabled it to become a major conduit for the highly prized wines of the Rhineland and Alsace (see GERMAN HISTORY).

The RHINE (and its distributaries Waal and Lek) was virtually a wine highway, linking Cologne with Dordrecht and Rotterdam. Moreover, Middelburg in Zeeland, on the island of Walcheren at the estuary of the Schelde, had been the principal port of call for a centuries-old and highly lucrative seaborne traffic which linked the Atlantic seaboard with Scandinavia and the lands of the Baltic; formerly the principal staple (official market) for the whole of the Netherlands and earlier still the out-port serving the Flemish and Brabançon cities of Bruges, Ghent, and Antwerp, it had been secured for the independent Netherlands after the rising against Spain in 1568.

Hanseatic League

Although merchants from the region had been handling wine from very early times, it was not until the late 13th century that the Dutch, principally Hollanders and Zeelanders, entered the thriving maritime commerce which linked the countries of the Atlantic seaboard with the Baltic, as associates of the German Hansa (the Hanseatic League). This powerful alliance of about 80 merchant towns had by that time established a virtual monopoly of Baltic and Scandinavian trade by organizing large fleets of merchant vessels to transport basic commodities in bulk. From 1237 they began to acquire rights in English markets; and from 1252 they acquired trading privileges in Flanders, with reduced customs in Bruges and its out-port Damme.

Thus they gained access to the Atlantic trade and the estuaries of the 'wine rivers' of Europe: Adour, Lot-Tarn-GARONNE, LOIRE, Seine, Schelde (Scheldt), Maas (Meuse), and Rhine-MOSEL, to which would later be added the Guadalquivir, for SHERRY, and the DOURO for PORT, or at least their prototypes. French wines, chiefly from Gascony and Poitou, French salt from the bay of Bourgneuf, English wool, and Flemish cloth constituted the major commodities traded for the produce of the northern lands. This was the commerce which enriched the cities of Ghent, Bruges, Ypres, Antwerp, and many others. Wine consumption was a mark of wealth in northern lands. At a time when a wage-earning man might have to spend one-third of his income on bread, noble households devoted more than one-third of their expenditure to wine, although cheap wine was readily available in taverns and inns, where it had to compete with locally brewed beer and ale.

Zeelanders and Hollanders played an increasing role in the transportation of wines from Bordeaux and LA ROCHELLE to England, Flanders, and the Baltic from the last quarter of the 13th century onwards, gradually supplanting the Flemings and Brabançons, and they were joined in the course of the 14th century by mariners and traders from Dordrecht, Zierikzee, and Middelburg. In the first quarter of the 14th century, wine represented respectively 31% and 25% of

imports into England and the Low Countries (Flanders, Zeeland), although this very high proportion was never equalled again. Much of this wine was re-exported: Gascon wine from England; Poitevin, Loire, and Rhine wines from Flanders and Zeeland.

The Dutch dominated the Bourgneuf salt trade during the 15th century, acquired a large share in the export of CLAIRET from Bordeaux and of the cheaper, white Poitevin wines from La Rochelle, and established a direct trade between Bourgneuf and the Baltic, carrying principally salt and wine and returning to the Low Countries with fish, furs, and grain. The chief commercial centre was the thriving port of Middelburg, recognized by the Habsburg government in 1523 as the official French-wine staple for the whole of the Netherlands, where merchant ships of all countries transported their wares.

After England's loss of Gascony in 1453, before which wine was exported from Bordeaux to England and then re-exported by licence, the Dutch secured the lion's share of the direct trade out of Bordeaux so that Hanseatic and Dutch vessels shipped huge quantities of wine to Middelburg. The western French wines of Poitou, Saintonge, and Aunis were transported in Dutch and Breton ships. Expensive sweet Mediterranean wines (from the Peloponnese, Crete, Cyprus, and Rhodes) were carried by ships from GENOA and VENICE. Some Rhine wines also found their way to Middelburg, but the bulk of these highly favoured wines travelled down the Rhine by barge to Dordrecht. From Middelburg and Dordrecht wines could radiate by sea or pass by river to Antwerp and thence to the rest of the region and beyond. The Dutch employed fleets of full-rigged ships of relatively large tonnage (up to 200 tons), which enabled them to undercut the freight charges of their competitors by a significant margin.

Expansion outside Europe

During the 16th century, three major changes, economic, religious, and political, contributed to the further expansion of Dutch commerce. The first was the fragmentation of the Hanseatic League itself, of which the Dutch were major beneficiaries and agents, enabling them to establish a virtual monopoly of Scandinavian and Baltic trade. The second, and much more dramatic, event was the undermining of Antwerp's commercial dominance by Spanish attempts to retain control of the Netherlands during the last third of the 16th century. The third was the declaration of independence from Spain made in 1581 by the seven northern provinces (Holland, Zeeland, Utrecht, Gelderland, Groningen, Friesland, and Overijssel). Although the United Provinces did not secure final international recognition until the treaty of Westphalia in 1648, they were from the 1580s a formidable maritime force, opposed to Spanish hegemony on religious and political grounds. After Antwerp's capture by Spanish forces in 1585, the United Provinces blocked the entry to the River Schelde and so cut the principal artery which linked Antwerp to Middelburg and the North Sea. The Dutch economy was thus for the first time decisively detached from the rest of the Netherlands in terms of capital, shipping, and the expertise of refugee Jews, who had earlier fled Spain and Portugal and migrated north with their commercial knowledge and connections to Amsterdam, which grew to become the major commercial, maritime, and banking centre of the Western world for the next century or so. Amsterdam, in north Holland, became heir to the Hanseatic League's Baltic trade and to Antwerp's international banking and commerce.

By the end of the 16th century, the Dutch fleet equalled the combined commercial fleets of Spain and Portugal and far outstripped those of France and England. It was thus able to take advantage of Iberian colonial expansion in the Americas and participate in South East Asian commercial colonialism. The DUTCH EAST INDIA COMPANY was founded in 1602; the West India Company in 1621. These major enterprises, which transformed the Netherlands into a colonial power

and a major competitor of the English, French, and Portuguese, were driven not by wine but by the desire to control as much as possible of the commerce of the New World and Asia: sugar, tobacco, calico, spices, and their manufactured products. But the handling of wine remained a significant part of the commercial interests of the independent Netherlands, whose fleets competed for markets around the globe. Wine, brandy, and vinegar constituted nearly 40% of Dutch imports from France in 1645; most of the 224 ships which loaded wine at Bordeaux in 1682 were Dutch; and wines, fortified wines, and spirits were carried to the furthest corners of their trading empire, to North America, Surinam, the Caribbean islands, South Africa, Ceylon, and the Malay archipelago (Sumatra, Java, Borneo).

Influence on wine styles

Dutch interest in the transport of and trade in wines helped shape the evolution of wine production according to the dictates of changing taste and the requirements of the long-distance transportation of a perishable product by sea. Until the end of the 17th century, most wines could not survive from one vintage to the next, and many were spoiled and undrinkable within six months of the vintage, partly because they were transported in large oak casks, 'tuns' of 900 l weighing 1,000 kg, inclusive of the wood, which constituted the units of freight. Even before the creation of overseas colonies, wine destined for the Baltic had to overwinter at some convenient point. The grape harvest occurred too late in the year to permit immediate transportation to the northern lands, since the Baltic and White Seas often became impassable from November onwards. To overcome these disadvantages the Dutch popularized *mistelles*, wines fortified by the addition of brandy to stop fermentation and prolong the life of the wine, and *vins pourris*, made from overripened grapes. They also introduced the French to the stabilizing effects of SULFUR candles (known in French as *allumettes hollandaises* for many years) and encouraged the production of distilled liquors, based on both grain and grape. Amsterdam and Rotterdam became the principal international markets for wines and brandy in the 17th century, sustained by regular and reliable supplies, bulk storage, and an international network of merchants. One effect was the increase in planting white grape varieties in western France, to satisfy the tastes of the Dutch market.

At the same time, they practised BLENDING wines from different areas to increase the bulk of more popular varieties, to improve the taste or increase the BODY of inferior wines, or simply to make them conform to the changing palates of consumers. From the 15th century, for example, the English came to prefer stronger and sweeter wines than formerly. Thus the weak *clairet* of Gascony was 'strengthened' by blending with CAHORS or Portuguese wines. When in the 16th century the English developed a liking for SACK, the white

wines of southern Spain (exported through Seville and Cádiz), and when at about the same time the CANARY ISLANDS and MADEIRA began producing sweet wines (malmseys and madeiras) from the MALVASIA grape (introduced from Crete), the Dutch entered that trade too, making significant inroads into the rapidly growing trade in Portuguese wines (via Lisbon, Lamego, and Oporto). And, of course, it was the Dutch who had the technical skills with which to drain the marshes of the MÉDOC in the mid 17th century, thereby enabling production of what were to be recognized as some of the finest red wines in the world.

Dutch prominence in the wine trade in the 16th and 17th centuries was merely one aspect of their general primacy in all aspects of international commerce during that period. They were principally merchants and shippers, controlling all aspects of trade, purchase, transport, storage, and sale to local merchants and retailers. Their purchasing power enabled them often to dictate advantageous terms to the producers and the large tonnage of their ships enabled them to transport their wares at relatively low cost. Such was their access to the wine-producing areas of Europe that they were able to circumvent the English embargo on all French wines during the Anglo-French war of 1690–6 by passing them off as Spanish, Portuguese, or even Rhenish and by transporting them in the appropriate casks.

By the 1690s, however, this dominance was being seriously undermined by an aggressive trade war with England, culminating in the Franco-Dutch war of 1692–4, in which Holland's commercial enemies conspired with France against her. A combination of protectionist legislation in England, widespread piracy, the successful French invasion of 1692, and the rapid rise of English seaborne trade (especially from Bristol and London) marked the end of the Dutch supremacy, though not of Dutch involvement in the world trade in wines and spirits.

The Dutch also played the crucial role in dictating the style of modern MUSCADET.

duty is levied on wine importation and movement into circulation from BOND in many countries at an extremely variable level. In general, countries in which viticulture is an economically (and therefore politically) important activity, such as France and Italy, tend to have extremely low duties on wine, while countries such as the UK which produce little or no wine, and/or those with restrictive policies on the sale of alcoholic drinks, such as Scandinavian countries, tend to have high duties. Wine duty may be a flat rate per litre, with fixed or sometimes variable rates according to style and ALCOHOLIC STRENGTH, as in the UK, or calculated ad valorem as in China and much of Asia. In HONG KONG, customs officials used to be issued with a set of current prices for all commonly encountered wines, but in 2008 the territory transformed itself into Asia's, or at least China's, wine hub by slashing wine duty to zero. For some historical background, see TAXATION.

E

Early Burgundy, California name for a grape once grown there in some quantity and eventually identified as the ABOURIOU of SOUTH WEST FRANCE. The same name has also been used in California for Blauer PORTUGIESER.

Early Muscat, bred in California as a TABLE GRAPE but has been successful on a very small scale as a wine grape in Oregon.

earthworms, segmented ANIMALS which have an important role in improving soil conditions for plant growth. Their burrowing improves soil mixing and aeration, and their feeding breaks down and redistributes ORGANIC MATTER, facilitating NUTRIENT uptake by the vine. Because a high level of mixing of organic matter is associated with SOIL FERTILITY, an abundance of earthworms is generally considered beneficial by many growers, especially those involved in ORGANIC VITICULTURE. Earthworms are encouraged by MULCHES, which reduce soil surface temperature, provide organic matter, and help retain moisture. They are discouraged by bare, HERBICIDE-treated soils, and their species diversity and biomass are reduced by TILLAGE and by copper-containing FUNGICIDES. See also SOIL BIOTA. R.E.S.

Easter Island, or Isla de Pascua in Spanish, is the most remote place for viticulture in CHILE. Distant about 3,700 km/2,299 miles from the mainland, this far-flung Pacific island is thought to have been first planted to vines around 1860 by French missionaries. They sited them on the slopes of the Rano Kau volcano to protect

them from the WIND, the main viticultural challenge here, but they ultimately abandoned their efforts. At the beginning of the 2020s, two projects were under way to revive the island's viticulture, one by winemaker Fernando Almeda and the other by businessman José Mingo, both working in conjunction with locals. In addition to 4 ha/10 acres planted with Chardonnay, Pinot Noir, Garnacha, and other varieties, both projects were reproducing plants from abandoned vines whose varietal identity is still unknown. The first wines from these young vines were expected in 2022. P.T.

eating grapes. See TABLE GRAPES.

échantillon, French for 'sample'. See SAMPLING.

Échezeaux, GRAND CRU of the village of Flagey-Échezeaux in Burgundy's Côte de Nuits, producing red wines from Pinot Noir grapes. While wines of VILLAGE or PREMIER CRU status in Flagey-Échezeaux are sold under the name of neighbouring VOSNE-ROMANÉE, the majority of the commune's vineyard land is shared between the two grands crus Échezeaux and Grands Échezeaux.

Échezeaux is perhaps fortunate to be rated grand cru in its entirety (36 ha/89 acres), as many of its wines are relatively light. The vineyard is made up of 11 LIEUX-DITS ranging from Les Treux, which has a deep CLAY soil with indifferent DRAINAGE, to Les Échezeaux du Dessus, where the soil is shallower and chalkier and the wine correspondingly finer. It is not the equal, however, of neighbouring Grands Échezeaux (8 ha), which also abuts CLOS DE VOUGEOT.

There are 21 owners of Grands Échezeaux and over 80 of Échezeaux. Proprietors of both include DOMAINE DE LA ROMANÉE-CONTI, Domaine d'Eugénie, Domaine Lamarche, and Domaine Mongeard-Mugneret.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

ecological viticulture. See ORGANIC, BIODYNAMIC, and REGENERATIVE VITICULTURE, BIOLOGICALS, and SUSTAINABILITY.

e-commerce, selling wine online rather than in a store or via a printed catalogue, has been around for almost as long as the internet, but it suddenly became more prevalent around the world when so many wine consumers around the world were confined to their homes by the coronavirus pandemic. Wine merchants unfamiliar with existing platforms found themselves leaning heavily on younger, junior members of staff more familiar with INFORMATION TECHNOLOGY.

economics of wine, a field of study that aims to improve our understanding of what affects the demand for and supply of different types of wines and wine grapes and, thereby, the prices, quantities, and qualities of wines sold in regional and national markets and traded internationally. This area of study has grown considerably in recent years, for several reasons. One is the increasing GLOBALIZATION of wine. Another is that wine growers have shown, perhaps more clearly than any other farmers, the possibilities for adding value to their primary product, particularly by differentiating it according to its TERROIR or, for those growers who also venture into winemaking, via wine marketing investments. Wine producers are increasingly investigating which specific attributes of wine appeal to consumers in order to better target production and marketing efforts domestically and abroad. Some producers and buyers also benefit from INVESTMENT IN WINE. The demand for the best vintages of iconic wines as a way of storing wealth has grown along with affluence, including in newly wealthy countries such as China.

The basic point that excess supply can depress prices was well understood at the time of DOMITIAN's command in the 1st century CE to pull up half of the Roman Empire's vines planted outside Italy in

the hope of holding back collapsing Italian wine and grape PRICES. For centuries, Spanish royalty also sought to restrict vine plantings in their Latin American colonies. More recently, Jean Milhau argued in his 1935 book, *Étude économétrique du prix du vin en France*, that wide variations in producer prices and incomes were due to huge swings in harvest volumes while CONSUMPTION remained insensitive (inelastic) to price. He argued that prices could be stabilized within certain limits by regulating the volumes released from the wineries' stocks and by distilling SURPLUSES. That idea became the cornerstone of France's wine policy in 1935, which also created a separate market organization for quality wines (see INAO). After the Second World War, integration of (initially six) European economies led to a single market and a common wine policy by 1970 (see EU). That policy soon involved compulsory DISTILLATION to support producer prices in an attempt to stem the flow of cheaper wines from Italy into France and appease social unrest in the LANGUEDOC—the so-called 'wine wars' of the 1970s. Its long-lasting effects included driving YIELDS up and quality down.

The study of wine demand initially focused on estimating the responsiveness of consumers to changes in price (relative to other beverages), taxes, and income. It then broadened to studying the many other aspects of wine that appeal to buyers such as regional reputations, varieties, brands, styles, closures, production methods, and vintages. Economists, most notably Orley Ashenfelter of Princeton University, have contributed to the reputation of VINTAGES by using econometric analysis to forecast the future value of each vintage's iconic wines, based on RAINFALL and TEMPERATURE data during the growing season. When Ashenfelter forecast in 1991 that the 1989 and 1990 vintages were likely to be outstanding for red bordeaux, many professional wine writers and judges at the time disagreed, but now there is almost unanimous agreement that they were exceptionally good years. More recently, economists have drawn on behavioural studies and neurosciences to explore, for example, the impact of price information on the consumer's

perception of wine quality. Some studies suggest that blind tasters often prefer cheaper wine if they are unaware of its price but, if told it is expensive, their perception of a wine's quality is raised, according to brain scans.

Even though international trade in wine has grown in significance only during the past three decades, economists have cited wine for two centuries in their teaching of international trade theory. This is because wine was used by English economist David Ricardo when in 1817 he introduced the compelling notion of comparative advantage to explain the benefits of free trade between textile-exporting England and wine-exporting Portugal following the METHUEN TREATY.

There is both an American and a European Association of Wine Economists (SEE WEB LINKS www.wine-economics.org and SEE WEB LINKS www.euawe.com respectively), each of which has an annual conference. The *Journal of Wine Economics* has been published commercially since 2006 (currently four issues per year published by Cambridge University Press), and wine economics is recognized by ACADEME at, for example, the ISVV in Bordeaux, the Free University of Bozen-Bolzano, UC DAVIS, the University of ADELAIDE, and STELLENBOSCH University. ecosystem, vineyard, the plant and animal communities which interact with each other and with their environment—TEMPERATURE, WIND, RAINFALL, and SOIL NUTRIENTS—in and around the vineyard. A vineyard is a living, functioning ecosystem. Because of the perennial

nature of vineyards, the diversity of organisms and their interactions is more complex than in annual cropping systems. Complex interactions can stabilize in an ecosystem through ecosystem services (ES) such as BIOLOGICAL control of pests, diseases, and weeds, reduction of SOIL EROSION and SOIL COMPACTION, carbon capture from the atmosphere, nutrient provision to the plants, etc.

However, agricultural practices can severely reduce these free services, with the result that high levels of artificial inputs such as PESTICIDES, FERTILIZERS, and deep RIPPING are needed. Vineyards typically have high pesticide inputs (see AGROCHEMICALS), which is costly to the business and to the environment as many of these compounds have detrimental 'off-target' effects on flora and fauna above and below ground. These effects can extend beyond the vineyard through run-off and drift.

Compared with other cropping systems, viticulture, especially wine grapes, is an excellent model for developing sustainable systems as the aim is to produce a reasonable amount of grapes that taste good and are then vinified. Leaf damage, some loss of grapes, some cosmetic damage to the berries, and even an occasional insect in the harvest do not pose a threat to wine quality.

SUSTAINABLE VITICULTURE schemes usually start by using (collective) monitoring, for example insect traps and weather stations, and recording systems to track inputs of water, energy, and fertilizers. Modelling disease risks based on these data can be used to decrease pesticide use and reduce costs. Some of these schemes—including Greening Waipara in New Zealand, the Saumur-Champigny biodiversity project, and the EU-funded BioDiVine project in St-Émilion and other European wine regions—also attempt to improve ES and functional biodiversity (i.e. biodiversity that is useful to the grower) to minimize inputs and their impact on the environment.

These projects involve growing plants, usually native species, either between or under vineyard rows, or the creation of hedgerows and shelterbelts alongside vineyards, aiming at improving regulation of pests and diseases by natural enemies. Such plantings can

provide these natural predators with SNAP—shelter, nectar, alternative food, and pollen, their key requirements. For example, parasitic wasps are a very important group of biological control agents. Having flowers in the vineyard can increase these insects' longevity there from three to 30 days because of the sugars and amino acids that floral nectars contain. The more traditional inter-row grasses that are used for vineyard COVER CROPS do not offer much SNAP as they produce no nectar.

This illustrates that a mix of different plants can have multiple functions, so that improving one ES service (grasses reducing erosion and compaction) can negatively affect another (lack of nectar for beneficial insects). Agroecology research is needed to determine whether creating biodiversity by growing specific plants, for example annual exotic flowering plants such as alyssum, buckwheat, and tansey, is more efficient than letting nature establish a more natural biodiverse vegetation by means of slightly adapted and cheaper management, for example reduced mowing, mowing alternate rows, use of roller crimpers on the cover crops, or fewer HERBICIDES.

A less expected but clearly welcome result from so-called 'landscape and biodiversity' projects is that growers gain a great deal of personal and communal satisfaction from this positive approach to biodiversity and readily communicate their experiences. Moreover, it makes the landscape more visually attractive for wine TOURISM, and social and economic aspects are an integral part of SUSTAINABILITY.

Ecuador bottles a considerable quantity of wine, but the extent of its vineyards is considerably more limited. TROPICAL VITICULTURE, enforced DORMANCY, and the considerable application of FUNGICIDES are essential here on the equator where it rains most days. The limited plantings of INTERNATIONAL VARIETIES are mainly at ELEVATIONS of over 2,500 m/8,000 ft near the capital Quito or on the coast in the hinterland of Guayaquil and anchored by the Dos Hemisferios winery. Tungurahua province, a valley near Ambato, south of Quito, now has a few small winery operations among the fruit orchards, and Viña del Guayacán in Loja is the first winery in the south of Ecuador producing premium small-batch wines. edel means 'noble' in German, and thus Edelfäule is German for NOBLE ROT, and EDELZWICKER is the name chosen to add lustre to a not particularly noble blend in ALSACE. Similarly, Gutedel is the German synonym for the not particularly noble CHASSELAS grape.

Edelzwicker, Alsace term, originally German, for what is usually a relatively basic blend. See ALSACE.

Eden Valley, wine region (High Eden is a subregion) abutting SOUTH AUSTRALIA's Barossa Valley, with high ELEVATION and a fine reputation for limey, long-lived RIESLING and elegant, medium-bodied Shiraz (Henschke's Hill of Grace, for example).

Edna Valley, California wine region and AVA on the ocean side of the coastal mountains. See SAN LUIS OBISPO.

education, wine. Education plays an important part in the production, sale, and enjoyment of a product as complex and, in many countries, as foreign as wine. Detailed knowledge of wine involves an appreciation of history, geography (inevitably including a host of foreign names), science, and technology, quite apart from the development of practical tasting skills.

Education for wine-producing professionals is discussed under ACADEME and is, naturally, concentrated in the world's wine regions. Some universities, such as BORDEAUX, offer courses, especially in tasting, that are open to wine merchants and the general public. There is even more overlap between wine-trade education, courses designed specifically for the wholesale and retail trade, and consumer education; the most enthusiastic wine consumers may well want to know more about wine than the less academically inclined wine traders. The Institute of MASTERS OF WINE, for example, the leading international wine-trade educational body which opened its notoriously stiff series of trade examinations to those unconnected with the wine trade in the early 1990s, admitted its first Master of Wine (MW) without any connection with the wine trade, a Hollywood lawyer, in 1993.

While trade education is usually undertaken by this sort of professional body (the leading international organization is the London-based WSET), consumer education may be undertaken by a wide range of lecturers and wine merchants. This can take the form of TASTINGS so informal as to constitute a party, tutored tastings, BLIND TASTINGS, or some form of wine TOURISM. This century has seen an explosion of interest in wine courses, especially in the US where many of those who run them belong to the Society of Wine Educators, in the UK with its Association of Wine Educators, and in Asia.

Other forms of wine education include both print and online articles (see WINE WRITERS), books (see LITERATURE OF WINE), various forms of audio-visual instruction such as television and radio programmes and online wine courses, aspects of SOCIAL MEDIA, and software (see INFORMATION TECHNOLOGY). Interactive wine tasting is a way of combining the practical with the theoretical.

Eger, town in north-east HUNGARY whose wines have been exported since the 13th century, although various Turkish incursions interrupted this trade. Eger's most famous siege was during the 16th-century Ottoman occupation when, according to legend, the defenders of Eger were so dramatically fortified by a red liquid which stained their beards and armour that the Turks retreated, believing their opponents to have drunk BIKAVÉR, or Bull's Blood. But the truth is that Bikavér production and bottling started only at the beginning of the 20th century.

The town gives its name to a PDO on the foothills of the volcanic Bükk Mountains where rainfall is low and spring tends to come late. This is one of Hungary's cooler wine-producing areas, and therefore the wines have good aromas and acidity. The geological make-up is diverse, with CALCAREOUS sections alternating with patches of LOESS, ALLUVIAL SOILS, and extensive VOLCANIC rocks, especially TUFF. The southern slope of the Nagy-Eged Hill is one of Hungary's most valuable vineyard sites, and the highest at 536 m/1,759 ft. Pajdos, Síkhegy, and Grőber are very distinctive too.

Grown on over 200 ha/500 acres, KÉKFRANKOS (Blaufränkisch) dominates Eger's vineyards, though KADARKA, the renowned grape of Eger's halcyon days, is being rediscovered, and Pinot Noir and Shiraz are also planted. As for white wines, Eger, like Balatonfüred-Csopak and Somló, produces some of the finest Olaszrizlings (WELSCHRIESLING) in all Hungary. Other fine whites are made from Chardonnay, LEÁNYKA, KIRÁLYLEÁNYKA, and HÁRSLEVELŰ.

G.R. & G.M.

egg whites play a surprisingly important part in the production of fine red wines. Their particular albumin content makes them highly desirable FINING agents for red wines because they act relatively gently, adsorbing harsh and bitter TANNINS in preference to the softer tannins and STABILIZING the colour of red wines prior to bottling. Five egg whites are usually sufficient to fine excess COLLOIDS from a 225-l/59-gal barrel of young red wine. The separation of yolks from egg whites can form an important part of CELLAR WORK in some seasons (and egg yolks can be a significant waste product of winemaking).

Egiodola, tannic French 1954 vine CROSS of FER SERVADOU with ABOURIOU whose total French plantings had fallen to 177 ha/437 acres by 2019. There are limited plantings in Brazil.

égrappage, French term for DESTEMMING grapes meaning literally 'debunching'.

Egypt , North African country which makes small quantities of wine from its 78,852 ha/194,848 acres of vineyard in 2020, about 99.5% of which is devoted to producing TABLE GRAPES. The ancient Egyptians provide us with some of the oldest depictions of winemaking techniques, however.

Ancient Egypt

Remains of grapes have been found in late Predynastic sites (*c.*3300–3000 BCE), but the vine is not part of the country's native flora and was probably introduced from CANAAN in Predynastic times, despite HERODOTUS' false claim (*Histories* 2. 77) that there were no vines in Egypt. The southern Levantine industry had matured to such a degree that by the time of Scorpion I (*c.*3150 BCE), one of the first rulers of a united Egypt, his tomb at Abydos was stocked with some 4,500 l/1,900 gal of imported wine from southern Canaan. The wine was laced with terebinth tree resin, to which fresh fruit (grapes and figs) and a variety of herbs (including thyme and savory) had been added. Beginning around 3000 BCE, the Egyptian pharaohs financed the establishment of a royal wine industry in the Nile Delta.

The best grapes were considered to come from the Nile Delta; by the time of the New Kingdom (*c.*1550–1050 BCE), viniculture had been introduced to the oases of the western desert and the middle Nile. Vines—irrigated, and manured with bird droppings—were grown in walled gardens, sometimes among other fruits such as olives, and trained over pergolas (see TENDONE).

As in ancient GREECE and ancient ROME, there were two distinct winemaking operations: treading, or CRUSHING, to yield some FREE-RUN juice; and PRESSING the remainder with a sack-press. When harvested, grapes were trodden by foot by labourers who could hang on to overhead supports or suspended ropes. The vat was deliberately shielded from the heat, and an offering of the must was made to the goddess Renenutet. Tomb paintings illustrate wine production amply, although the precise details are not always clear. After treading, the pressing was often carried out in a special sack-press with a pole fixed in a loop at either end of what was effectively a giant jelly bag. This was then twisted by several workers in opposite directions, and the liquid was collected in a vessel beneath. The liquid flowing out of the sack-press is always depicted as red. In

Old Kingdom times (*c.*2686–2181 BCE) the wine was transferred to large jars, later called AMPHORAE.

In scenes dating from the New Kingdom, MUST flows from the trough along a small conduit into a receptacle. In the sack-press apparently only the skins would have been pressed. Probably the FREE-RUN juice and the PRESS WINE were fermented together. Depictions show only the transfer of the must from the press into amphorae. In one illustration the contents of the press are transferred to large fermentation vats, then pressed in the sack-press and transferred into amphorae.

The actual alcoholic fermentation took place in the amphorae, from which the ancient Egyptians would then deliberately exclude air, just like many modern winemakers. The filled amphorae were covered with cloth or leather lids, smeared with Nile mud, and then sealed. Small holes to allow the continuing escape of CARBON DIOXIDE were later blocked up.

White wine is likely attested in the Scorpion I tomb, based on the yellowishness of the residue, and in some of the amphorae in the Tutankhamun tomb, based on chemical analyses. Egyptian wines were generally RESINATED WINES, from the beginning of the royal winemaking industry to the end of the Pharaonic period. Wine was also drunk for medicinal purposes, when it was sometimes flavoured with Levantine and Egyptian herbs, *kyphi* (a mixture of raisins, honey tree resins, herbs, and other plants), and sometimes other less pleasant ingredients such as asses' hair and the dung of various animals and birds.

Wine trade organization It is clear from the seals on amphorae and from the titles of certain officials that the manufacture and delivery of wine were already organized at royal level in the earliest periods. Wine is often shown in scenes on wall paintings. Lists from the Fifth Dynasty distinguish five types of wine according to origin. 'Wine from Asia' and Canaan is also mentioned, and Canaanite wine amphorae are found in the New Kingdom. Inscriptions on amphorae of that period usually indicate year, vineyard site, owner, and chief winemaker (rather more information than is given on most modern wine labels). Most but not all centres of wine production lay on the western arm of the Nile Delta.

Wine drinking Wine was drunk by gods, kings, and nobles, especially at feasts, and was rated only slightly behind beer, which was the most common beverage of ancient Egypt. Amphorae, often painted with vine leaves, are depicted on tables or resting on stands. The wine was sieved as it was poured out. Servants would fill small beakers for serving, sometimes carrying a second small jug (possibly containing water to dilute the wine, but more likely a herbal concoction). The wine was drunk from bowls or goblets (which sometimes rested on stands). The king Akhenaten and his family are shown drinking at the royal capital Tell-el-Amarna (14th century BCE). Priests received wine as part of their daily rations, likewise army officers and foreign mercenaries; but the workers of Amarna received none, an indication of its value. By contrast, the workers who had built the pyramids received a daily allotment of two 'bottles' or about 4–5 l/1–1.3 gal of beer.

Religion and wine Wine is said to be the drink of gods, and also of the dead (along with beer and milk). Thus it was important in cult worship and is frequently mentioned in lists of offerings, sometimes several sorts together. It was frequently offered as nourishment to deities by the king or private persons, also symbolizing purification. LIBATIONS of wine and water were made at temples and tombs throughout the country.

The goddess Hathor, 'the mistress of DRUNKENNESS', was the Egyptian equivalent of the Sumerian beer goddess Ninkasi. She was closely associated with a lesser goddess 'who makes beer', Menqet. One festival to honour Hathor, appropriately designated the 'the Drunkenness of Hathor', at her temple in Dendera, recalled the story of how the goddess had gone on a rampage to destroy a rebellious humanity in her form as the lioness goddess, Sekhmet. Just in time, Re diverted her from her mission by filling the inundated fields with 'red beer', which Hathor interpreted as a sign that she had accomplished her task. She then over-indulged and forgot to carry out the devastation of humankind. The yearly celebration at Dendera

coincided with the inundation of the Nile during the summer, when reddish iron-rich soils were washed down from the Atbara River in Sudan, giving the waters the appearance of 'red beer'. By drinking alcoholic beverages at the festival—both wine and beer—and celebrating with music and dance, humanity shared in Hathor's transformation into her more benign form as the feline Bastet.

Classical authors identified Osiris as the benefactor who bestowed wine on humankind, comparing him in this respect to the Greek god DIONYSUS. The grape certainly became a symbol of the dying and rising god. Vines depicted in tomb paintings symbolized the deceased's hope for resurrection. Other texts refer to wine as the perspiration of Re or as the eyes of the god Horus. His pupils are said to be grapes through which wine flows. In the later periods the term 'Green Eye of Horus' was used to refer to wine.

Modern wine production

The production and sale of wine in Egypt was state-controlled from 1963 until its privatization in 1998. Today, brewers Heineken own the leading and thoroughly modern Egyptian wine producer Gianaclis, and in 2021 there were two others. SULTANA (called Banati locally) and a range of INTERNATIONAL VARIETIES are grown on trellises, mainly in the north of the country, although VINE AGE is low and DROUGHT and heat remain challenges. Satellite technology is harnessed to apply DRIP IRRIGATION with precision. Grapes are picked between late June and early August and are generally chilled before transport to sophisticated wineries equipped with STAINLESS STEEL. French oak BARRIQUES are used for some wines, but most are drunk young.

Ehrenfelser is one of the more FROST-resistant better GERMAN CROSSES, developed at GEISENHEIM in 1929. Although it was said to be a RIESLING × SILVANER cross, DNA PROFILING has shown that it is Riesling × Knipperlé. It is not nearly as versatile in terms of site as KERNER, which became a more obvious choice as a flexible Riesling substitute. Total German plantings of Ehrenfelser had fallen to 36 ha/90 acres by 2019, mainly in the Pfalz and Rheinhessen.

Einzellage, literally 'individual site' in the wine regions of GERMANY. Almost all of Germany's vineyards are officially registered as one of approximately 2,600 Einzellagen, which can vary in size from a fraction of a hectare to more than 200 ha/494 acres, the average being about 38 ha. Only wines of the category QUALITÄTSWEIN are allowed to be labelled with an Einzellage. Names of Einzellagen must be preceded on labels by the name of the village in which they are located; thus a wine from the Mandelring vineyard in the village of Haardt is called Haardter Mandelring.

An Einzellage should not be confused with a Grosslage, which follows the same formula of 'town+vineyard name' but is in reality a

collection of many sites in the vicinity of—but by no means always clustered around—the town in question. See GROSSLAGE. D.S.

Eisacktaler, German for Valle Isarco, one of six subzones of the DOC of ALTO ADIGE producing pure, dry white wines as well as a red wine, suffixed with Klausner Laitacher, based on SCHIAVA, LAGREIN, and/or PINOT NERO.

Eisenberg, tiny wine village in Austria's SÜDBURGENLAND adjacent to and named for a high hill dominated by iron-rich SCHIST; its twin over the Hungarian border, Vaskereztes, shares the same etymology. Since 2008 Eisenberg has lent its name to an official DAC for BLAUFRÄNKISCH wines grown throughout the region. Those additionally labelled Reserve must be raised in cask or small barrels, must reach 13% alcohol, and cannot be marketed until the second calendar year following their harvest. D.S.

Eisheiligen, Germany's Ice Saints, including the saints Pancras, Servatius, Boniface, and Sophie, or *Kalte Sophie*, whose commemoration days fall between 11 and 15 May. After 15 May, the risk of spring FROST in the vineyards is deemed past.

Eiswein designates German wines produced from grapes frozen on the vine and pressed while still frozen. The deliberate picking of Eiswein with any significant frequency seems to have originated in the 1960s, and from the 1980s the practice became routine at most top estates, excepting those farming vineyards not prone to deep FROST. Freezing concentrates not just the SUGAR in the grapes but also ACIDITY and EXTRACT, and Riesling Eiswein is routinely the highest in acid (as well as some of the highest-priced) of any German wines. For best results, a frost of at least −8 °C/18 °F is required, for which grapes are generally harvested between five and

eight o'clock in the morning of the first sufficiently cold November or December days. Eiswein picked in January or even February is increasingly common, if seldom as high in quality. Such wines are still labelled for the calendar year of the growing season. Before 1971, Eiswein was frequently labelled for the date of picking or nearest Saint's Day (Nikolauswein, for example, designated a wine harvested on 6 December), but such information is currently not permitted on the label. Since 1982, Eiswein has had its own PRÄDIKAT with the minimum MUST WEIGHT of a BEERENAUSLESE, namely 110–128 °OECHSLE depending on the region and variety; in AUSTRIA the minimum is 25 °KMW (approximately 127 °Oechsle). The harvesting of Eiswein has become much more routine as a result of the widespread use of semi-permeable PLASTIC SHEETING that hugs the vines to protect grapes from birds and rain while waiting for a suitably deep frost. (Protection from wild boar is another matter, and more potential Eiswein is lost to these marauders than to any other cause.) While the classic concept of Eiswein for most growers is a wine from BOTRYTIS-free grapes, this is not a legal requirement, and the use of film sometimes traps humidity, thereby promoting botrytis. If the harvest does not achieve the requisite ripeness or the character deemed appropriate to Eiswein by the individual winegrower, the wine usually ends up being bottled as an AUSLESE or subsumed into another wine, even though these practices are technically legally questionable.

See also ICEWINE in Canada. D.S.

Eximenis, Francisc (*c.*1340–*c.*1409), Catalan Franciscan friar and author of *Lo Crestià* ('The Christian'), an encyclopedia of the Christian life. Thirteen books were planned but only four were finished. It is aimed at a popular, not a learned, audience, and hence it is written not in Latin but in the vernacular, Catalan. As a result it had little to no influence on other European authors of the Middle Ages (see LITERATURE OF WINE).

Its third book, *Lo terç del Crestià*, dated 1384, is concerned with sin. The section on gluttony deals with DRUNKENNESS (chs. 350–9) and the etiquette of wine drinking (chs. 362–7, 393–5). Eiximenis is aware of the medical properties of wine, but his interest is in the moral aspects of drinking. Drunkenness, he says, leads to every conceivable vice, but, taken in moderation, wine is a good thing. All other nations, except perhaps the Italians, drink too much: only the Catalans have the art of sensible drinking. This means three cups at dinner, three at supper: one should never have more than four, and there is to be no drinking between meals. Although he disapproves of the fastidious habits of connoisseurs, he does tell where the best wines are to be found. They are the strong, sweet wines of the Mediterranean, particularly MALMSEY (Malvasia), the Cretan Candia, and Picapoll from MALLORCA. He ranks Italian wines above French wines and insists that strong wines (these do not include the wines of France) should be mixed with water, the stronger the wine the more water. H.M.W.

Gracia, Jorge J. E., 'Rules and regulations for drinking wine in Francisc Eiximenis' *Terç del Crestià* (1384)', *Traditio*, 32/1 (1976), 369–85.

Gracia, Jorge J. E., 'Francisc Eiximenis' *Terç del Crestià*: edition and study of sources, chs. 359–436' (PhD thesis, University of Toronto, 1971).

Elba, Mediterranean island off TUSCANY, where emigration and the booming tourist industry have drastically reduced the role of wine in the overall economic picture. The entire island is covered by one DOC, called Elba, with 107 ha/264 acres in production in 2020, three-quarters of it white wine. The one DOCG is a sweet DRIED-GRAPE WINE, the red PASSITO-style ALEATICO. W.S.

Elbling, ancient, and some would say outdated, light-skinned vine variety cultivated in the Mosel Valley since the Roman era. At one

time it was effectively the only variety planted in LUXEMBOURG and dominated the extensive vineyards of medieval Germany (see GERMAN HISTORY). Today it is increasingly unpopular in Luxembourg (5% of the country's vineyard in 2020) and in Germany, where only 475 ha/1,174 acres remains, most of it in the upper reaches of the MOSEL above Trier, in which CHALK dominates SLATE and Riesling has difficulty ripening. Much of the Elbling grown here is used for SEKT. While the vine is distinguished for its antiquity and productivity, its wines are distinguished by their often searing acidity and their relatively low alcohol. DNA PROFILING in Austria suggested a parent–offspring relationship with GOUAIS BLANC.

El Dorado, California county and AVA. See SIERRA FOOTHILLS.

electrical resistance tomography. See PROXIMAL SENSING.

electrodialysis, a sophisticated, electrically driven membrane FILTRATION process which allows the removal of selected ions (electrically charged molecules), has been used since the 1960s to desalinate water and was adapted for use in the STABILIZATION of wine by INRA in the 1990s. In this context it is used to remove potassium, TARTRATES, and bitartrates. Despite the relatively high capital costs of the technology, it is gaining acceptance in the wine industry because it uses 80% less energy than cold stabilization, it is much faster, and its total running costs are up to 40% lower. The volume of water used to extract the tartrate salt has been significantly reduced by the use of REVERSE OSMOSIS, and there are said to be no adverse effects on wine quality. No further filtration is required to remove the potassium-bitartrate crystals before bottling, although the wine does have to be filtered prior to electrodialysis to avoid clogging the membranes. One of the greatest advantages of this process is that it allows great control over what and how much is removed from the wine.

Electrodialysis may also be used to remove calcium (another potential source of instability), to remove sodium chloride (see SALINITY), and to lower the PH of a wine without ACIDIFICATION.

Electrodialysis is more selective than ION EXCHANGE and is widely used in the EU and most other wine-producing countries that regulate winemaking processes—but only for tartrate stabilization. There are a number of units in wineries in Italy, France, Germany, and Spain, with others in South Africa and the US. Mobile units are in use in the EU, the US, Chile, Argentina, Australia, and New Zealand.

Apu Winery, named after a sacred mountain god, planted this experimental PINOT NOIR vineyard in the Curahuasi Valley in PERU in 2019 at an ELEVATION of 3,300 m/10,827 ft in the Andes Mountains. By PRUNING in January, the vines are better able to withstand the effects of the rainy season from November to March. © Apu Winery

electromagnetic induction. See PROXIMAL SENSING.

élevage, French word that describes an important aspect of winemaking but has no direct equivalent in English. *Élevage* means literally 'rearing', 'breeding', or 'raising' and is commonly applied to livestock, or humans, as in *bien élevé* for 'well brought up'. When applied to wines, it means the series of cellar operations that take place between FERMENTATION and BOTTLING, suggesting that the winemaker's role is rather like that of a loving parent who guides, disciplines, and civilizes the raw young wine that emerges from the FERMENTATION VESSEL. The word AGEING is often used as an alternative, although this may refer to both pre- and post-bottling.

For details of the various stages of *élevage*, see RED WINEMAKING, WHITE WINEMAKING, and BARREL AGEING.

elevation, the height above mean sea level of a location such as a vineyard, often mistakenly referred to as altitude. Local elevation of vineyards above valley floors or flat land determines their air drainage and TEMPERATURE relations, including liability to FROST. (See also TOPOGRAPHY, MESOCLIMATE, and CLIMATE AND WINE QUALITY).

The elevation of a vineyard can have important effects on its climate and therefore on its viticultural potential. Other things being equal, temperature falls by about 0.6 °C/1.1 °F per 100 m/330 ft greater height. However, the influence of elevation on climate varies

depending on whether the area is on the windward or leeward side of the mountainous area. Windward zones will typically be cooler and wetter with height, while leeward zones, known as rainshadows, will typically be warmer and drier. Good examples of this effect are found in ALSACE, eastern WASHINGTON, RIOJA, and MENDOZA. Planting vineyards at higher elevations is commonly considered a means of avoiding the impact of increasing temperatures related to CLIMATE CHANGE. For example, FAMILIA TORRES and Castell D'Encus in Cataluña have developed vineyards in the nearby Pyrenees, while Prager have been planting much higher land than previous generations in the WACHAU, and Bisol's Vigna 1350 project is high up in the Dolomites. Others seeking the benefits of elevation include Franz Haas and Alois Lageder in Italy's ALTO ADIGE and Gaia in Nemea, GREECE.

With the increased market emphasis on fresher styles of wine, ever-higher vineyard sites have also been sought in the warmer wine regions. Examples include the ADELAIDE HILLS, the Central Ranges of NEW SOUTH WALES, and VICTORIA in Australia; La Carrera in the Uco Valley and other high-elevation plantings in ARGENTINA; the foothills of the Andes in CHILE; and California's SIERRA FOOTHILLS.

The lower temperatures at higher elevations retard both vine BUDBREAK, reducing the risk of late frost, and, in particular, RIPENING, so that nights are cooler during the ripening period, leading to higher acid concentration. Effects on GRAPE COMPOSITION AND WINE QUALITY have been widely studied, for example in relation to TEMPRANILLO in Rioja. Such research is useful for predicting the impact of climate change on wine quality.

Elevated vineyards also experience more ULTRAVIOLET RADIATION, which is likely to increase quality because of stimulation of PHENOLIC synthesis.

Most of the world's highest established vineyards are in Latin America, but they are being challenged by new plantings in the Himalayas. Three of the world's highest commercial vineyards are Swiss-born Donald Hess's plantings in the northern province of Salta,

Argentina. Colomé, near Molinos, is at 2,200–2,300 m/7,218–7,546 ft; El Arenal, Payogasta, is at 2,400–2,500 m/7,874–8,200 ft; Altura Máxima, also near Payogasta, is at 3,111 m/10,207 ft). Even higher is the Pinot Noir vineyard planted by Apu Winery in 2019 at 3,300 m/10, 827 ft in Curahuasi, Peru, and those in Uquía, in Quebrada de Humahuaca, Jujuy, north of Salta, at 3,329 m. BOLIVIA has vines up to 2,640 m in the Cotagaita Valley. The highest vineyards in the US are in Fremont, Colorado (2,103–2,133 m/6,900–7,000 ft), and Mora, New Mexico (2,332 m/7,650 ft).

In the Himalayas in Asia, there are small commercial vineyards up to 2,900 m/9514 ft in the south-west of CHINA. The world's highest vineyard is said to be in Lhasa, Tibet Autonomous Region of China, at 3,563 m/11,690 ft. The highest European vineyard is probably in Vilaflor on the island of Tenerife, at 1,700 m/5,577 ft. On mainland Europe, there are vines at 1,368 m/4,488 ft at Barranco Oscuro in GRANADA and up to 1,090 m/3,576 ft and 1,250 m/4,100 ft in SWITZERLAND and AOSTA respectively. See also DIURNAL TEMPERATURE RANGE.

ellagitannins. See OAK FLAVOUR and PIGMENTED TANNINS.

El Niño, one phase of anomalous sea surface temperatures (SSTs) in the tropical Pacific that, together with the opposite phase La Niña, are the result of the 'southern oscillation' from west to east across the equatorial waters of the Pacific. The El Niño–Southern Oscillation (ENSO) is one of the planet's largest climate variability mechanisms resulting from atmospheric and oceanic interactions. It affects wine-region climates in North America, Australia and New Zealand, South Africa, South America, and Europe. Oscillations between La Niña (cold SSTs) and El Niño (warm SSTs) influence variations in precipitation and temperatures in many regions, especially those around the Pacific Ocean basin. However, the effect of ENSO on

climate variability varies tremendously in magnitude with each event and can have very different impacts depending on the location of the wine region; it is also often coupled with other more influential regional mechanisms. For example, El Niño events in 1982–3 resulted in a very wet winter in California while leading to drier and hotter conditions in Australia. G.V.J.

Elqui, valley in the northern Coquimbo region of CHILE historically important for the production of PISCO but increasingly known for its wine, especially those varieties coming from its higher ELEVATIONS.

embotellado is Spanish for 'bottled'.

Emerald Riesling, one of the earliest of the vine varieties developed at the University of California (see DAVIS) by Dr H. P. Olmo to emerge in VARIETAL (white) wine. It has been shown by DNA PROFILING to be a CROSS of Malvasia Aromatica di Parma and GRENACHE and had its heyday in the late 1960s and early 1970s before slumping towards oblivion. It is planted to a very limited extent in SOUTH AFRICA and ISRAEL. J.V.

Emilia, western part of EMILIA-ROMAGNA.

Emilia-Romagna, Italian wine region which stretches across north-central Italy from the eastern Adriatic coast to include vast tracts of inland Emilia in the west, which is quite distinct from coastal Romagna in the east (see map under ITALY).

There are four very individual areas, each producing distinct wines: the hills around Piacenza in the north-west bordering LOMBARDY; the plain in central Emilia around Parma, Reggio nell'Emilia, and Modena; the hills around Bologna; and the hills in

Romagna between Imola and Rimini bordering TUSCANY to the south-east.

The Colli Piacentini, geologically and climatically similar to the contiguous OLTREPÒ PAVESE of Lombardy, is divided into three subregions—Monterosso Val d'Arda, Valnure, and Trebbianino Val Trebbia—which may appear on labels. Many of its FRIZZANTE or lightly sparkling whites from MALVASIA Candia, the rare ORTRUGO, or Trebbiano, or reds from BARBERA and CROATINA (which after it has obtained its sparkle becomes Bonarda for reasons unknown) are made by the TANK METHOD in industrial volumes, although complex, TRADITIONAL METHOD versions are slowly gaining ground. The area's most interesting other developments come from the subzone of Riverargo-Vigolzone, with complex varietal PINOT NOIR and BARBERA, CABERNET blends, and Malvasia di Candia often labelled as IGT Emilia. The DOC Gutturnio, once a suffix to Colli Piacentini and with a CLASSICO subzone as its heart, produces sparkling red wine based on Barbera and Croatina, but it is the still red that has untapped potential. In the little-known Val Tidone, Gaetano Solenghi is one of the very few who still makes spectacular, ageworthy PASSITO wines from Malvasia Candia.

The flat Emilia plain is often associated with LAMBRUSCO. Since the 1970s this light, frothy, and often slightly sweet red has been a huge export success. Its industrial-sized production once completely dominated Lambrusco's image, but the trend is now in favour of the artisanal, dry, and often bottle-fermented versions produced by a new generation. (See LAMBRUSCO for more detail.)

The Colli Bolognesi, the hills immediately south-west of Bologna, are dominated by Cabernet Sauvignon, Merlot, and Chardonnay. The good results achieved here can be traced back to the pioneering but now defunct estate Terre Rosse, whose founder Enrico Vallania planted these varieties in the 1960s, aiming at making long-lived wine without any use of OAK. The local white Pignoletto (see GRECHETTO), producing fresh, lively, and often lightly sparkling whites,

now has its own Colli Bolognesi Pignoletto DOCG, although most Pignoletto ends up in the tanks of large bottlers and CO-OPERATIVES.

The Romagna hills, covered by the enormous DOC Romagna, are home to some of both the best and the worst of the region's output. Total production is dominated by co-ops turning out industrial quantities of insipid SANGIOVESE and TREBBIANO. The image of ROMAGNA SANGIOVESE has suffered particularly from this indifference, but a growing group of quality-focused producers have become instrumental in changing its tarnished reputation. (See ROMAGNA SANGIOVESE for more details.) ROMAGNA ALBANA, grown in the same extensive area as Romagna Sangiovese and elevated to DOCG in 1986 to considerable scepticism, is beginning to prove its worth with fine PASSITO and BOTRYTIZED versions as well as some serious barrel- or amphora-fermented dry wines, often from single vineyards.

Empordà, DOP in the extreme north-east corner of Spanish CATALUÑA separated from ROUSSILLON only by the French border (see maps under SPAIN and FRANCE). The zone has a long history of wine production, though it was nearly extinguished when PHYLLOXERA swept through the vineyards in the 1900s. Many of the TERRACES that climb the low foothills of the Pyrenees were never replanted. The climate is MEDITERRANEAN, with strong WINDS such as the tramontana that can protect the vineyards from FROST and VINE DISEASES but also stress the vines. Empordà used to produce RANCIO wines (*vi ranci*), sometimes called Garnatxa, the Catalan name for the GARNACHA

grape. This vine variety and Cariñena (CARIGNAN) still account for 80% of production, although for a long time they were mostly turned into BULK WINE for the local market. Inspired by the quality-conscious Castillo de Perelada estate, however, smaller producers such as and Espelt, Terra Remota, and Roig Parals have significantly changed the perception of a region that used to be known as Empordà-Costa Brava. V. de la S. & F.C.

Enantio, 1980s name for vine grown in TRENTINO to produce deep-red wine, still sometimes referred to as Lambrusco a Foglia Frastagliata, 'toothed leafed Lambrusco', which is unrelated to any other LAMBRUSCO. Recent DNA PROFILING at SAN MICHELE ALL'ADIGE revealed a likely parent–offspring relationship with NEGRARA Trentina, and it seems to be closely related to TEROLDEGO and LAGREIN too. There were 178 ha/440 acres planted in Italy in 2015.

encépagement, widely used French term for the mix of *cépages*, or VINE VARIETIES, planted on a particular property. These proportions (typically for a MÉDOC estate, for example, Cabernet Sauvignon 60%, Cabernet Franc 20%, and Merlot 20%) do not necessarily correspond to the proportions of each grape variety in a given wine, partly because different varieties vary generally in terms of productivity, but also because factors such as FLOWERING and FROST may dramatically influence the YIELD from each variety in a given growing season.

Encostas d'Aire, DOC within LISBOA on the slopes of the Serra d'Aire in western Portugal. In 2005, two subregions were accorded DOC status: Alcobaça and Medieval de Ourém. The former revolves around terroir (LIMESTONE-based soils) and (predominantly white) varieties; the latter, revived by a handful of producers (and spearheaded by Quinta do Montalto), enshrines ancestral viticultural and oenological practices inherited from 12th-century Cistercian

MONKS. Vines must be trained low and grown at relatively high density (minimum 4,000 vines/ha; 6,000 vines/ha is recommended). The permitted grape varieties, FERNÃO PIRES (80%) and TRINCADEIRA (20%), start fermentation separately (the latter on skins) and are blended towards the end of fermentation; Fernão Pires lends herbal lift and freshness, while Trincadeira contributes colour, red fruits, spice, and tannic grip to these intriguing garnet-hued wines. S.A.

Woolf, S. J., and Opaz, R., *Foot Trodden: Portugal and the Wines That Time Forgot* (2021).

Encruzado, fine Portuguese white grape variety most commonly planted in DÃO but also found in the PENÍNSULA DE SETÚBAL. It can yield well-balanced, full-bodied VARIETAL wines capable of AGEING and well-suited to BARREL FERMENTATION. Total Dão plantings in 2020 were 639 ha/1,579 acres.

engarrafado, Portuguese for 'bottled'.

England, the largest and warmest country in Great BRITAIN and the only one which produces wine in any quantity, albeit on a small scale relative to most European wine-producing countries.

History

Perhaps the Romans introduced viticulture to England, but, whether they did or not, they cannot be held responsible for introducing the grapevine itself, because archaeologists have found prehistoric remains of the pollen of VITIS VINIFERA vines at Marks Tey in Essex, as well as seed at Hoxne in Suffolk (see PALAEOETHNOBOTANY).

Both these finds go back to the Hoxnian Interglacial (i.e. the period between the Second and Third Ice Ages), when summers were warmer than they are now. Grape seeds dating from the Hoxnian have also been found in the NETHERLANDS, north GERMANY, DENMARK, and POLAND. Since the British Isles were still part of continental Europe at the time (they did not become separated until after the Fourth Ice Age), this shows that *vinifera* had spread to regions of northern Europe which are now too cold for grapes. The seeds and pollen found in East Anglia are not accompanied by remains of cereals or other signs of agriculture. A more recent find at a Roman site at Wollaston in the Nene Valley near Wellingborough in the south Midlands is of what appear to be planting holes together with grape pollen, suggesting that this was the site of a vineyard.

Seeds have been found at Roman sites in London, Bermondsey, Silchester in Hampshire, and Gloucester, and stalks at a Roman villa near Boxmoor in Hertfordshire, but all without any evidence of cultivation, so these may be the remains of imported raisins. And even if grapes were grown in England, we cannot prove that they were made into wine. Wine was certainly imported from Italy, even before the Roman invasion of 43 CE: remains of AMPHORAE testify to that. (See CELTS for evidence that a small quantity of wine was carried to Hampshire at the end of the 2nd century BCE.) The earliest wine drinkers in Britain were the Belgae, a Celtic tribe that had invaded Britain in two waves, the first in 75 BCE and the second in 20 BCE, after the Romans had put down the Belgic rebellion in Gaul. The British Belgae kept in close contact with their kinsmen in Gaul, who were prodigious drinkers of Italian wine. In the reign of Cymbeline

(Cunobelin), 10–40 CE, galleys came up the River Colne to Camulodunum (one mile from Colchester in Essex).

Wine consumption probably increased after the Roman invasion of Britain, for remains of amphorae and pottery drinking cups are common finds on the sites of Roman towns and country houses. Recent finds show that amphorae were manufactured at Brockley Hill, Middlesex, which appears to have been an important pottery centre, and also at other London sites. They are of a type that, according to archaeological evidence from southern France, were used as containers for locally produced wine; the London amphorae were probably the work of immigrant potters from France. The amphorae all date from 70–100 CE: perhaps this short period could be explained by the edict issued by the Roman emperor DOMITIAN, which, by reducing the number of vineyards in the provinces, put a stop to the Romano-British wine industry. Remains of imported amphorae are rare after 300 CE, but it seems unlikely that the Romano-British were now producing enough wine to meet their own needs. In any case, from the 3rd century onwards wine began increasingly to be transported not in amphorae but in wooden BARRELS, which are perishable, so one would not expect to find many amphorae dating from the 4th century CE and certainly no wooden casks.

Our earliest conclusive evidence for winegrowing in Britain, then, must be Bede's *Ecclesiastical History*, which he finished in 731. It opens with a general description of Britain and Ireland, including geography, climate, agriculture, animals, nations, and languages. 'Britain', Bede says, 'is rich in grain and timber; it has good pasturage for cattle and draught animals, and wines are cultivated in various localities' (Book 1, ch. 1). Unfortunately, that is all he tells us about Anglo-Saxon viticulture—although in any case Bede has been shown to be a less than reliable source of information on viticulture in Ireland. As well as growing their own, the Anglo-Saxons certainly bought wine from the Franks. In the 8th and 9th centuries, Southampton was one of the largest ports of northern Europe and well placed for trade with northern France, especially Rouen (see

PARIS). In return for animal hides, the merchants of Southampton obtained gold, silver, glassware, and wine. However, as Viking pirates began to capture more and more ships, overseas trade was disrupted, and if imported wine was available at all it must have been a rare luxury item.

The Anglo-Saxons' daily drink was beer, but they needed wine for the EUCHARIST: supply being erratic, it made sense for monasteries to have their own vineyards, as some had probably been doing since Bede's day (see MONKS AND MONASTERIES). A charter, dated 955, of King Edwy, great-grandson of King Alfred, grants a vineyard at Pethanesburgh, Somerset, to the monks of Glastonbury Abbey. But not all vineyards were owned by monks. The Laws of King Alfred regard viticulture as important enough to make it an offence for anyone to destroy a vineyard; no mention is made of monasteries here. An 11th-century document lists looking after the vineyard as one of the duties of the manager of a secular estate, and out of the 38 vineyards named in Domesday Book, only 12 were monastic. More importantly, if the figure is accurate—and William the Conqueror's surveyors did their work thoroughly—38 vineyards cannot possibly have produced a plentiful supply of wine for the whole of England. (According to the Bayeux Tapestry's depiction of William's invasion of England in 1066, he judged it as important to take wine with him as he did arms.)

Wine continued to be grown in England during the 12th and 13th centuries. There were vineyards as far north as south Yorkshire, and the praise lavished on the wines of Gloucestershire by the 12th-century chronicler William of Malmesbury demonstrates that English wine was no thin, sour plonk. Worcestershire, too, was renowned for its wine. This golden age of English viticulture was the result of a long period of warm summer weather, which started in the mid 11th century (see CLIMATE CHANGE). It ended abruptly in the 14th century, when the ocean currents changed and summers became wet and cloudy. Moreover, when on his marriage to Eleanor of Aquitaine Henry II acquired Gascony, and when King John (1199–1216) granted the citizens of BORDEAUX numerous privileges in order to win

their favour, Gascon wine became cheaper to buy for the English than any other wine, imported or home-produced. Around 1,300 commercial vineyards were grubbed up all over England, and grapes made way for more profitable crops: this is how the Vale of Evesham, still famous for its plums and apples, came to be planted with fruit trees. Monastic viticulture continued for longer, but between 1348 and 1370 the Black Death carried off one-third or more of the population, lay and ecclesiastic alike. Not only did many monks die, but the ensuing shortage of labour deprived the monasteries of their unsalaried workforce, the lay brothers. English viticulture did not cease altogether, but it was no longer commercially viable, even for the monks.

But with a wine-drinking Norman aristocracy, domestic production could never have satisfied demand. Via Rouen, then governed by the king of England, who was also duke of Normandy (until John lost Normandy), the English had ready access to the wines of the Île-de-France (see PARIS), which in 1200 were the most expensive on the English market, although people bought more of the wines of Poitou (see LA ROCHELLE) and Anjou (see LOIRE), probably with reason, for they must have been less acidic. With the rise of Bordeaux, this changed, and until the end of the HUNDRED YEARS WAR the English bought more wine from Gascony than from anywhere else, with wine being second only to wool in importance for English trade at this time. Wine was shipped to England, principally to the port of Southampton, twice a year from Bordeaux, in the autumn and in the spring. Even if the vintage had been early, the new wine did not usually reach England before November; the wines that arrived in the spring were the wines 'of rack', so-called because they were not racked off their LEES until the spring. The wines 'of rack', an early form of SUR LIE, fetched higher prices. Since there was nothing better in which to keep the wine than wooden casks, OXIDATION was the norm, and wine did not keep from one year to the next. The wine of the previous year was therefore sold off cheaply at AUCTION as soon as the new vintage appeared on the market in England. White wine was more expensive than red.

French wines were not the only wines to be drunk in 14th-century London. From the 1350s onwards, sweet wines from southern Europe began to be introduced (see VENICE, NAPLES, and GENOA), and they became the most expensive available. The most highly prized of these was 'vernage', the Italian VERNACCIA. Another favourite was 'malvesye', or MALMSEY, supplied mainly by Cyprus and Crete. Because of their additional strength and sweetness, these wines lasted longer than the thinner, drier wines that the English had been used to and were greatly prized. The wines of Alsace and the Rhine were highly valued because they were so brilliantly clear. Spanish wine, which was higher in alcohol than other wines, was regarded mainly as cheaper heady plonk, and better, more expensive, wines were often cut with it (see SPAIN, history).

Attempts were made to protect the consumer from ADULTERATION AND FRAUD, but their frequency suggests that they were not always successful. In 1321, a proclamation was made that in London all wines should be graded 'good' or 'ordinary' and the casks marked; everyone would have the right to see the wine drawn, and maximum prices were fixed. Merchants and innkeepers refused to cooperate and were promptly fined. The marking of casks was probably abandoned, but the right to see one's wine being drawn is reiterated from one writ and proclamation to the next, and one even says that taverners should keep red wines and white in different cellars: a note of desperation is clearly creeping in. A London proclamation of 1371 makes clear what the unfortunate drinker was subjected to: overcharging, adulteration, and wine that was off. It makes one grateful for clearly labelled, tamper-free modern packaging: the glass BOTTLE and modern CLOSURES have improved the wine drinker's life almost beyond imagination. H.M.W.

Modern English wine

The revival of viticulture in the British Isles—mainly in England but also in Wales (and even Scotland)—that began in the mid 20th century has matured into a small but significant industry with a planted area in 2021 of 3,750 ha/9,266 acres. Average annual production from 2016 to 2020 was 8.7 million bottles, including a record 13.11 million in 2018. While initially English wines were often light and acidic, CLIMATE CHANGE has led to a revolution in the VINE VARIETIES grown and in QUALITY IN WINE. This is especially true of the BOTTLE-FERMENTED sparkling wines which are increasingly being compared to champagne. English and Welsh wine is subject to EU winemaking regulations (although post-Brexit these are being slowly amended to be tailored to UK conditions) and is made strictly from freshly picked, UK-grown grapes.

The revival of viticulture began in 1945 when Raymond Barrington Brock started what became the Oxted Viticultural Research Station, a privately funded experimental NURSERY where, over the next 25 years, Brock trialled 600 vine varieties. Buoyed by the success of some of Brock's trials, the first commercial vineyard, all 0.4 ha/1 acre of it, was planted at Hambledon in Hampshire by Major-General Sir Guy Salisbury-Jones in March 1952. More vineyards followed, slowly at first, but as wines were produced from these early vineyards more pioneers took up the cause, and by the mid 1960s there were over 40 vineyards spread across the south of England and Wales. The hot summer of 1976 provided the spur for many new growers to enter the industry, and the area under vine rose to a high point of 1,065 ha/ 2,632 acres in 1993, after which it declined as competition increased and consumer demand for the still wines then typically based on GERMAN CROSSES waned. This decline continued until 2003 heralded an era of much warmer summers, as well as considerable success in tastings and the marketplace of SPARKLING WINES made from the champagne varieties Chardonnay,

Pinot Noir, and Pinot Meunier. Together they spurred a new wave of planting.

The biggest change in UK vineyards has been in the range of vine varieties grown. Varieties such as MÜLLER-THURGAU, REICHENSTEINER, MADELEINE × ANGEVINE 7672, HUXELREBE, SCHÖNBURGER, and BACCHUS, plus the French-American hybrid SEYVAL BLANC (which together accounted for 74% of the UK area under vine in 1980), have been widely replaced by Chardonnay and Pinot Noir, which were planted on about half of all English vineyard by 2014 and are almost exclusively used for sparkling wines. For still white wines, Bacchus is the most widely grown with around 9%, followed by Seyval Blanc with 4%. Reichensteiner and SOLARIS each claim 2%. Red-wine varieties, excluding Pinot Noir and Meunier, account for only 0.15% of the planted area. Red and rosé wines account for around 15% of production.

Almost 85% of England's 800 officially recorded vineyards (of 0.10 ha or more) and 191 wineries are located in the southern counties. East Anglia accounts for a further 11% of vineyard. The best are in the traditional fruit-growing regions of the UK on sheltered sites below 100 m/330 ft ELEVATION. To many people's surprise, vineyards are planted in almost every county of England, and Yorkshire boasts 15 wine producers. However, the chances of achieving commercial viability lessen the further north a vineyard is situated, with YIELDS and quality in some of the more challenging regions considerably lower than in the warmer southern counties.

Although much of the south of the UK and some of the western regions have a climate that is softened by the Gulf Stream, the MARITIME CLIMATE brings summer gales and high summer RAINFALL which can disrupt FLOWERING so that yields are dramatically reduced. In 2012, for example, spectacularly bad weather during pollination reduced the total UK crop by about two-thirds, with some large producers picking not a single grape. Official average yields are very low, around 25 hl/ha between 2011 and 2020, but well-sited, well-managed vineyards can expect to average 50–60 hl/ha.

Harvesting usually takes place between the end of September and the end of October, depending on variety and region, but in 2013 the latest grape harvest ever recorded in the UK saw some growers still picking Chardonnay on 20 November. Natural MUST WEIGHTS tend to be low by global standards, with most grapes achieving 7–9% POTENTIAL ALCOHOL, although with certain varieties and in warmer years, such as 2020, 13–14% has been recorded. Levels of natural acidity tend to be high, with PH around 2.9 to 3.2 and TOTAL ACIDITY (expressed as tartaric acid) between 8 and 15 g/l. Under current winemaking regulations, ENRICHMENT is allowed by up to 3% every year and 3.5% in 'abnormal' years. ACIDIFICATION is not permitted (nor often needed), except in sparkling wines post-DISGORGEMENT where 1 g/l may be added for STABILIZATION purposes (as in Champagne and other EU regions where sparkling wine is made).

The UK has its own CONTROLLED APPELLATION system, set up under EU regulations with four distinct categories. Those qualifying as PDO are known as Quality Wines; PGI wines are called Regional Wines; Varietal Wines are WINES WITHOUT GEOGRAPHICAL INDICATION labelled varietally which have gone through a certification process; and those which carry neither grape variety nor vintage are labelled simply UK Wine.

England and Wales are increasingly recognized as legitimate wine-producing regions, with wines regularly winning trophies and gold medals in UK and international wine COMPETITIONS. Where once the industry was populated by amateurs and retirees, today's modern vineyards are staffed by well-trained and experienced viticulturists and winemakers, many trained at PLUMPTON. Some vineyards are even into the second and third generations of the same family. While many smaller vineyards rely on TOURISM and local sales, more and more UK wines are stocked by bigger retailers and quite smart restaurants. Some vineyards even export their wines. English literature, wine in. References to specific wines in English literature are relatively common and provide a useful record of FASHIONS in wine styles and the history of wine imports to the British Isles from the time of Chaucer to the present day. Literary references to wine drinking are legion, presumably because it encouraged conversation—civilized, bawdy, or sometimes nonsensical. Generic 'wine' is mentioned too often to report, and more detailed and revealing references specifying wine type or provenance are scarce in English literature before the 17th century.

The first English writer to demonstrate a serious interest in wine was Geoffrey Chaucer (1345–1400), himself the son and grandson of a vintner. *The Canterbury Tales* are dotted with references to specific wines (see CONDADO DE HUELVA, for example). The Prologue details contemporary eating and drinking habits, while the 60-year-old knight in 'The Merchant's Tale' drank spiced wine in the form of 'ypocras, clarree, and vernage' (see VERNACCIA) for 'courage' in the bedchamber.

BORDEAUX was England's chief medieval wine supplier, and it dominates wine references in the literature until long after Aquitaine was ceded to France. William Shakespeare's (1564–1616) 'good familiar creature' in *Othello* would undoubtedly have been bordeaux, although 'sherris SACK' was Falstaff's favoured drink in *1 Henry IV*, and Sir Toby Belch's call for 'a cup of CANARY' in *Twelfth Night* also demonstrates the increasing importance of Spanish wines. Shakespeare's contemporaries Robert Herrick, John Webster, and Robert Burton certainly refer to wine, but only Burton (1577–1640) mentions the evocative names of Alicant, Rumney, and Brown

Bastard (respectively, wines from ALICANTE, sweet wines made in the Greek style, and a sweet blend from Portugal, presumably based on BASTARDO grapes).

The life of Samuel Pepys (1633–1703) seems to have been a succession of drinks if his diary provides an accurate record, with references to TENT, Canary, Rhenish (wine from the RHINE), and English wine from vineyards around London (see ENGLAND). Pepys also famously provides the first reference to New French CLARETS, in particular that of 'Ho Bryan' (HAUT-BRION). Pepys mentions champagne, as does the comic playwright Sir George Etherege (? 1634–91), who qualifies the reference with 'sparkling'. These, together with a brief note from Dean Swift (1667–1745), are the earliest mentions of what must have been a very new product (see CHAMPAGNE, history). Edward Ravenscroft (*fl*. 1671–97), the relatively obscure author of a rollicking farce *The London Cuckolds* (1682), is very forthcoming, with sack and PORT mentioned almost as many times as pretty women. John Gay (1685–1732) even published in 1708 a rather indifferent poem entitled 'Wine' which mentions the mysterious drink 'Golorence'.

In the 18th century, the number of references to wine by English dramatists, novelists, and poets rises dramatically. R. B. Sheridan (1751–1816) insists about claret in *School for Scandal* that 'women give headaches, this don't', and champagne appears more than once in his *Paris Sketchbook*. David Garrick (1716–79) provides one of the first mentions of burgundy in English: 'rich Burgundy with a ruby tint'. As today, however, opinions about the relative merits of various wine regions are divided. The observation of Tobias Smollett (1721–77) in his *Travels through France and Italy* that 'the Wine known as Burgundy is so weak and thin' is a useful indication of the general derision of any wine region other than Bordeaux.

Samuel Johnson (1709–84) and Parson Woodforde (1740–1803) both give disquieting insight into the prodigious quantity of food and drink which then customarily appeared at table. Boswell reports Johnson's observation that 'few people had intellectual resources

sufficient to forgo the pleasures of wine. They could not otherwise contrive how to fill the interval between lunch and dinner.' And during travels in Germany, 'I drank too much Moselle, imagining it to be a mere diuretic.' The next day he 'was uneasy from the Moselle'. There is a disparaging reference to Florence wine, which 'neither pleases the taste nor exhilarates the Spirits'.

Jane Austen (1775–1817) admits to some of her characters drinking wine, although only in appropriate quantities of course. Among very few references to specific wines, the treasured South African CONSTANTIA is considered a suitable restorative for a young lady in *Sense and Sensibility*. Keats refers to claret frequently in correspondence, but his most famous vinous reference is in 'Ode to a Nightingale' ('O, for a draught of vintage!' etc.). George Crabbe (1754–1832), whose works illustrate his somewhat grim sense of humour, describes the sorts and conditions of men who drink various wines in 'Champagne the courtier drinks the spleen to chase, the Colonel Burgundy, Port His Grace…' Crabbe's approver Lord Byron (1788–1824) is entertaining on the subject of wine and DRUNKENNESS, recommending 'hock and soda-water' as a hangover remedy. He also turned wines into verbs, as in 'We clareted and champagned till two' in a letter to Thomas Moore. In his *Don Juan* VI. 607–8, one of the most misquoted pieces of literature (often confused with Keats), Byron eventually declares, 'If Britain mourn her bleakness we can tell her, the very best of vineyards is the cellar', an admirable sentiment.

The 19th-century writers indicate the increasing range of wines imported to the British Isles as well as the widening appreciation and understanding of them. In *Melincourt*, Thomas Love Peacock (1785–1866) describes wine as both 'a hierarchical and episcopal fluid' and 'the elixir of life', and further references appear in *Crotchet Castle*. Peacock was clearly a burgundy aficionado, daring to suggest that 'an aged Burgundy runs an ageless Port'. George Meredith (1828–1909), who married the widowed daughter of Peacock, shares his interest in burgundy; precise references to Musigny and Romanée appear in *The Egoist* and *One of our Conquerors*. R. S. Surtees

(1805–64), the master of comic fox-hunting novels, brings port, champagne, and 'tolerable St Julien doing duty for Ch Margaux' into such pieces as *Handley Cross* and *Mr Sponge's Sporting Tour*. He sagely advises against the excesses of the previous century: 'no side dishes, no liqueurs, only two or three wines'.

At a somewhat more elevated level, William Thackeray (1811–63) names Beaune and Chambertin and also refers to claret, sherry, and madeira, also commenting, 'if there is to be Champagne have no stint of it … save on your hocks, sauternes, and moselles, which count for nothing'. This last quotation is from *Pendennis*, in which appears the character Captain Shandon, heavily based on William Maginn (1793–1842), who wrote under the pseudonym Sir Morgan O'Doherty, Bt. As a regular contributor to *Blackwoods Edinburgh Magazine* Maginn wrote many wonderful 'Maxims', many of which refer to or include wine and food: they are well worth searching out, as is the 'Spectator ab extra' of A. H. Clough (1819–61), an entire poem devoted to food and drink of which the first stanza has particular appeal for this writer:

Pass the bottle and damn the expense
I've heard it said by a man of sense
That the labouring classes could scarce live a day
If people like us didn't eat, drink and pay.

Henry James (1843–1916) is particularly descriptive about Burgundy and its vineyard in *A Little Tour of France*. Robert Louis Stevenson (1850–94) also enthuses over Burgundy in *Travels with a Donkey in the Cévennes*. His ill health led to frequent foreign journeys even as far afield as California: *The Silverado Squatters* is the first literary work to include reference to the vineyards there.

Other serious 19th-century writers who regularly included comments on wine are Robert Browning (1812–89), who clearly enjoyed Chablis; Charles Dickens (1812–70), whose novels, as one might imagine, mention punch more often than wine; and, most amusingly, Saki, or H. H. Munro (1870–1916), who delights in his

many comments on wines and the manners of those who serve it, such as 'the conscious air of defiance that a waiter adopts in announcing that the cheapest Claret on the list is no more'. Finally, Edward Fitzgerald (1809–83), the erudite translator of the 11th-century ARAB POEM *The Rubáiyát of Omar Khayyám*, must be cited, as one particular passage has cut wine merchants to the quick ever since publication: 'I often wonder what the Vintners buy, one half so precious as the goods they sell.'

The 20th century sees further geographical extension of the wine regions mentioned in English literature, as well as a greater awareness of the variety and quality of the products available. Hilaire Belloc (1870–1953) wrote much in praise of all sorts of drink, notably 'Advice', which is full of vinous references, and his 'Heroic Poem in Praise of Wine', which expresses the sentiment 'Dead Lucre: burnt Ambition: Wine is best'. The *Forsyte Saga* of John Galsworthy (1867–1933) abounds with references to hock, especially Steinberger. Aldous Huxley offers the somewhat jaded assessment that 'Champagne has the taste of an apple peeled with a steel knife', while Eric Newby in *Love and War in the Apennines* also paints a grim picture of the wine 'the Italians call *vini lavatori*'. But the balance is redressed by P. G. Wodehouse, whose characters' 'form' can often be restored by various vinous substances. Evelyn Waugh's diaries and letters inform us of his own serious wine-drinking habits, although only *Brideshead Revisited* among his works contains many specific wine references. He wrote a monograph *Wine in Peace and War* for wine merchants Saccone & Speed and was paid, according to his son Auberon, at the rate of a dozen bottles of champagne per thousand words. More recent novelists whose work displays a deep understanding of wine include Sybille Bedford and Dick Francis, who in one of his novels treats good wine extensively. Wine is one of several alcoholic drinks to figure largely in Kingsley Amis's work.

Are spy stories literature? Ian Fleming's James Bond has rather common tastes in champagne, and more than once Fleming mentions a vintage of Taittinger or Dom Pérignon which was never made. This usefully illustrates the way in which wine, mentioned by

authors throughout the history of literature, is used more for illustrative purposes than anything else. In ingested form, however, wine has probably offered writers more inspiration than opium, and their references to it have helped us better understand the chronology of importation and imbibing of wine through the ages. See also MEDIEVAL LITERATURE. H.G.B.

One wine-soaked novel I would like to have discussed with the late Bill Baker, who wrote the article above, is Paul Torday's successor to *Salmon Fishing in the Yemen*. The hero of *The Irresistible Inheritance of Wilberforce* drinks himself, knowledgeably, to death. Novelist Anthony Quinn reminds me that in Thomas Harris's *The Silence of the Lambs*, Hannibal Lecter boasts of eating a victim's liver with fava beans and a 'big Amarone', changed rather weedily in the movie, this former film critic notes, to a 'nice Chianti'. J.R.

enologist is the American and South African spelling of OENOLOGIST, just as enology is the alternative spelling of OENOLOGY, the study of wine and, especially, winemaking.

enoteca, term used frequently in Italy for a wine shop with a significant range of high-quality wines, while quite a few still offer the local wine or wines as *vino sfuso*, or in BULK, which are poured straight from the cask into demijohns brought along by customers. It contrasts with a *bottiglieria*, a shop with a more pedestrian selection, and a *vineria*, run by a *vinaio*, more of a tavern, in which wine is sold by the glass as well as by the bottle. Various enoteche in Italy offer tasting facilities, and some serve food to accompany the wines —from the mere appetite-stimulating to the most ambitious cuisine. The word comes from the same root as OENOTRIA, the ancient Greeks' name for Italy, and *theke*, Greek for a case or receptacle.

Enotria, corruption of the ancient Greek name for what is now Italy. See OENOTRIA.

enoturismo. See AGRITURISMO.

en primeur, wine trade term, French in origin, for wine sold as futures before being bottled. It comes from the word PRIMEUR. En primeur sales are a relatively recent speciality, but not exclusivity, of CLASSED GROWTHS by the BORDEAUX TRADE (see BORDEAUX, history). Cask SAMPLES of wines have customarily been shown in the spring following the vintage. Thousands of trade and media representatives descend on Bordeaux each spring for carefully organized programmes of tastings. Sales are solicited, through BROKERS and then NÉGOCIANTS, as soon as proprietors decide to announce their opening PRICE, and market reaction is keenly monitored by interested parties. A particular property often releases only a certain proportion, or *tranche*, of its total production, depending on its need for cash and reading of the market.

This form of early sale has long been available to the wine trade but was undertaken by wine consumers only from the late 20th century. It has been most popular in times of frenetic demand such as in the very early 1970s (when some wine was even sold *sur souche*, or on the vine before the grapes were picked) and since the 1980s, when a succession of good VINTAGES coincided with widespread economic prosperity and the accessibility of early VINTAGE ASSESSMENTS from the wine trade and press. The consumer pays the opening price as soon as the offer is made and then, up to two years later, having paid the additional shipping costs and DUTY, takes delivery of the wine after it has been bottled and shipped. The theory is that, by buying wine early, the consumer not only secures sought-after wines but also pays less. This is by no means invariably the case, however, as outlined in INVESTMENT IN WINE.

En primeur purchases have many disadvantages in periods of economic recession. Not only may prices stagnate or even fall, but there is a much higher risk that one of the many commercial concerns in the chain between wine producer and wine consumer will fail, leaving the consumer with the possibility of having paid for the wine without any certainty of receiving it. There is also the important fact that en primeur purchases inevitably mean investing in an embryonic product. A third party's assessment of a single cask sample taken when it is just six months old is a poor justification for financial outlay on a liquid that is bottled only a year later (and is particularly hazardous for a wine as notoriously transient as red BURGUNDY), unless the wine market is extremely buoyant.

Buying en primeur may make financial sense only for the most unanimously lauded vintages and the most sought-after wines, and then only in a rising market, although it can of course give a great deal of pleasure to those with a strong wine-COLLECTING instinct.

en rama, literally 'raw', a condition of fino or manzanilla SHERRY whereby, unlike mass-market BRANDS, it is only very lightly filtered before being bottled and sold.

enrichment (*enrichissement* in French, *Anreicherung* in German, *arricchimento* in Italian, *enriquecimiento* in Spanish), winemaking operation whereby the fermentable sugars of grape juice or MUST are supplemented in order to increase the ALCOHOLIC STRENGTH of the resultant wine. This is traditionally and habitually done to compensate for natural underripeness in cool regions or after particularly cool summers in warmer regions. The original process, generally called CHAPTALIZATION after its French promulgator CHAPTAL, involves adding sugar, whereas the wider term 'enrichment' encompasses the addition of sugar, concentrated grape must (see GRAPE CONCENTRATE), and rectified concentrated grape must (RCGM) and is the term favoured in official EU terminology. While it is

impossible to know the extent to which enrichment is used around the world, a report in 2012 suggested that in Europe an average of 55 million hl (1,453 million gal) of wine was enriched every year, corresponding to 30% of total EU wine production. It seems unlikely that it is still at this level.

Enrichment is the winemaking counterpoint to ACIDIFICATION, which is the norm in hot wine regions. Most regions' wine regulations set limits for these processes; most of them, as in Burgundy, for example, forbid the enrichment and acidification of the same batch of wine.

Geography

Enrichment is the norm in climates which cannot be relied upon to bring grapes to full ripeness every season: for example, throughout northern Europe, in the north-eastern wine regions of the United States, throughout CANADA, in BRAZIL, in JAPAN, and in much of NEW ZEALAND, especially for red wines.

At the coolest limits of vine cultivation it is a prerequisite of wine production. Within the EU, permission to chaptalize and the maximum permitted increase in ALCOHOLIC STRENGTH depend on the EU climatic zone in which an area falls. A country's own regulations may also forbid the practice unless permission has been specifically granted because of the vintage conditions.

The poorest summers in ENGLAND and LUXEMBOURG, for example, the so-called Zone A of the EU, yield grape sugar levels in some varieties that have difficulty reaching the legal minimum NATURAL ALCOHOL level of 5%. Here musts may be enriched to a maximum increase in alcoholic strength of 3% (3.5% in particularly unripe years).

Winemakers in Europe's Zone C1, which includes Burgundy, for example, may enrich their musts by up to 1.5%.

In Bordeaux, also in Zone C1, chaptalization has also been the norm historically; thanks to CLIMATE CHANGE and the development of alternative techniques for juice CONCENTRATION, however, the practice of enrichment is becoming a choice rather than a necessity except perhaps in difficult vintages such as 2021.

Enrichment is also much relied upon, especially for more commercial wines, in Eastern Europe, Switzerland, Austria, and Germany. Indeed the major distinction between Germany's better-quality wine (classified as wine with PRÄDIKAT) and ordinary QUALITÄTSWEIN was long that Prädikatsweine could not be enriched by added sugar (although they could include SÜSSRESERVE of comparable ripeness added for sweetening purposes after

fermentation). Similarly in AUSTRIA, sugar may not be added to wines of Kabinett quality or above. See PRÄDIKAT for the current situation.

In southern France, notably the Languedoc, Roussillon, the southern Rhône, Provence, and Corsica, and throughout the rest of the south of the EU, chaptalization is expressly forbidden, but enrichment using concentrated must of various sorts is often permitted and even encouraged, depending on the quality level of the wine and the characteristics of the VINTAGE. This sort of enrichment by adding concentrated must is commonplace in northern Italy and has provided an end use for vast quantities of otherwise SURPLUS wine made in southern Italy (see Materials below).

Winemakers prohibited from practising enrichment tend to scorn the practice as artificial and manipulative (just as those in cooler regions, prohibited from adding acid, are wary of the practice of ACIDIFICATION).

There are wine regions, however—such as TASMANIA, the recently planted vineyards on the southern tip of SOUTH AFRICA, and even some of the higher vineyards of northern Italy—in which chaptalization is prohibited, to the detriment of wine quality in some seasons, simply because they belong to a political unit whose other wine regions are too hot to need it.

Materials

SUCROSE is the usual enrichment material used. In northern Europe this has normally been refined sugar beet or, occasionally, cane sugar.

In an effort to help drain Europe's WINE LAKE, however, EU authorities tried to encourage the use of high-strength grape-sugar syrups made from SURPLUS wine, especially in Italy and southern France (see GRAPE CONCENTRATE and RECTIFIED GRAPE MUST for more details), but compulsory DISTILLATION and other market reforms have been more effective at reducing the surplus. Enrichment using grape concentrate is also permitted in Australia, but sugar may be added only to induce the second fermentation for sparkling wines.

Technique

The enrichment material may be added before and/or during FERMENTATION. Both sugar and acid tend to inhibit yeast growth, however. Adding the enriching sugar when fermentation is already fully under way avoids the delay which could ensue if it were added to the unfermented juice or must. It is also favoured as a way of extending the fermentation by some winemakers, especially in Burgundy.

About 1.8 kg/4 lb of sugar is needed to raise the alcoholic strength of 1 hl of wine by 1% (slightly less for less dense white and rosé wine musts), which means that stacks of sugar sacks can be a regular sight in many large and not-so-large French wine cellars.

When conducted properly, enrichment increases the volume of the wine negligibly, has no tasteable effect on the wine, and merely compensates for Nature's deficiencies in a particular growing season. Enriched wines certainly should not taste sweet, since all of the fermentable SUGARS should have been fermented into ALCOHOL; the wine should merely have more BODY and better BALANCE than it would otherwise have.

The non-winemaking observer may wonder, however, why in an age in which many consumers wish to curb their consumption of alcohol, when alcohol levels are rising, and there is a global wine surplus, the wine industry deliberately increases the alcohol content of so many of its products, in many cases to compensate for overcropped vines (see YIELD).

In recent years, concentration techniques such as vacuum evaporation and REVERSE OSMOSIS have become popular ways to enrich musts by removing water. In many ways, these subtractive techniques may be less 'unnatural' and open to abuse than additive techniques such as chaptalization. See also MANIPULATION.

Entraygues–Le Fel, AOC on the right bank of the upper Lot in SOUTH WEST FRANCE focused on the SCHIST hillsides of Le Fel and the GRANITE of Entraygues. Half the production is in red wine, and some rosé is made, the wines based on FER grapes (here called Mansois) although several local oddities are also allowed, including Négret de Banhars. The rarer whites are mainly CHENIN BLANC. With ten or so producers and no CO-OPERATIVE, quality is impressively high. P.S.

Entre-Deux-Mers, large area of the BORDEAUX wine region between the Rivers DORDOGNE and GARONNE; hence a name which means 'between two seas'. A high proportion of the vineyard land in this pretty, green region (which has much in common with BERGERAC to its immediate east) produces light, often slightly austere red wine made from MERLOT and CABERNET grapes and sold as BORDEAUX AOC. Indeed, since vine-growers converted their white-wine vineyards to red varieties in the 1960s and 1970s, the Entre-Deux-Mers district has become the chief source of red Bordeaux AC. The Entre-Deux-Mers region contains several other appellations, some of them enclaves such as GRAVES DE VAYRES, STE-FOY CÔTES DE BORDEAUX, and Côtes de Bordeaux St-Macaire. Haut-Benauge is another whose dry white wines have their own appellation, Entre-Deux-Mers Haut-Benauge. The PREMIÈRES CÔTES DE BORDEAUX and its sweet-white winemaking enclave lie between the Entre-Deux-Mers appellation and the river Garonne, in the same territory as produces red CADILLAC CÔTES DE BORDEAUX. Wines sold as Entre-Deux-Mers are dry whites made mainly from SAUVIGNON BLANC together with SÉMILLON, MUSCADELLE, and SAUVIGNON GRIS grapes. After Bordeaux AC, this is the biggest dry-white-wine appellation in the Bordeaux region, on a vineyard area that totalled 1,617 ha/3,994 acres in 2020. CLAY and SANDY clay predominate although there are pockets of LIMESTONE, especially just across the Dordogne from ST-ÉMILION. This is one of the few French wine districts to have adopted the LENZ MOSER system

of high vine TRELLISING to any great extent. Most Entre-Deux-Mers should be drunk as young as possible and without great ceremony.

J.R. & J.L.

Eola-Amity Hills, wine region and AVA within the WILLAMETTE VALLEY of Oregon.

enzymes, proteins present in all biological systems that act as catalysts by inducing or accelerating specific biochemical reactions. Enzymes, named using the suffix -'ase', are characterized by both the specificity of the chemical group or substrate they act on and the reaction which they catalyse. Endogenous enzymes are those that the organism itself produces, whereas exogenous enzymes are those that are prepared commercially.

Endogenous enzyme activities of the vine are central to the biological processes by which grape berries develop and ripen. Wine is the enzymatic transformation or FERMENTATION of grape juice by thousands of endogenous enzymes originating from the grape juice, YEAST cells, and other microorganisms.

BOTRYTIS also produces the enzyme laccase, which promotes very rapid OXIDATION and browning of juice and young wine exposed to oxygen. At the end of fermentation, exposure to any oxygen has to be avoided until the combination of higher ALCOHOLIC STRENGTH, TANNINS, and added SULFUR DIOXIDE reduce the laccase activity, thereby making the wine stable to enzymatic oxidation. Alternatively, heat treatment of the wine can be used to inactivate (denature) the enzyme.

Winemakers influence the outcome of enzymatic reactions (via PH, TEMPERATURE, SULFUR DIOXIDE levels, and choice of yeast and bacteria) to produce specific wine styles.

As not all endogenous enzymes are efficient under winemaking conditions, since the 1970s winemakers have increasingly used exogenous enzymes to speed up or improve some processes. Enzyme research is active and the range of exogenous enzymes

available is increasing. They are produced mainly from natural fungi, *Aspergillus niger* and Tricoderma species. Examples of these enzymes and their uses are described below.

Pectinases (polygalacturonase, pectin lysase, and pectin methyl esterase), also known as pectolictic enzymes, often in combination with cellulase and hemicellulase, can be used to break down PECTINS in cell walls to enhance juice extraction in white wines (see PRESSING) and colour EXTRACTION in reds during fermentation. Pectinases also reduce juice viscosity and thereby accelerate CLARIFICATION by breaking down pectin molecules in the juice.

Glycosidases release AROMA compounds (especially in varieties high in MONOTERPENES such as Muscat, Riesling, and Gewürztraminer) bound to sugars in an odourless GLYCOSIDE form thereby increasing the aromatic intensity of the wine. This process also occurs naturally but very slowly.

Glucanases are used to accelerate AUTOLYSIS in wines aged on yeast LEES. The enzyme breaks down the cell walls releasing MANNOPROTEINS into the wine. Glucanases are also used in wines affected by BOTRYTIS BUNCH ROT, which can have high levels of glucans (polysaccharides of glucose), which makes FILTRATION more difficult. Beta-glucanase breaks down these molecules, making the wine easier to filter.

Lysozyme, an enzyme isolated from egg whites, attacks the cell walls of LACTIC ACID BACTERIA and is used to inhibit MALOLACTIC CONVERSION.

epicatechin. See CATECHIN.

epigenetics refers to a range of heritable and reversible molecular processes that may change gene function but do not alter the underlying DNA sequence. These complex and interrelated processes play fundamental roles that are critical to gene regulation, contributing to plant growth, development, and response to environmental cues. Epigenetic regulation may be mediated by a number of processes known as markers. One such marker widely studied in plants is DNA methylation (i.e. the addition or removal of methyl groups (CH_3) on the cytosine base of genomic DNA).

It is becoming increasingly clear that these markers are critical in plant reproduction and particularly in a plant's response to its environment. DNA methylation plays an important role in phenotypic plasticity, which is the ability of an individual organism to change its observable traits in response to a change in its environment, including various types of stress and inputs. In some species, this provides a selective advantage. DNA methylation patterns have been identified in response to DROUGHT and salt tolerance and have also been used in differentiating grapevine CLONES that are genetically very similar (see DNA PROFILING).

In grapevines, epigenetic sensitivity to both environment and vine management has been shown to exist. In one study of 22 Shiraz vineyards in Australia's Barossa region, epigenetic profiles showed relationships based on location and PRUNING method even though the vines in those vineyards were genetically very similar. Comparable results were found with Malbec in MENDOZA. DNA methylation patterns have also been shown to differ with VINE AGE and PROPAGATION method.

While genetics is the main factor shaping diversity in the visible traits of grapevines and their fruit, epigenetics is likely providing an additional layer of variability that could influence grape development, such as TANNIN accumulation, and vines' adaptation to their environment. D.P.G.

Xie, H., et al., 'Global DNA methylation patterns can play a role in defining terroir in grapevine (V*itis vinifera* cv. Shiraz)', *Frontiers in Plant Science* (2017).

Épineuil, red-wine commune near AUXERRE whose name may be appended to that of BOURGOGNE.

éraflage, French term for DESTEMMING grapes.

Erbaluce, ancient but minor white wine grape speciality of Caluso in the north of the PIEMONTE region of north-west Italy. Dry Erbaluce used to be relatively light-bodied and acidic because it was picked too early, but serious, long-lived examples can now be found, along with TRADITIONAL METHOD sparkling wines. Erbaluce's most famous, if rare, manifestation is the golden sweet Caluso PASSITO. Total Italian plantings were 316 ha/781 acres in 2015.

erinose mite. The grapevine is the only known host in the plant kingdom to the grape erineum mite, *Colomerus vitis*, sometimes called grape leaf blister mite. The mite is widely distributed but usually causes only minor damage in commercial vineyards. The damage first appears as pinkish or reddish swellings or galls on the upper surfaces of the leaves. Beneath the gall, the concave portion of the leaf is lined with a felty mass of plant hairs or 'erinea'. This is one of the most unsightly grape-pest problems, yet it has negligible effects on vine performance. Control is usually by preventive applications of SULFUR dust, and, as this is often applied to control POWDERY MILDEW, these mites are often incidentally controlled.

M.J.E.

Ermitage, alternative and historic name for HERMITAGE in the northern Rhône. Occasional synonym for MARSANNE.

erosion. See SOIL EROSION.

Erste Lage, literally 'first[-class] site', is an expression that has entered German and Austrian wine discourse in recent years with numerous distinctive meanings best explained in historical context. While Germany's VDP growers' association professed an ongoing interest in vineyard CLASSIFICATION from the 1980s, this was always in the context of delimiting a premium class of dry wines, for which the name ERSTES GEWÄCHS was long entertained. Following the RHEINGAU growers' 1999 success in gaining legal recognition by the state of Hessen for the designation Erstes Gewächs, the VDP nationally adopted the name GROSSES GEWÄCHS for an almost identically conceived category, applying it by implication to those vineyard sites classified as worthy of generating a wine so designated. In 2003, the Mosel regional VDP, most of whose members placed emphasis on residually sweet Riesling, adopted Erste Lage for wines from top-ranked sites that failed the test of legal dryness imposed on Grosse Gewächse. In 2006, the VDP adopted Erste Lage as 'the unifying overarching concept in all regions for wines of the uppermost category', thus making Grosses Gewächs a name for legally dry (TROCKEN) wine from an Erste Lage.

In 2012, the VDP elected to make GROSSE LAGE the apex of its classificatory pyramid and to add a PREMIER CRU level, for which the term 'Erste Lage' was repurposed. A German wine law of 2021 recognizes the terms 'Erstes Gewächs' and 'Grosses Gewächs', specifying minimal POTENTIAL ALCOHOL, maximum YIELD, and earliest possible release dates for each category. However, what wines should be accorded Erstes or Grosses Gewächs status and how a corresponding vineyard classification would be determined has been left for regional committees to determine.

As of 2021, the regional VDPs of the AHR and the MOSEL have not made use of the Erste Lage category, while the VDP RHEINHESSEN has recognized a classificatory tier known as 'Aus Ersten Lagen', but

without according Erste Lage status to any specific, named vineyards.

In AUSTRIA, inspired in part by the VDP's classificatory efforts, the TRADITIONSWEINGÜTER ÖSTERREICH unveiled in 2010 their own evolving classification of Erste Lage sites, signified on labels by a logo intentionally patterned after that utilized by the VDP, featuring a prominent Arabic number 1. An eventual upgrade of certain sites to the status of GROSSE LAGE is envisioned. However, Austrian wine law currently recognizes no vineyard classifications. D.S.

Erstes Gewächs designates dry (TROCKEN) wines from a limited number of ostensibly top sites in GERMANY's RHEINGAU and HESSISCHE BERGSTRASSE. Quality-conscious Rheingau growers introduced this term in the 1990s to refer to their top dry wines from classic grape varieties, and their lobbying resulted in the 1999 recognition of this category by the German state of Hessen and its being permitted on labels. This legal monopolization by Hessen prompted the VDP growers' association to instead promote the term GROSSES GEWÄCHS, utilizing it in a very similar way, albeit without any state or national legal recognition. In 2013 it was agreed within the VDP that, to avoid confusion about the association's prestige category of dry wine, its Rheingau members would henceforth use the term 'Grosses Gewächs' to denote 'grand cru' wines and 'Erstes Gewächs' for a 'premier cru' level. A 2021 German wine law established Erstes Gewächs as a category of dry wine and set parameters for YIELD, minimum POTENTIAL ALCOHOL, and release date, leaving further specifications (such as a classification of vineyards) to the regional Schutzgemeinschaften ('protective associations') tasked with 'product specification' for PGI and PDO wines. See also ERSTE LAGE.
D.S.

erythorbic acid, alternative antioxidant to ASCORBIC ACID.

Erzeugerabfüllung, German word meaning 'producer bottling'. As in France (see MIS EN BOUTEILLE), the term may be used by CO-OPERATIVES as well as estates. The terms GUTSABFÜLLUNG and 'Schlossabfüllung' are officially defined in slightly more restrictive terms and are nowadays seldom used. D.S.

esca, FUNGAL DISEASE believed to be as old as vine cultivation. Although the causal agents are found in most of the world's wine regions, it is most severe in vineyards located in warmer and drier MEDITERRANEAN CLIMATES, for example in France, Italy, Portugal, Spain, and California. Esca affects mature vines (usually more than ten years old) and is characterized by white-rot symptoms in the wood. It is considered to be a complex of diseases that start with cuttings used in PROPAGATION (see TRUNK DISEASES). The Greek word *yska* signified both rotten grape wood and the spongy Basidiomycete fungal bodies.

The fungi *Phaeomoniella chlamydospora* and *Phaeoacremonium minimum* are known to be the main pathogens associated with esca. However, up to 24 other species of *Phaeoacremonium* and several *Cadophora* species have been reported in vines showing symptoms of esca. Additionally, esca is the only trunk disease in which Basidiomycete species play a role, with species in the genera *Fomitiporia*, *Fomitioporella*, *Inonotus*, *Inocutis*, and *Phellinus* regarded as the causal agents of the white rot.

The first symptoms—shoot tip and tendril dieback—are observed in mid spring, followed later in the season by tiger-striping of the leaves, which eventually turn reddish in red varieties and chlorotic in white ones. A third symptom, grey- to dark-brown speckling on the berry skin (hence the name 'black measles'), is economically worse for TABLE GRAPE growers than for winegrowers. The last symptom, apoplexy, is characterized by a sudden wilting of the vine, including shrivelling of the fruit and fallen leaves. Vines affected by apoplexy may appear completely healthy the following season. Internal wood symptoms include light- to dark-brown and black streaking similar to

that observed in vines with PETRI DISEASE. In older vines, a white rot characterized by a yellowish spongy mass of wood can be observed in the centre of the TRUNK and/or CORDONS.

Although there is currently no cure for the esca complex, research has shown that stress avoidance and the protection of PRUNING wounds using FUNGICIDES can significantly reduce the incidence and severity of the disease. ORGANIC growers are also trialling BIOLOGICAL controls that incorporate various strains of the non-pathogenic *Trichoderma* fungus to combat esca and other trunk diseases. More extreme management strategies include CURETTAGE and TRUNK RENEWAL. L.T.M. & J.R.U.-T.

Gramaje, D., et al., 'Managing grapevine trunk diseases with respect to etiology and epidemiology: current strategies and future prospects', *Plant Disease*, 102/1 (2018), 12–39.

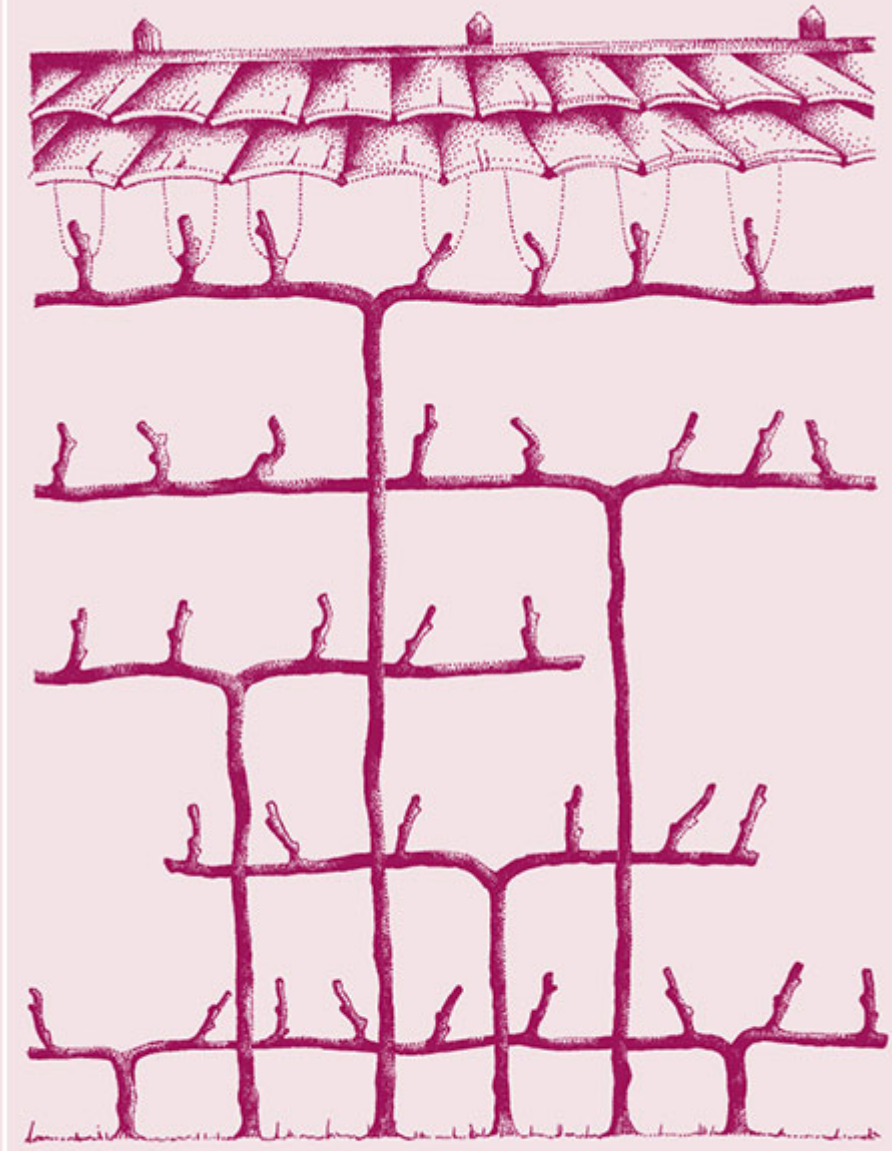
Gubler, W. D., et al., 'Esca, Petri, and grapevine leaf stripe disease', in W. F. Wilcox et al. (eds.), *Compendium of Grape Diseases, Disorders, and Pests* (2nd edn, 2015), 52–7.

Esgana Cão, synonym for the Portuguese white grape variety known on the island of Madeira as SERCIAL. Its full name on the mainland means 'dog strangler', presumably a reference to its notably high acidity. It can, occasionally, be found as an ingredient in VINHO VERDE and BUCELAS.

Espadeiro, minor grape variety producing mainly crisp pink wines in Portugal's VINHO VERDE country. It can produce quite heavily and rarely reaches high sugar levels.

espalier, a relatively unusual TRAINING SYSTEM, more desirable for aesthetic than commercial reasons, for vines or other fruit trees, by which the plant is trained to grow in a single plane to form a flat

shape, for example against a wall (see diagram below). Espalier training leaves a trunk and one or two arms with several canes which are trained in the same plane with a trellis or wire for support. Different vines are trained to different heights in the French Espalier de Thoméry. R.E.S.



Espalier

Source: G. Dalmasso, *Viticoltura Moderna*

espumante, Portuguese term for sparkling wine with a pressure of not less than 3 bar.

espumoso, Spanish for 'sparkling'. TRADITIONAL METHOD Spanish sparkling wine that is exported is most often labelled CAVA.

Esquitxagos, misleadingly interesting synonym for VALENCIA's bland white wine grape MERSEGUERA.

Estaing, miniature AOC on the banks of the Lot in the Aveyron *département* in SOUTH WEST FRANCE. Reds are based on FER and GAMAY grapes and the rarer whites on CHENIN BLANC, although the Cabernets and several local varieties are also allowed. A CO-OPERATIVE dominates production.

estate bottled, term used on labels which has a very specific legal meaning in the US, where an estate-bottled wine must be made and bottled at the winery using grapes from vineyards the winery owns or controls; both vineyards and winery must be in the AVA specified on the label. This is the American counterpart of CHÂTEAU BOTTLED or DOMAINE BOTTLED. Estate grown is not (yet) legally defined but indicates that the grapes come from vineyards owned or controlled by the producer.

estate wine, term in common parlance, but not in federal law, in the US that suggests loosely that the wine came entirely from grapes farmed on the winery's own property. 'Estate wine' may be casually construed to be exactly synonymous with ESTATE BOTTLED, which has legal status, but technically it is not.

In South Africa, 'estate wine' is a specific term for a wine that was grown, made, and bottled on a single geographical unit registered with the Wine and Spirit Board. Many German producers refer to

their most basic bottling of Riesling as their Estate Riesling, *Gutsriesling* in German.

esters, compounds formed by reaction of ACIDS with ALCOHOLS. The two most common forms of esters in wine are FERMENTATION esters, commonly found in the aroma of young white wine, and esters that are chemically formed during AGEING.

The fresh, fruity aroma of young wines derives in large part from the presence of the mixture of esters produced during fermentation, which is why it is usually called fermentation AROMA. The precise nature of esters formed during fermentation is strongly influenced by the fermentation temperature, as well as the YEAST strain and other factors. For more details, see TEMPERATURE.

Since wines contain much more ETHANOL than any other alcohol, and since the most common ester-forming volatile organic acid is ACETIC ACID, it is not surprising that the most common ester in wine is ETHYL ACETATE, but many more combinations are possible from among the acids and alcohols present; this helps to explain why wines differ so greatly in their aroma and, after years in bottle, BOUQUET. (See also ISOAMYL ACETATE.)

A number of esters that do not have a particularly marked odour are also present in wines. Among these are those resulting from reaction of the ethyl alcohol produced by fermentation with TARTARIC, MALIC, SUCCINIC, and other acids of the grape and wine, and such a process lowers the acidity and can mellow a wine.

When an acid reacts with an alcohol, water is produced in addition to the ester. This reaction is assisted or catalysed by the hydrogen ion, a substance plentiful in acid (low PH) solutions such as wines. Hydrogen ions not only catalyse the formation of esters from acids and alcohols but also function as catalysts for the splitting of esters into their acid and alcohol segments. The result of these two tendencies, formation and splitting, is that wines contain mixtures of the four participants in the reactions: organic acids, alcohols, the

several esters from the possible combinations, and water. The relative amounts of the four participants in the two reactions is governed by their concentrations and the reaction rates for formation and splitting. Given enough time, a state will be reached in which the net formation of esters just balances the splitting of them. This is known as the equilibrium state. In practice, the equilibrium state in wines is not reached but merely approached, because the formation rates for some esters are extremely slow under wine storage conditions. P.J.W. & V.L.

Waterhouse, A. L., et al., *Understanding Wine Chemistry* (2016).

Estonia, Baltic country south of FINLAND with a rich tradition for fruit wines, mostly made from apples and/or rhubarb but increasingly including grapes. Owing to the location, between latitudes 57.5 and 59.7° N, the climate is challenging, with an average temperature of only 5–7 °C/41–45 °F, dropping as low as −35 °C/−31 °F in wintertime. Spring FROST is common and autumn starts early, leaving only a short vegetation period. In colder spots, grapes are often growing in greenhouses, or vines are covered with GEOTEXTILES. In warmer plots, vines grow on open land. Climate warming has helped but has also brought diseases common in central Europe such as POWDERY MILDEW and DOWNY MILDEW. Both TABLE GRAPES and wine grapes are allowed for wine production, but the most common and best varieties for wine are the cold-hardy, early-ripening SOLARIS and RONDO. Other notable varieties are REGENT, Hasanski Sladki, and Zilga, but many more varieties grow in the gardens of hobby growers. By 2022, the country had more than two dozen commercial wineries, about half of them producing grape wines. However, in late 2021 the EU officially recognized Estonia as a wine-producing country, opening up funding and research opportunities for local growers and producers, so this number is expected to rise quickly. K.M.

Estremadura, old name for the DOP known since 2009 as LISBOA.

estufa, Portuguese word meaning 'hothouse' or 'stove', also applied to the tanks used to heat wine on the island of MADEIRA, thereby accelerating its development and maturation. The heating process itself is called estufagem. *Estufas* simulate the effects of the long tropical sea voyages in the 18th and 19th centuries when madeira (and SETÚBAL) was, at first accidentally and then deliberately, stowed in the hold of a ship to age prematurely as a result of the temperature changes involved in a round trip, or *torna viagem*, across the tropics. R.J.M.

ethanal, synonym for ACETALDEHYDE.

ethanol, common name for ethyl alcohol, the most potable of the ALCOHOLS and an important, intoxicating constituent of wine and all other alcoholic drinks. Ethanol, often called simply 'alcohol', is colourless and odourless but can have considerable impact on how a liquid tastes.

Ethanol is the most potent component of wine (and the most obvious of those that distinguish it from GRAPE JUICE), but it is probably the least discussed by wine consumers (unless in the context of HANGOVERS). For although ethanol does not have a taste, it has an effect, not just on the human nervous system but also on how a wine tastes. The ethanol content in a perfectly BALANCED wine should be unfathomable, but wines that are slightly too high in alcohol may 'burn' or taste 'hot', especially in the aftertaste. White wines high in ethanol (over 13%) may have a slightly bitter aftertaste. Ethanol contributes to VISCOSITY, and some argue that wines described as full-bodied, or having considerable BODY, are high

in ethanol while wines that are low in viscosity and body are low in ethanol. However, this is an oversimplification because many different compounds contribute to a wine's body and MOUTHFEEL. See ALCOHOLIC STRENGTH for ways in which the ethanol level may be manipulated.

Ethanol is produced in two ways, the most traditional and natural of which is by the fermentation by YEAST of solutions that contain SUGARS, such as that involved in wine production. It is required in huge volumes by industry, however, as a solvent for perfumes and as a raw material for the synthesis of products such as drugs, plastics, lacquers, polishes, plasticizers, and cosmetics. Most of the ethanol used by industry, other than that produced by distilling the European wine SURPLUS, is produced in factories by hydrating ethylene, a component of petroleum.

See ALCOHOLIC STRENGTH for the varied concentrations of ethanol to be found in different wines, HEALTH for the effects of alcohol consumption in the form of wine, and REDUCED-ALCOHOL WINES.

V.L.

Ethiopia in north-east Africa can produce quite respectable red wine and some white from vines grown at relatively high ELEVATIONS. The Awash winery in Addis Ababa, based on vineyards established by the Italian troops who occupied part of the country from 1936 to 1941, has been joined by a CASTEL project with 162 ha/400 acres of vines planted 2007–9 near Ziway, 160 km/100 miles south of the capital. It sells VARIETALS made from INTERNATIONAL VARIETIES under the brand names Rift Valley and Acacia from vineyards surrounded by a wide trench designed to deter pythons, hippopotamuses, and hyenas.

ethyl acetate (EA) is an organic aroma compound (ESTER) that can give a wine fruity aromatic qualities at low levels but is considered a FAULT at high levels when the aroma resembles that of nail-polish remover.

There is no legal limit for the level of ethyl acetate in wine, and it is not regularly monitored in the winery. The sensory detection threshold is around 12 mg/l, with healthy wines reaching levels of about 60 mg/l. Wines with over 150 mg/l EA are generally considered faulty.

EA is produced by both yeast and bacteria. YEAST naturally produce EA when fermentation by-products react with ETHANOL. This ester can be re-used by the yeast or it can be excreted into the wine. EA levels after fermentation can vary widely depending on the choice of yeast. Non-*Saccharomyces* species tend to produce higher levels of EA.

ACETIC ACID BACTERIA can also form EA by reacting with ethanol, and this is why EA is intrinsically linked to VOLATILE ACIDITY in wine. The presence of EA in a wine can enhance the perception of VA. However, when VA is measured in a wine, the ethyl acetate level is not measured as it is not a volatile acid. K.C.

ethyl alcohol, scientific name for ETHANOL, the alcohol most commonly encountered in wine and other alcoholic drinks.

ethyl carbamate is a naturally occurring component of all fermented foods and beverages. In the case of the YEAST *Saccharomyces cerevisiae*, ethyl carbamate is formed by the reaction between ETHANOL and urea, which in turn is produced by the degradation of the AMINO ACID arginine, one of the main NITROGEN sources in grape juice and MUSTS. In the late 1980s, ethyl carbamate was added to the growing list of compounds suspected of human carcinogenicity on the basis of animal tests.

Most wine types contain ethyl carbamate concentrations well below the limit suggested by US authorities of 15 µg/l per litre (60 µg/l in fortified wines). High-alcohol sweet wines which have been heated during production (such as MADEIRA) are likely to be the wines with the highest levels of ethyl carbamate. The level may also

be influenced by the yeast strain, by MALOLACTIC CONVERSION, and by high temperatures during MACERATION and storage.

ethylphenol. See BRETTANOMYCES.

Etna is Europe's largest still-active volcano on the east coast of SICILY near the city of Catania; the DOC of the same name produces high-quality reds, rosés, and sparkling wines based on NERELLO MASCALESE and whites from CARRICANTE. Viticulture has been practised for centuries if not millennia on Etna's black VOLCANIC soils, and vineyards and their position have largely been determined and at times obliterated by lava streams.

Until the beginning of the 20th century, the wines from Etna were in high demand in the north of Europe, especially for blending purposes. Huge volumes of grapes were vinified in palmenti (see PALMENTO), north-facing, naturally cool, gravity-fed cellars built into the slope. At nearby Riposto, casks filled with wines were rolled through the shallows of the sea to be lifted on to ships, the wine destined for France, among other countries, as blending material.

At the end of the 19th century, the Murgo estate was already producing large quantities of TRADITIONAL METHOD sparkling wine, while on Etna's still little-known west side the barons of Spitaleri di Muglia experimented with French varieties as well as Italian varieties Nerello Mascalese, NERO D'AVOLA, GUARNACCIA, Mantonico, CARRICANTE, and NEBBIOLO on steep, terraced vineyards at 800 m/2,625 ft in ELEVATION and higher.

Etna's vineyards survived PHYLLOXERA because the pest cannot thrive in the volcanic soils, but many of its vineyards, especially

those in high, hard-to-reach places, were abandoned. Others were pulled up, the high-density centenarian vineyards replanted with straight rows of vines trained on WIRES. Local agronomist Salvo Foti has been instrumental in preserving the traditional planting practice called *quinconce,* consisting of a square grid of 13 vines.

The Etna DOC was established in 1968, covering vineyards on the north and east side of the volcano and four towns in the south—Belpasso, Paternò, S. Maria di Licodia, and Biancavila—but Etna started its ascendance only in the early 2000s when Andrea Franchetti and Marc De Grazia independently bought land on Etna's north side, where vineyards can be found up to 1,000 m/3,281 ft and higher. Both first dabbled in INTERNATIONAL VARIETIES, but once they turned their attention to INDIGENOUS VARIETIES Etna began to see an enormous rise in popularity, resulting in huge investments and an influx of newcomers all keen to explore its cool volcanic terraces. Between 2011 and 2020 Etna more than doubled the number of producers (from 176 to 383) and area planted (from 5,682 ha to 11,183 ha/27,634 acres).

Today the Etna DOC forms a sickle shape around Etna's peak, leaving only the west side, where there was little viticulture post-phylloxera, outside of the DOC, even though its grapes are regularly sold to producers on the north side. Etna Superiore applies only to the commune of Milo, the undisputed CRU of long-lived, complex white Carricante. The whole denomination is divided into CONTRADE, districts named after the hamlets, which have conveniently provided the first step towards a cru system. W.S.

Foti, S., *Etna: I Vini del Vulcano* (2020).

Spencer, B. N., *The New Wines of Mount Etna: An Insider's Guide to the History and Rebirth of a Wine Region* (2020).

Étoile, L'. See L'ÉTOILE.

Étraire de l'Adui, or Étraire de la Duï, is a historic and increasingly rare grape variety grown before PHYLLOXERA on the fringes of the south-east Rhône Valley and Savoie. It is related to PERSAN.

Etruscans. The origins of viticulture in TUSCANY are as problematic as the origins of the Etruscan peoples who flourished in central north Italy from the 8th century BCE until being absorbed by the Romans from the 3rd century onwards. However, at its height, Etruscan society was heavily influenced by the culture of the Greek colonies of southern Italy. They imported fine Greek pottery for use in the SYMPOSIUM and made their own copies. The dinner and drinking party was a favourite theme in the lavish paintings which adorned their tombs. Indeed, the Etruscans became a byword among Greek and Roman moralists for luxurious living and then-eccentric customs, such as allowing wives to participate in banquets. There are literary references to Etruscan wine from the late 3rd century BCE, but much earlier, from the late 7th century, the wine was exported in a distinctive type of AMPHORA well beyond Italy to southern France. Indeed, it is likely that this early trade played a role in introducing wine and viticulture to GAUL. Various wines are attested throughout the region in the classical period, although none was universally recognized as of the highest class. See ORIGINS OF VINICULTURE.

EU stands for European Union, previously known as the European Community, a group of 27 advanced Western industrialized countries

co-operating on both economic and political fronts. Twenty-four of the 27 members produce wine (of which seven only in marginal quantities), making the Union the world's leading wine economy, producing 165 million hl/4,360 million gal in 2020 and accounting for 45% of the world's winegrowing areas, 65% of production, 60% of global consumption, and 70% of exports (including intra-EU trade).

The area under vine in the EU stood at 3.3 million ha/8.2 million acres in 2021, down from almost 3.5 million ha in 2013 and almost 4 million ha in 1987. This represents just over 45% of the total global vineyard area (these OIV statistics include vines used to produce RAISINS and TABLE GRAPES, and these two categories represent a higher proportion of total vineyard area in Asia than in Europe). According to official EU data, of the 3.2 million ha of vines planted for wine production in the EU, on average 1.2 million ha produce grapes for PDO wines, 1.5 million ha for PGI wines, and nearly 0.4 million ha for WINE WITHOUT GEOGRAPHICAL INDICATION. Spain has the most extensive area under vine in Europe (940,086 ha planted for wine in 2021) and, indeed, the world; Italy, however, produces more wine than Spain, which used to have the lowest-yielding vines in the EU (see SPAIN for how this has changed).

The main EU wine-producing countries are, in descending order of wine production: Italy, Spain, France, Germany, Portugal, Romania, Hungary, Austria, Greece, Bulgaria, Croatia, Slovenia, Czechia, Slovakia, Cyprus, and Malta. (BELGIUM, DENMARK, ESTONIA, LITHUANIA, the NETHERLANDS, POLAND, IRELAND, and SWEDEN also produce a small amount of wine.) In 2020, total EU production of wine was around 165 million hl/4,360 million gal (world production in 2020 was approximately 260 million hl, according to OIV statistics).

The EU is an important net exporter of wine, and exports to non-EU countries were worth nearly €14 billion in 2020–21, representing 28.4 million hl/750 million gal, or over 17% of production. Italy is the biggest exporter in the EU (and the world) by volume, with exports of 20.8 million hl worth €6.2 billion. Spain follows closely

behind in terms of volume with 20.2 million hl, albeit with lower earnings of €2.6 billion. France sits in third place in volume terms (13.6 million hl) but leads Europe and the world in terms of value (€8.7 billion). The US is the biggest market, taking 25.2% of EU exports by volume and 28.6% by value. Since Brexit, the UK has become the second most important export destination (rather than an internal market), taking 13% of EU exports by volume and 11.4% by value.

EU member states are also significant importers of wine both from other EU countries and from outside the Union. Germany, the world's second largest importer behind the UK, imported 14.1 million hl in 2020 worth €2.5 billion—57% of which was BULK WINE. France, the Netherlands, Belgium, Portugal, and Sweden are also significant wine importers. In 2020–21, the four top external sources for EU imports were South Africa, Chile, Australia, and the US, representing more than 60% of wine imports from outside the EU. Wine imported into the EU, known as 'third-country wine', must conform to European wine law and may not be blended with wine made within the EU.

The EU wine sector is subject to an overarching regulatory framework called the 'common market organization' (CMO), which is part of Europe's common agricultural policy (CAP). The wine CMO includes rules on the free movement of wine between member states, winemaking practices, labelling, and trade with 'third countries' outside the common market. Its defining feature, until 2008, was the segregation of the wine sector into QUALITY WINE, which was regulated to manage 'quality', and TABLE WINE, which was granted subsidies to control production and the market. This essentially political and cultural divide was imported from France's wine law, reflecting that country's efforts to manage production in the poorer Midi while protecting the more privileged producers of well-known wine regions.

From the very first wine CMO in 1970, it was evident that accommodating the more liberal rules (and cheaper wines) that existed in Italy and the stricter regime prevailing in France within a

single market would be a significant challenge. Blockades and violent protests through the 1970s and early 1980s, fuelled by rampant overproduction of table wine and nationalistic sentiment, testified to the difficulty of the task. The accession of Spain, Portugal, and Greece in the mid 1980s multiplied the complexity of the problems.

The wine CMO went through several iterations over the years, resulting in a proliferation of subsidies and controls, such as DISTILLATION, GRUBBING UP of vines, PLANTING RIGHTS, and price supports, ostensibly intended to bring supply and demand in the wine sector into balance. These largely failed because policymakers were torn between maintaining the incomes of the poorer producers of WINES WITHOUT GEOGRAPHICAL INDICATION and realigning the wine sector with the demands of the modern wine market. Usually the political imperative to prop up the poorer producers won out, resulting in a ballooning budget.

By the mid 2000s, a rethink of the wine CMO had become both essential and politically achievable. The sharp decline of traditional table wine, soaring production of wines with a geographical indication, the accession of new EU member states, budget constraints, and competition from the NEW WORLD were all factors.

The reform introduced in 2008 took the radical step of dissolving the quality-wine and table-wine categories. In their place a new hierarchy was created: protected denominations of origin (PDOs—covering AOC, DOC, DO, etc.); Protected Geographical Indications (or PGIs—covering VIN DE PAYS, IGT, Landwein, Vino de la Tierra, etc.); and wines without geographical indication. The last were granted permission to use grape-variety names on the label, thereby allowing the creation of a new class of VARIETAL wines. Each member state has its own precise terminology based on these overarching categories. The new hierarchy brought wine into alignment with the PDO/PGI system for other foods in the EU. Winemaking rules were linked to OIV recommendations as a means of benchmarking them internationally. Labelling was also simplified and liberalized to some extent.

The 2008 reform also transformed the regime for support measures, making them available to all categories of wine (not just wines without geographical indication) for a more targeted range of purposes, with a total budget of around €1.2 billion per year. In the first years of the reform, a key focus of support measures was, as before, to balance supply and demand, with grubbing-up measures contributing to a reduction in the total EU vineyard of 370,000 ha (10%), an exercise considerably more successful in some countries than others.

A further change in 2013 ended certain support measures, notably the notorious 'crisis distillation' (in pre-reform times, every year was a crisis year)—although emergency COVID relief saw a resurrection of this measure in 2021. In recent years, the focus of support measures has shifted towards 'investments in enterprises', 'restructuring and conversion' (largely making vineyards and wineries suitable for PDO/PGI production), and 'promotion' (i.e. offshore marketing).

The CAP reform adopted in 2021 for implementation in 2023 places more emphasis on environmental and social SUSTAINABILITY in agriculture—in line with the so-called 'European Green Deal' strategy. The range of financial measures to support 'green' initiatives and economic resilience to CLIMATE CHANGE is increased. Certain rules have also been modernized, allowing the use of DISEASE-RESISTANT VARIETIES in PDO wines, creating new categories for DE-ALCOHOLIZED WINE and PARTIALLY DE-ALCOHOLIZED WINE, and introducing mandatory INGREDIENT LABELLING and energy labelling for wine.

Alongside the wine CMO, the EU has negotiated a series of agreements with several non-EU wine-producing countries, including Australia (1998, 2008), Canada (2003), Chile (2002), South Africa (2002), Switzerland (2002), the US (1984, 2005), and the UK (2020). These agreements cover concerns such as reciprocal arrangements regarding oenological practices, the reciprocal protection and control of wine denominations (which in some cases implies the phasing out of GENERICS), trade facilitation, dispute-

resolution procedures, and in some cases tariff quotas. On the EU side, these agreements form a key part of a long-term strategy to secure protection for their GEOGRAPHICAL INDICATIONS, while for non-EU countries the incentive has been to improve their ability to compete in the EU market.

eucalyptus character refers to an aroma and flavour found in red wine, most commonly in Australia and California and also in Chile, described variously as 'eucalypt', 'camphor', or 'minty'. For some winemakers this characteristic is a selling point, whereas others prefer to avoid it or at least to limit its presence as far as possible. In 2010 the AWRI assessed consumer response to eucalypt flavour in red wines and found that, even at very low levels, most consumers reacted to the flavour, and more consumers preferred wines with the 'minty' flavour than disliked it.

Most species of Eucalyptus, which are native to Australia but are now grown on every continent, contain essential oils in their leaves and, depending on the species, the main component of the oil is a volatile compound called 1,8-cineole, commonly known as eucalyptol. It is present in a wide range of foods, beverages, and therapeutic products. Research on California Merlot has determined that 1,8-cineole can be perceived even at very low concentrations such as 1.1 µg/l and can be recognized at 3.2 µg/l.

While the compound may be found in wines made from grapes grown with no Eucalyptus trees nearby, research has indicated that Eucalyptus trees growing close to vineyards are the primary source of the flavour in wine and that only negligible levels found in wine are from grape-derived FLAVOUR PRECURSORS.

In one study, grapes harvested from rows further than 25 m (80 ft) from Eucalyptus trees gave wines with very low levels of 1,8-cineole while those grown closer to the Eucalyptus trees contained significantly higher amounts. The compound is at its highest levels in the skin of the grape berry and is extracted during fermentation on skins. While the absorption of the compound by grape berries is important, it is much less a factor than the presence of Eucalyptus leaves or bark in harvested grapes. MECHANICAL HARVESTING of rows close to Eucalyptus trees will, more than likely, produce bins of grapes containing numerous Eucalyptus leaves, and these have a very significant effect on eventual levels of 1,8-cineole in wine. Even during hand harvesting, Eucalyptus leaves can be trapped within the grape bunches. The key to managing 1,8-cineole levels in wine is therefore to control the amount of MOG (material other than grapes).

A further study showed that the compound could also be found at relatively high levels in Bordeaux Cabernet Sauvignon wines made from vineyards in which was found an invasive plant (*Artemisia verlotiorum*) that contains 1,8-cineole as a major constituent. It is possible that other regionally specific vegetation could also influence wine flavour. M.P.K. & D.L.C.

Eucharist, wine in the. The significance of wine in the sacrament of the Eucharist (also called the Lord's Supper or Holy Communion) derives from wine representing the blood of Christ in this most sacred celebration of the Christian church.

According to the New Testament, Christ instituted this ritual when he celebrated the Jewish Passover with his disciples, transforming it into the Last Supper. As he gave bread and wine to his disciples, he commanded them to 'do this in remembrance of me'. Christ singled out one of the four cups of wine consumed during the Passover meal and said: 'This cup is the new covenant in my blood. Do this, as often as you drink it, in remembrance of me.' The Eucharist then commemorates Christ's death on the cross: the wine represents the blood that he shed, while the bread represents his broken and crushed body.

In the Gospel of Matthew, Christ elaborates on and extends the mysterious meaning of this ritual:

> 'While they were eating, Jesus took a loaf of bread, and after blessing it he broke it, gave it to the disciples and said, "Take, eat; this is my body." Then he took a cup, and after giving thanks he gave it to them, saying, "Drink from it, all of you; for this is my blood of the covenant, which is poured out for many for the forgiveness of sin. I tell you, I will never again drink of this fruit of the vine until that day when I drink it new with you in my Father's kingdom."' (Matt. 26. 26–9)

In the Eucharist Christians remember the death of Jesus Christ to atone for the sins of the world and to heal and restore humanity's fractured relationships with God, each other, and the created world at large. Christians also believe that, through Christ's death and resurrection, death has lost its finality; and Christ invites believers to receive eternal life (1 Cor. 15. 51–7).

For Christians this act of remembrance is no mere recalling of a historical event or a theological idea. Rather it is an active participation in the reality of Christ's redeeming presence in the

world that harks back to his death and looks forward to his second coming (Isa. 25. 8, Rev. 21. 1–5). Christ will invite believers to the great wedding feast between God and his people in his Father's kingdom where His followers will savour wine in perfect and harmonious communion with the triune God of love and grace: Father, Son, and Holy Spirit. For Christians, drinking wine from the Eucharistic cup is therefore a most sacred experience of God's redemption.

The Jewish Scriptures foreshadow this as they speak of God's redemption as a great banquet and wedding feast where wine will flow in abundance (Amos 9. 14–15, Isa. 25. 6, Hos. 2. 18–23). The prophet Amos even speaks of a time when 'the mountains shall drip sweet wine, and all the hills shall flow with it' (Amos 9. 13). The imagery used here inspires a yearning for a restored paradise.

When Jesus performs his first miracle at the wedding feast of Cana, transforming water reserved for the Jewish rite of purification into an abundance of choice wine, he gives his first sign that in him the promises of old are being fulfilled (John 2). No longer are scapegoats, temple sacrifices or ritual cleansings needed for believers to draw near to God. Christ's death on the cross is the ultimate sacrifice and the saving bridge between God and humanity.

In the celebration of the Eucharist, Christians ingest this great mystery. As they eat consecrated bread and drink consecrated wine, they are reunited with God and each other into one spiritual family where love and forgiveness flow freely, like the choice wine at the wedding feast of Cana.

The celebration of the Eucharist then is the church's principal act of faithfulness as believers enter into the redemptive death of Christ only to be raised up into new and eternal life, united in Christ as God's beloved family that remains rooted in Christ, the only true vine (John 15).

Eucharist literally means 'thanksgiving' and harks back to its first celebration, where Jesus prayed the traditional Jewish prayer of thanksgiving over the bread and wine. It also expresses gratitude for the gift of God's salvation, forgiveness, and healing.

It is this positive understanding of wine in the Eucharist and in the BIBLE more generally (there are nearly one thousand wine and wine-related references in the Bible) that inspired monks and nuns to plant vineyards throughout Europe and beyond. See MONKS AND MONASTERIES.

Controversy

The celebration of the Eucharist has caused confusion, disputes, and controversy since its inception. The idea of drinking blood was condemned as an abomination in Jewish faith and culture, as blood was considered the centre of life and belonged to God alone. Early followers of Christ were misunderstood when they 'ate' the body of Christ and 'drank' Christ's blood in the form of bread and wine.

In the early church Christians celebrated the Lord's Supper in their homes, and it quickly became an expression of their status in society: some celebrated it as a lavish feast and got drunk on too much wine, while others were poor and left the Lord's Supper hungry. Rather than bringing Christians together into one family where resources were freely shared, it solidified their economic status and differences. The apostle Paul wrote a fierce letter against such divisive practice (1 Cor. 11).

During the Protestant Reformation in the 16th century, many disputes emerged surrounding the celebration of the Eucharist. The Reformers, including Martin Luther and John Calvin, reintroduced the drinking of wine in the Eucharist to all believers (over time it had been restricted to priests only). Controversies emerged as to how Christ was present in the celebration of the Eucharist and how often it should be celebrated: daily, weekly or even less frequently. Both Martin Luther and John Calvin emphasized the importance of the weekly celebration of the Lord's Supper. Other Protestant traditions confined it to the margins of their religious life.

The question of Christ's presence in the elements of bread and wine also became a topic of heated discussion during the Reformation. Orthodox and Catholic Christians have held to a strong understanding of Christ's presence in the elements of bread and wine. Martin Luther followed suit by calling this great mystery the 'real presence' of Christ in bread and wine. John Calvin believed that Christ's body and blood are spiritually present in the bread and wine, and Ulrich Zwingli argued that bread and wine have a mere symbolic function. Despite all these differences there was a shared belief that

Christ is present in the celebration of the Eucharist more generally speaking. Today we see a renewed effort to emphasize and celebrate the shared beliefs rather than the philosophically dense arguments.

From at least the 2nd century the idea that wine had to be used in the celebration of the Eucharist was challenged by some in the church. Great theologians such as Martin Luther, John Calvin, and John Knox fiercely defended the presence of wine in the Eucharist. They not only had their own wine cellars but were often paid in wine for their preaching ministries. It was only in the 19th century that this began to change when a Methodist minister, Thomas Welch, discovered how to pasteurize grape juice and keep it from fermenting into wine. The widespread use and abuse of distilled spirits in the 19th century led to the temperance movement, which led to PROHIBITION in the United States. Many Protestant churches in Britain and the US banned the use of wine in the Lord's Supper and continue to do so. The Orthodox, Catholic, Lutheran, Anglican, and Episcopalian churches have kept using wine in the Eucharist but many now offer grape juice for those who live in recovery or suffer from alcohol addiction.

Eutypa dieback, one of the most destructive FUNGAL DISEASES included in the TRUNK DISEASE complex that can lead to the replanting of whole vineyards. Originally known as dying arm, it is called *eutypiose* in France. Distribution is worldwide, over a wide range of climates, but with the highest incidence in regions with more than 300 mm/12 in rainfall a year. Today it is the most common trunk disease in South Australia (where it was first discovered in 1957), in south-west France, and in the North Coast and Sacramento regions of California. Studies conducted in the late 1990s estimated that California growers spend over $260 million a year in strategies to control the disease. Loss of net income caused by Eutypa dieback is estimated at $20 million a year in Australia for Shiraz alone.

Eutypa is caused by the diatrypaceous fungus *Eutypa lata*, which also attacks many other plants, especially apricots. Although recent studies have identified up to 11 other Diatrypaceae fungi associated with the disease, *E. lata* is the only one known to cause the foliar symptoms that characterize this disease and allow its identification in the field. Symptoms rarely show in vineyards less than eight years old, but this can be several years after infection has occurred. *E. lata* spores are released during or shortly after rain and can be spread up to 100 km/60 miles by wind. Infection in grapevines occurs mainly via PRUNING wounds in mild temperatures.

Eutypa dieback can be easily diagnosed in the spring: young shoots are stunted and yellow with small, misshapen, cupped leaves caused by toxins and/or secondary metabolites produced by the

fungus in the infected trunks cordons. Symptoms in the wood include wedge-shaped cankers which are indistinguishable from those seen in vines affected by BOTRYOSPHAERIA DIEBACK and PHOMOPSIS dieback. No VITIS VINIFERA variety is immune, but some such as Cabernet Sauvignon, Sauvignon Blanc, Grenache, and Syrah are more susceptible. Removing infected ARMS and TRUNKS, commonly known as vine surgery, may allow the vine to thrive, but once the infection begins downward movement in the trunk, TRUNK RENEWAL may be necessary. Painting or spraying the fresh pruning wound with approved FUNGICIDES is very effective in preventing infection. This disease can have drastic effects on yield, as old vineyards degenerate long after the onset of the initial infection. Given the commercial interest in wine made from old vines (see VINE AGE), this disease is particularly regrettable. R.E.S. & J.R.U.-T.

Gramaje, D., et al., 'Managing grapevine trunk diseases with respect to etiology and epidemiology: current strategies and future prospects', *Plant Disease*, 102/1 (2018), 12–39.

Euvitis, considered by many botanists to be one of two sections of the genus VITIS (see BOTANICAL CLASSIFICATION), the other being MUSCADINIA. These two are considered to be two separate genera by others, since *Euvitis* and *Muscadinia* vines differ in chromosome number and in appearance. All of the commercially important wine, table, and raisins belong to the genus *Euvitis*. R.E.S. & J.V.

Wan, Y., et al., 'A phylogenetic analysis of the grape genus (*Vitis* L.) reveals broad reticulation and concurrent diversification during neogene and quaternary climate change', *BMC Evolutionary Biology*, 13/141 (2013).

EU wine is wine at its most basically European, a blend of WINES WITHOUT GEOGRAPHICAL INDICATION from more than one country in the EU, sometimes referred to as Euroblends. They must be labelled 'Blend of wines from different countries of the European Union' or 'European Union Wine'. The constituents of such wines tend to vary with the vagaries of the bottom layer of the European wine market.

Evans, Len (1930–2006), promoter, taster, judge, consumer, teacher, and maker of wine who did more to advance the cause of wine in Australia than any other individual. Born in Felixstowe, England, he was an architect manqué, like his friend the late Michael BROADBENT, but in Evans's case the distraction was professional golf rather than wine. He emigrated to New Zealand in 1953 and arrived in Sydney, Australia, two years later, where his stepping stone into what was to become a lifetime's immersion in wine was working in a new hotel. His energetic enthusiasm for wine was such that by 1965 he was the first National Promotions Executive for the Australian Wine Board. Evans was one of the few to see that the future lay in table wine rather than in the sweet FORTIFIED drinks in which Australia then specialized. A natural performer and publicist, Evans caused such a stir that Australians were apparently convinced that real men could indeed drink table wine, and it become increasingly important to Australia's social life and economy.

By 1969 he was writing books and articles on wine, had left the Wine Board, and was starting up the Rothbury Estate in the HUNTER VALLEY and establishing his own restaurant-cum-dining club at Bulletin Place by Sydney Harbour. He collected people, preferably famous, with as much enthusiasm as seriously fine wine, but distinguished himself in his practical relish of both. He did not just transform BLIND TASTING into a competitive sport but even oversaw the creation of a game predicated on it, the OPTIONS GAME, which was subsequently put to work raising substantial sums for charity under Evans's direction.

In the late 1970s, it seemed as though Evans, by now an intimate of the great and the good of the wine world, was about to take it over. Financed by a tax lawyer friend Peter Fox, he acquired properties in GRAVES, SAUTERNES, and the NAPA Valley, with plans to staff them using an early version of the FLYING WINEMAKER concept. His exceptional tasting skills had also been recognized by his numerous invitations to judge at Australia's important wine COMPETITIONS and by his appointment as chairman of judges (the first of many) at the Royal Sydney Show.

In 1981, Peter Fox was killed in a crash and the Evans Wine Company was thrown into turmoil. From the remains, Rothbury survived, as did the Petaluma winery in the ADELAIDE HILLS, with which Evans was involved from the start. Evans attempted to rusticate himself at his much embellished mud hut 'Loggerheads' overlooking Rothbury.

From then he continued to write, broadcast, and keep tables or halls full of people entertained, while reminding them that wine is for drinking. His crucial part in educating those with clear potential in the Australian wine industry is commemorated by the Len Evans Tutorial, an annual orgy of blind tasting. He was awarded an Order of the British Empire as well as numerous wine industry distinctions and was made a Chevalier de l'Ordre du Mérite Agricole in 1994.

Oliver, J., *Evans on Earth* (1992).

evaporation, conversion of water (or other liquids) from the liquid to the gaseous or vapour state, brought about by the input and absorption of heat energy. It has important implications for both growing vines and maturing wines. High evaporation is favoured by high SUNLIGHT, high WIND speed, and low HUMIDITY.

Viticulture

There are three sorts of evaporation in the vineyard. First, there is evaporation from the soil, which is especially significant while the soil surface is wet. Then there is evaporation from the vine leaves, and lastly from other parts of the vine (bunches wet from rain, for example), which can have important disease implications.

The power of the atmosphere to evaporate water is related inversely to its humidity and directly to its temperature. Climate records of evaporation, or potential evaporation, have been sparse but are improving. Comparisons are further confused by the fact that different countries use different instruments for measurement of evaporation. Nevertheless, broad averages for regions can be estimated with fair accuracy, and these allow calculation of IRRIGATION requirements, for example.

Evaporation from the soil reduces the amount of water available to the vine and so can encourage WATER STRESS.

Evaporation out of grapevine leaves (a process known as TRANSPIRATION) takes place mainly through pores, or STOMATA, which form openings on the underside of the waxy leaf surface. It is regulated by opening and closing of the stomata, with partial closure taking place at night. Transpiration is increased by direct exposure to sunlight, which provides the energy needed for evaporation. The combined water loss from a vineyard is the sum of the evaporation from the soil and transpiration from the vines (and possibly any associated COVER CROP or weeds) and is called evapotranspiration.

Inadequate evaporation from wet leaves and bunches is a factor in FUNGAL DISEASE infection. Vine-growers in many climates deliberately trim vines and remove leaves from the vicinity of the bunches, partly to allow in more light but partly also to encourage air flow and evaporation and thus avoid diseases such as BOTRYTIS BUNCH ROT (see CANOPY MANAGEMENT). J.G. & R.E.S.

Wine maturation

Evaporation also causes a loss of liquid stored in BARRELS, other wooden containers, and porous vessels such as AMPHORAE. For a 225-l barrel, liquid loss varies from 1 to 9% per year. In new barrels, evaporation is very low for the first 40–60 days as the liquid impregnates the staves. Thereafter, the rate of evaporation is influenced by the conditions in the cellar and various cellar operations such as RACKING or TOPPING UP. When the cellar temperature is high and the relative humidity low, evaporation is high. Conversely, evaporation is low with high relative humidity and a low temperature. Wine subjected to BARREL AGEING in a high-humidity storage cellar will decrease in ALCOHOLIC STRENGTH, whereas that stored in a dry cellar will increase. This is why, in the low-humidity SHERRY bodegas of JEREZ, it is common practice to sprinkle water on the earth floors to raise the relative humidity and therefore prevent the alcoholic strength of the wine under FLOR film yeast from increasing to the point at which the yeast would be killed.

The way the barrels or containers are used can also affect evaporation. For example, the use of a glass or aseptic BUNG or overly frequent topping up exerts a positive pressure on the inner surface of the barrel, and this pressure pushes the wine into the stave or vessel wall, favouring evaporation. On the other hand, a barrel tightly sealed with a silicon bung or with a bung on the side will create a negative pressure, retaining the wine and diminishing evaporation.

Evaporation makes regular topping up of a barrel necessary. The space left by evaporation is called the ULLAGE.

Roussey, C., et al., 'In-situ monitoring of wine volume, barrel mass, ullage pressure and dissolved oxygen for a better

understanding of wine-barrel-cellar interactions', *Journal of Food Engineering*, 291 (2021), 110233.

evaporative perstraction is a relatively novel membrane technique used as a means of ALCOHOL REDUCTION. It lowers the alcohol content of wine by a process in which the wine and a stripping solution (usually water) pass through a microporous, hydrophobic hollow fibre membrane contactor on opposite sides. In essence it is the transfer of alcohol through a porous membrane between two phases that are moving in opposing directions.

Wollan, D., 'Membrane and other techniques for the management of wine composition', in A. G. Reynolds (ed.), *Managing Wine Quality 2: Oenology and Wine Quality* (2nd edn, 2021), 183–212.

evapotranspiration, total loss of water from a vineyard. See EVAPORATION and TRANSPIRATION.

Évora, UNESCO World Heritage Site, capital, and high-quality DOC subregion of the ALENTEJO in southern Portugal.

ex cellar(s), professional way of buying direct from wine producers and the price they quote, which excludes TRANSPORT and DUTY in the importing country and any retailer's margin. This price will invariably be less than one quoted to a tourist or consumer at the CELLAR DOOR.

excoriose, vine disease. See PHOMOPSIS.

exposure. Sometimes used to refer to the ASPECT of a slope. The English word 'exposition' is a commonly misused direct translation of the French term *exposition*.

extra brut. See DOSAGE.

extract, or dry extract, or total dry extract (TDE), the sum of the non-volatile solids of a wine: the SUGARS, non-volatile ACIDS, MINERALS, PHENOLICS, GLYCEROL, glycols, nitrogenous compounds, and traces of other substances such as PROTEINS, PECTINS, and gums. Sometimes sugars are deliberately excluded to give sugar-free extract. Wines' extract, including sugars, usually starts at 17–30 g/l but can vary considerably depending on the wine's SWEETNESS, COLOUR (red wines usually having a higher extract than whites, thanks to their greater PHENOLIC content), and age, since some extract is precipitated as SEDIMENT over the years. Cooler and wetter years, with higher levels of acidity in the grapes, are likely to produce wines with higher levels of dry extract, and BOTRYTIS is also likely to increase its concentration.

Historically, extract was determined by the simple but time-consuming expedient of evaporating a measured quantity of wine and weighing the residue, but this method is imprecise and has generally been replaced by using what is known as the Tabarié formula, techniques involving the measurement of ALCOHOLIC STRENGTH, the DENSITY, and the RESIDUAL SUGAR (if sugar-free extract is required).

To be high in extract, a wine does not necessarily have to be high in alcohol or BODY. Many fine German wines are high in extract and yet are low in alcohol and are light-bodied, especially Rieslings made from low-yielding vines. Dry extract helps a wine to age well, but there is otherwise no correlation between high extract and high QUALITY IN WINE.

Ribéreau-Gayon, P., et al., *Traité d'Œnologie 2: Chimie du vin: Stabilisation et traitements* (7th edn, 2017), translated by J. Towey as *Handbook of Enology 2: The Chemistry of Wine Stabilization and Treatments* (3rd edn, 2021), 81–98.

extraction in a wine context usually refers to the extraction of desirable PHENOLICS from grape solids before, during, and after FERMENTATION, although over-extraction is a common fault when colour is associated with quality so that phenolics dominate the wine, often making wines heavy and tannic. Such wines lack FRUIT and BALANCE. See MACERATION for more details.

Extremadura, one of the 17 autonomous regions in SPAIN and, perhaps surprisingly, the country's fourth most important wine region. Sheep are reputed to outnumber people in this semi-arid upland area between CASTILLA-LA MANCHA and PORTUGAL (see map under SPAIN). CORK is an important crop here, but most of the wine made here is sold in bulk for DISTILLATION and ends up as brandy de Jerez.

A single DOP covers most of the region's wine areas: RIBERA DEL GUADIANA. Cencibel (TEMPRANILLO), GARNACHA, GRACIANO, and, increasingly, Cabernet Sauvignon and Syrah dominate among red grape varieties, and PARDINA among white ones. But the region was still underperforming in 2021, except for Bodegas Habla, which bottles its wines under the PGI Vino de la Tierra Extremadura.

V. de la S. & F.C.

Ezerjó, white grape variety planted on about 369 ha/912 acres of vineyard in Hungary in 2021 but scarcely known elsewhere. Most of the wine produced is relatively anodyne, but Móri Ezerjó produced from the vineyards near the town of Mór enjoys a certain following as a light, crisp, refreshing drink. It also produces strong, sweet wines, BOTRYTIZED in good vintages. Ezerjó means 'a thousand boons'.

F

Faberrebe, or Faber, waning, early-ripening German vine cross bred by Georg Scheu at Alzey in Rheinhessen in the early 20th century. Most of its 228 ha/563 acres in 2020 were in the Rheinhessen. A little is also grown in England.

Factory House, handsome Georgian monument in OPORTO, standing on land granted in 1806 in perpetuity 'from this day and forever to the consul of the British nation and his corporation and their successors', is a testament to the historic role of the British in the port wine trade. The only surviving example of any Factory House, it is possibly the only actual building constructed as a meeting place for a 'factory', a body of traders or 'factors' buying and selling any commodity in a foreign country. The Portuguese were probably the first to establish such a factory, which they called a *feitoria*, in one of their earliest West African settlements. The first British factory was established by the East India Company near Bombay in 1613. By the beginning of the 18th century, British factories had been established in all major Portuguese ports, including of course Oporto, from which wine was an important export (see PORTUGAL). The Factory House, probably the first and only permanent meeting place for the Oporto factory, was begun in 1786 and finished, under the supervision of the consul John Whitehead, four years later. The cost of the land and the building was paid by the 'Outward Fund', voluntarily levied by the British shippers on their own exports of port.

The British factory's enjoyment of their grand, and determinedly exclusive, new clubhouse was cut short by the French invasion of Portugal in 1807. The official reopening of the Factory House took place at a dinner based on the number 11 on 11 November 1811. In the previous year, George III and the Prince Regent of Portugal had

signed a commercial treaty that stipulated that there should be no more British factories in Portugal. The factory itself was therefore abolished and replaced by the British Association in Oporto as British port traders trickled back to enjoy a period of unparalleled prosperity.

The British Association is made up exclusively of members drawn from the British port shippers. By the early 21st century, the remaining British-owned port companies accounted for less than one-third of all sales by volume but were still firmly entrenched in Oporto, as evinced by the city's Cricket and Lawn Tennis Club, the oldest British school in Europe, and an Anglican church.

The Factory House continues to be maintained for the exclusive use of the remaining British port shippers, although at such traditional Wednesday lunches as still take place there are often more Portuguese (directors of the British companies and their friends) than British around the table.

Delaforce, J., *The Factory House at Oporto* (1983).

Fair Play, California wine region and AVA in the El Dorado County area of the SIERRA FOOTHILLS. The region's vineyards sit at 2,000–3,000 feet in ELEVATION, and ZINFANDEL is the main grape variety, with Rhône varieties growing in importance.

fake wine. See COUNTERFEIT WINE and ADULTERATION AND FRAUD.

Falanghina. Falanghina Beneventana of Benevento province is the less common of Campania's two distinct Falaghinas, while the leafy-smelling Falanghina Flegrea of Campi Flegrei is Campania's signature white wine grape, which may have provided a basis for the classical FALERNIAN and is now the base for Falerno del Massico and Sannio DOCs. It produces attractive, unoaked, fragrant wines of real interest. Modern fermentation enabled producers to preserve its aromas, which gave it a new lease of life from the mid 1990s. There were

3,643 ha/9,002 acres of the latter in 2015, and 323 ha/798 acres of the former.

Falernian, or Falernum, was the most famous and most highly prized wine of Italy in the Roman period ('Do not try to compete with Falernian cellars', advised VIRGIL, *Georgics* 2.96). It was produced on the southern slopes of Monte Massico, the range of hills which runs down to the west coast of Italy in northern CAMPANIA. With a precision which was unusual for the Romans, three distinct zones, or CRUS, were distinguished: Caucinian on the hilltops, Faustian on the slopes (probably in the region of present-day Falciano), and Falernian proper at the edge of the plain. Recent archaeological survey has revealed numerous Roman farms in this region, and part of a vineyard of Roman date has been excavated. The vines were trained up trees (see ARBOREAL VITICULTURE) and also on trellises on poles of willow.

Falernian was a white wine of at least two types, one relatively dry, the other sweeter. As with other Roman fine wines such as CAECUBAN and MASSIC, it was normal to age it considerably. It was considered drinkable between 10 and 20 years. Its distinctive colour, deep amber, was probably the result of MADERIZATION, which may also explain the references to 'dark' Falernian in one source. The frequent descriptions of the wine's 'strength' and 'heat' suggest a high ALCOHOLIC STRENGTH. One curious claim was that it was the only wine which could be set alight! Despite the concern of PLINY in the second half of the 1st century CE that the reputation of Falernian was being endangered by a commitment to quantity rather than quality, the wine remained in the front rank until at least the 4th century CE.

The contemporary revival is Falerno del Massico, produced in white, blended red, and all-PRIMITIVO versions in modern CAMPANIA. See also ATHENAEUS. J.J.P.

Familia Torres, one of Spain's leading family-owned producers of premium wine and Spanish brandy, based in PENEDÈS, near Barcelona.

The present company was founded in Vilafranca del Penedès in 1870 by Miguel and Jaime Torres with the fruits of Jaime's investments in shipping and other commercial enterprises in Cuba. Miguel's son Juan expanded the business within Spain and left a thriving family business to his son, another Miguel, in 1932. After confiscation, disruption, and even winery destruction during the Spanish Civil War, Miguel rebuilt the business and as early as the 1940s decided to concentrate on selling wine in bottle rather than in BULK.

Perhaps the most significant development in the history of Torres came in 1959 when Miguel's son Miguel A. Torres went to study in DIJON. This resulted in experimental plantings of INTERNATIONAL VARIETIES imported from France and Germany. Torres also introduced vine TRELLIS SYSTEMS, a modern laboratory, TEMPERATURE CONTROLLED stainless-steel fermentation, and the bottling of red wines after just 18 months' BARREL AGEING in cool cellars hewn out of the hillside. All of these techniques, and a host of other innovations, were then unknown elsewhere in Spain.

Vindication of Miguel A. Torres's achievements came in 1979, when, in a well-publicized, international follow-up to the JUDGMENT OF PARIS, Torres Gran Coronas Black Label 1970 was voted winner of the top Cabernet class. In 1980 he spent a sabbatical year at MONTPELLIER and has since introduced higher VINE DENSITIES, MECHANICAL PRUNING, and a programme to recuperate Catalan INDIGENOUS VARIETIES. About 75% of all Spanish wine produced by Torres is exported.

On the death of his father in 1991, Miguel A. Torres became president of the company. He has also been one of Spain's most prolific wine writers and was one of the first wine producers in the world to take CLIMATE CHANGE seriously. With the Torres & Earth plan started in 2008, a CO_2 reduction of 34% per bottle was achieved by 2020. Torres owns about 1,300 ha/3,210 acres of vineyard in Penedès, PRIORAT, and other areas of Spain, 400 ha in Chile (established in 1978 near Curicó), and 32 ha in California. His sister Marimar owns and manages Marimar Estate in SONOMA County's Russian River Valley. In 1999—a decade earlier than most of its peers

—Torres founded its own distribution company in Shanghai, which today is one of the leading wine distributors in China. Since September 2012, Miguel A.'s son, another Miguel, has been general manager of Torres, while Miguel A.'s daughter Mireia directs the Innovation and Knowledge department, the Jean Leon winery which Torres acquired in 1994, and the Familia Torres Foundation. The fifth generation's most recent winemaking projects include Mas de la Rosa (DOQ Priorat), Purgatori (DO COSTERS DEL SEGRE), and a DO Penedès made from the local Forcada variety. The current generation has converted most of the Familia Torres vineyards to ORGANIC viticulture and is pioneering in Spain the evolution towards REGENERATIVE VITICULTURE. They aim to become a net zero emissions winery by 2040.

fanleaf degeneration, sometimes called fanleaf virus, one of the oldest known VIRUS DISEASES affecting vines. Records of it date back some 200 years in Europe, and there are indications that it may have existed in the Mediterranean and Near East since grape culture began. Rather than being a single disease, it is in fact a complex of related diseases which include forms known as yellow mosaic and vein banding. Shoot growth is typically malformed, leaves are distorted and asymmetric, and teeth along the edge are elongated. Shoots show abnormal branching with double nodes (see FASCIATION), short internodes, and zigzag growth. Leaves on infected plants look fanlike—hence the name. Bunches are smaller than normal, with poor FRUIT SET and many SHOT BERRIES. Sensitive varieties such as Cabernet Sauvignon can lose up to 80% of potential yield and have a shortened productive life.

The disease can be detected by INDEXING using varieties of other species of VITIS such as Rupestris St George, or with other plants such as *Chenopodium*, or more recently by serological tests using ELISA. The virus is spread by infected planting material, and this reached widespread proportions in the late 1880s with the adoption of grafting vines on to ROOTSTOCKS resistant to PHYLLOXERA. A second

means of spread was discovered in California in 1958. The NEMATODE *Xiphinema index* spreads the disease within a vineyard by feeding on the roots of infected plants and then healthy ones. Thus the symptoms of the disease spread slowly around an original infected plant.

There is no control for an infected vineyard, and it must be removed. The virus particle can survive in root fragments for over six years. Nematode populations were reduced by FUMIGATION, now often prohibited. The most successful method is to plant virus-free vines in a nematode-free soil. Fanleaf-free planting material is readily created by THERMOTHERAPY or TISSUE CULTURE. (See also NEPOVIRUSES.)

Bettiga, L. J., (ed.), *Grape Pest Management* (3rd edn, 2013).

Wilcox, W. F., et al., *Compendium of Grape Diseases, Disorders, and Pests* (2nd edn, 2015).

Fara, red wine DOC on the brink of extinction, covering in 2020 just 8 ha/20 acres in the Novara Hills of eastern PIEMONTE in north-west Italy. The wines are made from 50–70% NEBBIOLO, here called SPANNA.

Far North Zone in SOUTH AUSTRALIA has a single region, Southern Flinders Ranges.

fasciation, a growth abnormality, of SHOOTS in particular, in which the stem is broadened and flattened as though there were several shoots fused side by side. It is relatively rare in grapevines, although some varieties seem to be prone. The cause is unknown, but it is a common symptom of FANLEAF DEGENERATION infection. B.G.C.

fashion has played a part in wine consumption, and therefore eventually wine production, for at least two millennia. The wine drinkers of ancient ROME favoured white wines, preferably old and

sweet (see FALERNIAN, for example). Indeed, throughout much of the modern age, sweet, heady wines have been prized above all others. In the early Middle Ages, the wine drinkers of northern Europe had to drink the thin, tart, sometimes spiced ferments of local vineyards because TRANSPORT was so rudimentary, and RHINE wines were considered the height of fashion. But when these consumers were introduced to such syrupy Mediterranean potions as the wines of CYPRUS and MALMSEY, wines traded energetically by the merchants of, for instance, VENICE, a fashion for this richer style of wine was established. By the 16th century, for example, light, white ALSACE wine was regarded as unfashionable by the German wine drinker (see GERMAN HISTORY), who was, as now, beginning to favour red wines. Many fashions were restricted to one particular district or region, particularly before the age of modern communications. It is clear that the wines favoured by the French court in the medieval period, for example, were considerably influenced by fashion and, possibly, more pragmatically political considerations (see MEDIEVAL LITERATURE and ST-POURÇAIN).

Towards the end of the Middle Ages, fashion seems to have begun to favour not just RESIDUAL SUGAR but ALCOHOLIC STRENGTH too. Such wines as SACK and TENT from southern Spain were valued for their potency, although by the end of the 17th century seafaring and exploration brought a new range of drinks to the trendsetters of northern Europe which were very much more fashionable than any form of wine.

A new age demanded new products, and the most durable of these were the so-called New French Clarets (see CLARET and BORDEAUX, history), whose initial success was largely due to fashion. In the 18th century, however, no wines were more fashionable than a clutch of what a modern salesperson might call 'speciality items': Hungarian TOKAJI, South African CONSTANTIA, and Moldavian COTNARI. These were available in necessarily very limited quantities, but the wine styles created during or soon after this period illustrate the wine qualities regarded as fashionable then: PORT, MADEIRA, MÁLAGA, and

MARSALA are all remarkable for their colour, alcohol, and usually sweetness.

By the 19th century, much more detailed evidence of the wines then considered most fashionable is available, not just in the form of CLASSIFICATIONS and a number of books specifically comparing different wines (see LITERATURE OF WINE) but also in the form of price lists—for wine PRICES have reflected fashions in wine throughout history. It would surprise the modern wine drinker, for example, to see the high prices fetched by German wines compared with the classified growths of Bordeaux from the late 19th to the mid 20th centuries. The late 19th century was also a time when CHAMPAGNE was considered exceptionally modish in northern Europe, notably in St Petersburg.

In the 1920s and 1930s, wine in almost any form was extremely unfashionable. This was the age of the cocktail on one side of the Atlantic and of PROHIBITION on the other. These phenomena, together with the marked decline of traditional markets and a worldwide economic depression, threatened many small-scale vine-growers with penury (this was the era during which so many wine CO-OPERATIVES were established).

It was not until well after the Second World War, when some measure of real economic recovery and stability had returned, that wine slowly re-established itself as a fashionable drink (although it had long been a drink of necessity in wine-producing areas). As foreign travel became an economic possibility for the majority of northern Europeans, consumers in non-producing countries began to link wine with a way of life they associated with leisure, the exotic, and warmer, wine-producing countries.

By the late 1970s, wine CONNOISSEURSHIP itself was beginning to be fashionable, and the economic boom of the 1980s provided the means for a new generation of collectors. This led inevitably to a fashion for marathon 'horizontal' and 'vertical' TASTINGS of scores of bottles at a time. Buying wine EN PRIMEUR was particularly fashionable in this decade of superlative VINTAGES.

What has been most remarkable about fashions in wine consumption in the late 20th and early 21st centuries, however, has been how rapidly wine production has reacted to them and in some cases created them (see NATURAL WINE, ORANGE WINE, ROSÉ WINES, MOSCATO, PINOT NOIR, MERLOT, PET-NAT, REDUCED-ALCOHOL WINE, and wine BOXES among others). The speed of producer reaction is doubtless related to the development of wine criticism in media more immediate than books (see WINE WRITING).

Perhaps the most significant fashion of the 1970s and 1980s was for VARIETAL wines, especially but by no means exclusively in the NEW WORLD. This led to a dramatic increase in the area planted with INTERNATIONAL VARIETIES—Chardonnay, Cabernet Sauvignon, briefly Merlot, and subsequently, thanks to a single film SIDEWAYS, Pinot Noir, in particular. From about the 1980s winemakers reacted quickly to successive fashions for and then against obviously OAKY wines, both white and red.

The 1990s saw an even more significant development, however: a dramatic shift in consumer taste away from white wines to red. Just when a high proportion of northern CALIFORNIA's post-PHYLLOXERA replantings and AUSTRALIA's ambitious new plantings were assigned to the then-fashionable Chardonnay, it became clear that the wine drinker of the 1990s, particularly the new army of ASIAN wine consumers, would in fact much prefer red—partly for heavily touted perceived HEALTH benefits.

Towards the end of the last century, the phenomenon known as Parkerization (see PARKER, Robert M.) resulted in a marked increase in average ALCOHOLIC STRENGTH and depth of colour in reds. By the second decade of this century, however, there was a very obvious retreat from this style in most wine regions.

The fashion for international vine varieties was replaced in the early 21st century by one for INDIGENOUS VARIETIES and ALTERNATIVE VARIETIES. Rapid changes of varietal fashion are inconvenient for a plant that takes three years to produce a commercial crop, but there

is always TOP GRAFTING. Other 21st-century preoccupations include minimizing ADDITIVES and ALCOHOL as well as ORGANIC and BIODYNAMIC wines.

Fashion being as fickle as it is, this is one of the most frequently updated entries in this *Companion*.

fats. See LIPIDS.

fattoria, Italian for 'farm', also used for a wine estate. A *fattoria* is generally bigger than a PODERE, which is often a small farm carved out of a larger property and designed to be just large enough to be managed by one sharecropper/tenant plus family.

Faugères, progressive appellation in the LANGUEDOC region in southern France. A total of 1,780 ha/4,400 acres of vineyard, mainly at relatively high ELEVATIONS (250–400 m/820–1,312 ft) on schistous foothills of the Cévennes, look down on the plains around Béziers. The AOC Faugères vineyards are planted with quintessentially Mediterranean grape varieties that produce big yet elegant reds due to the elevation and SCHIST soils. Average yields are low, around 30 hl/ha, and 40% of the vineyard is certified ORGANIC with another 10% in conversion in 2021. The ubiquitous CARIGNAN, which by 2014 was limited to 40% of any blend, is being replaced by Syrah, Grenache (or its relative LLEDONER PELUT), and Mourvèdre, while Cinsaut is still grown for fruit and rosés. The white wines, only 4% of the production, are also hauntingly impressive and are based on ROUSSANNE, GRENACHE BLANC, MARSANNE, and VERMENTINO. Further plans are afoot to include more environmental measures in the AOC regulations for what is one of the Languedoc's distinctive and most consistent appellations. M.S.

George, R., *The Wines of Faugères* (2016).

faults in wines vary, of course, according to the taste of the consumer. Some diners will quite wrongly 'send back' a wine (see SERVING WINE and SOMMELIER) simply because they find it is not to their taste. Taste varies not only according to individuals but also according to nationality. Italians are generally more tolerant of BITTERNESS, Americans of SWEETNESS, Germans of SULFUR DIOXIDE, the French of TANNINS, and the British of decrepitude (see MATURITY) in their wines, while Australians tend to be particularly sensitive to MERCAPTANS and most Americans view HERBACEOUSNESS as a fault rather than a characteristic. To winemakers, however, wine faults are specific departures from an acceptable norm, the least quantifiable of which may be a lack of TYPICALITY. However, with the rapid growth of the NATURAL WINE movement, many winemakers and consumers are revising their opinions of what constitutes a fault. The reduced use of sulfur dioxide as a microbial inhibitor, the growing preference for SPONTANEOUS FERMENTATION and high-solids fermentation, and reduced FILTRATION create wines that walk a fine line between complex and intriguing or faulty and undrinkable.

Visible faults

Faults in a wine's appearance are generally either hazes, clouds, or precipitates in the bottle. STABILIZATION is designed to avoid all these hazards. Haze and cloud in bottled wines can have a variety of causes, of which the most common today is the growth of YEAST or BACTERIA. Mycoderma is a yeast-related fault which forms a film on the wine's surface (and so may be visible to winemakers, if not to wine consumers). Clouds from heat-unstable PROTEINS and from heavy-metal contamination do occur but they are much less frequent than they were in the era of copper and brass pipes and taps.

Precipitates, especially crystalline ones, are found from time to time and are usually the harmless result of excess potassium or calcium TARTRATES finally coming out of solution. Tartrate stabilization usually prevents this, but calcium tartrate may not form until several months after bottling, so it is very difficult to determine if a wine is calcium-tartrate stable. From white wines, these may form as needle-like colourless or white crystals on the end of the cork in contact with the wine or in the bottom of the bottle, where they look misleadingly like fragments of glass. From red wine, tartrate crystals are usually dyed red or brown from the adsorbed PHENOLICS. See SEDIMENT.

Visible bubbles in a supposedly still wine are frequently viewed as a fault. Some wines, particularly off-dry whites, are deliberately bottled with a trace of CARBON DIOXIDE gas to make them taste more refreshing. Bubbles in a bottle of older wine, particularly a red wine, usually indicate unintentional FERMENTATION IN BOTTLE, however, and are definitely a fault.

While most consumers would agree that cloudy wines are faulty (although see NATURAL WINE), there is much less agreement about COLOUR. Some wine judges in COMPETITIONS automatically disqualify rosé wines with a hint of amber, even though it is difficult to make a blueish-pink wine out of the GRENACHE grape variety, for example—and wines of all sorts and hues turn amber with age.

OXIDATION, which can brown wines prematurely, is a fault in young table wines but is best confirmed by the nose.

Smellable faults

Some wines smell so stale and unpleasant that the taster is unwilling even to taste them. The most likely explanation for this is a mouldy cork causing CORK TAINT. Such a wine is said to be CORKED, but a wine served with small pieces of cork floating in it indicates a fault in the SERVICE of the wine rather than a fault in the wine. Contact with fragments of sound cork does not harm wine.

Other off-odours can vary considerably. Oxidized wines (see above) smell flat and aldehydic (see ALDEHYDES). VINEGARY wines indicate the presence of ACETIC ACID due to microbiological activity by bacteria and yeast. ETHYL ACETATE, HYDROGEN SULFIDE, MERCAPTANS, excess SULFUR DIOXIDE, and the smellable compounds generated by some bacteria can all be reasons for judging a wine faulty. (See also REDUCTION.) The picture is complicated, however, by the fact that we all vary in our sensitivities to most of these compounds (see TASTING and LADYBUG TAINT), and some of them may be more acceptable in some sorts of wine than others. Acetaldehyde, for example, is the principal odorant of FINO sherries but definitely indicates over-oxidation in white wines and makes red wines taste vapid and flat. Although the average palate should not detect acetic acid on a fault-free wine, there are some much-admired, full-bodied red wines (such as some PORT, PENFOLDS Grange, and VEGA SICILIA) whose VOLATILITY was historically much higher than the norm. Many fine German winemakers at one time deliberately used relatively high concentrations of sulfur dioxide to preserve some of their best wines for a long life in bottle.

A wine may not smell clean because of the influence of one or several CONTAMINANTS such as agrochemical RESIDUES. If it smells of geranium leaves, there has probably been some bacterial degradation of SORBIC ACID, although this can easily be controlled by adding sulfur dioxide with the sorbic acid.

A wine may smell MOULDY either because of BACTERIAL SPOILAGE or because it has taken on the smell of a less-than-clean container.

Another much-discussed microbiological fault, which can cause a wine to smell mousy or animal/medicinal, has been attributed to the action of yeasts of the BRETTANOMYCES genus, closely related to Dekkera. More detailed studies on the causes of mousy off-flavour in wine have indicated that LACTIC ACID BACTERIA, including particular strains of *Lactobacillus* and to a lesser extent *Oenococcus* and *Pediococcus*, are capable of producing the off-flavour compounds responsible for this most unpleasant fault. It cannot normally be smelled in wine unless it is alkalinized or rubbed in the palm of the hand (an action which neutralizes wine acidity). This mousy flavour is volatile only at neutral or high PH, which explains why it is not immediately apparent but builds up in the back of the mouth once a wine has been swallowed or expectorated, as the palate slowly returns to neutral pH through the buffering action of saliva.

See also GEOSMIN, GERANIUM, MOULDY, TRIBROMOANISOLE, METHOXY-DIMETHYLPYRAZINE, and ISOBUTYL-METHOXYPYRAZINE.

Tasteable faults

Most faults are already obvious to the nose and need only confirmation on the palate (which is why in a restaurant it is, strictly speaking, necessary only to smell a sample of wine offered by the waiter). Some contaminations, notably from metal, are easier to taste than smell, however, and a wine that is excessively tannic or bitter (see BALANCE) will not display this fault to the eye or nose. See also CONTAMINANTS. K.C.

Goode, J., *Flawless: Understanding Faults in Wine* (2018).

Favorita, local synonym for the VERMENTINO cultivated near ALBA, both on the left bank of the Tanaro in the ROERO zone and slightly less successfully on the right bank in the LANGHE Hills. Gagliardo was one of the first to champion the variety in Roero, in 1974.

Federspiel, the middle in terms of MUST WEIGHT and alcohol among the three categories of dry white wine in Austria's WACHAU region—specifically from unchaptalized grapes of minimum 83 °OECHSLE/17 °KMW and harbouring 11–12.5% finished alcohol by volume. The name originates from falconry. See also STEINFEDER and SMARAGD. D.S.

Federweisser, German term for young wine popularly consumed before bottling—generally cloudy and often still fermenting—and typically referred to in Austria as Sturm or HEURIGER. Confusingly, the term 'Federweisser' is used in German-speaking Switzerland to refer collectively to white wines made from black grapes.

feinherb, a traditional term of approbation permitted on German wine labels since 2000 that is neither amenable to intelligible literal translation nor legally defined. Many growers use it as a substitute for HALBTROCKEN, a concept whose appeal to German consumers fell significantly towards the end of the last century. It remains widely used for wines of overt, albeit modest, sweetness. D.S.

Fendant, Valais name for the most planted white wine grape in SWITZERLAND, the productive CHASSELAS.

Fer, alias Fer Servadou (and many other aliases), is a characterful, tannic black grape variety traditionally encouraged in a wide range of the sturdy red wines of SOUTH WEST FRANCE. In MADIRAN, where it is often called Pinenc, it is a distinctly minor ingredient, alongside Tannat and the two Cabernets. In GAILLAC, where it is known as Braucol, it has overtaken DURAS to become the dominant variety. It is technically allowed into wines as far north as Bergerac, but today it is particularly important to the red wines of the Aveyron *département*, ENTRAYGUES, ESTAING, and the defiantly smoky, rustic MARCILLAC. The iron-hardness of the name refers to the vine's wood rather than the resulting wine, although it is well coloured, concentrated, and interestingly scented. Fer has also been invited to join the already crowded party of varieties permitted in CABARDÈS.

French plantings had grown to 1,570 ha/3,880 acres by 2019, and DNA PROFILING has shown it to be a progenitor of CARMENÈRE.

Féret, sometimes known as *Cocks et Féret*, important directory of Bordeaux châteaux which was first published in 1846 as *Bordeaux, its Wines and the Claret Country* by the Englishman Charles Cocks, who died in 1854 (*see* LITERATURE OF WINE). A French version followed in 1850, with the emphasis on classifying wines in order of merit, also published in Bordeaux by Féret. It played a significant part in establishing the 1855 CLASSIFICATION and continues to be updated,

expanded, and published by members of the Féret family to this day. It has always provided a useful historical record of the evolution of different properties' and districts' reputations. (The 1868 edition, for example, ranked PETRUS as a mere CRU BOURGEOIS.) As a sign of the times, the 20th edition of what is now known simply as *Bordeaux et ses vins* was published in 2023, in e-book format, in French, English, and, significantly, Mandarin.

fermentation, as it applies to wine, is the process of converting SUGAR to ETHANOL (ethyl alcohol) and CARBON DIOXIDE effected by the anaerobic (oxygen-free) metabolism of YEAST. It comes from the Latin word *fervere*, to 'boil'; any mass containing sugar that has been infused with yeast certainly looks as though it were boiling, as it exudes carbon-dioxide bubbles.

History

Before yeast's metabolic processes were properly understood, the word 'fermentation' was also used to describe a much wider range of chemical changes that resulted in the appearance of boiling and in some of which carbon dioxide evolved. These have included the leavening of bread, the production of cheese, and the tumultuous reactions of acids with alkalis. Today such changes involving the intervention of yeast or BACTERIA in aerobic processes are not usually considered true fermentations.

By the middle of the 19th century, understandings of science were such that opinions were divided about the nature of 'organized ferments' as opposed to 'unorganized ferments' in fermentation. Thanks to Louis PASTEUR, we now know that it is the organized ferments and their agents yeasts and bacteria that are primarily responsible for alcoholic fermentation. They act through their internal ENZYMES (enzymes were responsible for Pasteur's unorganized ferments), which, functioning as catalysts, mediate the series of reactions involved in the conversion of sugar into alcohol and carbon dioxide.

The net change during fermentation of one glucose molecule giving two alcohol and two carbon dioxide molecules expressed as a chemical equation is:

$$C_6H_{12}O_6 \rightarrow 2C_2H_5OH + 2CO_2$$

Many years and the research talents of several scientists—notably Embden, Meyerhof, and Parnas—have elucidated the successive steps in the apparently simple conversion of sugars to the metabolic end products, alcohol and carbon dioxide.

The complex process

The first steps in the process attach phosphate groups to the sugars. Next comes a series of steps in which the six-carbon sugar is split into two three-carbon pieces, one of which is then rearranged into the structure of the other. After some further rearrangements, this three-carbon molecule loses its terminal carboxylic carbon atom in the form of carbon dioxide gas. The residual part is the two-carbon compound ACETALDEHYDE, which goes next to alcohol if oxygen is lacking, or into another multi-step series of reactions eventually yielding energy, water, and more carbon dioxide if generous amounts of oxygen are available.

The net change when oxygen is present in excess is one glucose plus six oxygen molecules giving six carbon dioxide and six water molecules, as shown by this chemical equation:

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$$

Ideally for the yeast, therefore, the process should be carried out with generous quantities of oxygen available, for then much more cell-building energy is produced. For the winemaker, however, it is important that this process can be modified by limitation of the oxygen supply because then alcohol, rather than water, is produced along with carbon dioxide. Without the alcohol there would be no wine.

(It is interesting that this same series of steps in decomposition of sugar is employed by people during muscular activity, another form of fermentation. In human beings and other mammals, the three-carbon compound pyruvate is converted to LACTIC ACID and supplies energy for muscular action.)

A number of intermediate compounds are involved. The biochemical reactions converting one compound into its successor in this series are not 100% efficient, with the result that small amounts of certain of the intermediate compounds accumulate in the wine. These compounds and the products of their reaction with other

substances in the mixture contribute to what is known as fermentation, or secondary, AROMAS. Included among these compounds are acetaldehyde, ETHYL ACETATE, and numerous other ESTERS and FUSEL OIL.

Physical chemistry tells us that the reaction of six-carbon sugar to ethanol and carbon dioxide yields generous amounts of energy. A significant portion of this energy is captured during the process and used by the yeast for its own purposes. Another major portion of the energy, however, is not captured but appears as waste heat. Unless this waste heat is removed from the fermenting mass, its temperature will rise, reaching levels which damage or kill the yeast cells and stop the reaction, resulting in a STUCK FERMENTATION which can be very difficult to restart. Heat removal is not a major problem when fermentations are conducted in a small FERMENTATION VESSEL because the greater ratio of surface to volume furnishes sufficient radiation and conduction surfaces from which the heat can be dissipated. In a large container, however, the amount of heat liberated is so large that it cannot all be radiated or conducted away and some REFRIGERATION system is needed.

Monitoring fermentation

Progress of a fermentation can be monitored in several ways. The most obvious is by simply observing activity in the fermentation vessel: as long as carbon dioxide is vigorously given off, the yeast are still working. Laboratory fermentations are sometimes followed by weighing the fermentation vessel at frequent intervals, thus obtaining a record of the weight of carbon dioxide gas lost and therefore, by calculation, the amount of sugar remaining. Chemical analyses of the unfermented sugar remaining, or of the alcohol produced, are accurate measures of the course of fermentation but are seldom used as they are complex and time-consuming. The technique most commonly used in the cellar is a measurement of the DENSITY of a sample of fermenting juice.

Density can be determined quickly and with reasonable accuracy by floating a calibrated HYDROMETER in the juice. Although most hydrometers are calibrated to read the remaining sugar's percentage in weight, it must be remembered that this calibration is for a sugar in water solution. When alcohol, less dense than water, is added to the solution during fermentation, the hydrometer reading no longer gives a true reading of the sugar remaining. Indeed, when all of the fermentable sugar has been converted into alcohol, these hydrometers will give the apparently ridiculous reading of less than no sugar. The problem of deciding when the fermentation is complete matters because the presence of small amounts of sugar renders the wine susceptible to bacterial attack and necessitates different treatment after fermentation. Today there are quick, simple paper strips or pills which can reliably detect the presence of even very small amounts of fermentable sugars. Handheld density meters are increasingly common; these are faster, and data can be downloaded directly to a computer. Larger producers may have tanks that monitor fermentation using in-line densitometers or pressure sensors, with readings automatically fed into the computer system. (See also ARTIFICIAL INTELLIGENCE.)

Factors affecting fermentation

The time required for complete fermentation of white grape juice or crushed red grapes varies greatly. The TEMPERATURE maintained in the fermenting mass is the principal factor affecting duration of fermentation (as well as resultant character of the wine), more even than the initial sugar concentration (see MUST WEIGHT), YEAST type, the aeration of the MUST, and the quantity of micronutrients in the juice, especially NITROGEN. In general, red-wine fermentations are complete within four to seven, days but white wines, which are frequently fermented at much lower temperatures, may sometimes require longer, possibly two to three weeks, or occasionally months (see DRIED-GRAPE WINES, for instance).

Other factors which influence the course of a fermentation include agrochemical RESIDUES and various chemical additions such as too high a concentration of SULFUR DIOXIDE. In the most commercially minded wineries, fermentations may be deliberately hastened so that a single fermentation vessel may be used twice or even three or more times a season.

In the making of certain styles of wine, such as PORT, VIN DOUX NATUREL, and other VINS DE LIQUEUR, the fermentation may be arrested deliberately by the addition of alcohol, usually grape spirit. For sweet wines such as SAUTERNES, fermentation may be stopped by the addition of SULFUR DIOXIDE.

The above is an outline of the most usual sorts of fermentation, but there are many variants, including BARREL FERMENTATION, CARBONIC MACERATION, ROSÉ WINEMAKING, and, quite distinct from the primary or alcoholic fermentation, FERMENTATION IN BOTTLE, MALOLACTIC CONVERSION, and SECOND FERMENTATION.

See also MACERATION, the process that inevitably accompanies red-wine fermentation, and also RED WINEMAKING, WHITE WINEMAKING, and SPARKLING WINEMAKING. A.D.W.

Halliday, J., and Johnson, H., *The Art and Science of Wine* (1992).

Ribéreau-Gayon, P., et al., *Traité d'Œnologie* 1: *Microbiologie du vin: Vinifications* (7th edn, 2017), translated by J. Towey, as *Handbook of Enology* 1: *The Microbiology of Wine and Vinifications* (3rd edn, 2021).

fermentation in bottle plays an important part in SPARKLING WINEMAKING. In most still wines, however, it is one of the wine FAULTS most feared by winemakers in wines that have not been appropriately filtered (see FILTRATION). It usually results from the presence of some RESIDUAL SUGAR together with live cells of either YEAST or BACTERIA under conditions which favour their growth. (High ALCOHOLIC STRENGTH and high levels of SULFUR DIOXIDE inhibit the growth of such microorganisms.) It is also possible that a completely dry wine will appear to start fermenting in bottle if it contains a high concentration of MALIC ACID since live LACTIC ACID BACTERIA may metabolize the malic acid causing a MALOLACTIC CONVERSION in bottle.

The implications of a fermentation in bottle for the wine consumer can range from an inconsequential level of carbon dioxide in the wine to the generation of such large quantities of the gas that it explodes. This latter, potentially dangerous, occurrence is most likely if the wine contains significant amounts of fermentable sugar and is kept at warm room temperatures. If the fermentation is bacterial rather than by yeast, gas is usually produced, together with off-flavours, cloud, or haze (see BACTERIAL SPOILAGE).

A low level of gas in a wine, particularly a young white wine, is by no means necessarily a sign of unwanted fermentation in bottle. Many winemakers deliberately retain (from fermentation) or incorporate a low level of CARBON DIOXIDE to enliven some wines.

A.D.W.

fermentation vessel. The container in which FERMENTATION (or MACERATION, in the case of red wines) takes place can vary enormously in size, material, and design: from a small plastic bucket

(in the case of some HOME WINEMAKING) to an oak BARREL (in the case of white wines and a very few red wines undergoing BARREL FERMENTATION) to a CONCRETE or POLYETHYLENE tank or egg to what is effectively a vast, computerized STAINLESS STEEL tower (for high-volume everyday wines). Stainless steel has the advantage that both cleaning and TEMPERATURE CONTROL are much easier than for wooden or concrete fermentation vessels; most modern white and rosé wines, and many reds, are fermented in stainless-steel tanks. Polyethylene tanks are lighter and much cheaper than stainless steel and are also easy to clean.

Wooden fermentation vessels are still used by many winemakers, however. Traditional wine producers in Germany, Alsace, and the Loire may well use large, old, wooden CASKS which offer natural STABILIZATION and CLARIFICATION. Scrupulous attention needs to be paid to cellar HYGIENE to avoid contamination of the wine by microorganisms.

Red wine may be fermented either in large wooden casks or open-topped wooden vats. An open top requires constant surveillance since BACTERIA in the presence of oxygen can attack the floating CAP of skins, which will dry out and fail to achieve proper MACERATION without PUMPING OVER or PUNCHING DOWN. The cap may alternatively be kept SUBMERGED with a headboard or some other design feature.

Wooden fermentation vessels are treasured by some traditionalists for red-wine maceration, however, as they retain heat especially well, which favours the extraction process, and tend to have a much higher diameter-to-height ratio than some stainless-steel tanks, which favours the contact between wine and solids.

Modern stainless-steel tanks—and design modifications of them such as various autovinifiers (see AUTOVINIFICATION), computer-controlled fermentation vessels, self-draining vessels, and Vinomatic automatic vinifiers—are closed at the top and automatically offer a high degree of hygiene. Tronconic vats (shaped like a truncated cone), whatever they are made of, are better for punching down.

Concrete vats, both lined and unlined, are also widely and increasingly used for fermentation, even at highly respected FIRST GROWTHS in Bordeaux, where stainless steel is regarded as more sensitive to temperature variation. Unlined concrete also allows MICRO-OXYGENATION.

Clay, the original material for fermentation vessels, is making a comeback. See AMPHORA, QVEVRI, TALHA, TINAJA, and PITHARI.

fermented in bottle, legitimate description of a SPARKLING WINE made by the traditional, transversage, or transfer methods described in SPARKLING WINEMAKING. Only traditional-method wines could claim to be fermented in *this* bottle, however.

Fernão Pires, Portugal's most planted white wine grape, grown throughout central and southern PORTUGAL. Adaptable, it is not only productive but also manages to make distinctively scented, reasonably crisp wines and is now being taken more seriously in TEJO and LISBOA. Known in BAIRRADA as Maria Gomes, Fernão Pires was still planted on a total of 11,717 ha/28,953 acres of Portugal in 2020 and to a very limited extent in South Africa, Australia, and California.

Ferreira, one of the leading Portuguese port shippers, established in 1751. Dona Antónia Adelaide Ferreira, the *grande dame* of the DOURO Valley, was perhaps one of the most dedicated personalities in the PORT industry in the latter half of the 19th century. Born in 1811 in Régua, Dona Antónia devoted her life to the Douro, ruling her vast property portfolio of more than 20 estates as a benevolent dictator. She invested much of her considerable fortune in planting and improving her properties throughout this harsh terrain. The father of her first husband, António Bernardo Ferreira, founded one of the largest and most stately quintas in the Douro, the Quinta do Vesúvio, which the family owned until its sale in 1989 to the SYMINGTONS. Until 1987, Ferreira was owned by descendants of Dona Antónia, but the

company is now part of the extensive SOGRAPE portfolio, with Quinta do Porto the estate most closely associated with Ferreira. In the 1980s, the properties were the subject of considerable research and investment, with the company pioneering the vertical system of planting whereby vine rows are aligned uphill rather than along contours. Ferreira is the leading brand of port in Portugal and pioneered the production of high-quality dry red wines in the Douro, of which their famous Barca Velha was the prototype in 1952.

fertigation, the viticultural practice of mixing soluble FERTILIZERS with IRRIGATION water for direct application to grapevine roots. The technique is most often used with DRIP IRRIGATION systems, for which each vine has a water outlet. Fertilizers are placed in a tank through which the irrigation water passes, and so the vine is fed with appropriate amounts of water and nutrients as the irrigation season proceeds. Some nutrients such as NITROGEN are readily available in a soluble form (urea); others such as PHOSPHORUS require a relatively expensive formulation to render them immediately soluble. Some vineyard additions such as gypsum and lime are quite insoluble and also require special formulations. R.E.S.

fertility, viticultural term for the FRUITFULNESS of buds or shoots and also of vineyard soils. See SOIL FERTILITY.

fertilizers. Vines, in common with other plants, may require additions of fertilizers to overcome a deficiency in the soil of a particular nutrient (see SOIL NUTRIENTS). However, grapevines do not require such fertile soils as many other crops. Indeed, the vineyards most highly regarded in terms of the quality of wine they produce are generally grown on relatively infertile soils. While a modicum of nutrient stress may enhance quality, this is not to suggest that the fewer the soil nutrients the greater the wine quality. For example, a severe NITROGEN deficiency will limit shoot, root, and leaf growth as

well as fruit yield while also causing a STUCK FERMENTATION, potentially contributing to poor wine quality. Typically, a vineyard producing wine will receive less fertilizer than one producing TABLE GRAPES.

Fertilizers are commercial formulations rich in plant nutrients. They are typically manufactured (for example, superphosphate) but may be a mined natural product (for example, rock phosphate). COMPOST is not commonly used in large commercial vineyards because of its lack of cost-effectiveness. More commonly, compost made from a combination of plant materials and animal manures (mainly that of poultry, sheep, or pig) is used in smaller vineyards, where its use is encouraged for ecological benefits (see ORGANIC VITICULTURE and BIODYNAMIC VITICULTURE). Animal manures are also used alone, but, unless they are readily and cheaply available (for example from cattle deliberately kept on the estate or sheep grazing in the vineyard), their use is restricted because of the relatively high cost of applying sufficient nutrients in this form.

The mineral elements most likely to be deficient in vineyards are nitrogen, POTASSIUM, PHOSPHORUS, ZINC, BORON, IRON, MANGANESE, and MAGNESIUM. The fertilizers commonly used to overcome some of these deficiencies are therefore urea, calcium or ammonium nitrate, potassium chloride or potassium sulfate, superphosphate, zinc sulfate, boric acid or borate, and magnesium sulfate. Fertilizers supplying the macronutrients (see SOIL NUTRIENTS) nitrogen, phosphorus, and potassium are normally applied in amounts giving up to 50, 15, and 25 kg of nitrogen, phosphorus, and potassium, respectively, per ha per year. They can be spread on the ground under vine or applied through an irrigation dripline by FERTIGATION. The micronutrients (see SOIL NUTRIENTS) are required in small amounts only, typically less than 5 kg per ha, applied every four to five years. Thus fertilizers compensating for deficiencies of the micronutrients zinc, manganese, boron, iron, and MOLYBDENUM can be either mixed with other fertilizers and applied to the ground or else sprayed on to the leaves as foliar fertilizers.

The efficiency of fertilization varies with the type of fertilizer and the soil. For example, phosphate fertilizers are not readily available to plants grown in acid soils high in iron and aluminium oxides, so liming (see LIME) might increase growth because it makes phosphorus more available to the vine. Similarly, with high rainfall or irrigation, the nitrate form of nitrogen is leached so easily that it is lost to the vine roots unless they are very deep. The nitrate may end up contaminating nearby streams and groundwater, as has been reported in many countries, making fertilizer use in viticulture (and other forms of agriculture) the subject of scrutiny by those concerned with SUSTAINABILITY.

Fertilizer use can affect wine quality. Too much nitrogen can stimulate vine growth to such an extent that RIPENING is prejudiced, and the resultant wines may be thin, pale, and HERBACEOUS. Excessive use of potassium may also detrimentally increase wine PH and affect the colour stability of red wines. R.E.S. & R.E.W.

Christensen, L. P., and Smart, D. R. (eds.), *Proceedings of the Soil Environment and Vine Mineral Nutrition Symposium* (2005).

White, R. E., *Understanding Vineyard Soils* (2nd edn, 2015).

Fetească, Fetiaska, or Feteaska means 'maiden' and is associated with three important Eastern European vine varieties. The 'royal' Fetească Regală, thought to be a CROSS of 'white' Fetească Albă and Frâncușă, was (just) the most planted variety in 2021 in ROMANIA where it produces crisp, scented whites from 12,289 ha/30,367 acres of vineyard. It is also found in HUNGARY under the name Királyleánka. Romanian plantings of Fetească Albă, which almost certainly originated in the historic region of Moldavia (including today's Republic of MOLDOVA and the Romanian region of Moldova) and is often used for sparkling wines, totalled 12,076 ha/29,840 acres in 2021. It is known in Hungary as Leánka. In Moldova, where the two are often blended, Albă is more widely planted than Regală, and in UKRAINE statistics do not distinguish between the two. The dark-

skinned Fetească Neagră, whose red wines show potential when well vinified and yields are severely restricted, was much less common and planted on just over 3,100 ha/7,660 acres in Romania; it is also grown in Ukraine. DNA PROFILING suggests that the dark-skinned Fetească is a particularly old variety and may not be related to either of the light-skinned ones. J.V.

Fiano, strongly flavoured classical vine responsible for CAMPANIA's Fiano di Avellino DOCG in southern Italy. Wines made from this variety are assertive but lack the aromatic lift of Fiano Aromatico, or MINUTOLO. It is also planted in PUGLIA, MOLISE, and increasingly SICILY. Italian vineyard statistics do not distinguish between the two Fianos but show a total of 2,087 ha/5,157 acres. Total Australian plantings had reached 380 ha/939 acres by 2022.

Fiddletown, California wine region and higher of the two AVAs in the Amador County area of the SIERRA FOOTHILLS.

Fié, occasionally written Fiét or Fiers, old Loire synonym for SAUVIGNON GRIS. This CLONE has largely been abandoned because of its remarkably low yield, but producers such as Jacky Preys of Touraine pride themselves on their richer versions of Sauvignon made from particularly OLD VINES.

Fiefs Vendéens, small, scattered, Atlantic-influenced AOC zone south of the MUSCADET zone in the LOIRE, qualified by one of the communes Brem, Chantonnay, Mareuil, Pissotte, or Vix, each with its own ENCÉPAGEMENT. Most wines are summery GAMAY-based rosé, yet a few growers like Thierry Michon produce profound white from CHENIN BLANC and red from CABERNET FRANC, NÉGRETTE, or Pinot Noir. P.Le.

field blend, refers to a vineyard that is planted to a mixture of varieties and also to wines from these vineyards. Rare today, this was once a common-sense form of insurance since weather or disease does not affect all varieties in the same way. Such plantings are often found in older vineyards, especially in parts of SPAIN, PORTUGAL, ROUSSILLON, CALIFORNIA, and SOUTH AFRICA. Varieties in field blends are often complementary; for example, a high-acid variety randomly planted among a low-acid variety may improve wine quality when harvested and fermented as one, and this diversity is seen as a means by which to increase COMPLEXITY and BALANCE. Not to be confused with CO-FERMENTATION. See also GEMISCHTER SATZ.

J.E.H. & D.P.G.

field grafting, viticultural operation of planting ROOTSTOCK rootlings in their vineyard position and inserting SCION buds. It was common for replanting on PHYLLOXERA-tolerant rootstocks until the 1980s, when BENCH GRAFTING became more common, providing cheaper plants. Many types of bud insertion may be used, but CHIP BUDDING is common. The success rate is highest in warm to hot climates but can be erratic, and careful attention to watering, nutrition, and the tending of each vine is needed. This method is therefore most suitable for small vineyards with good soils and a well-trained workforce. It may also be used to change varieties on vine trunks infected with TRUNK DISEASE, but care must be taken to insert buds at least 30 cm/12 in below any trunk staining.

(See TOP GRAFTING for details of the viticultural operation of changing VINE VARIETY in an established vineyard.)

B.G.C. & R.E.S.

fifth growth. See the CLASSIFICATION of Bordeaux.

fill level, an aspect of individual bottles of wine which can be closely related to the condition of the wine. The lower the fill level when a wine is bottled, the more the space between the top of the

wine and the bottom of the cork (the so-called HEAD SPACE or ULLAGE) in which OXYGEN may be trapped in the bottle and may hasten the AGEING process. Most bottlers try to ensure that there is minimal ullage space in the bottle immediately after BOTTLING, a depth of 5–10 mm/0.2–0.4 in to allow for expansion if ambient temperature ever exceeds the usual bottling temperature of 20 °C. On modern bottling lines, the bottle may be flushed with INERT GAS before and after filling in order to limit as far as possible the oxygen in the head space (see TOTAL PACKAGE OXYGEN). Subsequent reductions in temperature cause a reduction in the wine's volume, thereby apparently lowering the fill level.

For wines designed for early consumption, this is unlikely to make much difference, but fill levels are important indicators of the condition of a fine and, especially, mature wine, so that fill levels should always be specified by the AUCTION houses and other fine-wine traders. The lower the fill level, the more likely a harmful level of OXIDATION and therefore the lower should be the selling price. Some sorts of wine, for example vintage PORT and SAUTERNES, seem more resilient to low fill levels than others.

During long-term AGEING, some wine is likely to be absorbed by the CORK, resulting in a drop in fill level of perhaps 7 mm after ten years. (To reduce this absorption effect, Ch MOUTON-ROTHSCHILD adopted a policy of using shorter corks from the 1991 vintage.) Other reasons for a low fill level include poor control during bottling, wine being bottled at too high a temperature, and a faulty cork. In any event, it is always wise policy to pick bottles with the highest fill levels off the shelf and to drink bottles of wine from the same case from lowest to highest fill level, since the wine in bottles with the lowest fill level is likely to be the most evolved.

Note that the fill level in wine GLASSES should ideally be less than half the height of the glass and never more than two-thirds, in order to provide somewhere for the AROMA to collect. V.L.

film-forming yeasts, sometimes called film yeasts, or mycoderma, comprise a group of grape- and wine-associated species of YEASTS which require OXYGEN for their characteristic growth and metabolism. For this reason they appear on the surface of wine in barrels or vats that are not kept completely filled. Some, such as FLOR, being strains of *Saccharomyces cerevisiae* and genetically closely related to wine fermentation strains, can add desirable oxidative aromas and flavours, whereas other species, often referred to as 'non-*Saccharomyces* yeasts', produce off-flavours, while others have a relatively neutral sensory impact.

Film-forming yeasts are widely dispersed in vineyard regions and are among the types encountered in spontaneous or non-inoculated fermentations. When sugar is present, they are producers of alcohol and carbon dioxide but have low alcohol tolerance. Thus, while they are active in the early stages of SPONTANEOUS FERMENTATIONS when traces of oxygen remain, they become dominated by the more alcohol-tolerant *Saccharomyces* species, which finish the sugar conversion. After fermentation, exposure of the wine to oxygen can stimulate film formation. These yeast species typically form more ESTERS, predominantly ETHYL ACETATE, and ALDEHYDES, and sometimes ACETIC ACID, than do *Saccharomyces*, consequently producing an undesirable, OXIDIZED flavour profile.

Initially, small islands of a thin film form on the surface of wines in tanks or barrels that are not completely full and, if left unchecked, can develop into a creamy to grey, dense biomass, referred to in flor wine production as 'velum' (*voile* in French, as in *vin de voile*). These yeasts require oxygen for film formation and thus act as a signal to the winemaker that a more frequent TOPPING UP regime is required. If wine has to be kept under ULLAGE, then maintaining a HEAD SPACE of inert gas and an adequate concentration of sulfur dioxide in the wine will usually prevent film formation. For white wines, the ACETALDEHYDE produced is a negative factor, but for red wines short exposure to a film of *Candida vini* (see below) does little damage.

Film-forming strains of *Saccharomyces* yeasts perform a vital function in the production of wines such as flor SHERRY, VIN JAUNE, and some TOKAJI.

Modern molecular methods, including whole-genome sequencing, are being used to redefine yeast genetic relationships, which has had implications for naming conventions. Previously the commonly encountered film-forming non-*Saccharomyces* species were said to belong to the genera *Pichia* and *Candida*, representing spore-forming (teleomorphic) and non-spore-forming (anamorphic) yeasts respectively. Such a generalization is no longer possible. However, it remains the case that teleomorphic and anamorphic forms of the same yeast can be known by different names. For example, the film-forming yeast species previously known as *Candida mycoderma* (anamorph), commonly observed on the surface of stored wine, is now known as *Candida vini* and also by the name of its teleomorph form *Kregervanrija fluxuum* (formerly *Pichia fluxuum*). Similarly, *Candida pelliculosa* (anamorph) is also known as *Wickerhamomyces anomalus* (previously *Pichia anomala*, teleomorph). Efforts are being made to resolve which names will take precedence.

films about wine. As wine has become more deeply embedded in popular culture, not least in the US, so films about wine have proliferated in the 21st century, but wine features strongly in at least three in the 20th century. Perhaps the earliest of the modern era was Hitchcock's *Notorious*, a 1946 spy thriller whose plot turns on the

whereabouts of the key to a wine CELLAR. Food was perhaps more important than wine in the 1987 classic *Babette's Feast*, but her one sumptuous blow-out meal served to her austere Danish employers included SHERRY, 1860 VEUVE CLICQUOT champagne, an 1846 CLOS DE VOUGEOT, and a cognac. There is no doubt about wine's role in the 1996 thriller *Blood and Wine*, which stars Jack Nicholson as a Florida wine merchant who turns to crime. The 1998 remake of *The Parent Trap* set male parent Dennis Quaid on a Napa Valley wine estate.

By far the most powerful mainstream film about wine ever was SIDEWAYS, the 2004 comedy set in CENTRAL COAST wine country. Its success spawned many other film treatments in which wine is more or less deeply embedded, but the most high-profile was *Bottle Shock*, a 2008 comedy drama based extremely approximately on Steven SPURRIER and the JUDGMENT OF PARIS taste-off between California and France.

At almost the same time as *Sideways* was released came the first of a series of documentary films about wine. Ex-sommelier Jonathan Nossiter's *Mondovino* was a passionate if somewhat tendentious complaint about growing GLOBALIZATION in wine. In 2012, *Somm* documented four young Americans' real-life quest for the MASTER SOMMELIER qualification involving BLIND TASTING tests deliberately made gruelling; this was followed up by two more films in the *Somm* series. Soon afterwards came *Red Obsession*, a high-quality Australian documentary about the Chinese love affair with red wine, bordeaux in particular. The same team made the popular *Blind Ambition*, released in 2021 and 2022, about four Zimbabwean refugees who became top sommeliers in South Africa. The 2016 documentary *Sour Grapes* about COUNTERFEITER Rudy Kurniawan made quite an impact.

In 2020 Netflix's drama *Uncorked* about a young man's quest to become a Master Sommelier joined a swelling corpus of wine-themed movies.

filtration, the process that removes particulate matter from a liquid. At the end of fermentation, wine contains a vast amount of

solids, including yeast cells, bacteria, grape cellulose, proteins, and pectins. All of these have to be progressively removed in order to produce a clear wine that is ready to be bottled. The first stage consists simply of settling under gravity to remove the gross matter. In a large winery, this might be accelerated by the use of CENTRIFUGATION or FLOTATION. This is followed by filtration.

There are two principal categories of filtration: depth filtration and surface or absolute filtration. Depth filtration involves the use of a relatively thick layer of a finely divided material such as DIATOMACEOUS EARTH, or pads made of cellulose fibres. As the cloudy wine passes through the layer, small particles are trapped in the tortuous channels and clear liquid passes through. This form of filtration is useful for removing large quantities of solid matter because the thickness of the filtration layer presents a large volume of medium in which the particles are trapped. The ROTARY VACUUM FILTER is the extreme example of depth filtration because it can be used to separate wine from the thick deposits at the bottom of a fermentation tank. A sheet filter fitted with thick pads of cellulose fibres is used for removing fine particles in preparation for the final filtration prior to bottling. The risk involved in using depth filtration is that, by increasing the pressure or flow-rate beyond the specified maximum, particles can be forced through the filter to the clean side.

Surface filtration, typically carried out before bottling, depends on a thin but strong film of plastic polymer material with uniform-sized holes which are smaller than the particles being removed from the wine. It is thus impossible for particles to cross the filter, hence the alternative term ‘absolute filtration’. The shortcoming here is that, if presented with too much particulate matter, the filter will become blocked. Tangential or cross-flow filtration is an ingenious development of surface filtration where the liquid flows parallel to the filter surface and keeps the filter membrane clear, avoiding clogging. The commonest form of surface filter, as used in many wineries, is the membrane filter, which consists of a set of membrane cartridges within a simple cylindrical housing. These are manufactured in a variety of pore sizes, from 5 to 0.45µ.

The use of the 0.45µ membrane is often incorrectly referred to as 'sterile filtration'. It is not totally sterile as in the production of intravenous liquids, but merely devoid of yeasts and bacteria that could cause degradation of the bottled wine at some time in the future. A more accurate term would be 'aseptic filtration'.

Filtration of wine is somewhat controversial in that it is recognized that minimum intervention is often the best approach since every time wine is handled, processed, or even moved, there can be a slight loss of quality. The best approach is to let time do the job by SETTLING. However, this is a slow process which often has to be accelerated, particularly for large-scale production. Correctly applied, filtration is perfectly satisfactory for the production of high-quality wine. D.B.

finca, Spanish for 'estate'. Finca Élez is a Spanish VINO DE PAGO created especially for the high-elevation estate of Manuel Manzaneque.

fine wine is a nebulous term, used by the AUCTION houses (and, less accurately, some pubs in Britain) to describe the sort of wines they sell, which roughly coincide with those described in INVESTMENT. For example, within Bordeaux, a wine would generally have to be of CLASSED GROWTH level or equivalent to qualify as 'fine'.

The extent to which this category of wine coincides with the best wine the world produces has declined slowly but steadily since the 1970s. Buying from, selling to, and in many cases in direct competition with the auction houses are the fine-wine traders who specialize in servicing the needs of COLLECTORS and the like. See BROKERS for more details.

Finger Lakes, a hotbed of cool-climate wines in upstate NEW YORK and birthplace of the state's VITIS VINIFERA revolution. The AVA,

established in 1982, is defined by 11 long, deep, skinny lakes carved by Ice Age glaciers that left behind diverse soil deposits of LIMESTONE, SHALE, GRAVEL, and silt. The region particularly excels with RIESLING but also supports an exceptionally rich array of grape varieties, from *vinifera* to native AMERICAN VINE SPECIES and French and American HYBRIDS. It also boasts an especially creative, energetic wine industry, with 144 wineries in 2021 producing everything from PET-NATS and PIQUETTES to TRADITIONAL METHOD sparkling wines and barrel-aged reds. For more details, see NEW YORK. M.J.D.

www.newyorkwines.org

www.fingerlakeswinealliance.com

fining, winemaking process with the aim of CLARIFICATION and STABILIZATION of a wine whereby a fining agent, one of a range of special materials, is added to coagulate or adsorb and precipitate quickly the COLLOIDS suspended in it. Fining (*collage*, or 'sticking', in French) is important because, by encouraging these microscopic particles to fall out of the wine, the wine is less likely to become hazy or cloudy after bottling.

Most young wines, if left long enough under good conditions, would eventually reach the same state of clarity as fining can achieve within months, but fining saves money for the producer and therefore eventually the consumer. Fining is most effective in removing molecules of colloidal size, which include polymerized TANNINS, PIGMENTED TANNINS, other PHENOLICS that can cause browning in young white wines, and heat-unstable PROTEINS. (Other reasons for clouds, hazes, and deposits in bottled wines include TARTRATES and BACTERIA. See STABILIZATION for details of other methods of removing them.)

Over the centuries, a wide range of fining agents has doubtless been essayed, but scientific and technical advances have eliminated those (such as dried blood powder) that are dangerous to health and those (such as various gums) that are less than fully effective in improving the wine. Many fining agents, deriving variously from EGG WHITES, milk, fish bladders, and American BENTONITE clay deposits, may strike consumers as curious winemaking tools, but it should be recognized that only insignificant traces, at most, of the fining agent remain in the treated wine. Nevertheless, in many countries, including the EU, Australia, New Zealand, and Canada, the use of any fining agent that is considered an 'allergenic substance' must be declared on the label if such a substance is above the detection limit in the finished wine (see LABELLING INFORMATION), and therefore many winemakers are dropping the use of animal-derived proteinaceous fining agents. In 2012 the OIV halved the detection limit for potentially allergenic proteinaceous fining agents set out in its oenological code. It is, however, important to distinguish between ADDITIVES such as OENOLOGICAL TANNINS, which are intended to change the flavour or structure of the wine, and PROCESSING AIDS such as bentonite, which are used to improve stability and/or clarity.

Today two general classes of fining agents are used: powdered mineral or plastic materials that are insoluble (including PVPP); and protein-based organic compounds in liquid form. Bentonite, an unusual form of clay, is particularly effective in adsorbing certain proteins and, to a limited extent, bacteria. SILICA functions similarly but somewhat less effectively. Kaolin, another type of clay, is even less effective than silica. Activated carbon (CHARCOAL) has been used to remove brown colours and is also effective in removing some off-odours. Potassium ferrocyanide may still be used as a fining agent for removing copper and iron (see BLUE FINING).

Organic compounds used as fining agents include proteins such as the CASEIN from milk, albumin from egg whites, ISINGLASS from the swim bladders of fish, and GELATIN from waste meat, which form insoluble complexes with the unstable pigments and tannins. There is

a tendency to move away from animal-based products in the interests of VEGETARIANS AND VEGANS; it is possible to obtain vegetable gelatin, and proteinaceous fining agents derived from peas and potatoes have been developed.

Everyday wines, both white and red, are normally fined earlier and to a greater extent than fine wines. Fining trials are always carried out to ensure the minimum effective amount of fining agent is added. Given the extra time accorded the making of fine wines, many of the potentially unstable components polymerize earlier and deposit without human assistance. In general, white wines need fining to preserve their lighter colour and to prevent heat-unstable proteins forming a cloud, while red wines need it to stabilize their colour and for a reduction of astringent and bitter tannins. The fining operation removes components that are soluble but potentially subject to polymerization and cloud or that may precipitate with time.

See also FILTRATION, which cannot remove these soluble substances and acts only on particulates. J.E.H. & D.B.

Finland has been growing grapes for over 100 years. Finland's countryside manor houses used to supply grapes such as Frankenthaler (TROLLINGER) to the Russian Imperial House. Greenhouses were used to ensure ripening. During the Finnish Civil War and its aftermath, much grape-growing knowledge was forgotten. In the 1970s, hardy Baltic varieties such as Zilga began to appear in the backyards of many grape-growing hobbyists; today, HYBRIDS and DISEASE-RESISTANT VARIETIES such as RONDO and SOLARIS are also common, and some VITIS VINIFERA vines are planted as far north as Vaasa. Most grape-growing happens in the south and south-west of the country and in the Åland Islands in the Baltic Sea. However, when Finland joined the EU in 1995 it forfeited the status of a wine-producing country in exchange for farm subsidies. Hence, grape wine is sold as 'an alcoholic beverage made from fermented grapes'. This favours wines made from fruits and berries other than

grapes, a long-standing Finnish tradition also protected by Finland's alcohol MONOPOLY, which prohibits CELLAR DOOR sales of grape wines.

I.S.

finish, TASTING TERM for the impression a wine gives at the end of the TASTING process. If the sensations provoked by the wine are prolonged, the wine is said to have a long or persistent finish. If not, the wine may be described as short. A long finish, or aftertaste, is, along with BALANCE, a sign of quality in a wine—so long as it is pleasant. But a finish that is too BITTER or TANNIC may be the result of a FAULT.

fino, Spanish word with two related meanings in the sherry-making process. Without its initial capital, *fino* refers to a type of wine that is the counterpoint to the richer, darker *oloroso* (see SHERRY). Fino with an initial capital refers to a style of wine, the commercial result of filtering and bottling a *fino*, the palest, lightest, and driest sherry style (along with MANZANILLA), and quintessentially the product of the *fino* type of sherry preserved and influenced by the film-forming yeast FLOR. Fino de Jerez is by far the most common, but Fino may be made in several sherry towns, including Chiclana, Chipiona, and Trebujena, as well as in MONTILLA-MORILES and CONDADO DE HUELVA. Most Fino has an alcoholic strength of 15% and is bone dry. A freshly opened bottle of true, dry, light Fino is one of the most appetizing wines in the world. For more details, see SHERRY. V. de la S. & J.B.

first growth is a direct translation of the French PREMIER CRU, but its meaning tends to be limited to those BORDEAUX wine properties judged in the top rank according to the various CLASSIFICATIONS: Chx LAFITE, LATOUR, MARGAUX, HAUT-BRION, MOUTON ROTHSCHILD, and d'YQUEM, together often with the unclassified but generally acknowledged star of POMEROL, PETRUS. Just below these red bordeaux in terms of status are the so-called SUPER SECONDS.

Fitou, rugged and remote red-wine appellation on 2,200 ha/5,434 acres of LANGUEDOC vineyard in two enclaves within the CORBIÈRES zone where it meets ROUSSILLON (see map under LANGUEDOC). When the boundaries of this, the first dry red wine appellation of Languedoc, were drawn up in 1948, local politics prevailed, and Fitou has remained with a great tract of Corbières bisecting it. The clay-limestone soils of Fitou Maritime (coastal Fitou) are quite different from the arguably potentially more interesting SCHISTS of Fitou Montagneux (mountainous Fitou), 40 minutes' drive inland—the purity in the wines of Domaine Bertrand-Bergé argue convincingly for the virtues of a mountain climate. The low-yielding vines on the infertile soils of these Pyrenean foothills are capable of great expression, but the appellation underperformed in the 1970s and 1980s. The region is even more in the grip of CO-OPERATIVES than the Corbières, with the Mont Tauch co-operative in Tuchan responsible for over half of all production. In the last decade, however, new dynamic estates have reinvigorated this appellation and shown what a mix of OLD VINES and fabulous TERROIR can achieve.

The traditional varieties Carignan and Grenache must make up 60% of the final blend with a minimum of 20% of each (this is one of the few appellations that demands a minimum Carignan component). A minimum of 10% of Syrah (better suited to Fitou Montagneux) and/or Mourvèdre (which thrives in Fitou Maritime) must be also included in the blend.

The two territories demarcated for Fitou may also produce RIVESALTES and MUSCAT DE RIVESALTES. M.S.

fixed acids, those organic ACIDS of wines whose volatilities are so low that they cannot be separated from wine by DISTILLATION. The two main fixed acids of wine are TARTARIC ACID and MALIC ACID, but several other non-volatile acids are present in small amounts. Unfortunately, the distinction between fixed and volatile acids is not precise because there are some acids which have intermediate volatilities. Among these are LACTIC ACID and SUCCINIC ACID, both

found in wine. The fixed acids are important in wines because they are the acids that give wine its refreshing tartness, as well as its natural resistance to bacterial attack. VOLATILE ACIDS, on the other hand, are more obviously odorous than fixed acids and generally produce fruity or, when present in excess, vinegary aromas. TOTAL ACIDITY, a standard wine measurement, is the sum of the fixed acids and volatile acids. A.D.W.

Fixin, appellation abutting Gevrey-Chambertin in the Côte de Nuits district of Burgundy, producing red wines of a similar style to its neighbour, though currently of lesser fame. Fixin wines have a similar sturdiness to Gevrey but have less powerful fruit and fragrance.

There are seven PREMIER CRU vineyards: Les Arvelets and Les Hervelets (partly interchangeable, as wine grown in the former may be labelled the latter), Clos de la Perrière, Clos Napoléon, Clos du Chapître, Le Clos, and Le Meix Bas. Dr Lavalle, writing in 1855, noted Le Chapître, Les Arvelets, and Clos Napoléon but singled out Clos de la Perrière for special praise since at that time the Marquis de Montmort sold it at the same price as his CHAMBERTIN.

Fixin Blanc is also made, though rare, as the AOC included just 5.29 ha/13 acres of Chardonnay in 2018.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

fizziness is the bubbling that occurs in a SPARKLING WINE when the bottle is opened and the wine is poured into a glass. In a sealed bottle the cork maintains a pressure of up to 6 atmospheres, and there is equilibrium between the dissolved CARBON DIOXIDE and the carbon dioxide in the HEAD SPACE. When the bottle is opened and the wine is poured into a glass, the pressure above the wine is reduced to ambient pressure of about 1 atmosphere, and the wine is said to be supersaturated with carbon dioxide.

In this state, carbon dioxide does not suddenly rush from the wine as bubbles. Carbon dioxide is lost by individual molecules diffusing

through the surface and by bubble formation at so-called nucleation sites, which are located on particles stuck to the glass or floating in the wine, and often from imperfections (rough spots) in the glass surface. Photographic research by Liger-Belair shows these sites are largely hollow cylindrical cellulose fibres from paper or cloth used to dry the glass. (Conversely resdidual chemicals from detergents or rinse aids may supress the formation of bubbles.)

Carbon dioxide molecules diffuse into minute gas pockets in the nucleation sites, forming a bubble, and when the bubble grows big enough, buoyancy causes it to lift off and rise to the surface of the wine. This process is then repeated so a stream of bubbles is seen emerging from each site. As the bubbles rise, carbon dioxide from the supersaturated wine continues to diffuse into them and thus they get bigger.

Bubbles reaching the surface of the wine can clearly be seen to have different diameters. This is because different nucleation sites have different shapes and sizes and because the nucleation sites are at different distances from the surface, so the bubble diameters grow by different amounts as they rise. The loss of carbon dioxide is very slow: a bottle or glass of gently bubbling fizz takes many hours to go flat.

It is often observed that the bubbles in old cellared bottles of CHAMPAGNE are smaller and slower (lazier) moving to the surface. This is simply because the bottle has, over the years, slowly lost pressure and thus the degree of supersaturation with carbon dioxide is less, resulting in slower bubble growth, both at the nucleation sites and on the way to the surface.

Most fully sparkling wines such as champagne are sold with a pressure of 5–6 atmospheres, about three times that inside a car tyre, which is the pressure which a normal champagne cork and bottle can withstand without undue risk. Such wines may be described as *mousseux* or CRÉMANT in French, *espumoso* in Spanish, *espumante* in Portuguese, SPUMANTE in Italian, and SEKT in German. Fizziness in champagne seems to be decreasing in the 21st century, perhaps due to the greater use of reserve wines.

Many wines are somewhere between still and this level of pressure, however. Wines with a gentle but definite sparkle may be described as PÉTILLANT or PERLANT in French, FRIZZANTE in Italian, SPRITZIG in German, *vino de aguja/vi d'agulla* (literally, needle wine) in Spanish/Catalan, and *frisante* in Portuguese, although many variations in nomenclature exist. European wine law defines a sparkling wine as any wine with an excess pressure of not less than 3 atmospheres (for quality sparkling wine, for example one with a PDO, it is 3.5), while a semi-sparkling wine has a pressure of 1–2.5 atmospheres. The amount of pressure can be controlled by the winemaker by varying the amount of sugar added at the second fermentation or TIRAGE stage or, in the case of CARBONATION, simply by controlling the amount of gas dissolved in the wine.

Some wines sold as still wines may fizz very gently, however. This could be a sign of a FAULT but is more likely to be a deliberate winemaking feature. See CARBON DIOXIDE for more details.

Fladgate Partnership, The, was formed in 2001 when Taylor Fonseca Vinhos S.A. (see TAYLOR'S and FONSECA) purchased CROFT and Delaforce (subsequently sold). The group, whose name was inspired by Taylor's full name—Taylor, Fladgate & Yeatman—remains family owned and is run by descendants of the Yeatman family. In 2022 it had 781 ha/1,931 acres of properties in the DOURO Valley with over 1.6 million vines.

Taylor's vintage PORT is consistently one of the most admired and longest lived, and its Quinta de Vargellas single-QUINTA bottling can often be almost as concentrated. Vargellas, Taylor's best-known

property in the remote eastern reaches of the Douro, was acquired in 1893 when it was still suffering from the ravages of PHYLLOXERA. This acquisition marked the start of Taylor's now considerable landowning and farming activities. Quinta de Terra Feita in the Pinhão Valley, which had been supplying port to Taylor's since the 1890s, was bought in 1974. In 1990 Terra Feita de Cima was added, followed in 1993 by São Xisto next door to Vargellas, which was further extended in 1999. Quinta do Junco was acquired in 1998. In the late 20th century Taylor's popularized the filtered LBV (late-bottled vintage) style of port. In the early 21st century it pioneered the release of special, small-volume releases of luxury ports.

In 1948 Taylor, Fladgate, & Yeatman acquired Fonseca and have continued to build on the firm's reputation for excellent, dramatic vintage ports. Quinta do Cruzeiro in the Pinhão Valley had been supplying wine for Fonseca since the 19th century and was acquired in 1973. Five years later the company bought Quinta do Panascal in the Távora Valley, which is a key ingredient in Fonseca vintage port as well as producing single-quinta vintage ports. Quinta de Santo António was replanted in the 2000s, and farming is entirely ORGANIC. Fonseca's best-known wine is probably the superior ruby reserve port Bin 27. Vintage ports from earlier-maturing years are sold under the name Guimaraens and are blended from the same properties as produce Fonseca vintage port.

With Croft came the 109-ha/269-acre Quinta da Roêda near Pinhão, and in 2008 the brand was used to launch rosé port, Croft Pink, on an unsuspecting world.

In 2013 The Fladgate Partnership purchased shipper Wiese & Krohn and its impressive stocks of mature tawnies. Eschewing Douro table wines, its focus is premium port, with a global market share of more than 33% of this category. The company has also ventured into wine-related hotels, first in the Douro with The Vintage House hotel and, since 2010, with the Yeatman in Vila Nova da Gaia overlooking Oporto. This was followed in 2020 by an ambitious cultural centre nearby, the World of Wine, or WOW. In 2020 and 2021 quintas Bragão, Arruda, and Vedejosa were added to the portfolio.

flash détente, also known as flash EXTRACTION, is a variation on THERMOVINIFICATION typically used to increase the speed/extent of extraction of colour from grape skins, treat mouldy grapes, and remove GREEN aromas. It can also be used to increase the intensity and complexity of high-quality well-ripened grapes from warm vintages. MUST is heated to around 85 °C/185 °F for a few minutes then introduced into a vacuum chamber. Under the partial vacuum, the boiling point of the must is lower than at atmospheric pressure, so some liquid vaporizes instantly. This weakens the skin cell walls and enhances extractability of POLYSACCHARIDES and TANNINS during maceration. The instant evaporation has the effect of cooling the remaining must down to around 30 °C. The vapour is condensed and this condensate, often rich in green aromas, can be kept separate or added back as desired, sometimes after treatment with activated carbon (see CHARCOAL). *Flash détente* is a useful technique, but it may accentuate harsh tannins when applied to underripe grapes. A gentler 'half' flash process is now also commonly used. In this variant, a weaker vacuum is used that cools the must to around 50 °C. ENZYMES are added and a warm maceration performed for several hours, sometimes during the filling of a large membrane press. This helps further improve and speed up extraction of sufficient polysaccharides and tannins. At 50 °C the added enzymes are around their optimum activity, but there is no risk of OXIDATION from LACCASE since this is denatured by the short time at 85 °C. *Flash détente* (in this context *détente* means 'release') systems are installed in France and to varying extents in other winemaking regions around the world. S.N.

flavescence dorée, a PHYTOPLASMA disease of the vine and the most serious and widespread of the diseases known generically as GRAPEVINE YELLOWS. The disease has the potential to threaten many of the world's vineyards and is becoming ever more widespread due to CLIMATE CHANGE. It is transmitted in the field by *Scaphoideus titanus*, an insect originally native to the eastern United States and Canada and apparently introduced to Europe after the Second World War, but

it may also be introduced to the vineyard via infected plant material from NURSERIES.

Flavescence dorée was the first recorded phytoplasma grapevine disease, appearing in the Armagnac region in south-west France on the vine variety BACO 22A in 1949. It spread rapidly throughout France towards the end of the 20th century. Affecting only isolated vineyards in Armagnac and the Languedoc in 1982, by 1987 it had spread to Cognac, throughout the Languedoc and to the northern and southern Rhône. By 1992 it had reached the Loire Valley, Bordeaux, and the Côtes du Rhône, arriving in the Mâconnais in 2014 and spreading to the Côte d'Or from there. It was recorded in the Jura and the Swiss Valais in 2016.

For symptoms and variants, see GRAPEVINE YELLOWS. R.E.S.

CABI, 'Grapevine flavescence doree phytoplamsa', Invasive Species Compendium.

www.cabi.org/isc/datasheet/26184.

flavonoids, a large group of PHENOLIC compounds that includes ANTHOCYANINS, CATECHINS, and the FLAVONOLS. More than 9,000 flavonoids from a wide variety of plant sources have been described. In wine, they contribute to COLOUR, ASTRINGENCY, TEXTURE, and possibly BITTERNESS, although this last is less well documented. Up to 90% of the phenolic content in red wine is made up of flavonoids; in white wines the proportion may be lower because of less EXTRACTION from the skins, stems, and seeds. The antioxidant and cancer chemopreventive capacity of many flavonoids may contribute to the HEALTH benefits of moderate wine consumption. G.L.C.

flavonols, a group of PHENOLIC yellow PIGMENTS belonging to the FLAVONOID family found mostly as GLYCOSIDES such as glucosides and glucuronides. QUERCETIN glycosides, the most common flavonols in

grapes, are abundant in vine leaves and present in skins and stems. Their concentration can be enhanced in grapes (and therefore in wine too) by exposing the berry cluster to the sun (see CANOPY MANAGEMENT). Indeed, Price and colleagues argue that the quercetin level in grape berries can be used as an index of the sun exposure they have experienced. Like CATECHIN, quercetin may enhance PIGMENT stability in young wines through CO-PIGMENTATION and has antioxidant properties similar to those of RESVERATROL (see HEALTH). The release of flavonol aglycones from the corresponding glycosides may also result in a hazy wine as these molecules are poorly soluble in wine.

B.G.C., P.J.W. & V.C.

Price, S. F., et al., 'Cluster sun exposure and quercetin in Pinot Noir grapes and wine', *American Journal of Enology and Viticulture*, 46 (1995), 187–94.

flavour, arguably a wine's most important distinguishing mark. As outlined in TASTING, most of what is commonly described as wine's flavour is in fact its AROMA (or alternatively, in the case of older wines, its BOUQUET). This, the 'smell' of a wine, may be its greatest sensory characteristic but is also the most difficult of its attributes to measure and describe. A wine's flavour could, in its widest sense, be said to be the overall sensory impression of both aroma (as sensed both by the nose and from the mouth) and the taste components and may therefore incorporate the other, more measurable, aspects of ACIDITY, SWEETNESS, BITTERNESS, occasional saltiness, ALCOHOLIC STRENGTH, FIZZINESS, and ASTRINGENCY. It has, further, been proposed that the definition of flavour be enlarged to include not just how a wine smells, tastes, and feels (including, for example, the burning sensation associated with particularly alcoholic wines) but also individual tasters' psychological predetermination, the all-important factor of SUBJECTIVISM including personal preferences, expectations, and ALLERGIES AND INTOLERANCES determined by individuals' cultural, regional, psychological, and physical influences. (See PHILOSOPHY AND WINE.) In this *Companion*, however, the word 'flavour' is used

interchangeably with 'aroma'. See also FLAVOUR COMPOUNDS and FLAVOUR PRECURSORS.

flavour compounds are, strictly speaking, all those substances in wines that can be smelled or tasted (see TASTING). However, the term is most often used in a narrower sense, synonymously with 'aroma compounds', to refer to those volatile molecules detected by the olfactory system. In this sense, flavour compounds are directly responsible for wine aromas and also for in-mouth aroma perceptions but not for those that are related to taste, touch, or chemesthesis (sensations felt when chemical compounds activate the trigeminal nerve—e.g. the cooling effect of menthol). Flavour compounds are also key determinants of the persistence of white-wine flavour (see LONG).

Volatile molecules in wine can be described as flavours only if they are present at concentrations above or close to their odour thresholds. Of the more than 1,000 volatile molecules found in wines, only about 80 can genuinely be considered to be wine flavours.

These flavours are present in a vast range of concentrations, from nanograms per litre (parts per trillion), typically 1–10 ng/l, to more than 100 g/l for ethanol. This wide range and the difficulty involved in analysing the most diluted compounds makes a comprehensive analysis of all relevant flavour compounds in wine complicated and expensive, requiring highly trained technicians and no less than three separate analyses using sophisticated analytical instruments.

In order to relate the flavour chemicals in wine to flavour perceptions, it is essential to understand that the olfactory system is not a chemical analyser but rather a communication system in which some messages (flavour perceptions) are associated with individual flavours, while other messages are carried out by groups of similar flavour compounds, referred to as aroma vectors. It has been estimated that the 80 wine flavour compounds can be grouped into 35 aroma vectors, which in turn can be classified into 10 aromatic categories. The most complex aroma vector is that of fruity ESTERS,

which includes up to 14 fruity-smelling ethyl esters that are responsible for the backbone of a wine's fruit flavours.

Eleven aroma vectors are by-products of fermentation, while 17 come from the grape and seven others come from oak wood or from OXIDATION. Some grape-related aroma vectors take a long time to develop because they are present in the grape as odourless FLAVOUR PRECURSORS. Some of these precursors will, after long AGEING periods, be converted into wine flavours by spontaneous, but tremendously slow, natural chemical reactions. This is one key explanation for the fact that the best wines require several years of ageing to develop their flavour fully. It also explains the subtleties of the connection between grape and wine flavours. The specific aroma of wines made from different grape varieties should be attributed not to the presence of specific aroma vectors but to the proportions of a number of vectors. Nevertheless, some aroma vectors are indeed represented more in wines from specific varieties, such as some TERPENES in wine made from Muscat, cis-rose oxide (another terpene) in Gewürztraminer, or 4-methyl-4-mercaptopentan-2-one (4MMP) in Sauvignon Blanc (see THIOLS).

The role that a particular aroma vector plays in a wine depends on its concentration and on the presence of other vectors that are 'competing' or 'potential partners'. A dominant vector which is clearly identified in the wine may be referred to as a flavour impact compound. Where an aroma compound is not dominant, it may still be identifiable or it may blend synergistically with other odours to produce a new one, usually of higher intensity. Some compounds, such as β-damascenone, are particularly notable as blenders. At normal levels (1–4 ug/l), β-damascenone acts mainly as a fruit enhancer; at higher levels (5–12 ug/l) it adds a ripe fruit character; and only at very high levels (>20 ug/l), usually found in DRIED-GRAPE WINES, it becomes an impact flavour compound.

Below are some of the most important grape-derived flavour compounds that have been identified so far.

Monoterpenes: linalool and geraniol (citrus-floral aroma) are particularly explicit in Muscat wines but add subtle floral notes to

other white varieties such as Riesling and Albariño. Cis-rose oxide (rose) is particularly noticeable in Gewürztraminer. PIPERITONE, p-menthane lactones, and neomenthyl acetate (mint) have recently been identified as key contributors to freshness in aged Bordeaux wines. ROTUNDONE (pepper) is responsible for these notes in Syrah, Graciano, Duras, and many other reds.

Carotenoid-derived (norisoprenoids): r-damascenone (ripe plum), particularly evident in wines made from sun-dried grapes such as Pedro Ximenez but ubiquitous in all wines. While d-ionone (violets) is seldom identifiable, it contributes to berry notes and has recently been shown to be significant in Pinot Noir. TDN (kerosene) is explicit in some old Rieslings but also found in most aged wines.

Polyfunctional thiols: 4-methyl-4-mercaptopentan-2-one (4MMP, box-tree, blackcurrant, passion fruit), 3-mercaptohexanol (3MH, grapefruit, passion fruit), and 3-mercaptohexyl acetate (3MHA, passion fruit, sweaty). These compounds are clearly perceptible in Sauvignon Blanc but are essential for the freshness of many other white and rosé wines and for the perception of blueberry and blackberry notes in reds.

Others: ethyl cinnamate and ethyl dihydrocinnamate (white flowers); dimethyl sulfide (truffle; but see SULFIDES); volatile phenols such as guaiacol, eugenol, and isoeugenol (spicy, carnation; but see BRETTANOMYCES); vanillins such as vanillin, acetovanillone, and methyl vanillate (vanilla, nutmeg); furaneol (sugar cotton/candyfloss); alkyl-2-methoxypyrazines (bell pepper).

flavoured wines, somewhat amorphous category of wines whose basic wine grape flavour is modified by the addition of other flavouring materials. VERMOUTH is a flavoured FORTIFIED wine, while the Greek RETSINA is perhaps the most strikingly flavoured unfortified wine.

History

Flavoured fermented fruit drinks predate pure grape wine. They were infused with herbs and spices in many ancient cultures for use as medical tonics, and resins were added to both flavour and stabilize such drinks.

Evidence of flavoured wines from the Neolithic era has been found from Asia to the Middle East. For example, in the Henan province of north-central China, pottery shards dated 6200–5600 BCE were found to contain dried residue of grape or hawthorn wine flavoured with sweet mead and bitter rice malt. Analysis has shown that a wine made in the Zagros Mountains in Iran *c.*5400–5000 BCE was preserved with terebinth (see ORIGINS OF VINICULTURE). Ancient Egyptians worshipped their god Ra with wine infused with honey, juniper, myrrh, and other aromatic herbs; complex samples have been analysed from 3150 BCE. One of the most stimulating examples of flavoured wines from a *c.*2500 BCE Iranian archaeological site was found to contain poppy, ephedra, and marijuana.

Descriptions and recipes abound in ancient texts from MESOPOTAMIA to ROME and GREECE. PLINY listed as wine flavourings virtually everything from figs and carob to artemesia. Herbs and honey not only covered off-flavours and also gave appeal to light-bodied wines (see GERMAN HISTORY). There have long been local specialities of wines flavoured with herbs, spices, flowers, or nuts.

In Europe throughout the 17th century, 'hippocras', red or white wine infused with sugar, honey, and exotic spices, was widely popular for its flavour and supposed aphrodisiac properties. The name refers to the *manicum hippocraticum* (Hippocrates' sleeve), the muslin bag through which the infused wine was strained. In south Central Europe, wine flavoured with spices imported from the east and south, and indigenous European herbs such as artemisia, evolved into the VERMOUTHS we know today.

Pliny the Elder, *Natural History*, translated by H. Rackham (1945), Book 14.

Younger, W., *Gods, Men and Wine* (1966).

Modern variations

Although high-quality modern craft VERMOUTHS can be found today, most non-fortified commercially available flavoured wines are dilute, low in alcohol, and with very fruity flavours, not unlike fizzy drinks. Such products should be distinguished from FRUIT WINES, whose alcohol derives from the sugars of the (non-grape) fruit itself.

Ford, A., *Vermouth: A Spirited Revival, with 40 Modern Cocktails* (2019). A.M.R.

flavourings are available to wine producers but are entirely illegal. Of the three sorts of flavourings used in the food and beverage industry—natural, nature-identical, and artificial—the last can be discounted because they are easily detectable, and natural and nature-identical flavourings are readily available, no more expensive, and still relatively difficult to detect. Natural and nature-identical flavourings which can add or increase the characteristics of grape varieties such as CABERNET SAUVIGNON and SAUVIGNON BLANC are available. Modern analytical techniques (see ANALYSIS) are able to detect additions at very low levels, and there have been a number of successful prosecutions. Since these flavourings are so intense, they can be effective at concentrations as low as 0.001% and the addition of, for example, 100 ml/3.6 fl oz of essence to a 100-hl/2,640-gal vat is an operation which could be performed easily and discreetly. G.T.

flavour precursors are odourless and hydrophilic forms of flavour molecules or of molecules that can eventually and spontaneously yield flavour molecules. They include GLYCOSIDES (sugar derivatives) and cysteinyl derivatives (derivatives of cysteine or GLUTATHIONE). These flavourless compounds occur naturally in grapes (and many other fruits) as products of the normal metabolic activity of the fruit, and they are both numerous and more abundant than the free FLAVOUR COMPOUNDS. Their importance to wine comes from

their ability to release and so augment, or keep constant during AGEING, the level of flavour compounds, some positive, some less so. They are essential for wine longevity as they constitute a pool of additional potential flavour molecules. Some precursors could also contribute to the persistence of flavour in the mouth, since some enzymes present in saliva can promote the release of the aroma while the wine is in the mouth.

In the case of glycosides, the release is by spontaneous HYDROLYSIS. Such hydrolysis can produce the aroma molecule directly, as with many linalool precursors (see MONOTERPENES), or can produce a molecule that is transformed by other spontaneous but slow natural chemical processes into the aroma molecule, for example β-damascenone or TDN. In these last two instances, the flavour takes much longer to be produced.

In the case of cysteinyl precursors, most of the release is carried out by YEASTS during fermentation, although they transform only a small fraction of the precursors. Most recent evidence supports the idea that the remaining precursors help, by slow spontaneous hydrolysis, to maintain a high level of the aroma molecule, which in this case is an unstable polyfunctional THIOL. V.F.

Ferreira, V., and Lopez, R., 'The actual and potential aroma of winemaking grapes', *Biomolecules*, 9/12 (2019), 818.

flavour scalping refers to the partial absorption from wine of some aroma and FLAVOUR COMPOUNDS by wine bottle CLOSURES and other types of packaging material (such as the bladders used in wine BOXES) during storage. This process mostly affects wine components that are the least soluble in water. Various flavour-scalping studies of sensorially relevant compounds in wine, some looking at changes in the same wines over several years, have shown that some compounds are not significantly scalped by any closures, while other compounds can be scalped by up to 98% depending on the closure type. The extent of absorption is a function of time in the bottle or other package and the sorptive capacity of the closure, with some

SYNTHETIC CLOSURES having a much greater sorptive capacity than natural bark CORKS or technical closures made of processed cork bark. SCREWCAPS have little or no sorptive capacity. Bottles sealed with a particular closure will exhibit little bottle-to-bottle variation in this phenomenon. Flavour scalping does not necessarily diminish wine quality since some wine components can have an unfavourable impact on wine aroma; it does not affect all wines equally and, indeed, will not affect many wines at all. M.A.S., D.J. & D.L.C.

Capone, D., et al., 'Flavour "scalping" by wine bottle closures', *Australian and New Zealand Wine Industry Journal*, 18/5 (2003), 16–20.

flétri, French term, from *flétrir*, meaning 'to wither', used to describe grapes which have been dried, or partially dried (*mi-flétri*), before fermentation to increase the sugar content. It is used most commonly in SWITZERLAND and occasionally in the Valle d'AOSTA. See also DRIED-GRAPE WINES.

fleuraison, or floraison, French terms for FLOWERING.

Fleurie, arguably the most prominent of the BEAUJOLAIS crus after MORGON. Its 827 ha/2,043 acres contain some of the region's most historically reputed LIEUX-DITS, including Poncié and Chapelle des Bois, with some soils composed of sandy pink GRANITE, but also rougher, altered granite and CLAY in spots, especially towards MOULIN-À-VENT in the north-west, where wines can be quite meaty and full-bodied. It is farmed by several of the region's most esteemed names, including Dutraive and Métras—all of which has made the wines increasingly dear. J.F.B.

Fleurieu Zone in SOUTH AUSTRALIA encompasses the regions of Currency Creek, Kangaroo Island, Langhorne Creek, McLaren Vale,

and Southern Fleurieu.

Flextank, trademarked brand of POLYETHYLENE tank. A flexitank, on the other hand, is a container used in the BULK TRANSPORT of wine.

flight, name for a series of different but related servings of wine, served in a bar or restaurant by the GLASS or as part of a TASTING. Australians tend to call them brackets.

flint, an ultra-fine-grained silica (silicon dioxide) rock found especially in association with CHALK that occurs sporadically across northern and central Europe as far east as Kazakhstan, as well as in parts of North America and South Australia. It originated on ancient sea floors as gelatinous masses of siliceous algae, which with time hardened into bands and lumps. Flint is seen today, usually as tough pebbles in the soil, in some vineyards in ENGLAND, CHAMPAGNE, and parts of the LOIRE such as SANCERRE and Pouilly-sur-Loire. Flint pebbles enhance soil DRAINAGE and, being inert, restrict nutrient availability (see VINE NUTRITION), though they can damage farm machinery.

Flint (*silex* in French) is tasteless and odourless but nevertheless is a popular metaphorical tasting term, especially for cool-climate white wines, perhaps an allusion to flint breaking to give points and edges or to the distinctive smell created by striking two pieces of flint together. That odour is due to the vaporization of polysulphane compounds arising from minuscule impurities in the flint. Use of the term 'gunflint' (*pierre à fusil*) alludes to the smell of steel sparking as it strikes the natural flint once used in firearms. A.J.M.

Maltman, A. J., 'The striking story of flint', *The World of Fine Wine*, 65 (2019), 146–53.

Floc de Gascogne is the Armagnac region's answer to the PINEAU DES CHARENTES of Cognac. This strong, sweet red and white VIN DE

LIQUEUR, awarded AOC status in 1990, is made by arresting the fermentation of local grape juice at an early stage by adding young armagnac, which in this case must have been produced by the same enterprise. The resulting liquid, of which about 17% is alcohol, is aged for at least nine months (although not necessarily in wood, as for Pineau). It is usually drunk as an aperitif but is also much used by Gascony's famously resourceful chefs.

flooding in wine regions is a common occurrence since many are located close to creeks and rivers. Boundaries for wine regions are often established based upon the drainage areas of the dominant rivers, with many vineyards planted on river terraces, on ALLUVIAL FANS, on hillsides, or alongside creeks. Flooding in wine regions can occur at any time of year with heavy winter rains the most common cause, although spring floods due to snowmelt and summer floods due to intense thunderstorms also occur in many wine regions.

The extent of flood damage in any area varies depending on the amount, intensity, duration, and area affected by precipitation. Vineyard damage from flooding occurs mostly from the physical impact of water movement, for example destruction of TRELLIS SYSTEMS, uprooting vines, or completely eroding vineyard blocks. Vineyards may also be compromised by prolonged waterlogging of the soil. Late-winter or early-spring flooding can drastically reduce the oxygen available to the vines roots, limiting their ability to take up nutrients or water and exacerbating the competition for oxygen between root and soil microorganisms. Flooding may also disrupt FLOWERING or increase disease pressure due to rain and high humidity.

Some mitigation of flood damage is possible, for example by planting above flood-prone areas, creating water pathways around vineyard blocks or installing drainage zones where water tables rise quickly. However, heavy rainfall events have become on average more intense and more frequent due to CLIMATE CHANGE, contributing to a global increase of flooding events of about 65% over the last 25 years. G.V.J.

flood irrigation. See IRRIGATION.

flor, or flor yeasts, are benevolent FILM-FORMING YEASTS which are able to form a veil (*voile* in French), velum, or film of yeast cells which floats on the surface of a wine. Flor yeasts are typified by those native to the JEREZ region of southern Spain which produce Fino and Manzanilla SHERRY. These yeasts have been assigned many names by different microbiologists over the years, including *Saccharomyces bayanus, S. beticus, S. capensis, S. cheriensis, S. fermentati, S. montuliensis*, and *S. rouxii*. However, they are now considered to be synonyms of *S. cerevisiae*.

Flor yeasts are all capable of fermenting sugar in an anaerobic phase of their metabolism. In Jerez they are the active sugar-fermenting yeast. When all fermentable sugar has been consumed, these yeasts have the capacity to switch to another metabolic phase in which they use alcohol and oxygen from the atmosphere to produce a waxy or fatty coating on the cells' exterior which permits them to float on the wine's surface. The flor yeasts begin to form as small white curds on the surface of the wine, typically in the spring after fermentation as the ambient temperature begins to rise. These increase in size until the surface is completely covered by a thin white film which gradually thickens and browns. They also produce ACETALDEHYDE and other products which characterize the aroma of film or flor sherries. This process is known as biological ageing.

Many studies have shown that these desirable yeasts will form films only in the narrow ALCOHOLIC STRENGTH range of 14.5 to 16%. Below 14.5 the usual result is VINEGAR; above 16% the yeast struggles and dies, resulting in an *oloroso* style of sherry. Film sherry cannot be made in STAINLESS STEEL tanks because the yeast uses so much alcohol that the wine becomes watery and eventually acetifies. In wooden barrels such as the BUTTS of Jerez, in the area's low-humidity cellars, there is enough preferential EVAPORATION of water through the wood that the water loss just balances the alcohol used by the yeast, the end result being sherry.

Flor yeasts have been studied in detail by Fornachon in Australia, by Niehaus in South Africa, and by CRUESS in California, all regions hospitable to the flor yeast strains and the PALOMINO grape used for sherry, and where wines similar to sherry have been produced (although see also CYPRUS).

Flor or a similar film-forming yeast has been observed on wines in many and varied parts of the world, both ancient and modern.

Flor wines are made in MONTILLA, RUEDA, and Huelva (see CONDADO DE HUELVA) in Spain and in the ALGARVE in southern Portugal, where flor is also used to make a rather crude aperitif wine. See also JURA, whose VIN JAUNE is very similar to sherry, and TOKAJI in Hungary. Similar wines are also made in ROMANIA and, by Plageoles, in GAILLAC.

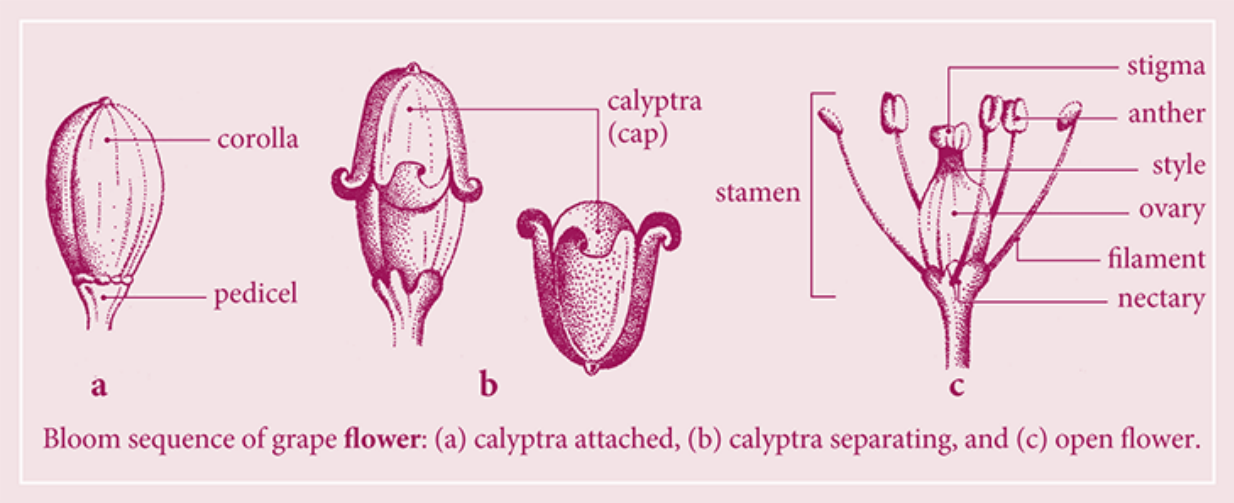
P.A.H.

Flora, CALIFORNIA aromatic white vine CROSS. Perhaps the most delicately aromatic of Dr H. P. Olmo's DAVIS creations (see also CARNELIAN, EMERALD RIESLING, RUBY CABERNET, and SYMPHONY), Flora is grown to a very limited extent in California, Australia, and New Zealand.

flotation, a technique of juice CLARIFICATION based on the tendency of grape solids to attach to rising bubbles. The solids rise to the top of a vessel, with the clear juice then removed from underneath. Gas, usually NITROGEN, is dissolved in juice under pressure, and this pressure is then released, creating very small bubbles as the gas comes out of solution. Adjuvants such as BENTONITE and proteins are usually added to improve flocculation of grape solids and bubbles. Gelatin was previously the most common protein used for the process, but vegan alternatives are increasingly common, including pea and potato proteins and fungi-derived CHITOSAN. Flotation is a faster and more energy-efficient method of juice clarification than cold settling. If air is used as the flotation gas instead of nitrogen, hyperoxidation (see OXIDATION) can be performed at the same time.

Flotation has its origins in minerals processing, but the techniques used in winery flotation are mainly from the water industry. Modern winery flotation began in Italy around 1990 with continuous wastewater-clarification-style systems with large, specialized separation tanks. Compact systems that work by recirculation of juice in a winery's existing tank and are better suited to smaller wineries have since been developed. Flotation has also been used in Australia since around 1980 as a secondary juice clarification stage after juice CENTRIFUGATION, in which case adjuvants are not as important since larger denser solids have already been removed. S.N.

flower cap of the vine is known as the CALYPTRA.



Bloom sequence of grape **flower**: (a) calyptra attached, (b) calyptra separating, and (c) open flower.

flowering, important event in the VINE GROWTH CYCLE, the process preceding the fertilization of vine flowers and their subsequent development into berries. The sequence of events includes the opening of individual flowers, with the CALYPTRA (fused cap of petals) being shed, POLLEN being liberated, and ovules becoming fertilized. Fertilization leads to BERRIES being set (see FRUIT SET), the stage following flowering.

Compared with many other plants, the vine has unattractive small green flowers, and the flowering process in the vineyard is so notably unspectacular that it is likely to be missed by the casual observer. The

vine-grower, however, is aware that this process is particularly important in the chain of events that leads up to HARVEST; with some varieties and some weather conditions, a poor flowering can mean financial disaster for the vineyard owner.

Flowering, or bloom, takes place about 6–13 weeks after BUDBREAK, the period being shorter for warm climates and early varieties. The vine flower usually contains both male parts (STAMENS) and female parts (a pistil-containing OVARY). The flowering process begins as the cap falls away, exposing the stamens. POLLINATION is the process whereby pollen grains are shed and land on the moistened stigma surface where they germinate. They then penetrate the style and fertilize the ovary, leading to fruit set and the creation of a berry. The fertilized ovaries form seeds, with up to four per berry. The wall of the flower tissue enlarges to form the SKIN and PULP of the grape berry. See diagram.

Most wine grape varieties have perfect, or hermaphroditic, flowers (that is, with well-developed and functional male and female parts). Some varieties such as CURRANT, SULTANA, and Perlette, more suitable for RAISINS and TABLE GRAPES, have non-functional or defective female parts. Berries from such varieties are typically seedless or have small, poorly developed seeds; they therefore tend to be small because of a lack of HORMONES produced by normal seeds.

Cold, wet, and windy weather at flowering has a bad effect on flowering and fruit set and—in countries such as ENGLAND where grapevines are grown at the cool limit of viticulture—is a major cause of poor YIELDS. Studies in Europe (in CHAMPAGNE, for example) have shown that regional vineyard yield can be correlated with the concentration of pollen in the lower atmosphere, which in turn can also be correlated with weather conditions. Many studies have shown that the vine flower is probably self-pollinated, with insects and wind making little contribution; even flowers surrounded by a bag tend to set perfectly (although cross-pollination between flowers is possible). However, grape flowers do release a pungent, reputedly aphrodisiac,

odour, from odour glands at the base of the pistil, which is known to attract insects. R.E.S.

Keller, M., 'Phenology and growth cycle', in *The Science of Grapevines* (3rd edn, 2020).

flowers, vine. The grapevine flower is not showy and has little attraction for birds, but it has the normal complement of sepals and petals surrounding the sexual parts: the male in the stamens and the female in the pistil. Flowers are grouped together on an inflorescence (see BUNCH). The five petals are locked together to form a cap or CALYPTRA, and at FLOWERING they fall off, usually as a unit joined at the base; this is called 'capfall', an important PHENOLOGICAL stage. Once the caps are off, the STAMENS expand to their full length and the inflorescence begins to look fluffy. A wet, glistening coating covers the stigma at the top of the pistil when it is ready to receive large numbers of POLLEN grains lodged on this surface.

Different species and varieties of grapevine have one of three types of flower. The most common, and most FRUITFUL, are those with bisexual or hermaphrodite flowers, whose pistil and stamens are both functional. Some vine varieties (such as MADELEINE ANGEVINE and MARATHEFTIKO) may have female or pistillate flowers, with a well-developed, functional pistil but with reflexed stamens which contain usually sterile pollen; with cross-pollination, using fertile pollen, these varieties become fruitful. And other varieties, particularly ROOTSTOCKS, may have male or staminate flowers (with functional stamens but no pistil) and therefore do not bear fruit. Most species of VITIS, in their native habitats, have male and female flowers on separate vines, which ensures cross-pollination and hence genetic diversity among the seedling progeny (see SEXUAL PROPAGATION). Commercial VINE VARIETIES are almost invariably bisexual and self-fruitful, and genetic diversity is avoided by VEGETATIVE PROPAGATION.

Flowering occurs in late spring when shoots have developed 17–20 visible INTERNODES. This is a crucial stage in the reproductive

development of the grape since a host of mishaps may lead to unsuccessful pollination or failure to develop into a berry (see FRUIT SET). B.G.C.

Keller, M., 'Phenology and growth cycle', in *The Science of Grapevines* (3rd edn, 2020).

flowers in vineyards may be deliberately planted at row ends or even between rows as COVER CROPS. Rose bushes at row ends are commonplace in the Médoc and, increasingly, elsewhere, either for aesthetic reasons or because they may act as early indicators of a POWDERY MILDEW attack. Flowers may also be planted between the rows as a pollen source to attract insects considered beneficial to vineyard ECOSYSTEMS.

Flurbereinigung refers to the wholesale restructuring to which most of Germany's vineyards have been subjected since the 1950s, involving improved accessibility, grading, consolidation of growers' highly fragmented holdings, and of course replanting. Without this restructuring, many vineyards would long since have been abandoned as not economically viable to till. But the process—which must be agreed to by a majority of landholders who share its costs with the state—is often contentious. Owners of vineyards marginally located or extremely difficult to access are offered the opportunity of opting out, and some vineyards have been deemed too steep and rocky to be amenable to restructuring. It is largely as a result of these two situations that ancient terraces and vines, some UNGRAFTED, remain in certain sites, especially along the SAAR and MOSEL. D.S.

flying winemakers, term coined by English wine merchant Tony LAITHWAITE for a team of young Australian winemakers he hired to work the 1987 vintage in French CO-OPERATIVE wineries. The idea was to apply Australian hard work and technological expertise to inexpensive grapes, thereby producing a unique range of wines for

his mail-order wine business. The original scheme depended on the fact that AUSTRALIA has a substantial number of highly trained winemakers (see ACADEME) who are relatively idle during HARVEST time in the northern hemisphere, where most of the world's wine is made. This sort of bought-in OENOLOGY initially worked best in areas with a considerable quantity of relatively inexpensive grapes but whose technical potential was yet to be realized. It thus excluded the classic wine regions and much of the NEW WORLD but decisively included southern France, much of Italy (especially Puglia and Sicily), and Iberia, Eastern Europe, some of the more open-minded South African wineries, and South America. The concept was such a success that it was much imitated and developed into a phenomenon with a long-term impact on winemaking techniques and wine styles all over the world (see GLOBALIZATION) in the 1990s, although the marked increase in local oenological training and skills has made the phenomenon less common.

By the late 1990s, several teams of itinerant winemakers had developed from permanent bases in both France and Britain. But in general hundreds of career flying winemakers have been replaced by much smaller numbers of recent oenology graduates who combine travelling with work experience in cellars and vineyards around the world before finding their vocational location or returning home. INFORMATION TECHNOLOGY has enabled virtual winemaking from a distance of several time zones and many thousands of miles. By the 21st century, the winemaker who had only ever made wine in a single location was almost the exception.

flysch, Alpine sedimentary rocks, typically a disordered combination of SANDSTONE and SHALE, formed under the sea from the detritus of the infant Alps as they rose rapidly and were vigorously eroded. Soils derived from flysch are quite varied, with some coarse and gravelly, some sandy, and some that are quite CALCAREOUS (see MARL), and they go by a host of different local names such as *opok*, *opoka*, *opoc*, *poca*, or *ponca*.

Foch, common North American name for the MARÉCHAL FOCH vine.

Fogoneu, minor red wine grape of the BALEARIC ISLANDS of Mallorca, where it is usually blended with CALLET and MANTO NEGRO, and Formentera.

foil, alternative name for the CAPSULE which covers the cork and neck of a wine bottle. The term is most commonly used for bottles of sparkling wine because in this case it is almost invariably made of metal foil, whereas the 'foil' covering tops of bottles of still wine may be made from a wide range of materials. Traditionally LEAD or lead alloys were used, but in Europe these were found to be a major source of soil contamination in disposal sites, and lead contamination of wine was traced to this source, so the use of lead foils has been phased out and was prohibited in the US and the EU in 1993. Older bottles with lead foils should be wiped carefully around the bottleneck between pulling the cork and serving. Various plastics, tin, and aluminium are also used. Of the two most common types, one is made from polyvinyl chloride (PVC) with an aluminium top and is heat-shrunk on to the bottle (alternatives made from more environmentally friendly polyethylene terephthalate (PET) are also available); the other is a polylaminate consisting of layers of polyethylene and aluminium which is spun into place. The foil is there largely for aesthetic reasons, since the CLOSURE should provide an airtight seal, and only a faulty one will allow any seepage of wine. The length and design of a foil is another purely aesthetic matter, although some clear identification on the top of the foil can be very useful in a CELLAR full of bottles on wine racks. In an effort to minimize packaging and waste, some producers have simply abandoned the foil, although within the EU this is not an option for those who make sparkling wines. Others have rediscovered the wax seal, which is thought to protect the cork and reduce the risk of seepage or oxygen ingress, as well as having aesthetic appeal.

foil cutter, gadget for SERVING wine which helps cut the FOIL neatly just below the lip of the bottle, with the twin advantages of avoiding unsightly and possibly dangerous torn metal edges and ensuring no likelihood of the wine's being poured over a foil which might taint it. Some foil cutters are blades incorporated into CORKSCREWS; others are separate prongs with small circular blades which cut the foil when rotated. Life without a foil cutter is quite feasible; living without one after being introduced to it is not.

Folgasão, vine of disputed origin producing promising whites from 41 ha/101 acres in 2020, mainly in Terras de Cister in northern Portugal.

Folle Blanche, white grape variety, a natural GOUAIS BLANC progeny, once grown in profusion along the Atlantic seaboard of western France, providing very acidic but otherwise neutral base wine for distillation by the largely DUTCH WINE TRADE. It never regained its position after PHYLLOXERA ravaged the vineyards of Europe in the late 19th century, and France's total plantings of Folle Blanche continue to decline: from 12,104 ha/29,910 acres in 1968 to 945 ha/2,335 acres in 2019, mainly for GROS PLANT production. It has also been grown to a very limited extent in California and possibly in northern Spain.

Folle Noire, occasional synonym for various French dark-berried grape varieties including JURANÇON and Fuella Nera. Unrelated to FOLLE BLANCHE. See BELLET.

Fondillón, strong, semi-sweet RANCIO wine from ALICANTE made from overripened dark-skinned MONASTRELL grapes and matured like an *oloroso* SHERRY. The wine is not fortified but naturally achieves 16% minimum alcohol; it is allowed a maximum 45 g/l RESIDUAL

SUGAR. Both SOLERA and static ageing are performed, with a minimum mean age of 10 years. F.C.

Fonseca, common Portuguese surname associated with two important but unrelated wine producers in PORTUGAL.

Fonseca is a highly respected PORT shipper, now part of the FLADGATE PARTNERSHIP. It was founded by the Fonseca and Monteiro families in 1815 and acquired by Manoel Pedro Guimaraens in 1863. With the exception of the 1955 produced by Dorothy Guimaraens, every single Fonseca vintage port between 1896 and 1991 was made either by Frank Guimaraens or his great-nephew Bruce. Bruce's son, Australian-trained fifth-generation David Guimaraens, continues the good work. Fonseca Guimaraens, as it was then known, was acquired by Taylor, Fladgate, and Yeatman in 1949, but the two houses maintain separate identities and styles of port within the group now known as the Fladgate Partnership, under which entry more detail can be found.

José Maria da Fonseca is a family company based in the south of the country at Azeitão in Arrábida on the SETÚBAL peninsula. Originally a producer of rich, fortified Setúbal, it is now more important as a producer of a wide range of unfortified Portuguese wines, notably under the name Periquita, designed for the international market.

food, wine as. See DIET.

food-and-wine matching may be an extremely complex, detailed subject, a set of rules embedded in one's national culture, or an activity only for gastro-bores, according to one's point of view.

For some of the most fanatical wine enthusiasts, food is an obstacle between palate and wine glass, whose flavours can get in the way of a decent wine-tasting session. For others, food without wine and wine without food is inconceivable, and the whole is greater than the sum of the parts.

It is perfectly physically possible to drink any sort of wine with any sort of food. But as anyone who has brushed their teeth with toothpaste and directly afterwards taken a sip of wine will attest, specific FLAVOUR COMPOUNDS can have a profound effect on each other and our perception of them. It is also recognized that certain foods have very specific effects on wine.

The following should be read in conjunction with the article on TASTING.

Traditional approaches are based on the premise that food-and-wine matching is an art, not a science, and can be broadly traced back to three roots.

French *gastronomie* led the way in establishing conscious and specific choices for food-and-wine pairings, particularly with the birth of *haute cuisine*. Escoffier, the highly influential French chef born in the mid 19th century, could be described as the father of food-and-wine pairing, but it was French-born wine merchant, gourmet, and prolific author André SIMON who turned it into a pursuit, famously saying, 'Food without wine is a corpse; wine without food is a ghost. United and well matched, they are as body and soul: living partners.'

Some regions, especially in Europe, have deeply entwined relationships between their local culinary traditions and their locally produced wines which have been embedded in the culture for centuries. This has informed a 'local wine with local food' mantra that inspires pairings such as Loire goat's cheese with Pouilly-Fumé, or lamb chops with rioja.

Two other old and long-held adages, 'white wine with fish and red wine with meat' and (attributed to British wine merchants) 'buy on apple, sell on cheese', formed the foundation for wine-pairing 'rules' which governed thinking for much of the 20th century. The first was based on a valid principle of matching the weight, power, and flavour intensity of the food with the weight, power, and intensity of the wine; however, it is a generalization that ignores many other factors. The second was also based on sound fact: that sweet, high-acid foods can make wine taste thin and tart, while oily, salty foods such

as cheese coat the mouth and can flatter or even mask tartness or thinness in a wine.

But, as Hanni points out, wine-and-food matching is an ongoing process of sensory adaptation. If a sensory message to the brain is constantly repeated (such as the taste of sourness in food), then it will suppress our sensitivity to the source of stimulation, making the wine that follows taste less sour.

Current interest in food-and-wine pairings can probably be traced to the United States, where it became a subject of intense scrutiny in the 1980s as wine producers, under pressure from so-called neo-Prohibitionists, sought to distance wine from drinks consumed principally for their alcohol content by putting it firmly on the dining table. The increasingly important role of professional SOMMELIER has contributed to a certain reverence for the subject. It has also led to a reactionary school of thought which insists that there is no such thing as food-and-wine matching—that you can and should drink any wine with any food, and the only thing that matters is that the wine suits your mood and your preferences.

One of the biggest changes over the last three decades has been a surge in wine-related scientific research in how we taste and smell and in the molecules and compounds that create flavours and TEXTURES. Spearheaded by neuroscientists such as Gordon M. Shepherd, bioengineers and food chemists such as Bernard Lahouisse and François Benzi, sommeliers such as François Chartier and the late Juli Soler, and chefs such as Ferran Adrià and Heston Blumenthal, the art of food-and-wine pairing has turned into a science.

Although it has long been known that there are certain foods which have very specific effects on wine, scientists are discovering that there are others which stimulate physiological and chemical changes in the sensory receptors of the mouth and the brain and change the way we perceive flavour and texture. For example, chemical compounds such as capsaicin in chilli and allicin in raw garlic stimulate the receptors in our mouth that detect heat and pain, which is why chilli and raw garlic ‘burn’. When these receptors are activated, wine feels colder, tannins feel more ASTRINGENT, and we are less able

to perceive fruit in wine. Sweetness and carbon-dioxide bubbles provide sensory distraction from the pain, which is why sparkling wines and off-dry wines are often recommended as good companions for spicy food.

Research also shows that flavour molecules are subject to synthetic processing—in other words, they interact with each other. Not only are there synergies and reactions between flavour molecules that can result in a totally different flavours, but the matrix of water, air, alcohol, fat, and protein through which we taste and process them by chewing, sipping, and swallowing profoundly affects perception, as does temperature. Aromas and other matrix molecules work like building blocks – they can enhance, amplify, transform, depress or cancel out other aromatic molecules. All this points to evidence that bringing food and wine together in the mouth, or even consuming them one after another, can trigger changes in flavour, texture, and perception that can alter the overall tasting experience. This helps us to understand why some combinations are so much better or worse than others. Ongoing studies by Lahousse, Coucquyt, and Chartier, among others, are exploring the synergies of flavour compounds not only to understand the science behind why classic pairings such as Cabernet Sauvignon with lamb work so well but also to create new, creative pairings by linking foods and wines that contain the same or similar molecular compound components and therefore result in flavour tonality when put together. For example, the nutty-, caramel-, curry-smelling SOTOLON found in VIN JAUNE, SHERRY, and SAUTERNES is also in fenugreek seeds (used in many curries), soy sauce, dried mushrooms, and maple syrup. Chartier suggests pairing curry with Sauternes.

Perfect matches, however, are unlikely for several reasons. We all have individual odour-perception thresholds, and studies show that of our 400 olfactory receptors, approximately one-third of them differ from person to person. In addition, our gender, age, state of health, and cultural conditioning also affect the way we taste. One person’s perfect pairing may not suit the next person. More recently, scientists and psychologists have become interested in our multisensory

experience of tasting, some suggesting that how well a dish goes with a wine might be as much affected by our senses of hearing, touch, and sight as by taste and smell. Playing different music, for example, may affect the way we experience how well a wine goes with a meal.

When it comes to specific combinations of food and wine, as well as general guidelines, it is useful to be aware of what Moore refers to as 'game-changer' ingredients. As well as chilli and garlic mentioned above, she includes lemon and vinegar for their piercing acidity, which can distort the taste of low-acid wines. If vinegar or lemon dominate the dish, choose a wine with high acidity. Herbs and spices can also alter the synergy of an ingredient or a dish with wine, depending on the intensity of the herb/spice and the amount used in a dish. Eugenol in cinnamon, clove, and nutmeg; piperine in black pepper; zingerone in ginger; allyl isothiocyanate in mustard, wasabi and horseradish; and sanshool in Sichuan pepper all stimulate the trigeminal nerve one way or another and in high-enough concentration may affect the perception of wine drunk at the same time.

Globe artichokes contain a substance called cynarin which is thought to inhibit the sweet receptors of the mouth. A mouthful of liquid such as water or wine removes the inhibition and makes the liquid taste metallically sweet. Suggested pairings are white wines with some astringency (such as SKIN-FERMENTED or ORANGE WINES) or bitterness.

A broad framework for food-and-wine pairing is more useful than rules or specifics. In fact, many clichéd wine–food suggestions are unhelpful. For example, a recommended pairing of Gewürztraminer with Asian food ignores the staggering breadth of Asian cuisine – and surely stems from the linguistic, not gastronomic, fact that Gewürz means 'spice'. However, a few simple principles can be relied on, as follows.

Salt reduces the impact of acidity, so salty food tends to be better with high-acid wines than low-acid wines.

Salt accentuates the flavours in sweet things (e.g. salted caramel), so salty foods such a cheeses can be very good with sweet wines.

Acidity in food has the impact of making a wine taste less acidic, so pairing a high-acid dish with a low-acid wine, even a balanced one, can make the wine taste flabby and flat. High-acid wines are best with foods strongly influenced by vinegar or sharp citrus.

Sweet food can make wines taste bitter and sour. Pair sweet foods with a wine that is a little sweeter than the food. Savoury dishes with a touch of sweetness, such as Moroccan pastilla, are often best paired with off-dry wines such as a Kabinett Riesling.

Humans are more sensitive to bitterness than to any other taste, and it is thought that there are five or six different types of bitter. Very bitter foods, such as chicory or some olive oils, can make a smooth, fruity wine taste too sweet. But in the kitchen, bitter ingredients are often balanced out in a dish by acidity, sweetness, fat or salt—so the same principle can be applied by pairing a primarily bitter dish with wines that are either bitter themselves (Italian wines often have bitterness), acidic, salty (such as coastal-vineyard Albariño), a little sweet (off-dry Riesling), or richly textured from lees or tannins.

Umami, that deeply savoury taste found in ingredients such as parmesan, yeast, soy sauce, dashi, anchovies, and tomatoes, tends to be complemented by sweetness, bright flavours, acidity, bitterness, and more umami—think of how well a rich, sweet, acidic tomato sauce goes with fresh basil, olives, capers, and chicken or meatballs. Umami therefore goes well with many wine styles: fruity, acidic, herbal, bitter, dry, savoury or sweet.

There is a theory that fat is the sixth sense of taste, and it is understood that we taste wine differently when paired with fatty foods. But fat is complicated because fatty foods not only activate the fatty-acid receptors on our tongues but also usually come with salt or sweetness (activating those receptors), plus they have the textural impact of coating our mouths. In addition, there are flavour compounds that are more fat-soluble, so fat can change the flavour

of a wine in our mouths. It is widely accepted that fatty foods are best paired with wines that have good acidity or texture (tannins).

A final rule of thumb is the use of bridging ingredients. Roast lamb with a tart, green sauce of lemon and fresh herbs would be fine with an ASSYRTIKO instead of a red wine. Salmon rubbed with Creole spices and grilled could be served with a fruity Merlot; poaching it and dressing it with hollandaise sauce and paired white burgundy would be perfect; and salmon yakitori calls for a fruity Pinot Noir or a fino sherry. foot treading, traditional method of CRUSHING only rarely found outside Portugal's DOURO Valley, where it is still used for the production of some of the finest ports. CHAPOUTIER of Hermitage and some BURGUNDY producers also use feet for breaking up the CAP of their top red unfortified wines.

Forastera, simple white wine grape from the island of ISCHIA near Naples.

Forcallat Tinta, blending grape grown on 360 ha/890 acres of CASTILLA-LA MANCHA, VALENCIA, and Murcia, making curious-smelling, light-coloured red wine.

forests, by supplying wood of a certain sort, have an important impact on the character and flavour of wine made using COOPERAGE made from that wood. See WOOD TYPES and OAK.

Forez, Côtes du. A range of GRANITIC and VOLCANIC hills between the upper reaches of the Loire River and Lyons in eastern France give their name to light, vigorous red and rosé wines made, like BEAUJOLAIS, from the GAMAY grape. The wines, designed for early drinking, may taste reminiscent of those of the Côte ROANNAISE to the north, although the region's higher elevation makes for a slightly less dependable climate. Full AOC status was granted to Côtes du Forez in 2000. Wines made outside the AOC regulations can take the IGP Urfé. Plantings had fallen to below 100 ha/250 acres by the early 2010s, but a new generation of winegrowers brought it up to 150 ha by 2020.

fortification, the practice of adding spirits, usually grape spirit, to wine to ensure microbiological stability, thereby adding ALCOHOLIC STRENGTH and precluding any further FERMENTATION.

The principle behind this addition of alcohol is that most BACTERIA and strains of YEAST are rendered impotent, unable to react with sugar or other wine constituents, in solutions containing more than 16–18% alcohol, depending on the strain of yeast.

The stage at which spirit is added has enormous implications for the style of fortified wine produced. The earlier it is added in the fermentation process, the sweeter the resulting wine will be. VINS DE LIQUEUR such as PINEAU DES CHARENTES, for example, are simply blends of sweet, unfermented, or hardly fermented grape juice with grape

spirit, known as *mistelles* in France (see MISTELA). An even stronger charge of alcohol is added before fermentation to a significant proportion of the rich grape juice used in the production of Australia's TOPAQUE AND MUSCAT. For most port-style wines (including the sweeter styles of MADEIRA) and for all VINS DOUX NATURELS, fortification takes place during fermentation. Much of the natural grape sugar is retained by arresting fermentation before its completion, thereby boosting alcoholic strength to a pre-ordained level: usually 18–20% in PORT but 15–16% in most vins doux naturels. In the making of SHERRY, similar wines such as MONTILLA, and the drier styles of MADEIRA, spirit is added to dry, fully fermented wine only at the end of fermentation. Any sweetness in such wines is usually due to a pre-bottling addition of sweetening agent, often itself a mixture of grape juice and spirit (see MISTELA, PX).

The spirit used for fortification comes from a variety of sources and could be based on grapes, sugar beet, cane sugar, agricultural by-products or even petroleum. Local regulations specify the types of spirit allowed for a given fortified wine, and only grape spirit is allowed for fortified wines of any quality. Carbon dating usefully allows the immediate detection of petroleum-based spirit in any wine, however.

The method of DISTILLATION of the spirit plays a part possibly even more important than its source. The most neutral spirits are the products of a continuous still, which contain a minimum of flavour congeners (the impurities which contribute to the character of a spirit) and tend to be used in the fortification of wines that are designed for early consumption and deliberately exhibit the characteristics of the base wine (the MUSCATS of southern France, for example). Spirits produced by pot-still distillation on the other hand are much more violently flavoured and are rarely used to fortify wines. A.D.W. & J.E.H.

fortified wines are those which have been subject to FORTIFICATION and therefore include SHERRY, PORT, MADEIRA, VERMOUTH,

MÁLAGA, MONTILLA-MORILES, MARSALA, TOPAQUE AND MUSCAT, VINS DOUX NATURELS, and several strictly local specialities. Liquids such as VINS DE LIQUEUR (see also MISTELA) made by adding spirit to grape juice rather than wine are not, strictly, fortified wines. Practically all warm wine regions (see AUSTRALIA, CALIFORNIA, CYPRUS, and SOUTH AFRICA, for example) make some sort of fortified wine, often in the image of port and sherry even if they are not allowed to use those protected names within Europe. It is an almost invariable rule that anywhere hot enough to produce good fortified wine is too hot to provide the ideal climate for its consumption. See also LIQUEUR WINE.

Fort Ross-Seaview, California AVA in the Sonoma Coastal Mountains. See SONOMA.

foudre, French for FUDER, commonly encountered in ALSACE.

Foundation Plant Services (FPS), a self-supporting service department of the University of California at DAVIS which produces, tests, maintains, and distributes disease-tested plant propagation material. It also provides plant importation, quarantine, and testing services.

fourth growth. See the CLASSIFICATION of Bordeaux.

foxy, usually pejorative tasting term for the highly distinctive flavour of many wines, particularly red wines, made from AMERICAN VINES and AMERICAN HYBRIDS, vine varieties developed from both American and European species of the VITIS genus, particularly *Vitis labrusca*. (Wines made from many other hybrids—SEYVAL and NORTON, for example—are completely free of foxiness.) The CONCORD grape, widely planted in NEW YORK State, is one of the most heavily scented, reeking of something closer to animal fur than fruit, flowers, or any

other aroma associated with fine wine, although the candy-like aroma is, incidentally, quite close to that of the tiny wild strawberry or *fraise des bois*. The compound chiefly responsibe for this aroma in NIAGARA grapes is 2-aminoacetophenone, while methyl anthranilate does the job in Concords. Earlier harvesting or long CASK AGEING reduces some of Concord's foxy characteristics. H.L. & B.G.C.

fractional blending, prosaic English name for the labour-intensive SOLERA system of maintaining consistency of a blended wine, particularly SHERRY, over many years.

franc de pied, French for UNGRAFTED.

France , the country that produces more fine wine than any other, and in which wine is so firmly embedded in the culture that such French people as are interested in wine have a quasi-spiritual relationship with it. In 2021, France held on to its claim of largest wine consumer in the EU (and second largest in the world, after the United States), although per capita wine consumption has fallen, from over 100 l a year in 1977 to under 50 l by the early 21st century, thanks to social changes and increased restrictions on advertising alcohol and on drunk driving. By the end of the 20th century, France's wine export market was also facing stiff competition from other wine-producing countries, although while third in export volume worldwide in 2021, it remains number one in terms of value, pulling in a record high of €15.5 billion according to FEVS, the Federation of French Wine and Spirits Exporters.

France is second only to Spain in land under vine, although the total area planted with vines has shrunk considerably since the late 1970s (see EU and its VINE-PULL SCHEME) down from 1.23 million ha/3.04 million acres to just under 800,000 ha (including vines dedicated to brandies and TABLE GRAPES) by the early 2010s, where it has held fairly steady since. Average annual wine production fell from

65 million hl in the late 1980s to under 50 million hl in the 2010s; in 2021, total production was 37.6 million hl, although that particular year was one of the smallest harvests since 2000, 14% lower than its previous five-year average.

There are few wine producers anywhere who would not freely admit that they have been influenced by the great wines of BORDEAUX, BURGUNDY, CHAMPAGNE, or the RHÔNE (see map). Other qualitatively significant wine regions, perhaps better appreciated within France than abroad, include ALSACE (for historical details of which see GERMAN HISTORY), BEAUJOLAIS, CHABLIS, JURA, LOIRE, PROVENCE, SAVOIE, and SOUTH WEST FRANCE. France's most important wine region by far in terms of quantity has long been the LANGUEDOC, plus ROUSSILLON to the immediate south, but vine-pull schemes have shrunk the regions' vineyard area and much improved the average quality of wine produced there. The Mediterranean island of CORSICA is also under French jurisdiction, although it shares many characteristics with the Italian island of SARDINIA.

Although the first instance of geographical DELIMITATION was in Portugal's DOURO Valley, France is the birthplace of the widespread application of the notion that geography, or TERROIR, is fundamental in shaping the character and quality of a wine. This resulted in the early 20th century in the much-copied AOC, or *Appellation Contrôlée* system. Its governing body is INAO. AOC wines are sold under the geographical name of the appellation rather than by vine variety, in contrast to the substantially VARIETAL wines of the NEW WORLD. AOC wines, considered within the EU's PDO category, represent an increasing proportion of all French wines, about 58% by 2018; IGPs make up another 34%. The rest is either distilled into cognac, armagnac, or other brandies or sold as VIN DE FRANCE. This category, created in 2009, includes very basic wines as well as an increasing number of high-quality wines deliberately made outside the restrictions of AOC and IGP rules. This is also the fate of wines rejected by AOC tasting panels.

Curiously, and perhaps because wine is so deeply entrenched in French history and culture, wine CONNOISSEURSHIP and to a certain extent the wine TRADE are not as evolved in France as, for example, in Australia, Belgium, Great Britain, Switzerland, and the United States. Although things are slowly changing, the average French citizen has bought and drunk little other than the wine produced closest to him or her, whether geographically or by virtue of family or friendship. This has tended to stifle the development of wine retailing, although the number of specialist wine MERCHANTS, known here as *cavistes*, has increased significantly since the early 1980s. As might be expected in a country associated with so many forms of gastronomic excellence, wine appreciation in France is closely tethered to the table. Wine is rarely drunk without food, and France's chefs and SOMMELIERS have been regarded as the rightful repositories of wine knowledge.

Although France is the world's principal wine exporter, it is also a major wine importer. Wine has been imported ever since Massilia was settled by the Greeks (see below), but it was the development of the Languedoc as a virtual factory for particularly light red wines at the end of the 19th and the beginning of the 20th centuries that meant vast quantities of strong, deep-coloured red wines had to be imported for BLENDING, from North African colonies initially and subsequently from southern Italy and Spain.

France is so important as a role model to the world of wine that many terms used internationally are French in origin (BLANC DE BLANCS and VERAISON are just two examples). France is recognized the world over as a centre of wine research and ACADEME and has benefited ever since the time of Colbert in the late 17th century from the country's ability to identify and solve potential problems on a national level (see OAK). The OENOLOGICAL and viticultural faculties of the universities of BORDEAUX and MONTPELLIER have long enjoyed international prestige, and considerable viticultural research emanates from INRAE stations.

One of France's great commercial strengths in recent years has been that it is the world's prime source of oak for top-quality wine and brandy COOPERAGE. France is the world's leading exporter of wine BARRELS.

History

Around 600 BCE, Greek immigrants arrived from Phocaea in ANATOLIA and founded Massalia (Marseilles) as a Greek city (see ancient GREECE). One of the colonists' importations was viticulture, although in 2013 Patrick McGovern found evidence that they were probably preceded by Etruscans (see ORIGINS OF VINICULTURE). In the 2nd century BCE, the settlement, now known as Massilia, had become vital to the Romans, by then a major power (see ancient ROME), if they were to safeguard their trading route with Saguntum (modern Sagunto, near Valencia in Spain). When Massilia was attacked first by the Ligurians and then by the Celtic tribes of the Allobroges and the Arverni (of modern AUVERGNE), self-interest made the Romans take on the defence of the city. As a result they gained a new province, named at first Provincia (modern PROVENCE) and later, with the foundation of the Roman city of Narbo (modern Narbonne) in 118 BCE, Gallia Narbonensis. Massilia remained Greek until 49 BCE.

In the eyes of the Greek colonists, vines grew where olives and figs grew: the commercial exploitation of the three together had long been characteristic of Mediterranean agriculture, so it did not occur to a Mediterranean people that the vine could be cultivated further north than the olive and the fig. The wines of Massilia were available in Rome, but they were cheap and nasty. Even before Caesar's conquest of Gaul in 51 BCE, the Gauls had consumed Italian wine in prodigious quantities, as the evidence from AMPHORAE found in France shows. The Greek geographer Strabo, who finished his *Geography* in 7 BCE, said that Massilia and Narbo produced the same fruits as Italy but that the rest of Gaul was too far north for the olive, the fig, and the vine (4. 2. 1). His statement may have been too sweeping, however, and in the 1st century CE good wine certainly did come from Gaul. PLINY tells us in his *Natural History* that in Vienna (modern Vienne in the RHÔNE Valley) the Allobroges produced RESINATED WINES which were a source of national pride and for which they charged high prices (14. 57). For more details, see GAUL.

Thus the first French wine of note was a Rhône wine. Yet at the same time or earlier the inhabitants of Gallia Narbonensis may themselves have taken the vine beyond the familiar territory of the olive and the fig, to GAILLAC in modern SOUTH WEST FRANCE. Archaeological evidence shows that in the second half of the reign of the Emperor Augustus (he was Imperator from 27 BCE to 14 CE), amphorae were being made in large numbers in workshops near Gaillac and near Béziers in the LANGUEDOC. This suggests that they were needed for wine that was grown there and not imported. The RIVERS Tarn and GARONNE would have provided convenient transport to the Atlantic coast, where BORDEAUX was already a trading post. Since these wines are not mentioned by any classical author, they probably did not reach Rome, unlike the wines of Vienne.

Gaillac and Vienne are beyond the northern limit for olive trees, but they do sustain another tree that is considered characteristic of Mediterranean vegetation: the evergreen oak, QUERCUS *ilex*. Where the evergreen oak grows, the climate is hot enough to produce a good grape harvest every year without fail. Yet viticulture advanced further north, away from the evergreen oak, to where the success of the vintage was no longer guaranteed. Bordeaux and BURGUNDY were next in line; by the 3rd century CE, wine was grown in both regions, despite the possibility of cold, wet summers when the grapes might not ripen fully. Yet even if the harvest failed occasionally, the demand for wine was such that the expansion of viticulture made economic sense.

The Romans had regarded the CELTS as drunks and, hence, a source of great profit—immoderate fools who drank wine unmixed with water until they fell into a stupor. But when the drunken Celts started growing their own wine, its reputation was soon to surpass that of the Italian wines that they had once imported. After Bordeaux and Burgundy came the LOIRE and the Île-de-France (the PARIS basin including CHAMPAGNE). By the 6th century CE, even the west of BRITTANY had vines, and wine was grown further north than it is now, well north of Paris.

As the Roman Empire disintegrated, Gaul ceased to be a Roman province and was overrun by Germanic invaders. The Visigoths, the Burgundians, and the Franks established kingdoms in Gaul; eventually, Aquitaine and Burgundy were subjected to Frankish rule. Under the Romans, the Gauls had been governed from the south; the Franks had come from the north, and Clovis, the first of the Merovingian kings (481–511), established Paris as the capital city of a kingdom that hardly extended further than the Île-de-France. Under CHARLEMAGNE and his heirs, the royal court's principal seats were Aachen (Aix-la-Chapelle) and Paris. Hence political power, and the wealth that went with it, were concentrated in the north. In the Mediterranean, wine was part of everyday life, but in Paris and Aachen, on the northernmost limits of viticulture, wine was a luxury item, and from a luxury item it became a status symbol. Also, because Gaul was largely Christian by the 6th century, the Church's requirements added impetus to northern viticulture (see EUCHARIST). Monasteries and churches needed wine; local magnates, both lay and spiritual, wanted good wine.

McGovern, P. E., 'The beginning of viniculture in France', *The Proceedings of the National Academy of Sciences USA*, 110/25 (2013), 10147–52.

Monastic influence

Monasteries had their own vineyards (see MONKS AND MONASTERIES and BURGUNDY), and so, often, did cathedrals. From the Carolingian era onwards, lay viticulture generally used the system of 'complant', which meant that a winegrower would approach an owner of uncultivated land with an offer to plant it. Since it takes about five years for new vines to start yielding a decent quantity of fruit, the grower would be given that length of time to work the vineyard; after that, half the land would revert to the owner, while the vines on the other half would become the possession of the grower, on condition that part of the harvest, or sometimes a monetary payment, be given every year in perpetuity. The Loire wine QUARTS DE CHAUME, for instance, owes its name to the complant mode of ownership and production: the *quart*, or fourth, refers to the share the vigneron owed the landowner (in 1440, the Abbey of Ronceray d'Angers); and *chaume* refers to an uncultivated plot that is to be planted with vines. As labour grew more expensive, the conditions became more favourable to the grower: in the course of the 13th century, the owner would often no longer reclaim half of the property, but the grower, and the grower's children and children's children after, would continue to make their annual payments in wine or money. The system made it possible for wild country to be colonized and cultivated at no expense to the landowner: in this way, the new winegrowing region of Poitou (see LA ROCHELLE) was planted so efficiently in the 12th and 13th centuries. The advantage to growers was that they were not serfs, tied to the land, but free, entitled to a large share of what they produced. It was therefore in their interest to make wine for which they could get a good price; nevertheless the owner exercised ultimate control, for the decisions of how and with what grapes to plant the vineyard was the owner's, as was the right to terminate the contract and evict the vigneron if the wine was not good enough.

In the Middle Ages, wine was France's chief export product, and the reasons why certain nations drink some wines in preference to

others go back to this period. The English drink CLARET because BORDEAUX was at one time governed by the English crown and later remained the largest supplier of wine to England. The Scots drink claret because of the Auld Alliance with France against England. The Flemish and the Dutch have traditionally bought wines of Burgundy because Flanders and the southern part of the Netherlands were part of the dukedom of Burgundy and Burgundy's trade routes were mostly overland to the north. But transporting wooden BARRELS of wine along bumpy roads was difficult and expensive: whether a region exported a large share of its wine or produced wine mainly for its own consumption depended on its proximity to navigable RIVERS rather than on the quality of its wines. Apart from its trade with the north, which did not develop until the 15th century, Burgundy did not export much wine, whereas regions accessible by water, such as the LOIRE, the Île-de-France around PARIS, and GASCONY, did. The chief ports were LA ROCHELLE, Rouen, and Bordeaux respectively, with Bordeaux serving both the Bordeaux area and the HAUT-PAYS.

The ships used to transport wine before the 12th century were longboats like the Viking ships. But in the 12th century, the new ports of La Rochelle and Gravelines (on the English Channel near St-Omer), as well as the new Flemish ports of Nieuwpoort (near Ypres) and Damme (near Bruges), adopted a new type of ship, the cog. The cog was a broadly built ship, with a roundish prow and stern, more manœuvrable than the old kind and specifically designed for carrying freight. Its capacity was far larger than that of the old longboat, and soon all other ports started using it as a more efficient way of transporting wine. The cog doubled up as a warship if need arose.

The unit in which wine was measured, the TONNEAU, derived from Bordeaux. A tonneau, or wooden barrel, could hold 252 old wine gallons, or 900 l/238 US gal. A Paris tonneau was 800 l, but, because of the prominence of Gascon merchants in London and English merchants in Bordeaux, the Bordeaux measure became the standard. Many cogs could hold as many as 200 tonneaux; in practice, a barrel containing 900 l was too heavy to handle, and casks half or one-quarter the size were used. Such was the importance of the medieval

wine trade that—from being the space occupied by a tun of wine—a tonneau, or ton in English, became the unit used for measuring the carrying capacity of any ship, whatever its load. H.M.W.

Modern history

The social turmoil of the French Revolution at the end of the 18th century made few important changes to the patterns of wine production (although it did engender an entirely new class of consumers and new styles of *restauration* for them). Until the middle of the 19th century, the vine was cultivated much more widely in France than it is today, and such now-abandoned areas as, for example, the Côtes d'AUVERGNE on the Massif Central, Paris, and the MOSELLE were flourishing wine regions. As communications improved, the patterns of the wine trade changed, although Bordeaux continued to operate with a certain degree of autonomy, thanks to its geographical position and long-established trading links with northern Europe, first ENGLAND and then the DUTCH WINE TRADE. The 17th and 18th centuries saw an explosion of interest in wine production in the Gironde, and by the mid 19th century, when the world's most famous wine CLASSIFICATION was formalized at a magnificent exhibition in Paris, the great CHÂTEAUX of the MÉDOC were enjoying a period of prosperity that would not be rivalled until the 1980s. Wine continued to be important to the Burgundian economy, and French wine was recognized throughout the civilized world as one of the cornerstones of civilization itself. CHAPTAL had devised ways of improving overall wine quality (for ADULTERATION AND FRAUD was rife in the immediate aftermath of the Revolution), and France was beginning to produce its own wine experts such as the widely travelled and independently minded JULLIEN. A historian might say that a catastrophe to end this golden age was inevitable.

In fact there was a series of catastrophes, all viticultural, which had devastating effects on both the quantity and quality of wine produced. Oidium, or POWDERY MILDEW, was the first of a succession of disastrous imports from North America, presumably the result of the 19th-century passion for collecting botanical specimens. Unlike European vines, most American vines are resistant to this FUNGAL DISEASE, and so it was not until it had been imported to Europe that

its effects—of reducing quantity, quality, and colour—were noted, in 1852. The 1854 vintage in France was the smallest for more than 60 years. French vineyards were just returning to health, thanks to the development of SULFUR dusting, when another curious vine condition was noted: inexplicable debilitation and, eventually, death. The cause was a tiny aphid-like insect, PHYLLOXERA, which was to ravage the vineyards of the world but affected southern France first, causing the greatest commercial havoc there while a remedy was sought. Since phylloxera affects only the roots of vines, the only effective solution was eventually found to be to graft European vines on to resistant American ROOTSTOCKS. But the renewed importation of North American plant material seems to have brought with it two more deadly American fungal diseases: DOWNY MILDEW, whose effects on wine quality and quantity were first noted in 1878 and lasted until well into the 20th century; and BLACK ROT, which was evident from the mid 1880s.

It is hardly surprising therefore that French vignerons saw their salvation in planting HYBRIDS, vines with at least some genes from AMERICAN VINE SPECIES to provide a defence against these completely new and unforeseen hazards to one of France's greatest glories. First, after considerable debate, American hybrids were planted, followed by, in the early 20th century, so-called FRENCH HYBRIDS, the results of which tasted more like the European VITIS VINIFERA vines' produce.

There was such a crisis in wine quality in the late 19th century that the great scientist PASTEUR was asked to look into the matter, and the result was a giant step forward for the science of winemaking, in which France has long been at the forefront of research (see University of BORDEAUX in particular).

By the turn of the century, the plains of the LANGUEDOC had been transformed into a great factory producing light red for drinkers in northern France, now commercially accessible thanks to the development of the RAILWAYS. These light wines were given weight, alcohol, and colour by the produce of new vineyards in ALGERIA.

Two World Wars left France's wine business in serious need of reorganization. Vigorous efforts were made to uproot hybrids, and a thorough programme of research dedicated to the concept of wine quality was initiated both in universities (see ACADEME) and in specialized research institutes. In the second half of the 20th century France became the world's most thoroughly and harmoniously organized wine producer, with the development of the powers of the INAO and increasing emphasis on the importance of the AOC system for which it is responsible.

In the 21st century, however, the number of vignerons who feel limited by the dictates of the AOC system has grown considerably, as has the number of wines sold simply as a VIN DE FRANCE, many of them classed as NATURAL WINES.

Geography and climate

France does not have the monopoly on fine wine production, but its geographical position is such that it can produce wine from an exceptionally wide range of grape varieties with a good balance of sugar and acidity, although CLIMATE CHANGE is evident throughout the country. With wine regions lying between LATITUDES 42 and 49.5° N, France can provide the two most suitable environments identified in CLIMATE AND WINE QUALITY for growing grapes. In the south, the MEDITERRANEAN CLIMATE can be depended upon to ripen grapes fully, but not so fast that they do not have time to develop an interesting array of FLAVOUR COMPOUNDS and PHENOLICS. In the west, relatively high latitudes are tempered by the influence of the Atlantic's Gulf Stream. In the east, centuries of viticultural tradition have established what seem to be potentially perfect marriages between grape variety and particularly favoured terroir in the more CONTINENTAL climate of Burgundy, Alsace, and Champagne, France's most northerly wine region where, over the centuries, the ideal wine style has evolved to take advantage of the area's climate and special geology.

France also has a wide variety of SOIL TYPES, much charted and revered (although see GEOLOGY and SOIL AND WINE QUALITY for a discussion of the limited extent to which they may affect wine quality).

Vine-growing in modern France is concentrated in the south, but there are vineyards in all regions other than the most mountainous and the coolest, which excludes most of the Massif Central, the high-elevation mass in the middle of the country, much of the alpine region on the south-east, and the flat north-western sector closest to Great Britain. See map.

Vine varieties

France conducts a full agricultural census only every decade or so. The most recent was conducted in 2020, accounting for 364 varieties.

CARIGNAN was France's most planted vine variety for many decades, thanks to its ubiquity across Languedoc and Roussillon, but by the turn of the century Merlot had assumed this role, accounting for 114,785 ha/283,640 acres by 2020. Second most planted was the white grape UGNI BLANC, grown chiefly for distillation into brandy, with 92,514 ha, while red grapes GRENACHE and Syrah came in third and fourth, with 87,745 ha and 67,040 ha consecutively. Cabernet Sauvignon continued a long downward trend, falling from 53,400 ha in 2000 to 46,971 in 2020, just a little ahead of Chardonnay at 44,141 ha. Carignan now takes a distant eighth place, with 31,273 ha, even behind Cabernet Franc (32,282 ha) and Sauvignon Blanc (31,773 ha).

The HYBRIDS, so widely planted in the mid 20th century, are all but a distant memory, though climate change concerns have increased openness to NEW VARIETIES such as Arinarnoa and Marselan, crosses which were authorized for Bordeaux vineyards in 2021. (See also VIFA.)

More attention is also being paid to France's treasury of traditional INDIGENOUS VARIETIES, either imported as a result of shifting political power (many of France's most planted red varieties were originally Spanish) or those still to be found in limited quantity in SOUTH WEST FRANCE. They are less numerous than in ITALY, but that probably reflects France's national efficiency and centralism.

Viticulture

Most vineyards in France are immediately recognizably French. With its generally reliable rainfall and supply of soil water, northern France has the highest VINE DENSITY in the world, with up to 13,000 plants per ha, and the vines are typically planted in neat, low-trained rows, often using GUYOT systems of pruning and training (typically dictated by the detail of AOC regulations). French vignerons have in general had centuries to match cultural practices to local conditions, although in the early 20th century many less suitable terrains were planted in an extension of classic zones. IRRIGATION is usually unnecessary in northern and western France and is strictly, if sometimes only theoretically, controlled in the south. The relatively humid climate of western France means, however, that frequent SPRAYING against FUNGAL DISEASES is often necessary. In the early 1990s, concern was increasingly expressed at the use of AGROCHEMICALS in many French wine regions, particularly Burgundy, where ORGANIC VITICULTURE and BIODYNAMIC VITICULTURE is increasingly common. Other common viticultural hazards are FROST in the north, HAIL in Burgundy, and DROUGHT in the south, with both of the last two on the increase. Crop levels can vary considerably since the weather during FLOWERING is by no means predictably fine; WINTER FREEZE has been known to kill a substantial proportion of vines, as in 1956; and spring frosts can seriously affect total national production, as in 1991 and 2021.

French viticultural research is of a high level and coordinated nationally under the auspices of INRAE, which has stations all over the country. Many of the world's vine-growers regard French NURSERIES as their prime source of planting material, and there has been considerable work on CLONAL SELECTION.

France's vine-growers are probably the most regulated and restricted in the world, however. For all wines other than the basic VSIG, dates of HARVEST are limited by regional annual decree, and YIELDS are minutely regulated. A low yield is generally regarded as the

safest prerequisite for wine quality, but in the 1980s the maximum basic yield allowed by AOC regulations was routinely increased by a so-called *plafond limite de classement*, or PLC, supplement often as high as 20%. Yields are now set annually. Since the late 1980s, CROP THINNING has been the norm for many quality-conscious producers. The 1990s saw the introduction of GRAPE SORTING tables to increase wine QUALITY. MECHANIZATION was introduced to lowlier appellations in the late 1980s and 1990s. PRECISION VITICULTURE techniques are in use at the better, larger properties.

Winemaking

In many wine regions, TRADITION has long been as important as SCIENCE in determining winemaking techniques, although France's winemakers can and do draw on many centres of OENOLOGICAL academe for instruction and research (see ACADEME for a list of those described in further detail in this *Companion*).

Techniques vary enormously in France's hundreds of thousands of *caves*, but in general—and in sharp contrast to the New World—PROTECTIVE JUICE HANDLING and an obsession with winery HYGIENE are relatively rare. Mastery of MALOLACTIC CONVERSION and OAK AGEING, on the other hand, have long been taken for granted.

Part of French winemakers' easy relationship with BARREL MATURATION comes from the fact that France is the centre of the world's wine COOPERAGE industry.

France is also the birthplace of CHAPTALIZATION, and a high proportion of its wines have depended on some degree of ENRICHMENT, although CLIMATE CHANGE suggests that France may need to introduce more widespread ACIDIFICATION too, forbidden for wines that have been chaptalized. Another winemaking practice once regarded as quintessentially foreign in France, the use of OAK CHIPS, is now tolerated for IGP and VSIG wines. Further up the quality ladder there is some experimentation with CONCENTRATION techniques.

Less than one-quarter of all wine consumed in France is white, and in the hot summers of the south of France rosé is more likely to be consumed than white, as a sort of red for high temperatures.

Wine quality categories

Of the average French harvest, wines from the most revered quality wine category AOC represent the most significant proportion, while the most basic wine for immediate consumption, that classified as Vin de France, or VSIG, is made in ever-decreasing quantity. In between these two categories lies the category of IGP wines. The remaining proportion of an average year's French wine production is designed for DISTILLATION into brandy such as cognac and armagnac.

For details of the history, climate, geography, vine varieties planted, and wines produced, see under regional, or even more geographically specific, names, including PARIS. Franciacorta, wine region in the hills immediately east of Brescia, with a relatively short history of producing TRADITIONAL METHOD sparkling wine from Chardonnay and Pinot Noir with some Pinot Bianco. Its name is a corruption of the medieval Francae Curtes, 'Curtes' meaning 'communes' and 'Francae' meaning 'exempt of taxes', referring to the region's privileged position at the time.

Spread over 19 villages, the area is also demarcated as DOC Curtefranca (formerly known as Terre di Franciacorta) for still white and red wines made from INTERNATIONAL VARIETIES. In the 1980s and 1990s these answers to Bordeaux and Burgundy, often treated to lavish amounts of new OAK, sold well, but this international style has largely lost its economic relevance. Franciacorta's history begins in 1961 with the release of the first traditional-method sparkling wine ever to be produced in the region, by the house of Guido Berlucchi.

Franciacorta modelled itself in both style and nomenclature closely on CHAMPAGNE, a strategy that has become an obstacle given the competion on the international stage and is not made any easier by the Prosecco's enormous success and much lower price point. Encouraged by the largest Franciacorta players, grape-growers began planting vines in the plains, which has led to overproduction and lower grape prices. The area under vine has grown from 800 ha/2,000 acres in the late 20th century to 2,900 ha/7,166 acres in 2020, producing 16 million bottles of sparkling wine annually.

CLIMATE CHANGE is perceived by the region as another challenge, with a recent solution being the legal inclusion of Erbamat, a neutral, low-alcohol, high-acidity variety. There is also a trend in zero-DOSAGE wines, made with no added sugar, mostly pioneered by producers working in ORGANIC or BIODYNAMIC VITICULTURE.

Franciacorta comes in various styles, almost all mimicking Champagne, if a little stricter in its ageing requirement of 18 months on the LEES for non-vintage wines. Rosé and Satèn, a Franciacorta bottled at lower pressure and hence creamier in texture, must age for 24 months; vintage Franciacorta at least 30; and the rarely seen Riserva for 60 months. W.S.

www.franciacorta.net

Franconia, English name for the German wine region FRANKEN, and a local name for the BLAUFRÄNKISCH grape variety in FRIULI in northern Italy.

Francs, village which gives its name to the small Francs Côtes de Bordeaux appellation on the RIGHT BANK between ST-ÉMILION and BERGERAC. The original settlement took its name from a detachment of Franks sent there by Clovis after defeating the Visigoths (see FRANCE, history). The wines have considerably more personality than regular BORDEAUX AOC, and the area's revival in the 1980s owed much to the Belgian Thienpont family (also associated with LE PIN and Vieux Château Certan). In 2020, 395 ha/976 acres of vineyard were producing sturdy Merlot-based reds on high clay-limestone slopes, many of which enjoy a favourable west/south-west exposure. Tiny amounts of Sémillon-based white, both dry and sweet, were also made in memory of a style once traditional for this area. For more detail, see BORDEAUX. J.R. & J.L.

Franken, known in English as Franconia, distinctive wine region in central GERMANY, with a total of 6,124 ha/15,133 acres of vineyard in 2019. Severe winters and autumns as well as spring FROSTS are among the challenges that result in some of Germany's most variable YIELDS, but this has not deterred a near tripling of total vineyard area since the 1960s. The features for which Franken wine is best known are arguably neither its grapes nor its distinctive soils and wines but rather the fact that nearly all of it is marketed in squat, flattened BOCKSBEUTEL bottles at prices most German growers can only dream of; as well, most is consumed within the region itself.

While representing just under one-quarter of planted surface (as does MÜLLER-THURGAU), SILVANER—introduced here 350 years ago as 'Österreicher'—is nonetheless rightly considered Franken's flagship grape, yielding robust, ageworthy, and minerally complex results. RIESLING and PINOT NOIR (though confined to one western sector) also excel. Several of the many vine crosses prominent in mid 20th century Germany—notably BACCHUS, KERNER, SCHEUREBE, and RIESLANER—are, like Müller-Thurgau, more successful than usual in Franken, whose soils high in active LIME seem to tame these grapes' less appetizing characteristics. The traditional field blend of diverse, multicoloured varieties called Altfränkischer Satz, or Frentsch, is undergoing a promising revival. Dry wines have dominated in this region since the 1970s, when Germany's Riesling-centric growing regions were only moving in that direction. Nobly sweet elixirs are relatively rare but can be stunningly complex and long-lived, like their Riesling relatives in other parts of Germany.

South of the city of Aschaffenburg along the right bank of the Main, Franken's westernmost vineyards, collectively known as the Mainviereck, feature dramatically steep SANDSTONE terraces whose late 20th and early 21st century revival has resulted in some of Germany's most impressive Pinot Noirs (as well as distinctive Riesling), notably from the Schlossberg and Centgrafenberg vineyards of Klingenberg and Bürgstadt respectively. Some 25 km/16 miles east but still along the Main, vineyards around Marktheidenfeld mark the transition from Triassic sandstone to fossiliferous MUSCHELKALK, Riesling sharing space with Silvaner. Vineyards dominate the eastern half of a huge northerly bow inscribed by the Main, as well as a plunge to the south that embraces the city of Würzburg, whose Stein, Innere Leiste, and Pfülben vineyards are among Franken's most celebrated sources of Silvaner and (in rather austere renditions) Riesling. Eastern viticultural Franconia includes numerous smaller outposts, but many vineyards are near the Main. Eschendorf, not far west of Würzburg, is especially notable for its Lump vineyard, where Muschelkalk intersects with the distinctive Triassic MARL known as Keuper, a geological formation that dominates vineyards in the Steigerwald of

Franken's southeast whose best-known wine village and site are, respectively, Iphofen with its Julius-Echter-Berg. D.S.

Frankland River GEOGRAPHICAL INDICATION within the Great Southern in WESTERN AUSTRALIA that stands out for top-quality Shiraz, Cabernet, and Grenache as well as dry RIESLING.

Frankovka, or Frankovka Modrá, Slovak synonym for the red BLAUFRÄNKISCH grape.

Franschhoek, or Franschhoek Valley, wine district in the Coastal Region of SOUTH AFRICA and home to many historic cellars. Established in the late 17th century to accommodate the influx of French Huguenots (the name means 'French Corner'), it is an important TOURISM centre within easy driving distance of Cape Town.

Fransdruif, or just Frans, traditional Afrikaans name, meaning 'French grape', for the PALOMINO FINO grape in South Africa.

Frappato, increasingly celebrated—and planted—Sicilian red grape variety which can add fruit and floral freshness to NERO D'AVOLA and NERELLO MASCALESE in the south-east of the island, notably CERASUOLO DI VITTORIA DOCG, but can also make juicy VARIETAL wines. Probably a descendant of SANGIOVESE, it was grown on a total of 965 ha/2,385 acres in 2020.

Frascati, LAZIO's most famous DOC. Named after the town of Frascati immediately east from Rome, the wine was for centuries based on the local MALVASIA del Lazio (a cross between MUSCAT OF ALEXANDRIA and SCHIAVA Grossa) locally called Malvasia Puntinata, or the rather neutral Malvasia Bianca Candia. The official production

rules, however, do not distinguish between the two and allow up to 30% of the high-yielding TREBBIANO Toscana, which has diluted the wine's character to that of a rather neutral white for everyday drinking, of which most is absorbed by Rome and its many tourists.

Rome's expanding suburbs have slowly crept up on Frascati's vineyards, causing a continuing decline in producing area, to 901 ha/2,226 acres in 2018. The once exceptionally high average yield of 112 hl/ha at the beginning of the century has dropped to 58 hl/ha but without a dramatic increase in quality.

In 2011, in an effort to improve the situation, the entire zone was elevated to DOCG for Frascati Superiore, for which the production regulations demand lower YIELDS (11 tonnes/ha rather than the 14 tonnes/ha for plain Frascati) and with a higher minimum alcohol, implying a wine made from riper grapes with more extract. The traditional sweet version of Frascati, Cannellino di Frascati, was also elevated to DOCG level, with the stipulation that the grapes must be late-harvested. They may also undergo partial drying, and the minimum RESIDUAL SUGAR must be at least 35g/l.

While Frascati's production is dominated by large operations, some of them regularly produce at least one superior bottling based on a higher percentage of Malvasia Puntinata, often complemented by the local Bellone grape. Examples such as the Superiore version from Casal Pilozzo express much more faithfully the original Frascati characteristics but have difficulty in finding a market willing to pay the premium. There are now some left-field examples as well, such as the SKIN-FERMENTED blends of Malvasia del Lazio and Bellone from Ribelà. W.S.

fraud, wine. See ADULTERATION AND FRAUD.

free-run is the name used by winemakers for the juice or wine that will drain without PRESSING from a mass of freshly crushed grapes or from a FERMENTATION VESSEL. Depending on the type of vessel used for DRAINING and the winemaking process, it constitutes 60–85% of the total juice available and is generally superior to, and much lower in TANNINS than, juice or wine whose extraction depends on pressing. Most modern white wine is made from grapes that pass through a DESTEMMER-CRUSHER before going into a draining tank with a perforated bottom through which the free-run juice passes to the fermentation vessel. Many winemakers boast of using only free-run juice in the production of fine white wines, but PRESS WINE, the wine produced by pressing what is left, may be useful as a BLENDING element.

In RED WINEMAKING, the free-run wine is that which, after SETTLING, is drained or RACKED away from the skins. In some wineries, free-run red wine is also recovered from specially designed transfer conveyors. Whatever remains goes into the press to yield press wine, which can be even more useful for its tannin concentration when making up blends of red wines.

freeze. See WINTER FREEZE.

freeze concentration. See CONCENTRATION.

Freisa, or Freisa Piccola, is a distinctive, wild-strawberry-flavoured red grape variety indigenous to the PIEMONTE region of north-west Italy and, more specifically, to the provinces of Asti, Alessandria, and Cuneo in scattered vineyards which reach almost to the gates of the city of Turin.

The vine has been known in Piemonte for centuries. DNA PROFILING has shown that Freisa has a parent–offspring relationship with NEBBIOLO. Freisa musts can be quite high in both ACIDITY and TANNINS like Nebbiolo, although its wines are coarser in terms of the tannins and flavours.

The wine exists as a VARIETAL in a range of styles but traditionally appears as a slightly frothy wine from a SECOND FERMENTATION, which retains some unfermented RESIDUAL SUGAR to balance the slight bitterness from the LEES. The frizzante or sparkling version of Freisa, with its decisively purple colour and aromas of raspberries and violets, is reminiscent of good LAMBRUSCO, if much more tannic and tart.

It is DOC in both dry and sweet (*amabile*) styles in the following areas: the larger Freisa d'ASTI and the minuscule Freisa di Chieri, the LANGHE, the MONFERRATO, and the rare Pinerolese. Its popularity has declined rapidly in recent years in its native Piemonte.

Modern technology, in the form of pressurized tanks, now permits producers better control of both the residual sugar level and the amount of CARBON DIOXIDE in the wine, and this type of Freisa, which does not undergo a second fermentation in the bottle, tends to be distinctively drier and almost imperceptibly fizzy. Today producers such as Aldo Vajra and Coppo make a more ageworthy, completely dry, and completely still type of Freisa aged in BARRIQUE, and a handful make a Freisa Nebbiolata, in which the wine is refermented on the skins of Nebbiolo used for BAROLO. Tannins abound in this style.

By 2015, total Italian plantings had fallen to 514 ha/1,270 acres. It is also known in California.

Freixenet. See HENKELL FREIXENET.

French-American hybrids. See FRENCH HYBRIDS.

French Colombard, common California name for one of the state's most planted grape varieties, the French white COLOMBARD.

French hybrids, group of vine HYBRIDS bred in France in the late 19th and early 20th centuries, usually by crossing or hybridizing AMERICAN VINE SPECIES with a European VITIS VINIFERA variety (see VINE BREEDING). These are also known as direct producers, hybrid direct producers, HDPs, or, in French, *hybrides producteurs directs*. One early response to the invasion of PHYLLOXERA in Europe was to plant American varieties, since most had phylloxera tolerance. In Europe they proved to be both hardy and resistant to a wide range of FUNGAL DISEASES, but, because of the strange, often FOXY, flavour of the wine they produced, it has been illegal to plant the likes of ISABELLA, NOAH, Othello, Black Spanish (JACQUEZ), and HERBEMONT in France since 1934.

The aim of the early hybridizers was to combine the pest and disease resistance of the American species with the accepted wine quality of the European wine species *vinifera*. (See DISEASE-RESISTANT VARIETIES for current breeding techniques with similar aims and promising results.) A group of French breeders such as François BACO, Castel, Georges COUDERC, Ferdinand Gaillard, Ganzin, Millardet, Oberlin, Albert SEIBEL, Bertille SEYVE, and Victor VILLARD, as well as, more recently, Joanny Burdin, Galibert, Eugene Kuhlmann, Pierre Landot, Ravat, Jean-François Seyve's sons Joannes and Bertille (who married Villard's daughter and developed the important SEYVE–VILLARD series of hybrids), and Jean-Louis VIDAL, produced thousands of new hybrid varieties with such aims in mind. They used AMERICAN HYBRIDS as parents as well as American vine species. *Vitis aestivalis*, *Vitis rupestris*, *Vitis riparia*, and *Vitis berlandieri* were common parents because of their excellent disease and pest resistance and a reduction in the strong fruit flavour associated with *Vitis labrusca*. Some of the ROOTSTOCKS used today were bred by these hybridizers, particularly Castel, Couderc, Ganzin, and Millardet. Active hybridizers

in other countries included the Italians Bruni, Paulsen, Pirovani, and Prosperi.

These hybrids were widely favoured because of disease resistance and high productivity, so by 1958 about 400,000 ha/988,000 acres of French hybrids were planted in France, or about one-third of the total vineyard area. Wine quality was, however, often inferior, especially from the earlier French hybrids. With continued crossing and back crossing, the objectionable features in the taste of the wine could be reduced (see diagram for NEW VARIETIES). French planting regulations since 1955 have deliberately discouraged vine varieties associated with poor wine quality, however, both hybrids and *vinifera*. With the exception of Baco 22A (also known as Baco Blanc), which may be used for armagnac, hybrids have been systematically phased out of French wine and brandy production, even though 20 older hybrids—including Villard Noir, CHAMBOURCIN, and PLANTET for red wines and Villard Blanc for white wines—are still authorized for wine in France, if only for WINE WITHOUT GEOGRAPHICAL INDICATION. There is currently renewed interest in these hybrids due to their disease resistance.

The French hybrids have been planted outside France and have made significant contributions at some time or other to the wine industries of the eastern UNITED STATES (see NEW YORK in particular), CANADA, ENGLAND, and New Zealand, where French hybrids were planted in the majority of vineyards into the 1960s and used for FORTIFIED WINES. From the 1960s onwards, in almost all of these regions these hybrids have been systematically replaced by *vinifera* varieties for reasons of wine quality, although in some sites in Canada and New York subject to WINTER FREEZE only a hybrid such as Vidal will survive (and has produced some fine ICE WINE), while Seyval Blanc is still grown to a limited extent in England. French paradox, term coined in the United States in 1991 to express the infuriating fact that the French seem to eat and drink themselves silly with no apparent ill effects on their coronary health. Immediately after this thesis was aired on prime-time television in the United States, with red wine consumption cited as a possible factor in reducing the risk of heart disease, US sales of red wine quadrupled, and GALLO had to put their leading branded GENERIC Hearty Burgundy on allocation. For more details, see HEALTH. A similar association between red wine consumption and health benefits has played an important part in the wine boom in ASIA.

Frescobaldi, one of Florence's most prominent noble families since the 13th century, are among the largest landholders in TUSCANY with a wide range of agricultural activities. The Frescobaldi holdings can be divided into three distinct blocks: the first, Tenuta di Castiglioni to the south-west of Florence, where the family started to produce wines as early as the 1300s; the second, to the east of Florence, which produces classic CHIANTI RUFINA from the Nipozzano estate and the wines of Pomino; and the third Castelgiocondo, in MONTALCINO, whose acquisition in 1989 made Frescobaldi the largest potential producer of Brunello. By 2022 Frescobaldi's substantial holdings in Montalcino also included the independently run Tenuta Luce della Vite producing a Brunello as well as Luce, a SUPERTUSCAN blend of Sangiovese and Merlot.

In 2000 Frescobaldi ventured outside Tuscany when it acquired the Conti Attems estate in FRIULI. In 2004 they acquired control of the Ornellaia estate in BOLGHERI, their first foray into what had been an Antinori fief. In 2018 a separate cellar was built for Masseto, the luxurious Merlot made on the estate that is sold exclusively through the Place de Bordeaux. Also in the Maremma, Frescobaldi now produce INTERNATIONAL VARIETALS on their Tenuta dell'Amiraglia and in 2014 finally became owners of a CHIANTI CLASSICO property when they acquired Tenuta Perano in Gaiole-in-Chianti. Gorgona, a blend of

Vermentino and Inzolia produced on the eponymous Tuscan island, is a social project in collaboration with the Gorgona Penal Institute.

fresh grapes. See TABLE GRAPES.

frisante, Portuguese term for a semi-sparkling wine with a pressure of 1–2.5 bar.

Friulano, name adopted for SAUVIGNONASSE in the early 21st century in FRIULI for the region's leading white wine variety once known, to the fury of Hungarians, as Tocai Friulano. Total plantings have been slowly declining but were 2,503 ha/6,185 acres in 2015, in all major DOC zones (FRIULI COLLI ORIENTALI, COLLIO, FRIULI GRAVE, FRIULI AQUILEIA, and ISONZO). Buttrio, Manzano, and Rosazzo in the Colli Orientali, and the areas between Cormons and Brazzano, between Brazzano and Dolegna, and Capriva di Friuli in the Collio DOC, are classic subzones. The wine itself is light in colour and body, is floral in aroma, and has pronounced green-almond notes. It is designed to be drunk young.

Friuli, or Friuli-Venezia Giulia, the north-easternmost region of Italy, borders on Austria to the north and SLOVENIA to the east and has long been a confluence of three distinct peoples and cultures: Italian, Germanic, and Slavic. (See map under ITALY.) Despite endorsements of local wines by the usual succession of popes, emperors, princes, and princelings, Friuli's history of distinctive wines remained largely hidden until the late 1960s, when the introduction of both German winemaking philosophy and TEMPERATURE CONTROL—innovations usually credited to producer Mario Schiopetto—gave Italy's first fresh, fruity, internationally styled white wines. This created a FASHION which has waned as Friuli's wines made from INTERNATIONAL VARIETIES became less distinctive and as interest in INDIGENOUS VARIETIES waxes. This style of (predominantly white) WINEMAKING is one of the

characteristic features of the region's production; the other is the large number of wines produced by each single estate.

Friuli's geographical position on land successively disputed by Romans, Byzantines, Venetians, and Habsburgs ensured that a large number of varieties would be available for planting. The white FRIULANO, RIBOLLA Gialla, MALVASIA di Istria, VERDUZZO, and PICOLIT and red REFOSCO DAL PENDUNCOLO ROSSO, REFOSCO Nostrano, SCHIOPPETTINO, PIGNOLO, and the acidic Tazzelenghe are considered indigenous (although see ROBOLA, for example). RIESLING, WELSCHRIESLING (here called Riesling Italico), TRAMINER, MÜLLER-THURGAU, and BLAUFRÄNKISCH (locally called Franconia) are imports from Austria. The French varieties PINOT BIANCO, PINOT GRIGIO, CHARDONNAY, SAUVIGNON, CABERNET, MERLOT, PINOT NERO, and CARMENÈRE were introduced during the 19th-century Habsburg domination (and greatly expanded during the replanting of Friuli's vineyards after the ravages of PHYLLOXERA), which lasted until 1918 in the case of the province of Gorizia.

The result has been a multiplicity of single VARIETAL wines in each of its four DOCGs and 12 DOCS. If the proliferation of DOC wines with varietal names attached to specific zones has created some confusion among consumers, the geography of Friuli's DOC structure is fairly easy to understand. Udine marks the northern border beyond which low temperatures make viticulture an impractical proposition in most cases. To the south of Udine exist two distinct bands of grape-growing territory: the two hillside DOCs of FRIULI COLLI ORIENTALI and COLLIO with calcareous MARL soils; and the ALLUVIAL plain with plentiful quantities of sand, pebbles, and rocks deposited by the various rivers —the Tagliamento, the Natisone, the Judrio, the Isonzo—which criss-cross the plain. These flatlands are divided into five DOCs, moving from west to east: LISON-PRAMAGGIORE (shared with Veneto), Latisana, FRIULI GRAVE, FRIULI AQUILEIA, and ISONZO. The HILLSIDE VINEYARDS give wines of greater personality. Isonzo, which borders Collio, stands out among the DOCs of the plain, its best wines able to challenge those of the hillsides.

Since 2018 the overarching DOC Friuli Venezia Giulia, previously an IGT covering the entire region, has been approved. Yields of 14 tonnes/ha seems overgenerous, suggesting the DOC's aim is to enable declassification of wines within the DOC system rather than resorting to the lower and more anonymous IGT. Additionally, this new umbrella DOC has managed to legally reserve the category 'Ribolla Spumante' exclusively for Friuli, prohibiting other regions, such as Veneto, to use the variety for varietally labelled sparkling wines. Since 2011 the DOC PROSECCO also covers the whole of Friuli (as well as that of neighbouring Veneto).

For more details, see CARSO, COLLIO, FRIULI AQUILEIA, FRIULI COLLI ORIENTALI, FRIULI GRAVE, ISONZO, and LISON-PRAMAGGIORE. W.S.

Zanfi, A., *Friuli: Terre, Uomini, Vino* (2004).

www.winesfriuliveneziagiulia.it

Friuli Aquileia, DOC within FRIULI in north-eastern Italy comprising 16 communes in whole or part on a plain south of Udine. The white must consist of at least 50% FRIULANO, while the Rosso must contain at least 50% REFOSCO dal Peduncolo Rosso. The balance in both can be any authorized variety, most of which are INTERNATIONAL VARIETIES, which dominate the production in the greater region. W.S.

Friuli Colli Orientali, formerly Colli Orientali del Friuli, literally the eastern hills (*colli*) of the FRIULI region in north-east Italy, comprising more than 2,000 ha/4,942 acres of vineyard.

The territory of the DOC begins to the east of the city of Udine near the SLOVENIAN border and continues to the border of the province of Udine. The dividing line between the Colli Orientali and the COLLIO DOC is neither geological nor climatic but simply historical: Udine and its province became part of Italy in 1866, while the

neighbouring area of Collio, in the province of Gorizia, was not reunified with the rest of Italy until the end of the First World War. The contiguous zones in fact have the same sort of soil: the so-called 'FLYSCH of Cormons', with alternating layers of calcareous marls and sandstone.

Wine has a documented history here, as in most parts of Italy, since the days of the Roman Empire, but the zone first began to attract significant attention in the 1970s, when cold fermentation techniques began to produce here (and in the Collio DOC) significant quantities of fresh, fruity, and aromatic white wines, predominantly based on INTERNATIONAL VARIETIES, especially Pinot Grigio, Chardonnay, and Sauvignon Blanc, pioneering efforts for Italy.

Significant development of red wines came in the 1980s as producers began planting Merlot, Cabernet Sauvignon, Cabernet Franc, and Pinot Noir, the wines frequently aged in small oak barrels. A certain number of these reds were released as an ambitiously priced VINO DA TAVOLA, because individual producers wanted to either distance the wines from their allegedly more facile antecedents, make an unorthodox blend of varieties, or copy the success of the highly priced SUPERTUSCANS. In the last decade the market has begun to turn away from these brawny styles, and the region's red wines have become less concentrated, less oak-driven, and more elegant.

White wines, particularly from Chardonnay or Pinot Bianco, are also moving away from BARREL FERMENTATION and BARRIQUE ageing towards fresher styles, while a range of SKIN-FERMENTED white wines, including the historical, copper-hued Pinot Grigio Ramato, have begun to attract attention.

Although international varietal wines, especially whites, still prevail, producers have begun to focus on INDIGENOUS VARIETIES and the specific TERROIRS of the subzones where historically they were cultivated: Cialla for RIBOLLA Gialla, VERDUZZO, REFOSCO DAL PENDUNCOLO ROSSO, and SCHIOPPETTINO; Rosazzo for Ribolla Gialla and PIGNOLO; Prepotto for Schioppettino; and Faedis for a scented local grape known as Refosco Nostrano. The red Schioppettino, saved from

extinction in the 1970s, is now cultivated by 20 producers who have founded an association dedicated to its promotion.

Friuli Colli Orientali has not one but two historic sweet wines, either LATE HARVEST or DRIED-GRAPE WINES: DOCG Colli Orientali del Friuli Picolit includes the subzone Cialla, while DOCG Ramandolo applies to Verduzzo and more or less covers the same area as DOC Friuli Colli Orientali. Both wines can be complex and long-lived.

W.S.

www.colliorientali.com

Friuli Grave, formerly Grave del Friuli, vast DOC zone in the FRIULI region of north-east Italy which sprawls across the southern portion of the provinces of Pordenone and Udine. This is flatland whose GRAVEL- and SAND-based soil has been deposited over the millennia by the many rivers and streams that cross the territory before adding their waters to the Adriatic. It owes its name to the same etymological root as the gravelly GRAVES region of Bordeaux in France. The DOC, with 2,000 ha/4,942 acres of vineyard producing 300,000 hl annually, is responsible for more than 50% of Friuli's output and is so large that it is more akin to an IGT than anything else. Exceptionally high permitted yields (91 hl/ha) make it difficult to see how the DOC contributes to good-quality wine production. Almost all INTERNATIONAL VARIETIES are grown here, with piercingly herbaceous Sauvignon Blanc once the DOC's flagship but now encountering fierce international competition. That is not to say that the DOC is unsuitable for the production of high-quality wines, but its formidable size precludes generalizations. W.S.

www.docfriuligrave.com/

frizzante, Italian wine term for semi-sparkling wine (as opposed to SPUMANTE, which is used for fully sparkling wines). *Frizzante* wines,

which can be dry, semi-sweet or sweet, generally owe their bubbles to a partial second fermentation in tank, a sort of interrupted TANK METHOD process (although see also PROSECCO COL FONDO). A wine labelled *frizzante* must have between 1 and 2.5 bar pressure, and *spumante* at least 3 bar. Often undervalued because of the production method, *frizzante* wines are economically very important, with 400 million bottles produced in Italy in 2020.

Fromenteau, name for several grape varieties, used as a synonym for both the ROUSSANNE of the Rhône and SAVAGNIN of the Jura. Fromenteau Gris is a synonym for PINOT GRIS.

Fronsac, small but once famed red-wine appellation in the Bordeaux region just west of the town of Libourne on the RIGHT BANK of the River DORDOGNE (see map under BORDEAUX). The wooded low hills of Fronsac, along with Canon-Fronsac, the even smaller and more famous appellation to the immediate south, constitute Bordeaux's prettiest countryside, and the region's elevation, unusual so close to the Gironde estuary, gave it great strategic importance. Fronsac was the site of a Roman temple and then of a fortress built by CHARLEMAGNE, who is locally supposed to have taken a particular interest in this wine. The wine benefited further in the mid 17th century when the Duc de Richelieu, also Duc de Fronsac and a man of considerable influence, replaced the fortress with a villa in which he entertained frequently. According to Enjalbert, the first great right-bank wines were produced, around 1730, in Canon-Fronsac. Even well into the 19th century, the wines of Fronsac were much more famous than those of POMEROL on the other side of Libourne.

The low-lying land beside the river and any alluvial soils further inland from the Dordogne and its tributary the Isle are entitled to only the BORDEAUX AOC, while the Fronsac and Canon-Fronsac appellations are concentrated on the higher land where LIMESTONE predominates and SANDSTONE is also characteristic. Merlot and

Cabernet Franc (Bouchet) are the dominant grape varieties, densely planted on the land entitled to the Fronsac appellation and the more restricted area, mainly around the villages of St-Michel-de-Fronsac and Fronsac itself, which are entitled to the supposedly superior Canon-Fronsac appellation. The region with its cool soils performs particularly well in hot vintages.

Wines made in the 1960s and 1970s were often both austere and slightly rustic. The 1980s saw considerable refinement of techniques and investment in winemaking equipment, notably some new barrels, so that Fronsac added suppleness to its density. It does not have the lush character of Pomerol but can offer a keenly priced alternative to more famous red bordeaux, with the juicy fruit of a St-Émilion and the ageing potential of a Médoc. Even the commercial muscle of the MOUEIX family, who owned Chx Canon-Moueix, La Dauphine, and Canon de Brem, as well as distributing several others, from the 1980s until the early 21st century, failed to win the region the success it probably deserves. The largest and most picturesque property on the entire right bank is Ch de la Rivière. In 2020 Fronsac had 774 ha/1,912 acres in production, and Canon-Fronsac 224 ha/553 acres, with red wine grapes only. J.R. & J.L.

Enjalbert, H., *Les Grands Vins de St-Émilion, Pomerol et Fronsac* (1983), translated by H. Coleman as *Great Bordeaux Wines* (1985).

Frontenac, relatively recent dark-skinned HYBRID, also known as Frontenac Noir, grown for PORT-style wines in the Upper Plains and Midwest of the United States. Its high acidity generally requires some RESIDUAL SUGAR. The MUTATION Frontenac Gris has produced some white wine, but the more recent mutation Frontenac Blanc may well prove more popular. Both Noir and Blanc are gaining ground in QUEBEC.

Frontignac, Australian synonym for MUSCAT BLANC À PETITS GRAINS.

Frontignan is the name of the wine long called Muscat de Frontignan, the most important of the Languedoc's four Muscats. Now a distinctly unglamorous town on the semi-industrial lagoon between Montpellier and Sète, Frontignan was famous for the quality of its MUSCAT for centuries. It was probably one of France's earliest vineyard sites, being close to the salt marshes around Narbonne. PLINY the Younger singled out this particular 'bees' wine' for mention in his letters. ARNALDUS DE VILLANOVA, who is credited with the discovery of the process by which most Muscat de Frontignan is made today (see VIN DOUX NATUREL), claimed that his daily ration of the wine, as advised by the then all-powerful Aragón monarch, made him feel years younger. It was popular in both Paris and London in the 17th and 18th centuries, doubtless with wider appeal then than the dry reds of south-west France that were also shipped north. 'Frontiniac' was specifically praised by the philosopher John Locke in 1676, while both Voltaire and, even further afield, Thomas JEFFERSON were well-documented and enthusiastic purchasers. In the 18th and 19th centuries, Frontignan clearly made red as well as white wines which were compared with those of that other favourite of our sweet-toothed ancestors, CONSTANTIA. See also LANGUEDOC, history, for details of a claimed link between Frontignan and Ch d'YQUEM.

Muscat de Frontignan, despite being one of the first AOCs, and certainly the first VIN DOUX NATUREL appellation, to be officially recognized, fell into decline for much of the 20th century. Only the rather lighter Muscat de BEAUMES-DE-VENISE somehow escaped the malaise that affected the market for France's sweeter wines until the 1980s, when the winemakers of Frontignan awoke as if from a deep sleep and started to produce a much higher proportion of more delicate, more refreshing, yet more characterful golden Muscats (although some dark, turgid, raisiny Frontignan can still be found). As in all Languedoc Muscats (see LUNEL, MIREVAL, and ST-JEAN-DE-MINERVOIS), only the finest Muscat variety, MUSCAT BLANC À PETITS GRAINS, should be used, and the final wine must be at least 15% alcohol with a sugar content of at least 110 g/l. Cheaper Muscats

made well outside the region but marketed vigorously to tourists do nothing for the image of this once-great appellation. CO-OPERATIVES dominate output, but much of the credit for revitalizing winemaking in Frontignan can go to Ch de la Peyrade, whose seaside vineyards may not be the Mediterranean's most picturesque but are reliably warm enough to maximize Muscat Blanc's potential.

A small proportion of Muscat de Frontignan is fortified so early it qualifies as a VIN DE LIQUEUR.

Muscat de Frontignan is also a common synonym for Muscat Blanc à Petits Grains in South Africa.

Fronton, red and rosé AOC of 2,400 ha/6,000 acres of vineyards in SOUTH WEST FRANCE just 30 km/19 miles north of Toulouse. The wines, often called 'the Beaujolais de Toulouse', are distinguished by local grape variety NÉGRETTE, which makes subtle reds with notes of wildflowers and sometimes liquorice. It must constitute at least 50% of a grower's vineyard, with Syrah and the Cabernets being the most important of the many other permitted varieties. Oak ageing tends to mask the grape's character, while ORGANIC production (as at Ch Plaisance) enhances it. The CO-OPERATIVE is an important producer. Rosé production is on the increase, but there is no white Fronton as yet, though some growers bottle whites as COMTÉ TOLOSAN. P.S.

frost, the ice crystals formed by freezing of water vapour on objects which have cooled below 0 °C/32 °F. Such frosts are known as white frosts, or hoar frosts. Black frosts cause freezing and extensive killing of plant tissue itself, without any necessary hoar formation. Frost is a major viticultural problem as it can damage and kill shoots and fruit, in spring and autumn. FROST PROTECTION is expensive and not always effective; see also FROST DAMAGE.

Frost frequencies are, in many studies, imputed arbitrarily from weather records. Temperatures as recorded in the standard Stevenson screen used by meteorologists, at 1.25 m/4.1 ft above the

ground, are always higher than at ground level. A screen temperature of 2.2 °C/36 °F is normally assumed to indicate a light ground frost, and one of 0 °C a heavy ground frost. Temperatures at vine height of −1 °C or lower after BUDBREAK in spring will usually cause serious injury to the young shoots. Even 'light' frosts can often cause damage somewhere in the vineyard, because their incidence tends to be patchy, depending on TOPOGRAPHY. Geiger covers this aspect in detail.

Two main types of frost are distinguished: radiation and advection. Radiation frost occurs typically on still, dry, cloudless nights. Without cloud, mist, or much water vapour to absorb and trap heat radiated from the ground and plant tissues, heat escapes freely to space, and rapid surface cooling results. Air in immediate contact with these surfaces then becomes cooled. The coldest air, being densest, remains or collects close to the ground and in depressions. Lowest air temperatures in the early morning on flat land are at 5–15 cm/2–5 in above ground, rising with height to a relatively warm 'inversion' layer, commonly some 15–30 m/49–100 ft above, beyond which temperatures gradually fall again with elevation. This pool of cold, dense air close to the ground is stable unless dispersed by wind or unless it can flow away by gravity to still lower regions (see TOPOGRAPHY).

Advective frosts result from such flows of already chilled air from elsewhere. They can originate locally, following valleys or other natural courses of AIR DRAINAGE, or arrive from up to several hundreds or perhaps thousands of kilometres away. J.G.

Geiger, R., Aron, R. H., and Todhunter, P., *The Climate near the Ground* (7th edn, 2009).

McCarthy, M. G., et al., 'Soil management and frost control', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

frost damage occurs in vineyards mostly in spring but also in autumn and occasionally summer, when the air temperature drops

below freezing (see also FROST). Ice forms in the plant tissue of buds which have begun to break, young shoots, leaves, and INFLORESCENCES, which may subsequently turn brown and die. The vine can respond by growing more shoots from BASAL BUDS, but these are typically less fruitful, and so the crop is reduced and delayed. Frost in the autumn causes DEFOLIATION, which is a problem if the fruit is not ripe and the vine's reserves of CARBOHYDRATES have not been restored. Frost has much more impact on YIELD than on wine QUALITY, although if SPRINKLER irrigation is used before harvest to ward off autumn frost, the additional water in the soil can have serious consequences for RIPENING.

FROST PROTECTION can be difficult and expensive, but frost is so destructive that vineyard owners are often forced to adopt extreme measures.

Typically cool-climate regions are more prone to spring frost. For example, in 1991 frost damage was so great in western France that total French wine production, which averaged nearly 55 million hl in 1991–2000, was less than 43 million hl/1,135 million gal. Equally bad were the severe spring frosts of 2021, which contributed to even lower yields of 36 million hl, 18% down on the five-year average.

However, spring frost damage to vines is by no means confined to cool viticultural climates. That is because the VINE GROWTH CYCLE is adapted to the general course of temperatures experienced, with spring budbreak delayed in cool climates until the average mean temperature reaches about 10 °C/50 °F, as described under CLIMATE CLASSIFICATION. More damaging can be short-term TEMPERATURE VARIABILITY, such that an early spring warm enough to induce budbreak may frequently be followed by a return to killing frosts after growth has started, as occurred in north and central Italy as well as in France in 2021. The early growing season was advanced by unseasonably warm weather (24–27 °C/75–80 °F in north-east France at the end of March) followed by arctic cold temperatures in early April, with clear nights and temperatures below −9 °C/16 °F recorded in some vineyards. Paradoxically, such events can occur in

otherwise hot vineyard regions, such as the high plains of TEXAS, which were also severely hit in 2021. This is because the early spring is often hot, which encourages early budbreak, but this may be followed by cold of arctic origin which can severely damage vines.

Note the distinction between frost and WINTER FREEZE, a related but different vine injury. R.E.S. & J.E.H.

frost protection. The first way to avoid FROST, which can so easily destroy the grapes for one year, is to plant on slopes from which surface-chilled air can drain away freely (see AIR DRAINAGE). Free-standing and projecting hills offer the best protection because they have no external sources of chilled air and so what slips away must be replaced from the warmer atmosphere above (see TOPOGRAPHY). This is the most effective form of frost protection, but it is generally an option only when developing vineyards in new regions that allow such VINEYARD SITE SELECTION.

Planting on frost-prone sites is normally confined to grape varieties with naturally late BUDBREAK, such as (where the growing season is long enough) CABERNET SAUVIGNON, CARIGNAN, MOURVÈDRE, CLAIRETTE, and TREBBIANO. RIESLING, SYLVANER, MÜLLER-THURGAU, and SAUVIGNON BLANC are classed as having mid-season budbreak. Unfortunately some of the prime-quality varieties grown in COOL CLIMATES, such as PINOT NOIR and CHARDONNAY, burst early and are very vulnerable to spring frosts (see CHABLIS, for instance). The selection of individual sites with minimal frost risk is crucial for such varieties. Some HYBRIDS are more cold-hardy. The risk in any situation can be reduced to a small extent by late PRUNING, but this can delay the effective time of budbreak by only up to about a week.

Another method, employed on flat land subject to radiation frosts, is to use high TRELLIS SYSTEMS so that the main vine growth stands above the coldest air layer that settles close to the ground on still nights. In practice, however, there is little difference in frost sensitivity of commercial trellis systems, and this method offers

limited benefit. COVER CROPS between the rows also needs to be cultivated or rolled by the time of budbreak, so as to lower the effective cooling surface. If the soil is compacted, it most readily absorbs day heat to depth and reradiates it continuously through the night. STONES AND ROCKS in the soil surface assist in this.

Stationary WIND MACHINES are often employed to break up the sedentary lower cold-air layer and mix in warm upper air; these have become part of the vineyard landscape in NAPA and SONOMA Valleys and in ONTARIO, for example. They are expensive to install and use a lot of fuel, but in the long run they are less expensive than HELICOPTERS, which are widely used for the same purpose in NEW ZEALAND and can cover a much wider area but have to be hired by the hour. There is also a mobile fan machine that gathers cold air and blasts it vertically upwards, mixing it with the warmer air. Fog-creating machines have also been used to mix the inversion layer and to minimize frost damage.

Small oil burners, often referred to as smudge pots, can also create limited local heating which may help to promote convectional mixing of upper and lower air. They have lost favour because of the numbers of pots required, not to mention fuel, smoke, lost sleep, and the general inconvenience of operating them in the cold darkness of the early morning. French *bougies antigel* (anti-frost 'candles'), usually filled with paraffin (often candle-factory waste) or with stearin as a greener alternative, are increasingly popular but still labour-intensive.

Burning straw bales—so that the smoke prevents the sun from burning the buds or shoots after frost—was used in Burgundy after the severe frosts of 2017 and 2018, for example, but the practice is prohibited or strictly controlled.

In vineyards with sprinkler IRRIGATION, the SPRINKLERS can be turned on when temperatures fall to danger levels. (In vineyards where irrigation is not permitted, Chablis for example, water has to be taken from a nearby river or reservoir.) This aspersion technique both warms the vines and soil directly and (if the soil was previously dry) improves its heat conductivity so that more warmth comes up

from below. The release of latent heat as the water freezes on the vines protects the vine tissue from injury. However, the additional water in the vineyard may be unwelcome. The use of heated vineyard wires has shown good results, but installation is expensive. Other forms of equipment, such as static or trailer-mounted gas-heated blowers, have not so far been widely adopted. Trials with various vine treatments, such as CHITOSAN or essential oils, have so far been inconclusive. R.E.S. & J.E.H.

www.wine-searcher.com/m/2021/04/the-complete-guide-to-fighting-frost

fructose is, with GLUCOSE, one of the two principal SUGARS of the grape and sweet wines. It is a six-carbon atom sugar, or a hexose. Common table sugar, SUCROSE, is made up of one molecule of fructose and one of glucose.

The grapevine leaf in the presence of sunlight, water, and carbon dioxide makes sucrose by a complicated series of steps called collectively PHOTOSYNTHESIS. The sucrose is transferred in the plant sap from the leaf to the grape berry. There the sucrose is split into fructose and glucose, the forms in which it is stored in the berry. The vine is unusual among fruiting plants in the extent to which it is capable of concentrating the two sugars, fructose and glucose, in its berries; sugars routinely represent 18–25% of grape juice weight, while 12% is the norm in apple and pear juice.

Fructose accumulates in the grape berry along with glucose but at lower concentrations during the early stages. However, at RIPENESS, and especially when grapes are overripe, fructose levels often exceed those of glucose. The glucose–fructose ratio is thus an indicator of grape ripening (roughly 1:5 at veraison but less than 1 at full ripeness). This is important because fructose is remarkable in that it has between 1.3 and 1.8 times the sweetening power of either glucose or sucrose (which has led to its manufacture in large quantities for use in so-called diet foods).

During FERMENTATION of grape juice, both fructose and glucose are consumed. Furthermore, in the acid and enzymic environment of grape juice, any sucrose present is split into its constituent parts, fructose and glucose, and will consequently be fermented. With selected strains of wine YEASTS, nearly all the fructose and glucose are converted to alcohol and carbon dioxide, leaving the wine with only traces of fermentable sugars. A.D.W. & B.G.C.

früh is German for 'early'. Thus, for example, Früher Roter Malvasier is early red MALVASIA.

Frühburgunder, or Blauer Frühburgunder, increasingly highly regarded, small-berried MUTATION of SPÄTBURGUNDER (Pinot Noir) which ripens a good two weeks earlier. By 2020, total German plantings stood at 233 ha/576 acres, most notably on the steep slate slopes of the AHR Valley and on the red sandstone soils around Bürgstadt in FRANKEN, where low-yielding examples exhibit intense fruit. Also known as Pinot Noir Précoce.

Frühroter Veltliner, 'early-ripening, red-skinned VELTLINER', is a pink-skinned grape variety most commonly encountered in Austria, sometimes under the name Malvasier, where plantings, mainly in the WEINVIERTEL district of Lower Austria, had fallen to 253 ha/625 acres by 2021. The wine produced is often less distinguished than that made from Austria's most common grape variety GRÜNER VELTLINER, being notably lower in acidity in many cases. Yields are also generally lower. DNA PROFILING in Austria showed that Frühroter Veltliner is not related to Grüner Veltliner at all but is a spontaneous CROSS between ROTER VELTLINER and SILVANER.

In Germany, it has been known in Rheinhessen, as Frühroter Malvasier or occasionally Roter Malvasier; in Hungary as Korai Piros Veltelini. It is slightly less rare in Czechia (under the name Veltlínské Červené Rané) and Slovakia (as Veltlínske Červené Skoré). In

France's Savoie, it is known confusing as both Velteliner Rouge Précoce and Malvoisie, the latter also used for PINOT GRIS.

fruit. To a VITICULTURIST, 'fruit' is a synonym for GRAPE, the former used more commonly than 'grapes' in English-speaking countries. To an OENOLOGIST or wine taster, fruit is a perceptible element essential to a young wine. Young wines should taste fruity, although not necessarily of grapes or any particular grape variety. During bottle AGEING, the fruity FLAVOUR COMPOUNDS in a good wine evolve into more complex elements, sometimes described as BOUQUET; in a less good wine, the fruit simply dissipates to leave a non-fruity wine sometimes described as 'hollow'. The word fruity is sometimes used in wine descriptions concocted for marketing purposes as a euphemism for 'sweet'. See also RIPENING.

fruit-driven, a TASTING TERM used to convey the fact that a wine has a dominance of grape-derived fruit flavour rather than being dominated by flavours that originate from processes or treatments which the wine has undergone such as BARREL FERMENTATION, BARREL AGEING, LEES CONTACT, MALOLACTIC CONVERSION, or, in the case of a sparkling wine, the influence of yeast AUTOLYSIS.

fruit fly. See DROSOPHILA and MEDITERRANEAN FRUIT FLY.

fruitfulness, viticultural term describing the average number of bunches of grapes per shoot. It can also be used to describe the potential productivity of buds. A shoot of low fruitfulness will have zero or one bunch only, while a fruitful one may have two or three or, very rarely, four. Some varieties are known to be very fruitful, common examples being the so-called FRENCH HYBRIDS, no doubt due to their part-American parentage. At the other end of the fruitfulness spectrum is SULTANA, which has notoriously low fertility of buds at the

base of canes. Most of the commercially important wine grape varieties fall between these two extremes, and two bunches per shoot is most common. Where fruitfulness is low, the vine-grower must prune to CANES as opposed to SPURS, as shoots which arise from short spurs will typically be of lower fruitfulness, arising as they do from BASAL BUDS.

Potential fruitfulness is determined at about the time the vines flower, as the buds are developing on the growing shoot. This process is known as INITIATION and is encouraged by warm, sunny weather and an open CANOPY that allows the sunlight to penetrate to the developing buds and adjacent leaves. By late summer it is usually possible to estimate the potential number of bunches which will be produced the following year by dissection and microscopic examination of the buds. The vine-grower anxiously assesses fruitfulness just as soon as the small bunches are evident on the developing shoots in spring. Normally, the higher the bunch number the higher is the potential yield of that season, although of course there are many other critical stages, especially FRUIT SET, before the harvest is brought in. R.E.S.

Iland, P., et al., Flowering and fruit set', in *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

fruit set, an important and delicate stage of the vine's development after FLOWERING which marks the transition from flower to grape berry. The setting period of about a week is a critical one for the vine-grower, since it is a major determinant of the size of the crop, yet the grower can do little to change the course of events. Only 'set' or fertilized flowers grow into the berries from which wine is made; the others fail to grow and eventually fall off. Fruit set occurs immediately after flowering and is the result of successful POLLINATION achieving fertilization of the ovules and the development of seeds. The GRAPE SEED contains an embryo, formed by the union of the sperm cells from the POLLEN and the egg cell of the OVARY. Most wine

grape varieties contain up to four seeds. The more seeds there are, the larger is the berry.

Only about 30% of flowers become berries, although the range can be from almost zero to 60%. Those flowers that do not set fall from the bunch in a process called 'shatter'. It is not clear whether fruit set is more influenced by organic nutrition (CARBOHYDRATE supply) or by HORMONES, but the crucial role played by the weather during this period is beyond dispute.

At one extreme, and common in hot DRY-FARMED regions, high temperatures and winds, low humidity, and attendant WATER STRESS can reduce fruit set. On the other hand, cold, cloudy, and rainy weather at flowering commonly reduces fruit set, and such conditions can cause widespread yield losses. Strategies to improve fruit set include using BALANCED PRUNING to avoid rapid shoot growth, ensuring balanced VINE NUTRITION (particularly NITROGEN, BORON, and ZINC) and water supply, topping shoots during flowering (see TRIMMING), or the application of certain chemical GROWTH REGULATORS such as CCC (2-chloroethyltrimethyl-ammonium chloride) before flowering. CINCTURING vine trunks at flowering is labour-intensive and likely to be used only for TABLE GRAPES.

A new process known as Thermal Plant Treatment (TPT) has demonstrated significant improvement in fruit set in California and Oregon. Gas-fuelled heater-blowers mounted on a trailer direct a transient air blast of 150 °C/300 °F into the canopy during fruit set. This has led to an increase of around 25% in berries per bunch across several trial sites.

Fruit set can be said to have been poor when fruit yield is lower than normal as a consequence of COULURE, which leaves few berries per bunch, MILLERANDAGE, which leaves a high proportion of seedless berries and 'live green ovaries' (LGOs) per bunch, or both.

fruit wines, made by the FERMENTATION of fruits other than grapes, include cider and perry but not beer or sake, since these last derive their fermentable sugars from hydrolized starch. Drinks made from tree fruits and berries are particularly common in cool-climate regions of North America, the UK, France, and northern Europe.

Berries contain so little fermentable sugar that sugar-cane-derived SUCROSE or other tree fruits or grapes may be added (a form of ENRICHMENT) to obtain sufficient ALCOHOL for stability (see STABILIZATION). Fruit ACIDS split the sucrose into fermentable GLUCOSE and FRUCTOSE, as does a natural ENZYME found in YEASTS.

In most cases, acid levels are so high that it is necessary to dilute the crushed fruit to reduce tartness in the resulting wine, although some tree fruits require acid additions for balance. Citrus fruits have high levels of CITRIC ACID; MALIC ACID dominates the acid mix in apples and other tree fruit. (Grapes are distinguished by their high levels of TARTARIC ACID, which is more resistant to attack by BACTERIA.)

Lack of yeast NUTRIENTS can be a problem in persuading fruits other than grapes to ferment. Commercial preparations of deactivated yeast, nitrogen, phosphorus, and potassium to make up the fruit's natural deficiencies are commonly available to those who practise HOME WINEMAKING.

Top-quality cider, made from fresh, bitter or bittersweet apples, fermented using AMBIENT YEAST, with no added sugar or acid, is enjoying a revival, particularly in cooler parts of North America and northern Europe. So-called co-ferments in which grapes are fermented with other fruits and flowers, but which may not be labelled as wine, are also gaining in popularity. Ciderkin is a PIQUETTE made from apple must.

With the exception of craft cider, few fruit wines improve with AGEING. Primary fruit flavours fade rapidly, and most are best consumed within a year of bottling. A.D.W.

Fuder, German word for a large wooden BARREL, typically one with a capacity of 1,000 l/264 gal used in the MOSEL region. (The STÜCK is more commonly used in RHINE regions.) A Halbfuder contains 500 l and was traditionally used for transporting wine from the Mosel. The French equivalent is *foudre*.

full. A wine is described as full, or full-bodied, if it is high, but not excessively high, in ALCOHOL and VISCOSITY. See BODY for more details.

Fumé Blanc is the curious descendant of the Loire synonym BLANC FUMÉ for the white grape variety SAUVIGNON BLANC. In the early 1970s, California's famous ideas man Robert MONDAVI had one of his most famous inspirations, that of renaming the then unfashionable Sauvignon Blanc as Fumé Blanc, thereby imbuing it with some of the glamour of imported French Pouilly-Fumé. He also gave it some OAK AGEING and a dark green bordeaux-shaped BOTTLE (both entirely alien to Pouilly-Fumé). This formula proved a runaway success, and Fumé Blanc became the highly successful name of a wine type in America, Israel, and elsewhere, even though there was little agreement about what defined it. By the 21st century, the name was waning in popularity.

fumigation, the viticultural practice of fumigating vineyard soils with the aim of killing soil-borne VINE PESTS or VINE DISEASES. Less common than in the past, it is usually carried out before planting. The earliest example of viticultural fumigation was the use of carbon bisulfide in France to combat PHYLLOXERA in the 1880s. Approximately 68,000 ha/167,960 acres were treated, requiring the painstaking insertion of about 30,000 holes per ha (12,000 per acre). Phylloxera is now controlled by GRAFTING, and today fumigation is used primarily to control the NEMATODE vector *Xiphenema index* of the virus disease FANLEAF DEGENERATION, but also for ARMILLARIA ROOT ROT, CROWN GALL, and occasionally squirrels and gophers.

Fumigation is difficult since it requires deep injection of a volatile chemical or gas which will permeate every pore to kill effectively. The exercise is most effective if the soil is porous and not too wet. Newly fumigated vineyards in environmentally conscious areas such as California are covered with a large plastic sheet to prevent the fumigant being lost to the atmosphere. Some fumigants were banned in the early 1990s since they were found to contaminate groundwater, and the use of ozone-depleting methyl bromide was banned in the EU in 2010. Where possible, resistant ROOTSTOCKS are a better alternative, as well as the application of post-planting PESTICIDES. R.E.S. & J.E.H.

Fumin, renascent dark-berried vine speciality of the Valle d'AOSTA whose firm produce, from 25 ha/62 acres in 2015, is usually blended.

funds, wine. Wine funds aggregate investors' funds with a view to creating a professionally managed, balanced portfolio of FINE WINES. The first credible wine funds were the UK-based operations The Wine Investment Fund and the (now defunct) Vintage Wine Fund, which opened for business in January 2003.

Wine investment funds emerged as a result of the steady growth in the value of fine wine and with it the new respectability of fine wine as a part of SWAG, the tangible asset class that comprises silver, wine, art, and gold. The prestige conferred by fine-wine ownership and the thrill of the chase have contributed to the phenomenon of wine investment in general and the wine investment funds in particular.

In parallel with art funds, the mid 2000s saw a glut of wine funds, and by 2014 there were more than a dozen such operations across Europe, the US, and Asia with estimated investments under management of between £150 and £200 million.

Wine funds were originally aimed at professional investors and high-net-worth individuals. While certain professional businesses have now been active for many years, other funds have been hampered by

low liquidity, growing too fast in a relatively small market, questionable valuation standards, and poor portfolio selection.

Wine funds necessarily rely on a continuing rise in overall fine-wine prices in order to provide returns to their investors. It was of considerable concern to wine funds and their investors when the Bordeaux bubble burst in mid 2011, following an unprecedented pricing surge for the region's successful 2009 and 2010 vintages. Many businesses running purely as wine funds did not survive. Fund managers taking a long-term view, creating diverse portfolios, and paying particular attention to PROVENANCE are presumably the ones most likely to succeed today. A.H.L.R., C.A. & E.L.

Lister, E., 'Liquid Assets', *World of Fine Wine*, 32, 33, 34.

fungal diseases, very large group of vine diseases which are caused by small, mostly microscopic, and filament-shaped organisms. Since fungi lack chlorophyll they need to live on other organisms to obtain nourishment. Fungal diseases have been of major significance in affecting grape production over centuries, with important consequences for both quantity and quality. Today they receive little public attention since they can successfully be controlled by a wide range of AGROCHEMICALS. In fact the famous fungicide BORDEAUX MIXTURE was used commercially to control DOWNY MILDEW in 1885 and for 50 years was the most important control of other fungal and bacterial plant diseases. Fungal-disease epidemics are commonly related to weather conditions; examples are downy mildew and BOTRYTIS BUNCH ROT, both of which are favoured by warm, wet or humid weather, while POWDERY MILDEW is favoured by overcast, cool weather.

Many of the economically important fungal diseases originated in America, and therefore common varieties of the European VITIS VINIFERA species have no resistance. Thus, when powdery mildew was introduced in 1847 and then downy mildew in 1878, French *vinifera* vineyards were devastated. Fungal diseases can attack shoots and leaves but also developing bunches and ripe fruit. Some fungi such as

Armillaria and *Verticillium* attack roots. Of more recent concern are a group of fungi which cause TRUNK DISEASES. They spread in vineyards and are also common contaminants of young vines propagated in grapevine NURSERIES.

Botrytis is the fungus with which wine consumers are probably most familiar. In its benevolent form (see NOBLE ROT), it contributes to a high proportion of the most famous SWEET WINES. The more common malevolent form (see GREY ROT) causes substantial yield and quality losses, on the other hand.

Common fungal diseases are ANTHRACNOSE, ARMILLARIA ROOT ROT, BLACK ROT, BOTRYTIS BUNCH ROT, BUNCH ROTS, COLLAR ROT, DEAD ARM, DOWNY MILDEW, ESCA, EUTYPA DIEBACK, POWDERY MILDEW, TEXAS ROOT ROT, VERTICILLIUM WILT, and WHITE ROT. Other groups of vine diseases include BACTERIAL DISEASES, PHYTOPLASMA diseases, and VIRUS DISEASES.

fungi, a group of small and often microscopic multicellular or filamentous organisms which derive their energy living as saprophytes on dead plant or animal tissue or as pathogens on living tissue. Fungi include YEASTS important in fermentation and many organisms causing vine FUNGAL DISEASES.

fungicide, type of PESTICIDE that is effective against FUNGAL DISEASES in vineyards. The first of the modern fungicides used for any crop was the BORDEAUX MIXTURE used on grapevines against DOWNY MILDEW in 1885. Fungicides are applied by SPRAYING at times which are deemed effective to prevent fungal development or control existing disease. Fungicides are thus classified as protectants or eradicants,

depending on the timing of application. Protectant fungicides are applied before the fungus infects the vines, and they prevent infection by inhibiting fungal development on the plant surface.

Eradicant fungicides are effective when applied after the infection has occurred. They can either inhibit or kill fungi present on or in the vine, thus preventing these fungi from further disease development. A typical characteristic of eradicants is their ability to penetrate plant tissues, most being systemic. Some eradicant fungicides can be applied one week or more after infection and still be effective.

Systemic fungicides have the ability to infiltrate and move within plants. Movement may be relatively localized, such as from one side of a leaf to the other (translaminar), or extensive, via the vine's vascular system. Contact fungicides are not absorbed by plant tissue: they act on the surface, and so good coverage of the target is critical. Examples include SULFUR and COPPER formulations. Copper ions are toxic to zoospores of downy mildew and prevent infection on the surface of plant tissue.

Mixtures of active ingredients may be used in formulations for different purposes and may take advantage of synergistic effects: copper oxychloride and zineb mixtures, for example, or to create mixtures of protectant and eradicant fungicides, as for copper oxychloride and metalaxyl. Some fungicides may be used against more than one fungal pathogen: azoxystrobin is effective against both downy mildew and BOTRYTIS BUNCH ROT, for instance, whereas others have a narrow range of action.

It is important to keep levels of fungicide RESIDUES below limits specified for toxicological reasons. For wine grapes, there is an additional consideration: residues of some fungicides will inhibit yeast activity, thus affecting fermentation and resultant wine quality.

As with other pesticides, the potential for development of resistance to fungicides varies according to the type of fungicide. Fungicides can be grouped according to their mode of action as either multi-site or single-site inhibitors. Multi-site inhibitors are toxic in more than one way, and the chance of developing resistant strains by mutation is therefore low. This group includes protectant

fungicides which have been widely used in viticulture for decades without any significant decrease in efficacy. Single-site inhibitors have more specific toxicity; because they inhibit only one or a few steps in fungal metabolism, the chance of resistant strains arising is much greater. Many of the newer fungicides fall into this group. Strategies that delay or prevent the development of resistant strains include restrained use, the use of mixtures of multi- and single-site inhibitor fungicides, and alternation of single-site inhibitors during the season. Over time, resistance to fungicides used for POWDERY MILDEW and BOTRYTIS BUNCH ROT has developed.

Some 'natural' substances have been tested and proven to be effective against fungal pathogens. Activated potassium bicarbonate, paraffinic oil, and milk or whey have been researched for powdery mildew control. In some cases commercially available products have been developed. Species of *Aureobasidium*, *Bacillus*, and *Trichoderma* have been found to compete with fungal pathogens such as downy mildew and BOTRYTIS and reduce infection levels. Other compounds, it is suspected, elicit plant disease resistance mechanisms; if applied ahead of infection, they can reduce damage by fungal disease. See also AGROCHEMICALS. P.R.D. & M.E.

furfurals. See OAK FLAVOUR.

Furmint, fine, fiery white TOKAJ grape variety grown most widely in Hungary; in Štajerska Slovenija (Styrian Slovenia) just over the

Slovakian border from Tokaj and in Croatia under the name Pušipel (sometimes, Moslavac); and in Romania. It is also being revived in Austria for both dry and sweet wines, particularly in Rust (see RUSTER AUSBRUCH), where it dominated until the early 20th century and was reintroduced from Tokaj by Robert Wenzel in the 1980s. DNA PROFILING has shown that it has a parent–offspring relationship with GOUAIS BLANC; the other parent is thought to be the totally obscure Alba Imputotato frrom Romania. Furmint is also a parent of HÁRSLEVELŰ.

Helpfully for the great sweet wine that is Tokaji, the grapes are particularly sensitive to NOBLE ROT, yet the wine is characterized by very high acidity, which endows the wine with long ageing potential, high sugar levels, and rich, fiery flavours. In Tokaji it is usually blended with up to half as much of the more aromatic grape variety Hárslevelű, and some Sárga Muskotály (MUSCAT BLANC À PETITS GRAINS) is also sometimes included in the blend.

Furmint can easily produce wines with an ALCOHOLIC STRENGTH of 14% or higher, and sturdy, characterful dry Furmint can age extremely well, in addition to being delicious in youth. Although most of Hungary's 3,605 ha/8,908 acres of Furmint are in Tokaj, in Somló it can also make impressively concentrated dry wines. The vine buds early, but ripening slows towards the end of the season, and in some years the BOTRYTIZED (*aszú*) grapes may not be picked until well into November.

The vine has been known in Tokaj since at least the late 16th century, and it is still grown to a limited extent in South Africa, where it was imported in tandem with Hárslevelű.

fusel oil, or fusel oil alcohols, a general collective term for the complex and varied mixtures of natural organic chemicals, largely higher alcohols, that are separable as wine is distilled into brandy. It can be removed by efficient distillation, but varying amounts are retained in brandies for its contribution to the flavour. It is predominantly a by-product of the nitrogen metabolism of the YEAST

during fermentation and of only minor importance to the wine drinker since it represents such a small proportion of wine aroma.

futures. In wine, wine bought before it is bottled and therefore long before it can be delivered. See EN PRIMEUR and INVESTMENT.

FYROM. See NORTH MACEDONIA.

G

Gabon, Central African country on the Atlantic coast where viticulture dates back to 2003 with the creation of the Domaine d'Assiami, the one and only vineyard in the country. Imagined by former President Omar Bongo Ondimba in his native region after his meeting with Dominique Auroy, French founder of a TAHITI vineyard, the estate saw its first vines planted in 2008 on the SANDY soils of the Batéké plateau, in the village of Assiami in the south-east of the country. Located just 300 km/186 miles south of the equator, the region has a TROPICAL CLIMATE, hot and humid, with an average of 1,900 mm/75 inches of rain per year, most of it falling March–April and October–November. In order to achieve optimal grape quality, the vines are managed to draw out the ripening phase between June and September, when rainfall is typically less than 150 mm/6 in.

J.-B.A.

Gaglioppo, predominant red grape variety in CALABRIA in the far south of Italy whose mid-ruby, quite tannic wines can be hauntingly scented, sometimes of roses. DNA PROFILING has shown it to be a natural CROSS of SANGIOVESE and Mantonico Bianco and therefore a sibling of NERELLO MASCALESE. It thrives in dry conditions and is occasionally found further north. Italy's total plantings of the variety stood at 4,626 ha/11,431 acres in 2015.

Gaillac, dynamic, variegated AOC in SOUTH WEST FRANCE that is also of considerable historic importance. As outlined in the history of FRANCE, archaeological evidence suggests that Gaillac may have been one of the first viticultural centres of ancient GAUL, with wine production well established in the early years of the 1st century CE.

Gaillac certainly seems to have been producing wine long before BORDEAUX, the port through which its wines would have been shipped after being transported down the rivers Tarn and GARONNE. BARBARIAN invasions then curbed wine production until it was revived by MONKS at the Abbey of St-Michel-de-Gaillac in the 10th century. Gaillac wines were highly prized both locally and in northern Europe, especially ENGLAND, in the Middle Ages. Its export trade was thwarted, however, by the protectionist measures imposed by the merchants of Bordeaux.

The Albigensian Crusade and the religious wars of the 12th–13th centuries inevitably disrupted trade, although there is evidence that the English were once more buying Gaillac with enthusiasm in the 16th century, and the region, along with LIMOUX, was already associated with SPARKLING WINE production in 1680.

The powerful, deeply coloured red wines of Gaillac continued to be prized by blenders in the early 19th century when ADULTERATION AND FRAUD were rife, but the arrival of PHYLLOXERA towards the end of the century drove many local farmers to exploit crops other than the vine.

In modern times, around 60% of Gaillac's annual production of 155,000 hl/4,094,667 gal is red wine, with 30% white—including dry, sparkling, and sweet wines—and the rest rosé. Gaillac wines are made on both sides of the river Tarn. On the north bank, there is a subsidiary area called Gaillac Premières Côtes, where some of the best wines are made and where the production rules are stricter. Further north is the Cordes plateau, its CHALKY soils the source of many of Gaillac's best dry whites.

The most distinctive local white grape variety is white- or pink-skinned MAUZAC, whose wines have a strong apple-peel aroma and sometimes a certain astringency. LEN DE L'EL is another increasingly popular local variety, and MUSCADELLE is the third principal grape. The three together must make up at least half of any dry white Gaillac. Sauvignon Blanc is also allowed, although iconoclasts such as Robert Plageoles happily ignore it, opting instead to produce a range of

idiosyncratic wines such as a *vin de voile* aged under FILM-FORMING YEAST and a *vin* DOUX from ONDENC, an old variety now making a comeback and a reminder that, until the 1960s, dry white wine was not made in Gaillac.

Gaillac also produces a slightly fizzy white called Perlé, and sparkling wines are made here by the *méthode gaillacoise*, a close relation of the *méthode ancestrale* (see SPARKLING WINEMAKING). These range in style from dry to sweet.

Gaillac reds can have the structure of a good bordeaux but more spicy flavours, substantially based on the spicy DURAS and full-bodied FER (called Braucol locally), sometimes supplemented by Syrah as well as other local varieties. The relatively recent arrival GAMAY was planted in the 1960s to provide Gaillac vignerons with income from PRIMEUR wines. The AOC regulations of Gaillac hint at thousands of hours of local political manœuvre. There is a clear division between the aspirations of the most innovative independent growers and the forces of mass production driven by the local CO-OPERATIVES and NÉGOCIANTS. P.S.

Gaja, one of the most renowned producers of high-quality, estate-bottled wines in PIEMONTE, traces its origins to 1856 when the Gaja family opened a tavern in their home town of BARBARESCO and began serving their own wines to accompany the food. By the end of the 19th century, the wines were already being bottled and supplied to the Italian army in Abyssinia, a highly unusual development in their home district of the Langhe, where a tradition of bottled wine assumed real significance only from the 1960s. The firm became an important force after the Second World War under the direction of Giovanni Gaja, who began an important series of vineyard purchases in what is now the Barbaresco DOCG zone, a strategy that has given the house a total vineyard area of 101 ha/249 acres, dwarfing all other family-owned Barbaresco houses, and an excellent selection of superior vineyard sites.

Gaja wines gained worldwide recognition under Giovanni's son Angelo Gaja, who took over in the late 1960s. Trained at the oenological school of Alba and at MONTPELLIER, an indefatigable traveller in the world's major viticultural areas, and a tireless and charismatic champion of his native region and its wines, he gave a new international perspective to the wines, pioneering small BARREL AGEING of both Barbaresco and BARBERA and introducing INTERNATIONAL VARIETIES to the vineyards of Piemonte (his Cabernet Sauvignon is called Darmagi, Piemontese for 'what a shame', supposedly his father's reaction). He also acquired land in nearby BAROLO, with the 1988 Barolo Sperss marking a return to the zone from which the Gaja family made a wine from purchased grapes until 1961.

In the 1990s Gaja expanded his horizons even further, purchasing the Pieve di Santa Restituta estate in Montalcino, where the first BRUNELLO DI MONTALCINO produced under his supervision was made in 1993 and, more recently, the development of the Ca' Marcanda estate in BOLGHERI on the Tuscan coast.

In 1999 Gaja announced that he was renouncing the name he had made so famous and selling all the wine previously sold as Barbaresco DOCG, including his fabulously expensive single-vineyard Sorì San Lorenzo, Sorì Tildin, and Costa Russi bottlings, as DOC Langhe Nebbiolo, the catch-all appellation for declassified Barolo and Barbaresco and for wines containing up to 15% 'foreign' varieties such as Cabernet Sauvignon, Merlot, and Syrah. But now that Gaja's daughter Gaia, with her brother Giovanni and sister Rosella, is at the helm, the Barbaresco denomination has been restored on labels, with further geographical precision expected. In 2017 Gaja founded IDDA, a JOINT VENTURE with Alberto Graci on Etna's little-known but promising south-west flank rather than in the overcrowded north.

Steinberg, E., *The Vines of San Lorenzo* (1992).

Galen, Greek physician whose work in the 2nd century CE was influential in Greece, Rome, and beyond. He identified the antiseptic

properties of wine. See ATHENAEUS and MEDICINE.

Galen, *Selected Works*, translated by P. N. Singer (1997).

galestro, the local name for soils of finely splitting scaly CLAY (*argille scagliose*) and MARLY clay that characterize many of the best vineyards in CHIANTI CLASSICO as well as in parts of MONTALCINO. The region's bedrock consists of an intricate arrangement of marls, CALCAREOUS marls, fine SANDSTONES, and scaly clay. The resulting soils are in places flaky and lustrous, well drained yet moist. A.J.M.

galet, or galet roulé, is a French term for a pebble, cobble, or even a boulder (see GEOLOGY) that is well rounded due to abrasion through continual rolling in fast-moving water.

The celebrated river-worn galets of CHÂTEAUNEUF-DU-PAPE and other parts of the southern Rhône are composed of strikingly white QUARTZITE. Although it is probably the underlying CLAYS and SANDS that are more significant for vine growth, these *galets* are so iconic that the name is now applied to rounded rock fragments in other vineyard regions, irrespective of their composition. In the Boutenac area of CORBIÈRES, for example, the *galets* are formed from a brown-stained quartzite; in California's ARROYO SECO, *galets* are a mixture of rock types; and Walla Walla, WASHINGTON, has old river channels filled with *galets* of dark BASALT. A.J.M.

Galet, Pierre (1921–2019), father of modern AMPELOGRAPHY based in MONTPELLIER. Galet's working life was devoted to the science of describing and identifying VINE VARIETIES on the basis of minute botanical observation—an expertise he perfected while hiding from the German occupation in the international VITIS collection in the grounds of the Department of Viticulture at the University of Montpellier. From 1946 to 1989, Galet was part of an elite teaching group that included Jean Branas, Denis Boubals, and François

Champagnol at ENSA (now Montpellier Institut Agro), regarded as a centre of viticultural ACADEME. He taught thousands, including Paul Truel, whose own work was of worldwide significance, and Jean-Michel Boursiquot, who has succeeded him. Other acolytes include Lucie Morton (US), Umberto Camargo (Brazil), Erika Maul Dettweiler (Germany), and Anna Schneider (Italy).

Galet began by self-publishing a prodigious body of work which he continually updated. His foundational four-volume *Cépages et vignobles de France* came out between 1956 and 1964. Volume 1 was devoted entirely to American *Vitis* species, ROOTSTOCKS, and French-American HYBRIDS; Volumes 2 and 3 to VITIS VINIFERA wine grapes and Volume 4 to *vinifera* TABLE GRAPES. In 1988, when Volume 1 had become a rare book, he published Tome 1: *Les Vignes américaines*, 553 pages with colour illustrations. This was followed by Tome II: *L'Ampélographie française*, 400 pages devoted to *vinifera* wine grapes. His original Volume 4 on table grapes remains available but not renewed. Ever-active, at age 95 Galet oversaw an astonishing compilation of his ampelographic writing in *Dictionnaire encyclopédique des cépages*, illustrating and characterizing almost 10,000 grape varieties.

Beyond ampelography were Galet's two volumes of *Maladies et parasites de la vigne* (1977 and 1988). His textbook on general viticulture *Précis de viticulture*, first published in 1970 with the final 7th edition in 2000, was an essential reference. In 1983 he was lauded by the OIV for the entirety of his published work and awarded the Officier de l'Ordre du Mérite Agricole in 2013.

Outside the classroom, Galet's authoritative vine identification, which predated genetic sequencing, helped settle legal disputes and informed wine regions around the world as to which grape varieties they were growing under which names. He travelled to vineyards throughout the Americas, North Africa, Cyprus, Afghanistan, Nepal, Thailand, and South Korea (Truel inspected the vineyards of Australia and Portugal). For those who learn his methods, grape leaves become the face of the grape variety—recognizable wherever they may be. This creates a special and intimate relationship with vines

growing freely up a tree or constrained to a trellis before their fruit makes its way to the table or glass. L.T.M.

Galicia, Spain's Atlantic north-west and one of the country's 17 autonomous regions encompassing the DO wine regions of RÍAS BAIXAS, RIBEIRO, RIBEIRA SACRA, MONTERREI, and VALDEORRAS. Separated by mountains from CASTILLA Y LEÓN, Galicia has developed in isolation from the rest of Spain, the region being geographically and culturally closer to northern Portugal than to Madrid (see map under SPAIN). The locals speak Gallego, a close relative of Portuguese. The wines also used to share an affinity with the light, acidic VINHO VERDE produced south of the Miño (Minho in Portuguese), the river that divides this part of Spain from Portugal, but they have become fuller and more substantial with the recovery of INDIGENOUS VARIETIES and the use of modern winemaking techniques.

Wines were exported from Galicia as early as the 14th century, but northern European merchants quickly moved on in search of fuller-bodied wines from the DOURO in northern Portugal. The progressive fragmentation of agricultural holdings left the region with a subsistence economy, and since the 19th century the countryside has suffered from depopulation as people move away to find work. Many of the magnificent TERRACES in the PORT vineyards of the Douro were constructed by itinerant labour from Galicia. Since Spain joined the EU in 1986, however, Galicia has benefited from a massive injection of funds which has transformed its wine industry.

Climatically, Galicia is a transition region from the wet Atlantic coast to the typicial Mediterranean conditions of the Peninsula. On the coast, RAINFALL averaging more than 1,300 mm/50 in a year is compensated for by an annual average of over 2,000 hours of

sunshine. Vines flourish in these humid conditions, and YIELDS of over 100 hl/ha (5.7 tons/acre) are unequalled anywhere else in Spain. Most of the vineyards are towards the south in the provinces of Orense and Pontevedra and also in Lugo to the east. Rías Baixas, with its prized ALBARIÑO grape, was the engine of Galician rebirth, and its vibrant, dense wines can command high prices. But success has also meant, in the case of some producers, excessive yields and an abusive reliance on such techniques as the use of selected YEASTS. On the Miño river, wines are often blends of Albariño, LOUREIRA, and CAÍÑO BLANCO.

Inland, the Ribeiro DO is making impressive progress. Local whites are complex blends dominated by TREIXADURA and TORRONTÉS, while reds from native varieties are making a remarkable comeback. In the inland Valdeorras and Ribeira Sacra DOs, light reds from the MENCÍA grape are prevalent, but the appley, white GODELLO grape is their main asset. The youngest DO, MONTERREI, has historic significance. It, too, has joined Galicia's dramatic improvement in wine quality.

gallic acid, a measurement of TANNIN.

Gallo Winery, E. & J., based in Modesto, CALIFORNIA, is the largest winemaking operation in the world and is still family-owned and family-operated. Gallo was developed by the brothers Ernest (1909–2007) and Julio (1910–93) from the vineyards of their father, who shipped grapes for HOME WINEMAKING during PROHIBITION. On the eve of Repeal in 1933, the brothers obtained a licence to manufacture and store wine, and on the demise of Prohibition at the end of that year they began the rapid expansion of their business. Their father and uncle had been associated with the wine business, and winemaking in some form went on in the CENTRAL VALLEY, where the Gallos lived and grew grapes, throughout Prohibition.

Nevertheless, Ernest Gallo's success in establishing a national distribution network—first, while still in his teens, as a grape broker, and then for wine—stands as an extraordinary feat, particularly in view of the business milieu of the era, still dominated by the thuggish outlaw element nurtured by Prohibition.

Julio's special charge was production. By 1935, just two years after Repeal, the winery was producing 350,000 gal/13,300 hl of wine, and in 1936 the brothers built a new facility with a capacity of 1.5 million gal. The new winery's design showed their concern for the highest level of technical efficiency, as its capacity showed their determination in pursuing new and larger markets. In common with most large California wineries, the Gallos at first sold largely in BULK to bottlers; in 1937 they began to promote their own label and to devise their own marketing methods. The development of the firm thereafter was as a completely self-contained enterprise: it either owned its own vineyards or signed growers to long-term contracts; built its own glass factory; maintained its own sales force; acquired control over distributorships; and operated its own research department, its own print shop, and its own transport company. All this continues today. The company is quite remarkably powerful—and quite remarkably secretive.

By 1950 Gallo had the largest wine-production capacity in the United States, and by 1967 it held first position in sales. Moreover, Gallo's sales and marketing operation was long considered the academy for such functions in America. At one time, almost all the top wine sales executives in the US had at least a short stint with Gallo on their résumés. In the 1950s and 1960s, Gallo so revolutionized concepts of wine retailing in America that it was said that Gallo salespeople knew more about a store's inventory than its owner. No wonder Gallo has been accused of having a domineering influence over the rest of the industry, particularly, through its sheer size, in the councils of the trade organization the (California) Wine Institute.

Known from the beginning for sound, inexpensive wines of every kind, including FLAVOURED WINES, wine coolers, FRUIT WINES, brandy,

and bulk-process SPARKLING WINES, Gallo inevitably became synonymous with basic JUG WINE.

From 1977, however, Gallo made a determined effort to associate its name with better-quality wines, VARIETALS sold in bottles stoppered with a CORK. By the early 1980s, Gallo was already the largest purchaser of grapes in the Napa Valley. By the end of the 1980s, Gallo had become the largest vineyard owner in Sonoma County. After years of buying grapes and wine from the North Coast, Ernest and Julio signalled their faith in Sonoma County by buying Frei Brothers in Healdsburg in 1977. Gallo have since added MacMurray Estate Vineyards, J Vineyards & Winery, Asti Winery, Laguna Ranch, Del Rio Vineyard, and Two Rock Vineyard in the Russian River Valley; Frei Ranch, Chiotti Vineyard, and Stefani Vineyard in the Dry Creek Valley; Barrelli Creek Vineyard in the Alexander Valley; and the legendary Monte Rosso Vineyard in the Sonoma Valley.

In the 1990s, Gallo began acquiring properties in the Central Coast, including the Olson Ranch in Monterey County and Sunnybrook Ranch in San Luis Obispo County.

Between 2012 and 2017, Gallo purchased Talbott Winery and Sleepy Hollow Vineyard in the Santa Lucia Highlands; Rancho Real and the renowned Sierra Madre Vineyard in Santa Barbara County; Snows Lake Vineyard in Lake County; Ledgewood Creek Vineyard in Solano County just east of the Napa Valley; and Cypress Ranch, a portion of the Palisades Vineyard, and the famous 1,300-acre Stagecoach Vineyard in the Napa Valley.

In 2002, Gallo acquired the highly regarded Louis M. Martini Winery, the first time the company had ever purchased a BRAND, soon to be joined by the Mirassou brand. In 2005, Gallo acquired the Barefoot Cellars brand, which has grown to be the largest-selling wine brand in the world. William Hill Estate Winery and the Canyon Road brand were purchased in 2007, along with Edna Valley Vineyard in 2011. The next year Courtside Cellars in San Miguel was added, along with its first acquisition in Washington State, Columbia Winery. Gallo continued to expand its premium portfolio so that by 2020 it

also owned Asti Winery, The Ranch Winery, Orin Swift Cellars, Locations, Pahlmeyer, and Jayson by Pahlmeyer.

In 2021 Gallo announced the acquisition of more than 30 brands from CONSTELLATION BRANDS, including Black Box, a bag-in-BOX operation; Clos du Bois, Estancia, Franciscan, Mark West, Ravenswood, Taylor, Vendange, and Wild Horse in California; Hogue in Washington State; and Arbor Mist flavoured wines and Manischewitz KOSHER wine in New York State, adding five new wineries. The Nobilo New Zealand Sauvignon Blanc brand was also acquired in a separate transaction with Constellation, and Denner Vineyards in Paso Robles was bought by Gallo in late 2022.

Gallo began importing Italian wine in 1996, which it sold under the name Ecco Domani. Gallo currently imports wine from Argentina, Chile, France, Italy, Spain, New Zealand, and Spain. Maze Row Wine Merchant is its premium wine import arm.

Today Gallo is the largest exporter of California wines, and it currently has offices in the UK, Germany, Poland, Hong Kong, Japan, Canada, and Mexico.

Hawkes, E., *Blood and Wine: The Unauthorized Story of the Gallo Wine Empire* (1993).

Galotta, red grape CROSS bred in Switzerland by André Jaquinet at CHANGINS from ANCELLOTTA and GAMAY, producing deeply coloured, tannic, full-bodied wines often used in blends. Authorized in 2009, there were 57 ha/141 acres planted by 2020.

Gamaret, red grape CROSS bred in Switzerland by André Jaquinet at CHANGINS from GAMAY and REICHENSTEINER. The variety has good rot resistance and makes quite powerful, structured wines. Total Swiss plantings had reached nearly 439 ha/1,085 acres by 2020. It is more popular than fellow cross GARANOIR, is authorized in Beaujolais, and is occasionally found in Italy.

Gamay, or Gamay Noir, ancient Burgundian red grape variety solely responsible for the distinctive, evolving, and no longer unfashionable wines of BEAUJOLAIS. GALET cites 30 different Gamays, many quite unrelated to the Beaujolais archetype, many of them particular CLONAL SELECTIONS of it, and many more of them red-fleshed TEINTURIERS once widely used to add colour to vapid blends. Red-fleshed versions can still be found, particularly in the Mâconnais and Touraine, and France grew 115 ha/284 acres of Gamay Teinturier de Bouze in 2019. The 'real' Gamay is officially known as Gamay Noir à Jus Blanc to draw attention to its noble pale flesh, and it is a natural offspring of Pinot and Gouais Blanc (see PINOT).

The introduction of Gamay to the vineyards of the CÔTE D'OR in the late 14th century was viewed as scandalous by those whose livelihood did not personally depend on rearing productive vines, and great efforts were made to retain PINOT NOIR at the expense of the less noble newcomer.

The vine is a precocious one, budding, flowering, and ripening early, which makes it prone to spring FROSTS but means that it can flourish in regions as cool as much of the Loire. It can easily produce too generously, and the traditional GOBELET method of training is designed to match this aptitude to the GRANITIC soils of the better Beaujolais vineyards.

Although today an increasing proportion of Beaujolais, particularly from the CRUS, is vinified like red burgundy with full BARREL AGEING and is expected to age for several years in bottle, Gamay juice long tended to be vinified in a hurry, not least because of strong market pressure in the 1970s and 1980s for Beaujolais NOUVEAU. As a wine, Gamay tends to be paler and bluer than most other reds, with relatively high acidity and a simple but vivacious aroma of freshly picked red fruits, often overlaid in the Nouveau era by the less subtle smells associated with rapid CARBONIC MACERATION such as bananas, boiled sweets, and acetone. In the Mâconnais and Switzerland, it is often blended with Pinot Noir, endowing the nobler grape with some precocity but often blurring the very distinct attributes of each.

Gamay and Beaujolais are entirely interdependent. Few wine regions are so determinedly *monocépagiste* as Beaujolais: in 2019 all but 800 ha of the Rhône *département*'s 14,832 ha/36,651 acres of vines were Gamay Noir. Vinification techniques vary, but most common are local variants on SEMI-CARBONIC MACERATION. Similar, often lighter and arguably truer, wines are made from the Gamay grown in the small wine regions of central France, particularly those around Lyons and in the upper reaches of the Loire such as CHÂTEAUMEILLANT, Coteaux du LYONNAIS, Coteaux du GIENNOIS, Côtes d'AUVERGNE, Côtes du FOREZ, Côte ROANNAISE, and ST-POURÇAIN.

Outside Beaujolais, perhaps because its wines were so long unfashionable, the Gamay vine has been losing ground. In the Côte Chalonnaise and the Mâconnais between Beaujolais and the Côte d'Or, Gamay was displaced as principal grape variety by Chardonnay during the 1980s, and Pinot Noir plantings had surpassed those of Gamay by the 21st century. The generally unexciting quality of Gamays made here is expected to continue this trend. Gamay took up just 117 ha of the Côte d'Or's valuable vineyard in 2019.

Gamay is widely planted in SAVOIE, grown especially in the CRU of Chautagne. It is also grown all over the Loire, especially in the Loir-et-Cher *département* upstream of Tours, but is not glorified by any of the Loire's greatest appellations. Gamay de Touraine can provide a light, sometimes acid, but usually cheaper alternative to Beaujolais, but it is most widely grown west of Touraine, alongside Sauvignon, for such light, lesser-known names as CHEVERNY and Coteaux du VENDÔMOIS. Considerable plantings in the south-west, greater Loire, and the Mâconnais brought France's total area of Gamay Noir up to 23,187 ha/57,296 acres in 2019.

Outside France, the most notable attempts to develop this under-appreciated variety have been in North America, with the first plantings in the 1970s. In 2020, Ontario boasted 172 ha/425 acres, British Columbia 76 ha/189 acres, and Oregon 55 ha/136 acres, the last two showing growth in recent years. Oregon even hosts an annual 'I Love Gamay' festival. While California has plantings of

Gamay Noir, the variety referred to as Napa Gamay is actually VALDIGUIÉ.

Gamay is also grown in small quantities in New Zealand, Australia, South Africa, and Italy, and it is often confused with BLAUFRÄNKISCH (to which it may well be related) throughout eastern Europe. It plays a relatively important role in the vineyards of TÜRKIYE, SERBIA, and KOSOVO.

Beyond Beaujolais, it is chiefly valued by the Swiss, who grow it widely and often blend it with Pinot Noir to produce Dôle (*see* SWITZERLAND).

Gamay del Trasimeno. See GRENACHE NOIR.

Gambellara, dry white wine from the VENETO region of north-east Italy. Based on GARGANEGA grapes (a minimum of 80%, with 20% of TREBBIANO di Soave or Trebbiano Toscano), it is produced in the townships of Gambellara, Montebello Vicentino, Montorso, and Zermeghedo, only a short distance from SOAVE but in the neighbouring province of Vicenza. Gambellara covers only about 600 ha compared with Soave's 6,991 ha/17,275 acres in 2020 but with generally more Garganega and lower yields from its VOLCANIC soils. Since the enlargement of the PROSECCO zone, much of the Garganega planted on the plains south of the town of Gambellara has been replaced with GLERA, so HILLSIDE VINEYARDS represent a healthy 60% of the Gambellara total.

Soil research conducted at the beginning of the century identified six subzones—Faldeo, Taibane, Monti di Mezzo, San Marco, Creari, and Selva—which have begun to appear on labels. Much of

Gambellara's output has lacked ambition, but perceptions are changing with estates such as the biodynamic La Biancara Estate, with its SKIN-FERMENTED wines, even if some of the wines are labelled IGT rather than Gambellara, not least because of a quality-control system unwilling to recognize the wines as typical.

The DOC Gambellara zone is elevated to DOCG for the sweet RECIOTO di Gambellara, which has a long history in the region, while Gambellara CLASSICO is not a smaller, historic subzone but a wine with higher alcohol and from (marginally) lower yields. Gambellara VIN SANTO is a PASSITO wine made from grape bunches dried for at least 60 days. W.S.

Gamé, Bulgarian name for BLAUFRÄNKISCH.

www.consorziogambellara.com

Gamza, name for KADARKA in BULGARIA.

garage wines, unofficial, late 20th century term for wines made with ambition in such small quantity that a garage would suffice as winery. Their makers were known as garagistes. Although the term came to be used globally, the phenomenon was first observed on Bordeaux's RIGHT BANK, with miniature wine estates producing ultra-modern, deep-coloured, early-maturing, often sweet, oaky, flattering reds, typically in quantities of a few hundred cases, apparently aimed to catch the eye of then-omnipotent wine critic Robert PARKER. LE PIN in Pomerol was the archetype and is the only one to have experienced sustained demand.

Echikson, W., *Noble Rot: A Bordeaux Wine Revolution* (2004).

Garanoir, red grapevine CROSS created at CHANGINS by André Jaquinet from GAMAY and REICHENSTEINER. It makes less concentrated, softer, fruitier wines than its sister cross GAMARET and was planted on 230 ha/568 acres in Switzerland in 2020.

Gard, IGP for the *département* which stretches from the coast of Nîmes inland to the Cevennes Mountains. The smaller IGPs Cévennes and Coteaux du Pont du Gard as well as the AOCs of COSTIÈRES DE NÎMES, TAVEL, and LIRAC sit within it. Mediterranean varieties mix with INTERNATIONAL VARIETIES, often appearing in varietally labelled wines.

Garganega, vigorous, productive (often over-productive), late-ripening white grape variety of the VENETO region in north-east Italy. Its most famous incarnation is SOAVE, in which it may constitute anything from 70 to 100% of the blend, often sharpened up by the addition of TREBBIANO di Soave (VERDICCHIO) but increasingly plumped up by CHARDONNAY and other imports. In the Soave CLASSICO zone, with yields kept well in check and where it is allowed to ripen fully, it can produce the fine, delicate whites redolent of lemon and almonds which give Soave a good name. Naturally high in acid, it can give balanced yet steely wines that have an alluring, delicate spiciness. The vine is also responsible for GAMBELLARA. Other wines in which it plays a major part include Bianco di CUSTOZA, Colli Berici, and Colli Euganei, and it is also grown to a more limited extent in both FRIULI and UMBRIA. In 2007, DNA PROFILING revealed that Garganega is identical to Sicily's GRECANICO DORATO. Italian vineyard statistics reported 8,522 ha/21,058 acres of Garganega in 2015 (but the over 4,000 ha of Grecanico Dorato are listed separately). Garganega also seems to be a parent of a wide range of Italian varieties. It is also grown in Australia.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Garnacha is the Spanish, and therefore original, name for the increasingly fashionable grape known in France and elsewhere as GRENACHE. Its most common and noblest form is the dark-berried and light-fleshed Garnacha Tinta (Garnaxa in Catalan). As this variety, ubiquitous in much of Spain, has been re-evaluated from weed to asset (spurred on initially by PRIORAT's success and more recently by the finesse of wines from the Sierra de GREDOS, northern NAVARRA, and RIOJA Oriental), VARIETAL versions have become more common, as have blends with the firmer TEMPRANILLO, and the word 'Garnacha' is increasingly seen on wine labels.

Even after extensive GRUBBING UP in the 1980s and 1990s, when the variety was under-appreciated, in 2004 a total of 82,300 ha/203,300 acres made Garnacha Tinta Spain's second most planted red wine grape after Tempranillo. By 2020 Spain's Garnacha Tinta total had fallen to 58,764 ha/145,209 acres, very slightly more than the BOBAL total and little more than one-quarter of the Tempranillo total. It is grown particularly in Aragon and Castilla-La Mancha, being an important variety in such wine regions as Rioja, Navarra, Empordà-Costa-Brava, Campo de Borja, Cariñena, Costers del Segre, the Gredos Mountains, Madrid, La Mancha, Méntrida, Penedès, Priorat, Somontano, Tarragona, Terra Alta, Utiel-Requena, and Valdeorras. In Rioja it provides stuffing and immediate charm when blended with the more austere Tempranillo. The cooler, higher vineyards of Rioja Alta are reserved for Tempranillo, while Garnacha is the most common grape variety of the warm eastern Rioja Oriental region, where the vines can enjoy a long ripening season. The juiciness apparent in these early-maturing riojas can be tasted in a host of other Spanish reds and, especially, rosados. Garnacha has been adopted with particular enthusiasm in Navarra, where it has been the dominant grape variety and dictates a lighter, more obviously fruity style of red and rosado than in Rioja. In many other

areas, Garnacha is typically DRY-FARMED as an old BUSH VINE (average vine age is high) so that the wines can be quite concentrated and tannic.

Perhaps the most distinctive, and certainly the most expensive, Spanish wines based on Garnacha Tinta (sometimes incorporating some Garnacha Peluda, more commonly known as LLEDONER PELUT) are from Cataluña's Priorat, making concentrated wine in which the produce of old Garnacha vines is often blended with Carignan grapes, and from the Gredos Mountains.

Garnacha Blanca is the light-berried GRENACHE BLANC, of which in 2020 there were about 2,972 ha/7,344 acres in Spain, where it plays a role in full-bodied, north-eastern whites such as those of Alella, Priorat, Tarragona, Rioja, and Navarra. Old-vine Garnacha Blanca is particularly important in Cataluñya's TERRA ALTA.

Garnacha Tintorera, Spanish synonym for the red-fleshed ALICANTE BOUSCHET, Tintorera being Spanish for 'dyer' or TEINTURIER. Also known as Negral. Spain grew 35,562 ha/87,876 acres of this variety in 2020.

Almost three-quarters is in CASTILLA-LA MANCHA, where its deep colour is presumably much appreciated.

Garonne, river that rises south of Toulouse in SOUTH WEST FRANCE and flows north-west towards the Atlantic and on which the city of BORDEAUX is situated. The confluence of the Garonne and the DORDOGNE, between MARGAUX and BOURG, marks the southern end of the GIRONDE estuary. The Garonne was an important trade route through south-west GAUL in the era of ancient ROME and continued to play a vital role in the medieval wine trade, where there was particular commercial rivalry between the wines produced upriver in the HAUT-PAYS, either on the Garonne or on its tributaries the Lot and the Tarn, and those produced in Bordeaux's immediate vicinity.

Today the Garonne links, travelling north-west down river, FRONTON, LAVILLEDIEU, BRULHOIS, BUZET, Côtes du MARMANDAIS, CADILLAC CÔTES DE BORDEAUX, GRAVES, and Bordeaux's sweet-white-wine areas SAUTERNES and BARSAC.

garrafeira, word used by winemakers, wine bottlers, and wine collectors in PORTUGAL meaning a 'private wine cellar' or 'reserve'. The term was once widely used on wine labels to denote a red wine from an exceptional year that has been aged for at least 30 months before sale, including at least 12 months in bottle. White and rosé garrafeira wines, which are now fairly rare, must be aged for at least 12 months, including at least six months in bottle, to qualify. The law additionally states that the term can be used only for DOC or VINHO REGIONAL wines with outstanding organoleptic characteristics. Traditionally most garrafeiras were blends of wines from different parts of the country, labelled with the name of the merchant who bottled them. Under legislation introduced in the early 1990s, all garrafeiras must display their region of origin. See also PORT.

R.M. & S.A.

Garrido, minor speciality of the CONDADO DE HUELVA region in southern Spain.

garrigue, French word for Mediterranean scrubland that is sometimes borrowed as a TASTING TERM for wines with aromas reminiscent of wild herbs.

Garrut is a Catalan synonym for Monastrell or MOURVÈDRE.

Gascony, proud region in SOUTH WEST FRANCE which today comprises armagnac country and such wines as MADIRAN and TURSAN. In the Middle Ages it was incorporated into Aquitaine and was therefore, like BORDEAUX, under English rule for nearly 300 years from

the middle of the 12th century. The IGP Côtes de Gascogne and the overlapping IGP Gers were launched in the 1970s by the Grassa family (owners of Domaine du Tariquet, the largest single estate in the south-west) and the CO-OPERATIVE Producteurs Plaimont, largely in response to the decreasing sales of armagnac. The white wines, based mostly on COLOMBARD and UGNI BLANC grapes, have become extremely popular for their vivacity, freshness, and boiled-sweet character, and they have spawned a host of independent growers. There are also Merlot-based reds and rosés, generally less interesting. P.S.

Gattinara, small but historically important wine region in the hills between the towns of Vercelli and Novara in the ALTO PIEMONTE producing red wines based on NEBBIOLO, called Spanna here. Its vineyards, already classified in the 16th century, encompassed only 111 ha/274 acres in 2020. In the 19th century, these hills were far more widely planted with Nebbiolo than the LANGHE, and the wines were more highly prized than either BAROLO or BARBARESCO. The long decline of viticulture here was halted when Gattinara was awarded DOCG status in 1990. In 2004 an overarching DOC, Coste della Sesia, including the Lessona and Gattinara zones, was created to safeguard its wine production. Although production regulations faithfully reflect the historical practice of blending in the local UVA RARA and/or VESPOLINA grapes (maximum 10%), used in the past to compensate for unripe Nebbiolo grapes in cool vintages, practically all Gattinara is now made of 100% Nebbiolo, a sign of improved viticulture, lower yields, and, possibly, CLIMATE CHANGE. Gattinara is a seriously ageworthy wine with mandatory ageing of 35 months (47 months for Riserva), and SINGLE-VINEYARD WINES are the rule rather than the exception. The region received a further boost in 2019 when Roberto Conterno of Barolo's Giacomo Conterno estate took a majority stake in the historic Nervi estate. Conterno's move will undoubtedly be followed by other investors in the near future. W.S.

Gaul, part of western Europe closely approximating to modern France which existed before the rise of classical ROME. The elites of the CELTIC communities beyond the Alps were large-scale consumers of wine long before they were producers. The accoutrements of the Greek and Roman dinner party are frequently found amid the grave goods of Celtic chieftains. Their passion for wine was even claimed as the motive for the Gallic invasions of the Mediterranean world from the 4th century BCE onwards (see e.g. Livy, 5. 33). The import of wine from Etruria (see ETRUSCANS) and the arrival of Greek settlers at Massilia (Marseilles) in the late 7th century BCE stimulated viticulture in southern Gaul. From them the Gauls 'got used to living by the rule of law, and to pruning the vine, and planting the olive' (Justin, 43. 4. 1). The widespread ready market in Gaul for wine, as well as the slaves who were offered in exchange, was a major stimulus for exports from Italy, particularly in the last century BCE (Diodorus, 5. 26). But the real impetus for the creation of local vineyards came with the arrival of Roman settlers from the end of the 2nd century BCE. By the end of the 1st century BCE southern France and the RHÔNE Valley (Gallia Narbonensis) were planted with all the fruit that Mediterranean visitors expected. But beyond the Cévennes was a world where 'no vine, olive, or fruit grew', as the great scholar VARRO (*De re rustica*, 1. 7. 8) noticed while on campaign there. The reasons for this were part sociological and part ecological. Some tribes banned the drinking of wine and even massacred traders, in the belief that consumption undermined their manliness and was the explanation of their defeats by Julius Caesar's armies. More significant was the need for vines which were resistant to FROST. The 1st century CE was a time of considerable development in the south, including wines from Baeterrae (Béziers) and around Vienne (see CÔTE RÔTIE), where the Allobrogica vine was noted for producing a wine with a natural resinated taste. Wines from this region competed in the markets of Italy and the western Mediterranean, as the finds of the distinctive local AMPHORAE confirm. Elsewhere in Gaul it is more difficult to trace the introduction of viticulture. The GARONNE was an

important trade route from an early date; so it is highly likely that the BORDEAUX region was developed in the 1st century CE. On the other hand, the first references to vineyards in BURGUNDY, on the MOSELLE, and in the area of PARIS belong to the 4th century CE. However, recent archaeological finds suggest that viticulture may have developed considerably earlier in many regions than the inadequate literary sources suggest. The scale of production should not be exaggerated. Viticulture in regions such as the Moselle continued after the end of the Roman Empire. However, the modern map of wine production in France owes less to the Romans than to the Christian Church in the post-Roman period (see CHARLEMAGNE and MONKS AND MONASTERIES).

Dion, R., *Histoire de la vigne et du vin en France des origines au XIXe siècle* (1959).

Gavi, or Cortese di Gavi, is a renowned Italian dry white DOCG zone of 1,511 ha/3,733 acres and the most interesting expression of the CORTESE grape in PIEMONTE (but see also CUSTOZA). It is produced in 11 communes (Bosio, Carrosio, Capriata d'Orba, Francavilla Bisio, Gavi, Novi Ligure, Parodi, Pasturana, San Cristoforo, Serravalle Scrivia, and Tassarolo) in the south-east of the province of Alessandria. Although the name of each commune (and even single vineyards) may appear on labels, stylistic differences are not always evident, and most wines are blends of more than one commune. The best Gavi are elegant, with aromatic white fruit, mineral notes, and a long, tangy, citric finish. In the past the wines tended to be rather neutral, caused by excessively high maximum yields, which have recently been reduced to 60 hl/ha, and lower yet for single-vineyard wines. For a white wine best known in its still form, Gavi comes in a surprisingly wide range of styles: FRIZZANTE, SPUMANTE, and METODO CLASSICO (with a minimum required LEES CONTACT of 18 months), as well as MÉTHODE ANCESTRALE. Although there are several BARRIQUE-aged examples, most producers

stick to the conventional temperature-controlled fermentation in stainless steel. More interesting Gavi tends to come from producers who focus on ORGANIC and BIODYNAMIC practices and ferment the wine with ambient YEAST.

Thanks partly to the high quality achieved by the pioneering La Scolca estate in Rovereto di Gavi, the wine enjoyed great commercial success in the 1960s and early 1970s. Increasing competition in its category from TRENTINO, ALTO ADIGE, and FRIULI has subsequently put Gavi under a certain commercial pressure, but the trend towards INDIGENOUS VARIETIES in combination with its inimitable style, appreciated by an international market looking for lighter wines, works in Gavi's favour. GDC, vine-TRAINING SYSTEM. See GENEVA DOUBLE CURTAIN.

Geelong, wine region in the Port Phillip Zone of the Australian state of VICTORIA. Its cool, dry climate lends itself to complex, intense Pinot Noir and Chardonnay. Shiraz also does well. Most of the 45 producers are small, both family-owned and -operated.

Geilweilerhof. See JULIUS-KÜHN-INSTITUT.

Geisenheim University, former research institute for viticulture, horticulture, beverage technology, and landscape architecture, since 2013 known properly as Hochschule Geisenheim University. Founded in 1872 by Eduard von Lade to improve the science of growing fruit, particularly apples, it has continued a tradition of combining education with applied research. In 1876 Professor Müller joined

Geisenheim as a biologist and in 1882 bred the variety MÜLLER-THURGAU, which later became one of the most planted in Germany.

Today research in VITICULTURE and OENOLOGY focuses on environmental stress effects on grapevine physiology and fruit maturation, with particular emphasis on the possible effects of CLIMATE CHANGE on viticulture and on biotic stresses such as VINE DISEASES; quantifying greenhouse-gas emissions from viticultural soils; studying the effects of elevated CARBON DIOXIDE on all aspects related to grapevine development and fruit quality; the development of new biological and technological strategies to minimize the use of PESTICIDES in both ORGANIC and conventional viticulture; molecular and physiological studies of PESTS and diseases; secondary metabolites formed during fruit development, focusing on FLAVOUR PRECURSORS and PHENOLICS and their dynamics during fruit processing and winemaking; WATER STRESS and the use of new technologies to guide irrigation for grapes and horticultural crops; molecular and traditional genetics, including VINE BREEDING for DISEASE RESISTANCE, CLONAL SELECTION for improved quality and vine health, plant regeneration *in vitro*, research on the adaptation of ROOTSTOCKS to different soil and climate conditions, the genetics of PHYLLOXERA resistance and of YEAST and BACTERIA, and the detection of GENETICALLY MODIFIED organisms; all aspects of wine microbiology; steep-slope viticulture (see HILLSIDE VINEYARDS) and the development of new technologies for MECHANIZATION such as REMOTE SENSING, GLOBAL NAVIGATION SATELLITE SYSTEMS in machine guidance, efficient SOIL WATER management, as well as an economic evaluation of vineyard management under these conditions; new technologies in juice and wine production related to SUSTAINABILITY and consumer expectations; the replacement of wine ADDITIVES by new membrane technologies; and alcohol and acid management in the vineyard and winery. Other areas of activity include identifying and describing objective analytical and sensorial parameters for wine quality as well as optimizing CLOSURES and PACKAGING for wines. Other studies focus on wine ECONOMICS and

market research, including studies on consumer preferences, the dynamics of the global wine market, success factors in marketing, enterprise management, and economic analyses of different segments of the wine industry. M.C.

gelatin, the gel familiar in jelly and jello, used by winemakers as a FINING agent. This animal product is particularly useful for precipitating excess TANNINS as large insoluble molecules which can be removed by FILTRATION. Gelatin is deliberately avoided by those making VEGETARIAN AND VEGAN WINES.

Gelber Muskateller. See MUSKATELLER.

gemischter Satz, German term for an interplanting or FIELD BLEND of multiple grape varieties and, by implication, for a wine made from the CO-FERMENTATION of fruit from such plantings. Once common, such plantings are now rare throughout the German-speaking world. In Vienna, although a distinct minority, they are the basis for that urban growing region's DAC known as Wiener Gemischter Satz. See WIEN.

generic wine, one named after a wine type (and usually borrowed from a European place name), as opposed to a VARIETAL, which is named after the grape variety from which the wine was made. Such wines have been particularly common in Australia and the United States. Early CALIFORNIA wineries borrowed European place names

shamelessly. Before PROHIBITION one could buy not just St-Julien and Margaux made in the state but even wines named after particular châteaux. After Prohibition, stricter laws limited such borrowings; towards the end of the 1980s, Red Table Wine, White Table Wine, and Rosé began to replace place names on many of the more reputable labels. An EU–US trade agreement implemented in 2006 limited the use of so-called semi-generics to BRANDS that existed before the agreement was signed, but Chablis, Burgundy, and other borrowed names remain in widespread use by a number of large-volume producers, giants GALLO foremost among them. The generic term must be preceded by the place of origin, for example California Chablis or American Champagne. However, the agreement did nothing to demand even the faintest approximations of the original in terms of grape varieties or style. Chablis could and can be just as sickly sweet as Rhine, and both can be made from THOMPSON SEEDLESS or any other white grape. Burgundy, Chianti, and Claret could all come from the same tank and probably have done.

While generic names can still be found on many wine labels, particularly in non-exporting or developing wine regions, bilateral trade agreements between the EU and other wine-producing countries have continued to limit the use of generic names. Thus, for example, the Australian company PENFOLDS had to change the name of their most famous wine from Penfolds Grange Hermitage to Penfolds Grange. No third-country wine entering the EU may carry a geographical name recognized as a European wine name.

Outside Europe, CHAMPAGNE, or its local-language equivalent, is still occasionally used as a generic name for SPARKLING WINE, although not usually for the best-quality products, and the CIVC are particularly active in trying to prevent this.

generoso is a Spanish and Portuguese term for a FORTIFIED WINE.

genetic modification, sometimes called genetic manipulation or genetic engineering, a modern approach to breeding which involves

transfer of genes between organisms. This technology has applications in both VITICULTURE and OENOLOGY, and the techniques used are extremely useful for the study of other aspects of vine biology and for more wide-ranging YEAST research.

A proposed benefit of genetic modification is the ability to insert foreign genes, responsible for a particular desirable characteristic, into the genetic material of traditional VINE VARIETIES such as Cabernet Sauvignon, without altering the genes responsible for their other characteristics. There are hopes of introducing resistance to FUNGAL DISEASES and VIRUS DISEASES as well as to INSECT PESTS by the use of this technique, as well as improving berry RIPENING and quality. Whether such genetically modified vines can retain the same variety name remains to be legally tested. Research groups around the world have produced genetically modified vines; since the late 1990s and early 2000s, field trials have been in progress in Germany, Italy, Australia, and the US with the aim of improving fruit quality and disease resistance. Many governments have introduced strict testing procedures for genetically modified organisms, and consumer resistance in parts of Europe has been considerable. It is expected that the commercial availability of genetically modified vines will depend on market acceptance of wines derived from these plants.

Biotechnology's powerful array of tools has, arguably, seen its widest expression in the modification of the DNA of YEAST. It is the precision with which this can be done in yeast that has driven progress in this area. In its most basic form, a gene which codes for a protein having a particular property can be added, replaced, or removed to change that property. In this way, a genetically modified (GM) yeast can acquire new characteristics, such as the release of enhanced varietal flavour, by introducing a gene that liberates a TERPENOID or THIOL aroma compound from grape-derived precursors, or it can be freed of an undesirable property, such as excess HYDROGEN SULFIDE production. An extension of GM, synthetic biology, allows for more complex engineering to be performed, including the

expression of complex biosynthetic pathways from other organisms. This can include providing yeast with the ability to produce plant-derived compounds such as terpenes, ANTHOCYANINS, and VANILLIN. Genetically complex properties—such as fermentation robustness or temperature profile, for which relevant genes have not yet been identified—cannot yet be modified at the gene level in a targeted way.

GM yeast tend to arouse the same concerns as do any other GM products. They have been approved for use in wine production in only a few countries, including the US and Canada. Early examples include the GM wine yeast ML01, produced in Canada. It has two new genes which enable it to consume malic acid, negating the need for the bacterial MALOLACTIC CONVERSION. This yeast is used to improve the taste and colour stability of wine as well as to avoid the production of undesirable compounds (HISTAMINES). Newer strains, capable of making various monoterpenes, raspberry-ketone or LACTIC ACID during wine or beer production, are now being generated in the US, where specific labelling is not required for wine produced using GM yeast, provided that the yeast has been removed and is no longer detectable (see PROCESSING AIDS).

While GM yeast are still not widely approved for use in winemaking, this technology also facilitates an understanding of the genetic basis for many important winemaking properties of yeast and can therefore greatly assist yeast modification by conventional breeding techniques. The development of non-GM yeast in which hydrogen sulfide production has been eliminated is a good example of the benefit of this GM technology. P.A.H. & A.B.

Geneva double curtain, often abbreviated to GDC, a vine-TRAINING SYSTEM whereby the CANOPY is divided into two pendent curtains, trained downwards from high CORDONS or CANES. The system was developed by Professor Nelson SHAULIS of the Geneva Experiment Station in upstate New York in the early 1960s. The vines are planted in about 3-m/10-ft rows and the TRUNK divided at about 1.5 m height to form two parallel CORDONS about 1.3 m apart. The foliage is trained downwards from these cordons, forming the so-called double curtains. This training system was one of the first examples of a DIVIDED CANOPY developed in the NEW WORLD; by reducing shade, it increases both yield and grape quality (see CANOPY MICROCLIMATE). While initially developed for the American variety CONCORD, the system has been applied to VITIS VINIFERA wine grapes, especially in Italy. It was one of a number of TRELLIS SYSTEMS advocated as part of CANOPY MANAGEMENT improvement in the 1990s. The GDC system is particularly useful for high-VIGOUR vineyards with wide row spacing. While most wine-grape varieties have more erect shoots than the American vines GDC was developed with, it has been found suitable for use in many vineyards, and some notable increases in yield and wine quality have resulted from use of the system. Genoa, north-west Italian port and the principal city of the LIGURIA region. After the fall of ancient ROME and the BARBARIAN invasions, Genoa was occupied by the Lombards, a Germanic tribe, in 642. Under the Lombards, the region disintegrated economically, and the old Roman highways across the Apennines and along the coast were not maintained. It took Genoa until the early 11th century to recover fully from the effects of Lombard rule.

Genoa was therefore initially at a grave disadvantage compared with the city that was to become its deadly rival, VENICE. The Genoese navy had fought to protect its ships from Saracen sea power in the two centuries before the Crusades, together with Amalfi, Pisa, and Venice, and Genoa had established trading posts in the Byzantine empire, although it was nowhere near as successful in this as Venice. Nevertheless, Genoa's rise, like Venice's, was at first based on its eastern trade, and by the time of the Crusades it was battling with

Venice, and occasionally Pisa, for economic control of the eastern Mediterranean. The Latin kings of Jerusalem were dependent on Venetian, Genoese, and Pisan naval power for their protection, and so they granted these cities trading areas in their ports. Whereas Venice continued to trade mostly with Constantinople and the Near East, Genoa's interests centred largely on Palestine and Syria. Along with sugar, glass, and textiles, it shipped wine from vineyards there, many of which had been planted by Christian settlers, to Italy, where these strong, sweet wines were accounted a luxury and bought by rich merchants for their own consumption.

Along with luxury goods acquired in the East, Genoa also began to export cheap bulky goods such as grain, salt, oil, alum (for dying woollen cloth), and wine to western and northern Europe. The overland route was prohibitively expensive, and so from the 13th century onwards Genoa organized regular sailings to Bruges and Southampton in galleys, which used their oars to get into and out of ports swiftly, regardless of the prevailing winds. The voyage still took several months, and only strong, sweet wines such as VERNACCIA ('vernage'), produced mainly in Liguria, and the MALMSEYS of the Aegean had any chance of arriving in drinkable condition. The Venetians did not follow the Genoese galleys until 40 years later. In the late 14th century, Genoa abandoned its galleys in favour of the much larger cogs, which had a capacity of 700 to 800 tons and could travel from Genoa to Southampton with only one stop on the way, at Cádiz (see SPAIN).

Geographe, moderately cool, gently hilly wine region in WESTERN AUSTRALIA with 790 ha/1,952 acres of vines in 2020.

geographical delimitation and geographical designation. See DELIMITATION, GEOGRAPHICAL.

geographical indication (GI) is a catch-all term that is intended to accommodate the various approaches to the labelling of geographical DELIMITATIONS across the globe. It encompasses those straightforward systems typical of NEW WORLD countries that control only the origin of the grapes, as well as the European CONTROLLED APPELLATION model that also regulates conditions of production such as variety and yield.

In 2021, the OIV published the following definition: 'Any denomination protected by the competent authorities of the country of origin, which identifies a wine or spirit beverage as originating in a specific geographical area, where a given quality, reputation or other characteristic of the wine or spirit beverage is essentially attributable to its geographical origin.'

GIs can vary greatly in size and consequently in the promise of specificity that they convey. South Eastern Australia and France's Pays d'Oc are immense, covering many thousands of hectares, whereas the smallest, such as the Burgundy grands crus, cover just a few hectares. But in every case they should be more than a mere indication of source. They must signify a link between a place and the characteristics of the wines that are produced there.

Geographical indications were recognized as a special form of intellectual property in 1994 through the WTO's Agreement on Trade Related Aspects of Intellectual Property. The agreement defines a GI as 'an indication that identifies a good as originating in the territory of a country, or a region or locality in that territory, where a given quality, or reputation, or other characteristic, of the good is essentially attributable to its geographical origin'. This definition applies not only to wine but to all products.

Every one of the 159 member countries of the WTO is required to provide a means for the legal protection of GIs against misuse. Wines and spirits have a higher level of protection than other products, but it would be fair to say that each country interprets its obligations differently, resulting in a diverse range of approaches to GI protection as well as a reasonable amount of controversy.

Many countries have incorporated the term 'geographical indication' directly into their legislation, including Australia and China. The EU created the Protected Geographical Indication (PGI) category for wines in 2008, although this is seen as a lower guarantee of typicality than the more strictly controlled Protected Designation of Origin (PDO) category. geographical information system (GIS), database which can store, analyse, and display in map form geographically related data such as soil type, climate, ELEVATION, and crop history. GIS is an essential tool in PRECISION VITICULTURE. R.G.V.B.

geology is the scientific study of the solid Earth, although the term has also come to refer to the materials and processes involved with it. Vineyard geology, therefore, means the ground in which the vines are rooted. The loose earth on the surface is derived from bedrock. Such earth is called SOIL if it has incorporated moisture and ORGANIC MATTER and can therefore support plant life. Because grapevines can thrive in strikingly stony soil and even root into bedrock, the distinction in vineyards between rock and soil is unusually blurred.

Many of the world's vineyards are located on sediment that is now distant from its source, while in others the soil is derived from the local bedrock, which may be visible as outcrops protruding through the loose material. All exposed bedrock is under constant chemical and physical attack (weathering), breaking it down into the fragments

generally called stones (see STONES AND ROCKS). Smoothed pieces a few centimetres or so across are referred to as pebbles or, if larger, cobbles. As the material is further fragmented, it becomes SAND, SILT, and CLAY. Loose material on hillsides tends to slip down the slope due to gravity (see COLLUVIUM). The world's largest vineyards are on flat plains, carved by rivers over millennia and now covered by ALLUVIUM. All these fragmented products and the bedrock itself are composed of minerals.

Minerals

In geology, minerals are natural, inorganic solids in which the constituent atoms have an ordered, systematic structure. (In the nutrient sense, minerals are soluble single elements; see VINE NUTRITION.) The two most abundant elements in the outer part of the Earth are oxygen (46%) and silicon (28%); consequently the most common minerals are various silicates, in which the two elements are rigidly bonded together, alone in the case of QUARTZ (silicon dioxide) but usually with a number of other elements.

Some minerals relevant to vineyard geology are not silicates but are composed of a single element, such as CARBON (the mineral graphite), largely responsible for the colour of rocks such as dark SHALES; and SULFUR, found in VOLCANIC areas. Non-silicate compounds include the oxides (e.g. hematite, the iron oxide contributing to the distinctive red colour of TERRA ROSSA) and sulfates such as gypsum. Especially important are the carbonates, particularly calcium carbonate (the mineral calcite). Materials dominated by calcite, such as LIMESTONE and MARL, are described as CALCAREOUS.

The silicate minerals are complex and numerous, including the family of mica minerals such as silvery muscovite and shiny black biotite; iron-calcium-magnesium minerals such as pyroxene and amphibole; serpentine, a magnesium silicate unusual in that it can be inimical to grapevines; feldspar, a large group of important rock-forming minerals; and quartz, often referred to as silica. This last can assume a wide variety of forms, including the grey, rather opaque form known as FLINT.

CLAY is used to denote a particularly fine grain size in soils, but it is also the name of a family of flaky silicate minerals found in rocks and soils that are especially varied and intricate.

Rocks

Fundamental though minerals are, more noticeable in many vineyard soils are the larger stony pieces: the rigid, solid aggregates of minerals termed 'rock'. Rocks are classified into three groups according to their origin.

Igneous rocks solidified from a melt. Lava chills at the Earth's surface to form rocks such as BASALT, often with associated volcanic products such as TUFF. Molten material at depth tries to move upwards, progressively cooling until the mass finally solidifies while still deep underground, forming a plutonic igneous rock which may eventually be exposed at the surface by erosion of the overlying rocks. GRANITE is the most widespread plutonic igneous rock in vineyards.

Sedimentary rocks come about because of the weathering of outcrops into loose particles, in geology called 'sediment'. Over time, it tends to be moved across the land surface and out to sea, but at any stage the sediment may be stationary long enough for the grains to become naturally bonded together into a coherent mass, a sedimentary rock. The particle sizes that constitute SANDSTONE, siltstone, and claystone correspond to the grain-size terms for soils described above. Conglomerates have reasonably smooth pebble-sized fragments; in breccia the fragments are angular. Claystone is often referred to as mudstone, especially if it incorporates silt-sized fragments. Shale is a variety of mudstone which tends to splinter along uneven weaknesses, giving a rock that is soft and easily eroded. From the Latin for 'clay' (*argilla*) comes the adjective 'argillaceous', in French *argilo-*, added to rock names where there is a significant clay content. In warm, shallow seawater, accumulations of dead organisms made of calcite and chemical precipitates of calcium carbonate become hardened into limestone, including subvarieties CHALK and dolomite, the latter rich in magnesium. Some clay content gives an argillaceous limestone; even more, a marl or even a calcareous claystone. A certain cachet is often attached to calcareous

materials in vineyards but largely for circumstantial rather than scientific reasons.

Metamorphic rocks are formed when rocks deeper underground experience greater pressure and are progressively warmed, slowly undergoing a variety of chemical and physical changes. At any stage, the changes may cease and a combination of uplift and erosion may lead to the material being excavated and visible at the surface. The metamorphic processes can imbue the rock with a planar aspect and a tendency to split. Where it is not possible to discern the individual minerals responsible for this, the rock is known as a SLATE. If the minerals are visible—though then the clean-splitting property is less marked—it is called a SCHIST. If the secondary planes consist of bands of different minerals, it is termed a GNEISS. Marble is the metamorphic equivalent of limestone; QUARTZITE is metamorphosed quartz-rich sandstone.

Geological time and fossils

Vineyard descriptions often mention periods of geological time. A famous example is the controversy over whether true CHABLIS can be produced from Portlandian as well as Kimmeridgian soils. These two terms refer to intervals of geological time rather than to the actual nature of the material, what geologists call its lithology. For viticulture, it is really the lithology and its properties that are relevant, not the remote geological time period in which the bedrock happened to form. However, the age of the overlying soil, typically hugely younger than its parent bedrock, is relevant in that it influences SOIL DEPTH and SOIL FERTILITY.

Fossilized seashells catch the eye in a number of the world's vineyards (see MUSCHELKALK, for example), and microfossils, visible only under the microscope, are essential constituents of important vineyard soils such as CHALK and ALBARIZA. Nearly all fossils are the result of durable geological minerals (most commonly calcite and quartz) replacing and replicating the shape of the original organism. Consequently, despite much mythology, fossils bring nothing different to the nutrition of the vines or the composition of the resulting wine.

Role of vineyard geology

Fundamentally, it is the interplay between erosion and variously arranged bedrock of differing toughness that governs the lie of the land and all that stems from that (see, for example, ELEVATION, HILLSIDE VINEYARD, and TOPOGRAPHY). More directly, the intensity and spatial orientation of planes of weakness in bedrock influence water and vine-root penetration, and its propensity for weathering helps determine the SOIL DEPTH. SOIL COLOUR affects the thermal and ULTRAVIOLET RADIATION behaviour of soil and therefore vine performance.

However, much research indicates that the chief physical effect of geology is its influence on how easily water is stored and transmitted in soil (see DRAINAGE). Two properties are fundamental: porosity expresses what proportion of the substance is space, available for water storage; permeability represents how well water can flow through the material. A good vineyard soil balances the two (see SOIL WATER and SOIL STRUCTURE). In bedrock, water flows partly by using interconnected pores between the constituent mineral particles and partly along the cracks and fissures which exist to some extent in all solid rock.

The other dominant role of geology is its provision of SOIL NUTRIENTS or MINERAL nutrients essential for vine growth. Most are needed only in very small quantities, and the majority of rocks possess ample supplies. However, their availability to vine roots is another matter, because the elements are tightly bonded in the physical soil framework and somehow have to become loosened, dissolved, and transported. In fact, it has been estimated that although a typical vineyard sited on GRANITE will contain abundant potassium, as little as 2% might actually be available to the vines. MYCORRHIZAL fungi and other microorganisms may be involved, but usually chemical weathering acts to generate clay minerals which, thanks to their CATION EXCHANGE CAPACITY, can release elements into water in the soil so that the roots can absorb them (see VINE

NUTRITION and VINE PHYSIOLOGY). However, the weathering processes are too slow to yield a fresh supply of nutrients each year; in practice, much of the nutrient supply comes from recycled decayed material in the form of ORGANIC MATTER. Thus stones and bedrock have relatively little direct role in nutrient supply. The vine roots do not distinguish the origin of their nutrients: a complex geology does not lead to complex wines.

Geology and wine flavour

Before modern science, winemakers thought, understandably, that vines and hence wine were made entirely of matter derived from the soil, laying the basis for the European tradition of a special alliance between soil and wine that continues today (see TERROIR). Despite discoveries such as the pre-eminent roles of PHOTOSYNTHESIS and microbial FERMENTATION, it still seems *de rigueur* in winery descriptions to at least mention the vineyard geology and, often, to extol some special virtue. For some enthusiasts, the Earth–wine relationship approaches the mystical, an intimacy unparalleled in any other agricultural product.

In practice, in much of the world the geological factors outlined above tend to be overridden by artificial manipulation: earth moving, RIPPING, drainage installation, COVER CROPS, and the rest. Two particularly conspicuous interventions are IRRIGATION and the application of FERTILIZERS: WATER STRESS is engineered; nutritional imbalances are routinely corrected.

The extent to which the natural vineyard geology affects wine flavour is unclear. Claims that wines made identically from adjacent sites taste different simply because the geology differs are hard to evaluate because other natural factors will vary along with the geology, particularly concerning MESOCLIMATE, CANOPY MICROCLIMATE, and soil microbiology. Similarly, because its properties interact with a whole matrix of other factors, a soil that is superb in one place may well perform differently elsewhere. Wines of comparable character can come from very different soils, and statements that certain types of geology are always best for a particular grape variety lack consistency, as do assertions about which soils give what qualities to wine. Some wine attributes are given names that sound geological, such as ‘mineral’, ‘earthy’, or ‘flinty’, but they have no literal connection with the soils. Vineyard minerals and rocks are practically insoluble and do not volatilize—prerequisites for giving taste and odour.

Scientifically, geology is clearly important for vine performance and can therefore influence the character and flavour of the finished wine. But its role is indirect, subtle, and complex. Anecdotes notwithstanding, vineyard geology cannot—in any direct, literal way—be tasted in wine. A.J.M.

van Leeuwen, C., and de Rességuier, L., 'Major soil-related factors in terroir expression and vineyard siting', *Elements*, 14/3 (2018), 159–65.

Geoponika, a compilation of advice on agriculture put together about 950 CE at the behest of the scholarly Byzantine Emperor Constantine VII Porphyrogenitus, as part of a grand scheme of digests of knowledge. It was heavily based on a compilation of some three centuries earlier by Cassianus Bassus from Bithynia, who in turn used a collection made by Vindonius Anatolius of Beirut in the 4th century CE. Of the 20 books, the largest section, Books 4–8, consists of a long list of precepts on viticulture and winemaking. The work was much used in the Middle Ages and was translated into Arabic, Syriac, and Armenian. In 1157 Burgundio of Pisa translated the books on viticulture into Latin. J.J.P.

Dalby, A., *Geoponika: Farm Work. A Modern Translation of the Roman and Byzantine Farming Handbook* (2011).

Georgia, independent state between the Black Sea and southern slopes of the High Caucasus. One of the world's great and historic centres of both wild and cultivated vines, it contains the autonomous republics of Apkhazeti and Adjara as well as the former autonomous district of South Ossetia.

History

Wine is integral to the culture of Georgia, a small country whose history is a succession of struggles for independence from such empires as the Assyrian, Roman, Persian, Byzantine, Arabian, Osmanli, and Russian—and, latterly, that of the Soviet Union. Throughout all these struggles, Georgia has retained a strong identity, including its own language, customs, Christian religion, and a national reverence for wine that has persisted for more than 8,000 years and which is kept alive in Georgia's famous *supra*, a feast punctuated by traditional dancing, singing, and toasts, lubricated with jugfuls of wine and moderated by the *tamada* or toastmaster. Archaeology provides ample evidence that viticulture was long an important occupation of the Georgian people and wine drinking an integral part of their culture. Wine residue, grape seeds, special knives for vine pruning, stone presses, pottery, silver and gold vessels for wine, and jewellery depicting grape bunches and leaves dating back to 6000–5000 BCE have all been unearthed in the Shulaveris-Gora Neolithic site in Lower Kartli and other sites in Georgia. Rich ornaments of fruited vines are found on the walls of ancient churches in Samtavisi, Ikalto, Zarzma, Gelati, Nikortsminda, and Vardzia. According to Apollonius of Rhodes (3rd century BCE), the Argonauts, having arrived in the capital of Kolkhida-Aia (nowadays Kutaisi) centuries earlier, saw twining vines and a fountain of wine in the shade of the trees.

Georgian legends and folklore bear witness to that people's love of the grapevine. Georgia adopted Christianity in the 4th century, and the first cross was made of vines to show that the Christian faith and the vine were the most sacred treasures of the nation.

The Middle Ages was Georgia's golden age of wine. For many centuries, viticulture was of great agricultural and economic importance to the country. In the second half of the 19th century, vineyards covered 71,200 ha/176,000 acres, but FUNGAL DISEASES and PHYLLOXERA reduced the total vineyard area to 37,400 ha by the

beginning of the 20th century. In order to restore the vineyards, the country had to import phylloxera-resistant ROOTSTOCKS.

The 20th century was the era of Soviet winemaking; during this time, a number of Georgian TERROIRS were identified and developed, but quality was routinely, and efficiently, sacrificed for the vast quantities required by the Soviet market. GORBACHEV's anti-alcohol campaign of 1985–7 dramatically reduced the market for Georgian wine, although it mainly affected the state vineyards since no Georgian farmers would be willing to pull out their own vines. In 1990, as the Soviet Union was disintegrating, the total area of the vineyards was 115,599 ha/285,500 acres, down from a peak of 134,300 ha in 1976. Viticultural investment was sorely needed. By 2004, the total was 37,419 ha; in 2021 it reached 50,000 ha.

P.T.H.U.

Viticulture and vine varieties

Vines in Georgia (unlike those in RUSSIA) do not need WINTER PROTECTION, and new vineyards are planted to GRAFTED VINES. Vineyards mostly use TRELLIS SYSTEMS and various TRAINING SYSTEMS such as CORDON, GUYOT, traditional Georgian systems, and PERGOLAS.

WILD VINES are widely distributed in Georgia, where *Vitis vinifera* subsp. *silvestris* can still be seen. By both natural and artificial selection, they have given rise to more than 500 identifiable INDIGENOUS VARIETIES and CLONES. The two most widely planted are the indigenous RKATSITELI and SAPERAVI. Although INTERNATIONAL VARIETIES are also appreciated, around 95% of Georgian wine is made from indigenous varieties, including the light-skinned Chinuri, Goruli Mtsvane, Khikhvi, Kisi, Krakhuna, Mtsvane Kakhuri, Tsitska, and Tsolikouri; and the dark-skinned Aladasturi, Aleksandrouli, Avasirkhva, Asuretuli Shavi, Chkhaveri, Mujuretuli, Ojaleshi, Otskhanuri Sapere, Saperavi, Shavkapito, Tavkveri, and Usakhelouri. Many of these Georgian varieties were ignored during the Soviet era because of their low YIELDS but are now being more widely planted and are valued for quality potential and for their distinctiveness. However, one of the difficulties Georgia currently faces in exporting wines is that foreign consumers are unfamiliar with the names and flavours of these traditional Georgian grape varieties. The ancient and uniquely Georgian tradition of fermenting, storing, and ageing wines in clay QVEVRI buried underground has never been lost and, in fact, has seen a noticeable revival in the 2000s. This winemaking method was inscribed on the UNESCO Representative List of the Intangible Cultural Heritage of Humanity in 2013, and in 2020 the OIV General Assembly adopted a definition of white wine with maceration, a special category applicable in particular to wines made in qvevri. Even though qvevri-makers are a dying breed, qvevri wines have begun to attract international attention, particularly among proponents of NATURAL WINE.

Climate and geography

Georgia's TOPOGRAPHY and GEOLOGY are complex. Mountains of the High Caucasus in the north account for about 30% of its total area. The peculiarities of the relief determine a great diversity in the country's soil and climatic conditions, which, in turn, influence grape culture. The climate varies from moderate to subtropical. In the east, annual rainfall is 300–800 mm/12–32 in; the west sees 1,000–2,800 mm/40–110 in. HAIL is a perennial threat.

Georgia has ten viticultural regions: Kakheti and Kartli in south-eastern Georgia; Meskheti in the south; Imereti in the centre; Racha and Lechkhumi in the north; and Adjara, Guria, Samegrelo, and Apkhazeti near the Black Sea. These encompass 25 CONTROLLED APPELLATIONS, 18 of which were recognized by the EU in 2021, with others still awaiting final approval.

Kakheti has always been the most important wine region in the country. It is home to almost 70% of Georgia's vineyard, produces about 80% of its wine, and comprises the richest agricultural land in the south-east of the country in the Alazani and Iori valleys. The climate here is generally moderate, in parts subtropical, with wide variations in annual precipitation depending on location. Cinnamonic forest soils (reddish with high mineral content and enriched with CLAY) and CALCAREOUS soils, some of them ALLUVIAL, are found in the region.

In terms of MESOCLIMATIC conditions and types of wines produced, Kakheti can be subdivided into three main subregions and 19 appellations (e.g. Tsinandali, Mukuzani, Kvareli, Manavi, Napareuli, and Kindzmarauli). The principal grape varieties are Saperavi for reds and Rkatsiteli, Mtsvane Kakhuri, Khikhvi, and Kisi for whites. Alongside more modern technologies, these regions produce the traditional Kakhetian wines, made distinctively tannic and flavourful by FERMENTATION in special clay qvevri followed by an extended MACERATION of up to six months, very much as wines were made thousands of years BCE. Kindzmarauli's speciality is semi-sweet reds. It is in this region that Georgians and incomers have invested most of their hopes for the future of Georgian wine.

Kartli is the heart of Georgia; it inspired the original name for the country, Sakartvelo, and occupies a vast territory in the Mtkvari Valley, including the Mukhrani Lowlands and Gori. These wines are the country's most European, and the region produces the fruit for 15% of Georgia's sparkling wines and brandy production. The zone is moderately warm, with hot and dry summers; vineyards must be irrigated because of the low rainfall (350–500 mm/19 in per year). Main grape varieties are Chinuri and Goruli Mtsvane for whites and Shavkapito and Tavkveri for reds. The capital of Georgia, Tbilisi, where wineries making mainly sparkling wines and brandy are located, is in this zone. Tbilisi's oldest winery, founded in 1897, has a unique collection of ancient wines.

Imereti, the second largest of Georgia's wine regions, is in the eastern part of west Georgia, in the basins and gullies of Rioni Kvirila and other rivers. The most important grape varieties are Tsitska, Tsolikouri, and Krakhuna for whites and sparkling wines and Aladasturi and Otskhanuri Sapere for reds. The one appellation is Sviri. In addition to using modern winemaking methods, Imereti also uses a very particular technique, similar to Kakheti's except that grape skins are added to the clay jars (here called *churi*) during fermentation, a little like Italy's GOVERNO, and this is followed by a maceration of six to eight weeks.

Racha and Lechkhumi comprise Georgia's smallest wine region but one of the country's most important winemaking centres. Vineyards are mainly in the Rioni and Tskhenistskali valleys. Moderate rainfall (1,000–1,300 mm/40–50 in a year), southerly exposure, and the assortment of local vine varieties such as Tsulukidzis Tetra and Tsolikouri for whites and Aleksandrouli, Mujuretuli, Usakhelouri, and Orbeluri Ojaleshi for reds encourage grapes with a sugar content as high as 30%. The region is famous for its natural semi-sweet wines such as the reds of the Khvanchkara and Usakhelouri appellations. Demand for these wines on some markets is so high that Aleksandrouli, Mujuretuli, and Usakhelouri grapes fetch some of the highest prices in the country. Producing high-quality wines from these grapes is a growing trend.

Meskheti, one of Georgia's most ancient winemaking regions, is the origin of some of the oldest Georgian grape varieties. Although viticulture is challenging here, with vineyards traditionally terraced high on the slopes along the Mtkvari river at 900–1,300 m/2,950–4,265 ft, where it is very dry and IRRIGATION is needed, the region is experiencing a revival and a remarkable growth of new plantings.

Towards the Black Sea, the regions of Apkhazeti, Adjara, Guria, and Samegrelo are all known for both semi-sweet and dry wines. Guria, in the south-west, is humid and subtropical. Vines are mainly

in the Supsa and Gubazouli valleys and mostly still trained using the traditional methods known as *maghlari* (up trees; see ARBOREAL VITICULTURE) or *olikhnari* (up low trees or tall poles); the main varieties are Chkhaveri, Jani, Mtevandidi, and Skhilatubani. Samegrelo, the ancient region of Colchis, is also humid and subtropical, with long summers and cold winters. Ojaleshi is the main variety, with its own PDO Salkhino Ojaleshi introduced in 2020; Chergvali, Cheshi, Chvitiluri, and others are also grown, all mostly *maghlari* trained. Apkhazeti, a historic winemaking region in north-western Georgia, is planted mainly with Avasirkhva, Amlakhu, and Kachichi. Adjara, which has many climatic microzones, has seen a revival of viticulture and winemaking in recent years. The local varieties are Brola, Khopaturi, and Mekrenchkhi.

The future for Georgia

Georgia has an enviably strong wine and hospitality culture, national belief in its wines, a wide range of high-quality INDIGENOUS VARIETIES, a unique tradition of fermenting wines in qvevri, and no shortage of historically established TERROIRS. The Georgian government and private sector's changing vision for the future of Georgian winemaking pressured exporters to improve quality and to look further afield to markets such as western Europe, the US, Japan, China, and Hong Kong; by 2022 Georgian wine was being exported to over 60 countries. Although annual per capita consumption is around 20 l/5 gal, exports are crucial since much of the domestic demand is satisfied by HOME WINEMAKING. Around one-quarter of the 400,000–450,000 tons of grapes harvested annually in Georgia are used for 'family wine'. Imported wines represent just 3% of the total domestic market.

Foreigners have invested in the Georgian wine industry since the mid 1990s, and government support programmes have attracted new investments in vineyards, wineries, winemaker training, and regulatory oversight. Georgia continues to pursue its course of moving closer to Europe and promoting its wines more effectively

around the world through the Georgian Wine Association and the Georgian National Wine Agency.

geosmin, a compound with a strong earthy or muddy aroma that is a by-product of soil bacteria and fungi, particularly *Penicillium expansum*, and is usually associated with wine FAULTS. Found in red and white wines made with rotten grapes, it is also present in some wines with CORK TAINT. The same aroma arises when rain falls on dry earth. See also MICROBIAL TERROIR.

La Guerche. S., et al., 'Origin of (–)-geosmin on grapes: on the complementary action of two fungi, botrytis cinerea and penicillium expansum', *Antonie van Leeuwenhoek*, 88/2 (2005), 131–9.

geotextiles, permeable fabrics used as an alternative to burying vines for WINTER PROTECTION, particularly in CANADA. Trials have shown that this method results in less damage to the vines and the soil and better YIELDS.

Willwerth, J., et al., 'Best management practices for reducing winter injury in grapevines', Brock University, Cool Climate Oenology & Viticulture Institute (2014).

www.brocku.ca/webfm/Best_Practices_Manual__Winter_Injury_Sept_14_(5).pdf.

geranium, pejorative TASTING TERM for the smell of crushed geranium leaves that is given off by wines in which LACTIC ACID BACTERIA have reacted with the fungistat (a chemical that prevents fungi from growing) SORBIC ACID. This geranium smell, which occurs in very varied concentrations and for which the compound 2-ethoxyhexa-3,5-diene is responsible, first appeared in wines during the 1970s, when sorbic acid use became common. Its formation can be prevented by adding SULFUR DIOXIDE at the same time as the sorbic acid to prevent the growth and activity of the lactic acid bacteria responsible. A.D.W.

German crosses, an important group of VINE VARIETIES that are the result of VINE BREEDING, an activity that was particularly vigorous in the first half of the 20th century but which continues to this day, most notably at Geilweilerhof, GEISENHEIM, and the research institutes of Freiburg and Weinsburg.

The man who bred Germany's first commercially successful modern cross was in fact Swiss, Dr Hermann Müller (see MÜLLER-THURGAU), whose eponymous vine variety was to become the most planted in Germany in the second half of the 20th century, almost 100 years after it was developed. A succession of new crosses followed in the 20th century, notably from research institutes at Alzey, Freiburg, Geilweilerhof, Geisenheim, Weinsberg, and Würzburg, producing a large number of NEW VARIETIES usually designed to achieve the high MUST WEIGHTS encouraged by the German wine law of the time. The most successful white wine varieties, in descending order of area planted in Germany at the beginning of the 21st century, are KERNER, BACCHUS, SCHEUREBE, FABERREBE, HUXELREBE, ORTEGA, MORIO-MUSKAT, REICHENSTEINER, EHRENFELSER, SIEGERREBE, OPTIMA, and Regner. Others include PERLE, NOBLING, WÜRZER, KANZLER,

SCHÖNBURGER, FREISAMER, Findling, RIESLANER, Juwel, ALBALONGA, and, more popular in England than Germany, PHOENIX. Few of these crosses make distinctive, attractive, and characterful wines, although Kerner, Ehrenfelser and, particularly, Scheurebe and Rieslaner can make fine wines if sufficiently ripe. More typically, the vines have been planted to yield good quantities of wines with high must weight.

Successful German crosses for red wine include DORNFELDER, HEROLDREBE, and HELFENSTEINER, bred by Dr August Herold in the 1950s, as well as a host of others bred usually for their COLOUR, such as REGENT, DOMINA, or red-fleshed TEINTURIERS, including Deckrot, DUNKELFELDER, and Dacapo. RONDO has proved popular in England.

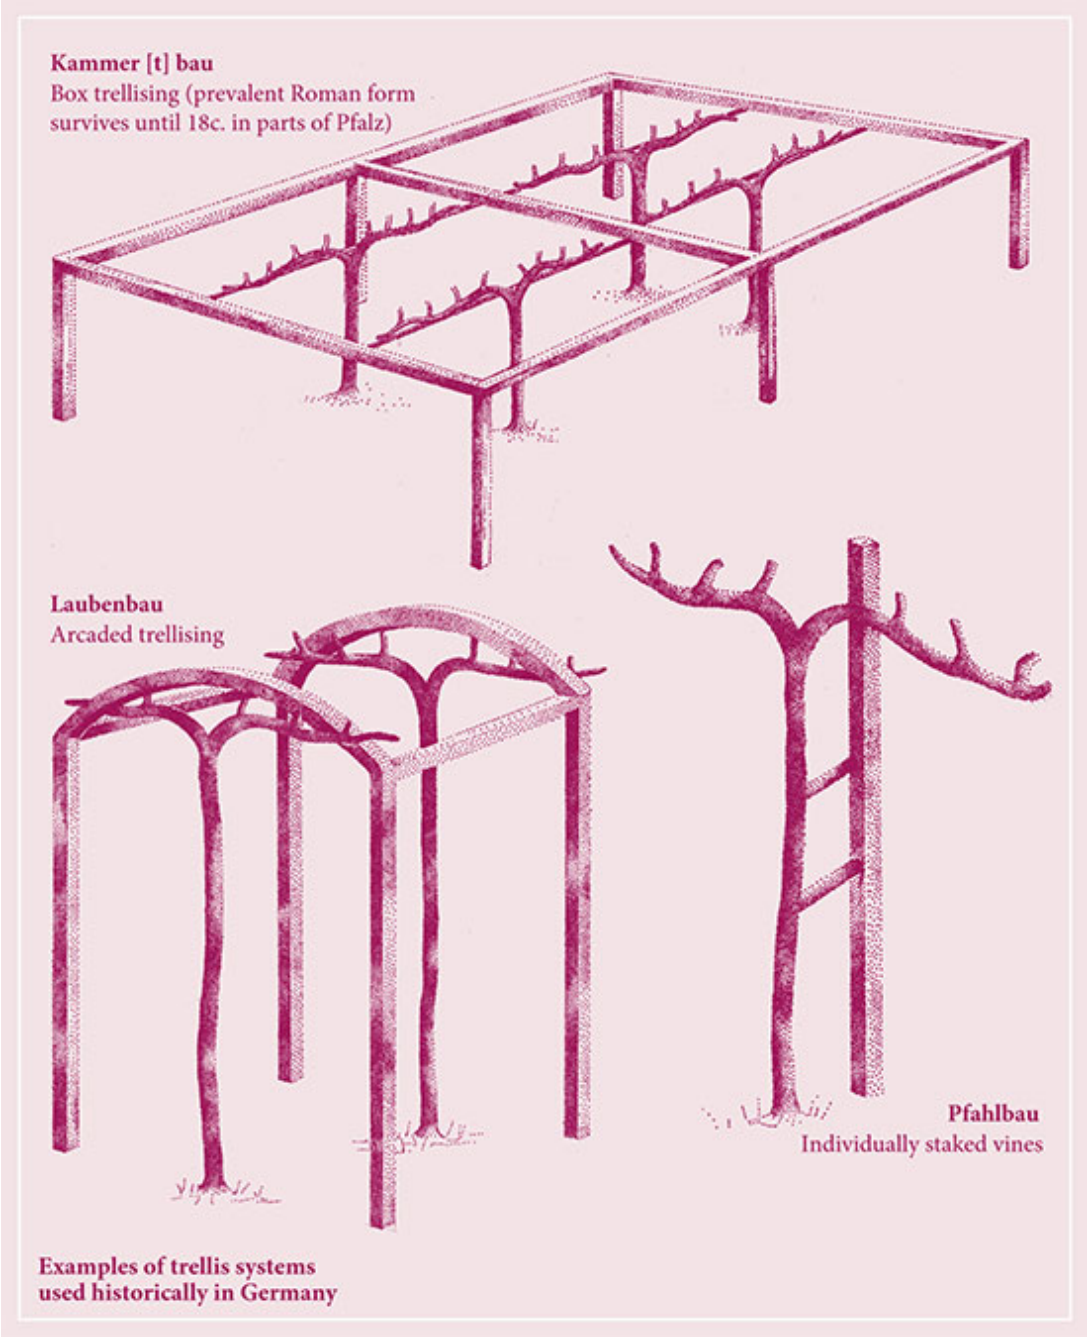
German history. This article encompasses the history of wine production not just in GERMANY but also in ALSACE.

The origins of viticulture to 800 CE

Although the WILD VINE *Vitis vinifera silvestris* may be traced back to prehistoric times on the upper Rhine, the cultivated, wine-yielding vine species VITIS VINIFERA—and with it viticulture in Germany—almost certainly owe their origins to the Romans (see ancient ROME).

Although archaeological discoveries have unearthed curved pruning knives near the sites of Roman garrisons on the left bank of the Rhine which can be dated to the 1st century CE, we cannot be sure they were used for vines. Emperor PROBUS (276–82) is traditionally regarded as the founder of viticulture in Germany, but firm literary evidence only occurs with the tract *Mosella*, written around 370 by the Roman author Ausonius of Bordeaux, who lyrically describes the steep vineyards on the banks of the river.



Examples of trellis systems used historically in Germany

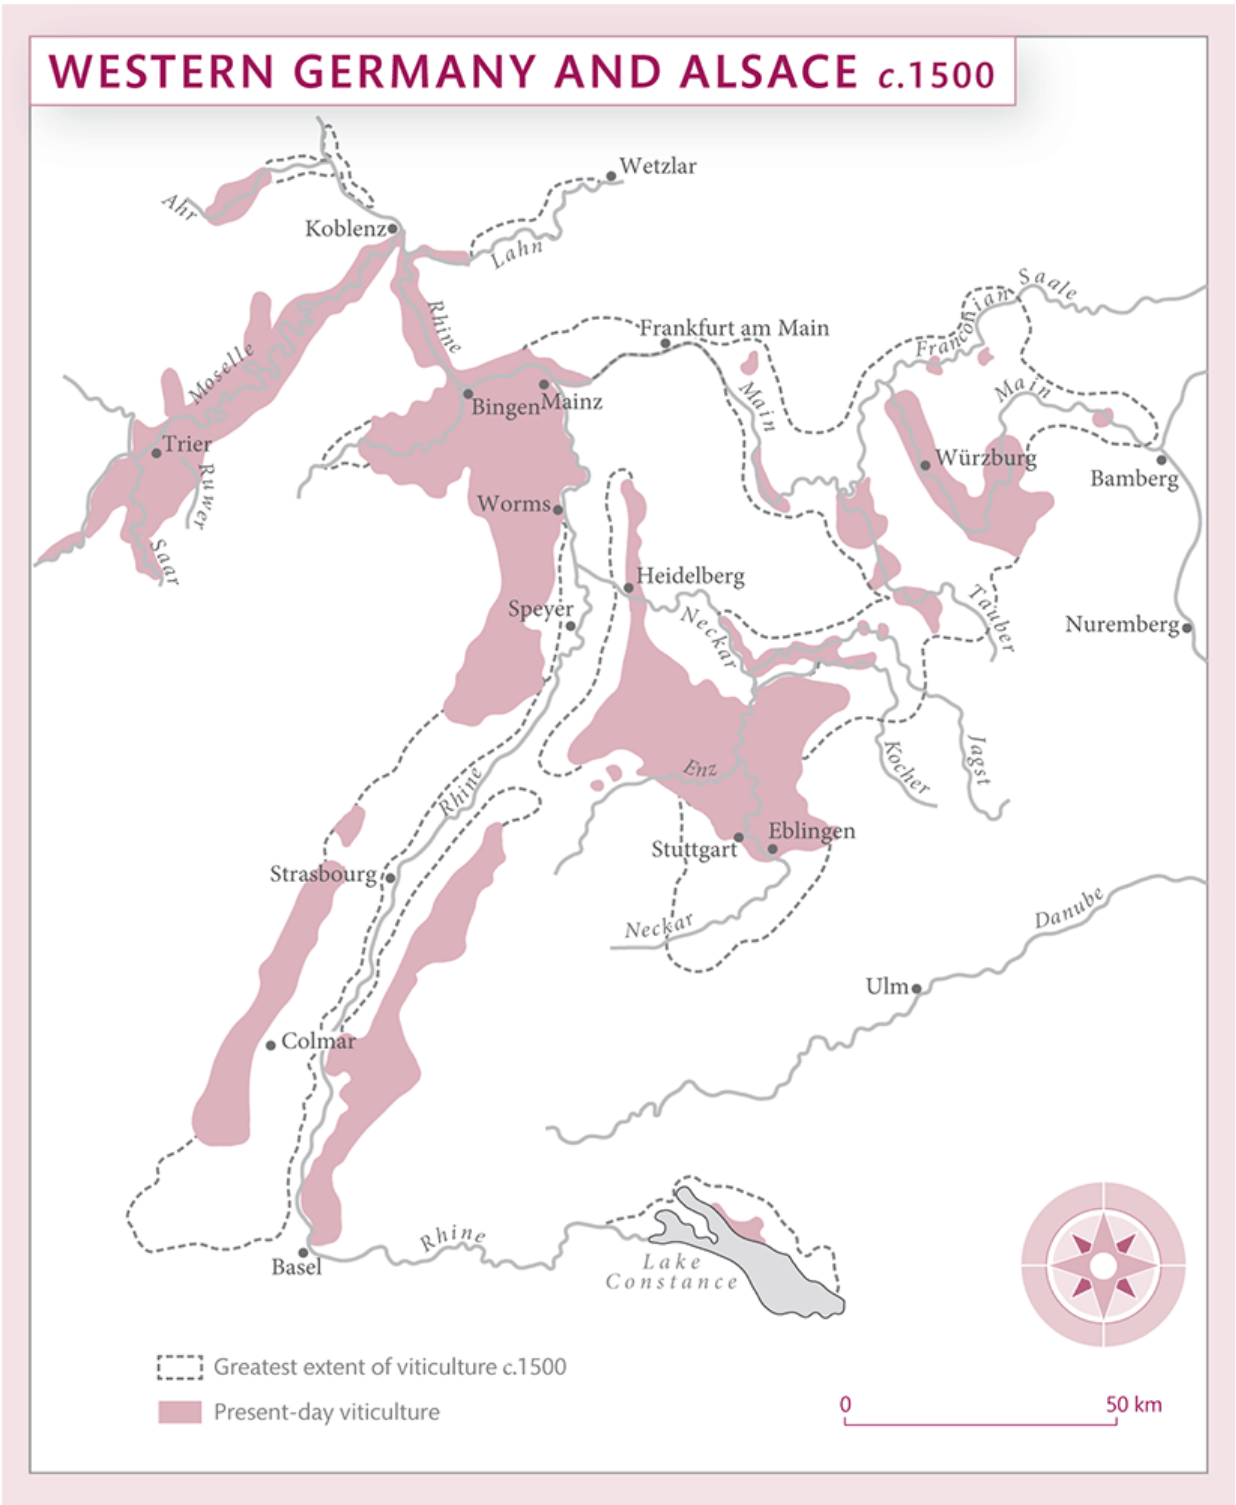
Continuity of viticulture is suggested by the use of typically Roman forms of TRELLIS SYSTEMS on low and high frames (*Kammer*(*t*)-, and *Lauben-* or *Rahmenbau*), which survived in parts of the Palatinate as late as the 18th century. Evidence of winegrowing under the Merovingians can be seen in the pious donations of their kings: Dagobert I (622–88) gave vineyards at Ladenburg on the Neckar (in what is now the most northerly, Oberrhein district of BADEN) to the

church of St Peter in Worms. This grant is especially significant, since it offers one of the earliest pointers to vines on the right bank of the Rhine.

Until the era of CHARLEMAGNE, nevertheless, winegrowing was concentrated west of the Rhine: from Alsace down river into the Palatinate (the modern German wine regions of PFALZ and RHEINHESSEN) and thence downstream along the middle Rhine as far as Koblenz. Winegrowing extended up three left-bank tributaries: the NAHE Valley down to Bingen, where winegrowing is securely documented from 750; the Mosel (with its own tributaries, the SAAR and RUWER), where the tradition of Roman viticulture was vigorously maintained by monastic foundations such as St Maximin and St Martin in Trier; and the most northerly European winegrowing district, the AHR Valley south of Bonn, where vines had been planted on sheltered slopes from at least the 3rd century CE.

East of the Rhine, in the districts beyond the frontier of Roman occupation, the spread of viticulture went hand in hand with the missions of Christian monks such as St Kilian in Franken and St Columban in Bavaria.

Apart from the existence of red wines, cited by the north Italian poet Venantius Fortunatus around 570, next to nothing is known about grape varieties and the quality of wine in this period. T.S.



Scott, T., 'Medieval viticulture in the German-speaking lands', *German History*, 20 (2002), 95–115.

Viticulture's importance in the Middle Ages

From the foundation of the Carolingian empire, the history of German wine can be traced with greater confidence. CHARLEMAGNE's numerous capitularies (law codes, relating particularly to landholding) contain instructions to his officials to plant vines. His true significance, however, lay in the support he gave to the spread of Christianity, for churches and convents were the principal cultivators and consumers of quality wine (see MONKS AND MONASTERIES).

Many vineyards still famous today originate in monastic settlements of the High Middle Ages. In the RHEINGAU, Archbishop Ruthard of Mainz (1088–1109) founded a Benedictine abbey on the slopes above Geisenheim, the Johannisberg, later known as SCHLOSS JOHANNISBERG. In 1135, his successor, Archbishop Adalbert, gave the Steinberg vineyard above Hattenheim to the Cistercians, whose KLOSTER EBERBACH remains the informal headquarters of the German wine trade to the present. On the river MOSEL, Archbishop Baldwin of Trier founded the Carthusian priory of St Alban in 1335, which was endowed with vineyards at Eitelsbach on the Ruwer, the Karthäuser Hofberg. In FRANKEN (Franconia), too, the bishops of Würzburg actively encouraged viticulture along the river Main.

Elsewhere, secular princes played a leading part, especially in the Palatinate, where the count-electors had promoted Bacharach on the Rhine as the entrepôt for wine from their many territories on both banks of the river.

Although viticulture was dominated by the Church and the aristocracy, bourgeois ownership of vineyards was common, too, either corporately by city councils or by individual merchants and investors.

The rapid expansion of viticulture after the millennium, which came to a halt only in the 16th century, can largely be attributed to the recovery in population and the rise of towns as centres of consumption and exchange: 'a wine landscape is an urban landscape' ran the medieval tag. But the spread of vineyards into the higher

valleys, often far from urban centres, can only be explained by the foundation of the new ascetic religious orders, Cistercians and Carthusians, who established their houses from the 12th century at a deliberate distance from civilization. In Alsace, for example, vineyards followed convents into the remote valleys of the Vosges. Apart from the heartlands of medieval viticulture in Alsace, the Palatinate, and the Mosel Valley, all of which witnessed the further intake of land for vineyards up to 1500, winegrowing had spread by 1300 to the Rheingau, and throughout BADEN (with vineyards on Lake Constance from the 8th century), WÜRTTEMBERG, and Franken.

By 1500, even the rolling uplands of Swabia and the heavily afforested valleys of northern Franken had been cleared for vines. There viticulture reached its greatest extent in the 15th century, covering perhaps four times the area under vines today (see map of Western Germany and Alsace *c.*1500).

In eastern Germany, the Ottonian emperors promoted viticulture in their Saxon dynastic lands from the late 9th century. Vines were planted on the Elbe around Dresden and Meissen, and on the Saale and Unstrut, especially around Freyburg (see SAALE-UNSTRUT). Even in Brandenburg around Berlin and Jessen, east of Wittenberg up to Torgau, vines were grown on a commercial basis from the 14th to the 16th centuries. In the eastern part of the empire, Kloster Pforte near Naumburg played a similar role to that of Kloster Eberbach in the Rheingau.

The sites chosen for planting were by no means those on which wines still thrive today. Low-lying level sites were preferred; in Alsace, acknowledged as producing the best wines of medieval Germany, vineyards stretched across the plains from the Ried down to Mulhouse. From the 10th century, vines were at last being planted on slopes in TERRACES, with low walls to prevent SOIL EROSION. The famous slopes of the Rheingau were initially planted in the 11th century: first the Rüdesheimer Berg, then in the 12th century the Johannisberg and Steinberg, with the slopes of Rauenthal not planted until the 13th.

Vine varieties Workaday wine was made everywhere from the ELBLING grape, by far the commonest medieval variety, with RÄUSCHLING widely planted in Baden. SILVANER, which arrived in Franconia only in 1659, was extensively grown, but rarely as a high-quality grape in its own right; until the 20th century, it was generally planted together with Traminer and Riesling (see GEMISCHTER SATZ). Of the better grapes, MUSCAT (red and white) was grown on the Rhine and in Alsace, TRAMINER chiefly in the latter. RIESLING is first documented at Rüsselsheim on the river Main just east of the modern Rheingau in 1435, though a century earlier a vineyard in Kinzheim in Alsace was known as 'zu dem Russelinge'. The variant orthography of these early references, however, makes it difficult to determine whether the Riesling or the Räuschling grape is meant. There is every likelihood that Riesling had been established and recognized as a high-quality grape much earlier than the sources suggest, for in 1477 Duke René of Lorraine, in praising the red and white wines of Alsace, mentioned in particular its Riesling.

In the Middle Ages, many Alsace wines were fortified (see FORTIFICATION) or spiced (see FLAVOURED WINES) in order to compete with the fuller-bodied Mediterranean wines such as SACK and MALMSEY. Red wine was made from the Blauburgunder (PINOT NOIR) grape on the upper Rhine in Alsace and throughout Germany where it was spread by Cistercian MONKS from the 12th century (Affental had already acquired a reputation by 1330). In Württemberg, by contrast, where much of the production, then as now, consisted of light red wines, the TROLLINGER grape already predominated. The Ahr Valley may have been planted with red grapes, but those cannot have included Pinot Noir, which was not introduced there until the 18th century. T.S.

Scott, T., 'Medieval viticulture in the German-speaking lands', *German History*, 20 (2002), 95–115.

The wine trade in the Middle Ages

Although the quantity of wine harvested in medieval Germany never approached that of France, Italy, or the Iberian peninsula, production on the left bank of the Rhine always exceeded local consumption, so that commerce in wine became an economic necessity. Until the rise of towns, the wine trade was largely in the hands of the Church. Because the best vineyards lay along the Rhine and its tributaries, shipments of wine could pass easily down one of the great arteries of European trade to northern Germany, the Low Countries, Scandinavia, and England. Ease of transport, however, was offset by the numerous tolls which local lords levied on cargoes shipped down the Rhine.

Cologne and Frankfurt dominated Germany's medieval wine trade, a point tellingly illustrated by the decision of Kloster Eberbach, the important abbey in the rural depths of the Rheingau, to acquire its own cellars in Cologne in 1162 and in Frankfurt 50 years later. But their pattern of trade differed.

Throughout the Middle Ages, Cologne's trade with the Baltic, Scandinavia, and England was far more extensive than Frankfurt's. The city's wine trade reached its peak in the late 14th and early 15th centuries. Cologne continued to play a major role in the export of the best German wines, but its trading area was increasingly exposed to the rise of beer as the everyday drink of northern Germany. It was Frankfurt's merchants who increasingly specialized in Alsace wines, although their popularity was challenged during the 15th century by wines from the Palatinate and the Rheingau.

Although German wines were firmly established in northern Europe during the Middle Ages, there were limits to their share of the market. In the southern Low Countries 'Rhine wine' was consumed, but it had to compete with the heavier wines of Burgundy, Auxerre, and also Bordeaux. In England, too, German wines faced a stiff challenge from France, as the trade with Gascony flourished from the 12th century. But German wine was not confined to northern

markets. Alsace wines were extensively exported to southern Germany, Switzerland, and central Europe. T.S.

Scott, T., ‘Medieval viticulture in the German-speaking lands’, *German History*, 20 (2002), 95–115.

Crisis and decline, 1500–1650

The Thirty Years War, which ravaged Germany in the early 17th century, left few viticultural regions unscathed, with the exception of Württemberg, thanks to ducal intervention and support. But the real problem arose from the loss of manpower through the casualties of war. The decline in exports of ALSACE wines is symptomatic of the difficulties. Wine consumption was dictated by FASHION, and by 1500 taste was moving away from the often spiced (see FLAVOURED WINES) white wines of Alsace towards those of the PALATINATE and the RHEINGAU, as well as to the lighter wines of FRANKEN. At the same time, demand for heavier red wines was increasing, so that Alsace found itself having to plant more PINOT NOIR vines together with 'Lampersch' (a red wine variety from Lombardia in Italy) to compete with imports from France and the Mediterranean.

The excessive expansion of vineyards up to 1500 brought about a slump in the land market by 1540, with a consequent collapse in the price of wine, much of it in any case of dismal quality, having been grown on sites quite unsuitable for viticulture.

It is no coincidence that the widespread agrarian rebellion of 1525 known as the German Peasants' War was concentrated in the winegrowing areas, where the peasantry had been exposed to the fluctuations of the market, demands by lords for higher taxes on its crop, and the need to subdivide holdings into unprofitably small PARCELS by the laws of partible inheritance (see BURGUNDY, history), and yet peasants were compelled to cling to their foothold in commercialized viticulture for want of alternative employment.

Throughout the century, viticulture retreated from the cooler, more remote valleys; poor-quality vineyards in the plains were abandoned in favour of slopes with better exposure and drainage. As the century wore on, the demand for grain for bread and brewing swelled, so that corn prices outstripped wine prices, and much land reverted to tillage. Nevertheless, on the eve of the Thirty Years War, around 350,000 ha/865,000 acres of land in Germany were still under vines,

over four times the extent of viticulture today. The 16th century also saw greater emphasis on better-quality white varieties.

A first classification Although the use of individual site names to distinguish quality (as opposed merely to identifying different vineyards) was largely unknown before 1800, there is one striking instance of ranking by quality in this period. In 1644 the council of Würzburg in FRANKEN classified the city's vineyards into four groups.

Recovery and improvement, 1650–1800

The recovery of German viticulture after the depredations of the Thirty Years War was slow and painful. Only FRANKEN (Franconia), which had been the scene of fierce fighting in the 1630s, experienced a swift recuperation in vineyards and wine prices in the 1650s. In the PALATINATE, viticulture was not fully restored until the 1710s. There many growers, despairing of making a decent living, emigrated to America in the early 18th century. The region was further afflicted by the wars of Louis XIV of France from 1674 to 1700, as indeed were districts on the left bank of the Rhine as a whole, including the MOSEL.

The vineyards of BADEN and WÜRTTEMBERG, which had suffered least the previous century, may have declined by as much as 80% by the end of the 18th century. In ALSACE, however, the loss of a workforce was partly compensated for by policies to encourage immigration from France, Lorraine, and Switzerland.

Efforts to improve viticulture from the late 17th century onwards pursued a double strategy: to encourage the planting of better-quality grape varieties, often on selected new sites, while at the same time prohibiting the clearing of land for vines where only poor quality could be expected. In what is now the MOSEL, for instance, the Abbey of St Maximin had been replanting at Grünhaus on the RUWER since 1695; as many as 100,000 new cuttings, it has been reckoned, were put down. But at the other end of the scale, more land was constantly being taken in by small growers, so that the prince-archbishops of Trier issued an edict in 1720 banning the clearing of forest for new vineyards.

In 1750, another decree enjoined the production of natural, unsugared (*naturrein*) wines, and in 1786 the last archbishop-elector, Clemens Wenceslas (r. 1768–1801), a keen champion of viticulture, ordered that inferior grapes be grubbed up and replaced with the RIESLING vine. At Bingen, the archbishop of Mainz decreed in 1697 that the famous Scharlachberg ('scarlet slope', perhaps because it once grew red wines) be planted exclusively with Riesling.

Likewise in the Rheingau, Constantine, prince-abbot of the ancient Benedictine abbey of Fulda, which had acquired the site and castle of Johannisberg (see SCHLOSS JOHANNISBERG), ordered the replanting of the vineyards with Riesling and 'Orléans' vines in the 1760s. In this period, the sources begin to distinguish the quality of Rhine wines according to village or, on occasion, site.

Vine varieties In Alsace, improvement owed nothing to the French crown, everything to local initiatives by institutions such as the Jesuit College at Sélestat, which began to plant Riesling in 1756 in place of lesser vines. Alsace saw the development of two new varieties in the 18th century. In 1756 Johann Michael Ortlieb of Riquewihr pioneered an early-ripening clone of RÄUSCHLING, the Kleiner (small) Räuschling (also known as Ortlieber or, in Alsace, as KNIPPERLÉ). In 1740 the mayor of Heiligenstein by Barr, Erhard Wantz, introduced a new variety under the name of KLEVENER.

In much of southern Germany, Silvaner was displacing ELBLING, but the real innovation was the development of PINOT GRIS by Johann Seger Ruland in Speyer around 1711. Although it spread quickly, the Ruländer suffered a rapid decline because its early ripening meant that its harvest could not be held back until the later-maturing Riesling, so that peasant growers preferred to let it rot rather than gather it early only to have to deliver up a fine wine as a tithe to their feudal lords. Not until tithing was abolished in the wake of the French Revolution did Ruländer establish its rightful place among German wines of distinction.

The 17th and 18th centuries also saw the first attempts to make specially selected or late-picked wines. Use of the term CABINET to indicate a wine of reserve quality is first encountered at Schloss Vollrads in the Rheingau in 1716, then at Kloster Eberbach in the Rheingau in 1739. The picking of individual ripe berries off the stalks (*Abrappen*) was also deployed, particularly with Traminer grapes, to make what were in effect AUSLESEN, although the wines were relatively short lived. Nevertheless, the potential of picking grapes affected by NOBLE ROT was well recognized by the early 18th century.

Despite these advances, the period up to 1800 was a troubled one for German wine in export markets. Cologne and Frankfurt maintained their leading role in overseas trade, and the 18th century witnessed the first wine AUCTIONS of quality wines. Cologne's merchants were proud of their adherence to the oenological equivalent of the brewing purity laws (*Reinheitsgebot*), which forbade

blending Rhine wines with those from the south, especially France and Italy. Yet their stranglehold on the market in Rhenish wines was challenged in the 1670s when English merchants began to buy at source. T.S.

Bibliographical note: There is no reliable survey in English. For readers of German, Bassermann-Jordan, cited above, remains an indispensable guide, but some information may be gleaned from O. W. Loeb and T. Prittie, *Moselle* (1972).

The rise of modern viticulture, 1800–1900

The French Revolution and its aftermath wrought profound changes in German viticulture. During the Revolution itself, the PALATINATE was invaded and occupied, although in the succeeding Napoleonic Wars it was barely affected. The whole of Germany on the left bank of the Rhine was ceded to France, which proceeded to reorganize the region's administration into four departments.

On the MOSEL, these political upheavals led to around one-fifth of the vineyards, many of them owned by the Church, changing hands, and once the estates of the empire had agreed upon the abolition of all ecclesiastical principalities at the diet of Regensburg in 1803, another 25% came under new ownership.

Although after the fall of Napoleon the Church regained some of its estates, a new and substantial class of peasant and bourgeois vineyard proprietors had been created. On the right bank of the Rhine in the RHEINGAU, Johannisberg (see SCHLOSS JOHANNISBERG) passed through several hands, including Napoleon's general Marshal Kellermann, before it fell to Austria at the Congress of Vienna in 1815 and was bestowed upon Prince Metternich, then foreign minister. On the Main, the estates of the prince-bishops of Würzburg in FRANKEN, or Franconia, were acquired after a short interlude by the Bavarian crown in 1816.

In ALSACE, however, the repercussions of the Revolution were quite different. Once it had become part of the French customs area, growers hastened to increase production in order to capitalize upon a huge internal market. The result was the renewed planting of inferior vine varieties on low-lying sites. Moreover, the imposition by France of tolls on foreign wines hurt Alsace in particular, since it elicited reprisals from Baden, Württemberg, and Switzerland, all still important customers for Alsace wines.

At the Congress of Vienna, the political map of Germany was redrawn. The Mosel became part of the Prussian Rheinprovinz; RHEINHESSEN (west of the Rhine) was absorbed into the grand duchy

of Hesse-Darmstadt together with the Bergstrasse; the Rheingau fell to the dukes of Nassau; and what remained of the Palatinate, the Pfalz proper, was reunited with Bavaria. From 1805/6 Saxony (see SACHSEN) and WÜRTTEMBERG had been elevated to kingdoms, BADEN to a grand duchy. The regulation of customs dues between these independent states became a matter of urgent necessity.

When Bavaria and Württemberg joined Prussia to create the general customs union (*Zollverein*) of 1834, followed by Baden and Hesse-Darmstadt the next year, all the major winegrowing districts were in open competition with each other. As a result, the better wines prevailed and the market in lesser wines collapsed, although at least the *Zollverein* enabled German wines to compete on more favourable terms in the domestic market with French wines, especially those from BORDEAUX, which had begun to reach the north German cities in huge quantities in the 1820s. Baden and Württemberg were the worst hit by the new competition. In Baden the tithe was abolished in 1833, but the area under cultivation constantly receded, and many winegrowers emigrated to ALGERIA or VENEZUELA.

The development of the transport network, above all the RAILWAYS, allowed rapid and easy distribution of the better wines from the more favoured regions, so that Württemberg's production declined by 40% in the 19th century. Franken, too, suffered because of Bavaria's link with the Palatinate and the loss of workers to the emerging industry; the area under vines shrank by 60% between 1850 and 1900.

Only the foundation of the German empire in 1871 put an end to all internal customs barriers. Yet the reabsorption of Alsace and Lorraine in that year brought little relief to winegrowers there. Alsace may have constituted 26% of German vineyards, yielding 39% of production after 1871, but its wines were threatened by imports of cheap wines from France, sweetened wines from across the Rhine, and preferential trade treaties signed by Germany with Austria and Italy in 1891 and with Spain in 1893.

Quality in the ascendant Quality of production became the central concern of German vine-growers and administrators after 1800. The beginnings of quality DELIMITATION can be traced to the 1830s. Wine ordinances in the German states began to prescribe that grapes of different levels of ripeness should be harvested separately. Their measurement was greatly facilitated by systems for weighing the must to achieve a specific MUST WEIGHT, refined in the 1830s by the Pforzheim physicist Ferdinand OECHSLE, whose system is still in use today.

Growers' associations for the improvement of wines and viticulture were founded in many German territories. The state authorities, moreover, played a vital role by establishing schools of viticultural research and teaching. Württemberg was the pioneer in 1860 with its academy at Weinsberg, followed by Prussia's establishment of the institute at GEISENHEIM in 1872, after it had annexed the Rheingau from Nassau in 1866. The Hessian wine academy at Oppenheim dates from 1885; in 1899 citizens of Neustadt an der Weinstrasse founded a wine school to serve the Palatinate; Mosel (Trier) and the Nahe (Kreuznach) acquired a Prussian academy in 1893. These endeavours were underpinned by the creation of state domaines. The earliest was set up by Baden at Meersburg on Lake Constance in 1802, followed shortly thereafter by the Bavarian state domaine in Würzburg and the Herzogl. Nassauische domaine at Kloster Eberbach from its abbatial estates throughout the Rheingau. After its acquisition of Nassau, the domaine was owned by Prussia. At the end of the century, Prussia established further state domaines: in 1896 on the Saar/Moselle with estates at Ockfen, then extended to Avelsbach and Serrig, and on the Nahe at Niederhausen in 1902.

The emphasis on quality, however, placed the smaller peasant growers in a quandary. Without the capital to invest in better vines and winemaking equipment, they were left with inferior grape varieties on poorer sites in a shrinking market. The only solution, albeit imperfect, was to seek safety in numbers by banding together

in CO-OPERATIVES. The first such growers' union was formally established on the River AHR in 1869.

Towards the end of the century, viticulture fell victim to Germany's late industrialization, which sucked LABOUR into the cities. In terms of marketing, the German wine trade was torn between the lure of the controlled addition of sugar—pioneered by the chemist Ludwig Gall (the German counterpart to Jean CHAPTAL in France), which helped to make thin, sour wines from sun-starved soils saleable (see CHAPTALIZATION) —and the reputation which attached to untreated, *naturrein* wines. The first national Wine Laws of 1892 and 1901 had permitted controlled sugaring, but the wine law of 1909 restricted sugaring to 20% of the undiluted wine. In 1910, four groups of natural-wine auctioneers formed the Verein Deutscher Naturweinversteiger (VDNV), today known as the VDP.

One answer was to turn the more acidic vintages into sparkling wine, known in German as SEKT. With some good vintages in the 1860s, Sekt had become a highly popular drink in Germany by the late 19th century.

The true threat to German viticulture, however, lay in VINE PESTS and VINE DISEASES—DOWNY MILDEW in particular and PHYLLOXERA (*Reblaus* in German), which first appeared in Germany in 1874 in Bonn-Annaberg and Karlsruhe before being found in vineyards in the Ahr Valley in 1881. T.S.

The 20th-century wine industry

The first half of the 20th century was a period of deep recession in the German wine industry. The area under vines shrank still further, from around 90,000 ha/220,000 acres in 1914 to less than 50,000 ha/123,000 acres in 1945. Both World Wars placed severe strains on Germany's domestic economy and caused considerable dislocation in its export markets. Exports had reached a peak of 190,000 hl/5 million gal by 1914, but in the aftermath of the First World War the situation was bleak.

The major growing regions on the left bank of the Rhine were occupied by France until 1930. In the PFALZ region, moreover, the activities of separatist groups severely disrupted civilian life up to 1924, which hit the wine industry in particular. A series of bad vintages from 1922 until 1932, in combination with the raging inflation and the economic hardship of the Weimar period, ruined many wine merchants and growers, especially the smaller proprietors. A flood of imports from France and Luxembourg, as specified by the Versailles Treaty, undercut the prices which German producers could charge; many growers faced bankruptcy, and by 1928 exports had collapsed to no more than 39,000 hl/1 million gal per annum.

The Nazi era helped to revive domestic consumption of German wine, but the National Socialist policy of subordinating all private associations to state control (*Gleichschaltung*) meant, for the wine industry, that all independent professional bodies except the VDNV were abolished and replaced by a single Union of Viticulture under one president, thereby destroying the enterprise and initiative of individual growers and regional wine associations. The end of the Second World War heralded the return of some of the consequences of the First. German growers faced a shortage of labour but an abundance of cheap imports from France and Algeria. In their zone of occupation in the Pfalz and Moselle, the French requisitioned wine and blocked its movement on a grand scale.

The parlous state of exports in the 1930s persuaded some merchants, principally those trading to the United Kingdom, to try to increase sales by marketing BRANDS, which could contain more than one grape variety, were sourced from more than one region of production, and were usually sweetened. This is the origin of LIEBFRAUMILCH.

Undoubtedly the most significant step forward for German viticulture in the first half of the century was the wine law of 1930, which went far towards rectifying the deficiencies of the 1909 law. It provided a clear definition of what constituted a natural, as opposed to a CHAPTALIZED, wine and also forbade the blending of red and white and of German and foreign wines.

Viticulture Between 1950 and 1990 German viticulture underwent a dramatic transformation. The area under vine once again expanded steadily and in the modern era measures well over 100,000 ha/250,000 acres. But the most startling development was the increase in YIELDS. At the beginning of the century the average of 20 hl/ha (1.1 tons/acre) was no more than what might have been expected of an abundant vintage in any preceding century. By 1950 that had doubled to 40 hl/ha, and by the 1980s it frequently exceeded 100 hl/ha (5.7 tons/acre), although today's more discriminating growers are cropping less heavily.

From the 1950s there was a radical restructuring of German vineyards, known as FLURBEREINIGUNG. The number of individual sites has been substantially pruned, and since the German wine law of 1971 a new vineyard register has been compiled and average wine quality has improved immensely. T.S.

Germany , major wine producer in Europe with both wines and problems quite unlike those of anywhere else. Grape-growing in Germany is a small but culturally conspicuous part of the country's farming industry. Germany's annual wine production of 7–8 million hl/185–211 million gal has made it Europe's fourth biggest wine producer for many years, albeit distant behind France, Italy, and Spain. Unlike France and Italy, however, Germany makes about as

much wine as it consumes, while also being the largest importer of wine in the EU. Regrettably German wine law has scarcely helped the country's wine reputation, and the majority of German wine is still sold in BULK, often on price rather than quality. These unfortunate factors notwithstanding, the profile of German wine—in particular that of Riesling—has risen significantly in prestige at home and abroad since the 1990s. What's more, while nearly all of Germany's growing regions can still be considered COOL-CLIMATE and capable of producing wines with incomparable finesse, the struggle to ripen grapes sufficiently that dominated viticulture here for centuries has eased dramatically thanks to CLIMATE CHANGE as well as viticultural and attitudinal changes.

Wine-growing regions

Geography and climate

Over the centuries, the German vineyard has expanded and contracted. See GERMAN HISTORY and map there. Many of Germany's best vineyards are on the steepest slopes, quite unsuited to anything other than the vine. Overlooking the rivers RHINE, Neckar, Main, NAHE, AHR, and MOSEL and its tributaries, their high cost of cultivation is justified only by the quality of the wine they can produce. In the steep vineyards, three times as many labour hours are spent tending the vine as is the case on flat or gently sloping terrain, where the natural position of the vine-grower is on the seat of a tractor.

Several other factors limit MECHANIZATION in the vineyards, among which are the tradition of selective harvest and the smallness of the holdings, although that has been somewhat mitigated by the wholesale vineyard reorganization known as FLURBEREINIGUNG. Vine-growing in Germany was once the work of peasants, controlled by the Church and the nobility. In 2020, roughly half of Germans who grow wine grapes do so part time with average holdings of slightly under 2 ha/5 acres, selling their fruit to merchants or more likely participating in a CO-OPERATIVE (*Winzergenossenschaft*), the category responsible for around 30% of German wine production. Since the late 20th century, picking at larger estates has generally been done by temporary workers from eastern and southern Europe, among whom Poles and later Romanians have been pre-eminent.

For more geographical detail, see map of Germany and Alsace in this entry; see also entries under the names of individual wine regions which are, in declining area of total vineyard, RHEINHESSEN, PFALZ, BADEN, MOSEL, WÜRTTEMBERG, FRANKEN, NAHE, RHEINGAU, MITTELRHEIN, SAALE-UNSTRUT, AHR, HESSISCHE BERGSTRASSE, and SACHSEN. Most German wine labels carry the name of the region in which the wine was produced.

Viticulture

The vine-growing regions of the EU are divided into climatically different zones. In Germany, Baden shares Zone B with several French regions including Alsace, Champagne, and the Loire Valley. Although the remaining German regions are all in cooler Zone A, their MACROCLIMATES and MESOCLIMATES are perhaps the most varied of all the world's vineyards. Mesoclimatic variations within a single site or EINZELLAGE can result in simultaneous pickings of the same variety which exhibit significant differences in potential alcohol and flavour. According to research at GEISENHEIM, the average alcohol content of wine of the same vineyard can vary from one vintage to another by over 6%. The degree of LATITUDE, topographical features such as a favourable exposure to the sun, shelter from frequent cold winds or damaging FROSTS, and the ELEVATION are some of the factors which dramatically influence the quality of German viticulture.

Some 5–7% of Germany's vines are individually supported by POSTS, particularly in the Mosel, where relatively tight spacing between vines on steep slopes is the norm. But this method is in decline as old vineyards continue to be subjected to *Flurbereinigung* and workers with the requisite skills disappear. Elsewhere, vines are trained on WIRES in rows, often with wide spacing, although an international 21st-century FASHION for tight spacing is influencing German replanting.

Some 4–5% of all vines—particularly in the Mosel, where some villages and vineyards never succumbed to PHYLLOXERA—are UNGRAFTED. But this proportion is also in decline, as is average VINE AGE due to ongoing *Flurbereinigung*. And incidences of phylloxera led to bans on ungrafted plantings. Although German research stations, most notably Geisenheim, have for nearly a century been famous for their clonal selections, which dominate Germany's vineyards, many growers are increasingly enthusiastic about MASS SELECTIONS.

Among growers whose aim is to produce top-quality fruit, PRUNING is usually to 6–8 buds per square metre, depending on the variety. To

produce a more concentrated must, excess bunches of grapes are removed in the months following the FLOWERING in June and often again in late summer (see CROP THINNING). The aim in VINE TRAINING in recent decades has been not just to harvest healthy, ripe grapes but also to delay or reduce sugar accumulation (whereas, for most of the 20th century, high must weights were the principal goal) and sometimes to reduce costs by facilitating MECHANICAL PRUNING and MECHANICAL HARVESTING. Machines are increasingly used even at prestigious estates, sometimes employed for speed after human hands have cost-intensively performed a 'negative Auslese' to remove rotten or otherwise imperfect fruit. Training and pruning regimens are undergoing considerable rethinking in climatically altered scenarios where even SUNBURN has become a significant problem. (In another sign of the times, the German wine law was amended in 2021 to allow IRRIGATION in years of DROUGHT or excessive heat.) Among the many factors insufficiently emphasized in the 1971 German wine law was YIELD: Germany's average yields have long been the highest of any significant wine-producing country, generally well over 70 and sometimes over 100 hl/ha. But considerable attention is given to that factor in 2021 legislation, prompted in part by yield reduction having been a major theme of the VDP growers' association.

Ripeness can vary significantly from one bunch to another on the same vine as well as within the cluster, not to mention the presence or absence of BOTRYTIS. Riesling growers in some regions of Germany, notably the Rheingau, have for two centuries responded with selective picking of individual clusters or even berries, and in the course of the late 20th century this became nearly universal practice among quality-conscious German Riesling growers, with at least a portion of most vintage's crop, resulting in sweet wines with a PRÄDIKAT level of AUSLESE and above, but often also ensuring entirely healthy fruit for the dry (TROCKEN) wines that make up the majority of production. However, some influential growers make a point of practising block picking for some wines, showcasing the sort of complexity that comes from bunches and berries in diverse states of

ripeness and botrytis influence. Prior to the late 20th century, block-picking was the norm.

While Germans exhibit a high level of support for SUSTAINABLE and ORGANIC VITICULTURE, vines' disease sensitivity, difficulty of vineyard access, and precipitation patterns in German wine regions have slowed the spread of organic viticulture compared with the situation in neighbouring Austria and France. In the Mosel, for example, PESTICIDES or HERBICIDES sprayed from helicopters are the only effective means of reaching vines on ultra-steep, rocky slopes. Such sprays easily drift into neighbouring vineyards, a deterrent to going organic. Under such circumstances, there is no point in a small landholder attempting to work organically, as the sprays will inevitably drift into his or her vineyards. But the 21st century has seen organic and BIODYNAMIC VITICULTURE making significant inroads in Germany, even on the Mosel.

Winemaking

While Germany has been a leader in winemaking technology as well as viticultural research, a movement towards minimal intervention and rediscovering traditional methods is a significant part of today's German wine scene. The resulting tension is reflected in the practices of most cellars. Sophisticated PRESSES, typically operating at two atmospheres or less, are sometimes essentially programmed to re-enact the regimen of ancient basket presses, and not a few strong young German growers have rehabilitated antique specimens of the latter. CENTRIFUGES, FILTERS, FINING agents, and ENZYMES are employed by many estates to ensure ultra-clean juices that are then fermented with carefully selected YEAST cultures. But the virtues of minimal gravity settling, retention of solid matter, and SPONTANEOUS FERMENTATION (which in the Mosel never went entirely out of fashion) are being affirmed by a growing share of winegrowers. Early RACKING, CLARIFICATION, and BOTTLING of young white wines is still the norm, but the role of LEES CONTACT as well as lighter FINING and FILTRATION and later bottling in enhancing flavour and stability are taken increasingly seriously by many winegrowers. CHARCOAL-fining to remove off-aromas and flavours in vintages featuring GREY ROT and other fungal infections is still common but is increasingly seen as a last resort. Sensitivity to levels of SULFUR DIOXIDE, albeit lagging, has tracked international trends.

Extremely varied weather this century has forced German growers to practise, most unusually, ACIDIFICATION (initially in 2003) and to rediscover DEACIDIFICATION techniques. Resort to CHAPTALIZATION is nowadays rare within the ranks of Germany's top growers—hard as that is for any grower born before 1960 to imagine. Many other techniques that have become prevalent elsewhere remain illegal in Germany, notably CRYOEXTRACTION (EISWEIN may not be made using a freezer), REVERSE OSMOSIS, and other post-harvest means of must CONCENTRATION.

Since the 1980s, dry wine has come to dominate the so-called fine-wine market inside Germany, especially in restaurants and among consumers of premium-priced bottlings, where TROCKEN came to be viewed as an imprimatur of drinkability, not to mention social respectability. But many German winegrowers remain committed to making wines with some sweetness, especially from Riesling, albeit very differently than of old. Addition of SÜSSRESERVE, the usual means of rendering or fine-tuning sweet wine during the 1970s and 1980s, has almost completely given way to practices such as arresting fermentation through a combination of low temperatures, adding SULFUR DIOXIDE, and STERILE BOTTLING. The results of stopped fermentation are chemically and organoleptically different from those of adding Süssreserve. Only the latter allowed growers to experiment in order to determine optimum BALANCE and achieve a desired RESIDUAL SUGAR level. At least as common today as taking measures to guarantee a certain level of residual sugar are measures taken to reduce residual sugar in a wine whose fermentation has stopped above the legal limit for a dry wine (see TROCKEN): supplementary inoculation with cultured yeast, warming to restart fermentation, and BLENDING. Riesling especially, if left to its own fermentative devices, has a habit of coming to rest HALBTROCKEN, half- (or medium) dry, a state that most contemporary German growers seem somehow to find ideologically repugnant and many German consumers seem to spurn.

BARREL MATURATION in casks of varying sizes is frequently practised with Riesling, not to mention with red wines. Use of the traditional 1,200-litre *Stückfass*, 2,400-l *Doppelstück*, and 1,000-l Mosel FUDER never died out and are today increasingly employed, especially by top estates. And as elsewhere, 300- and 600-litre and even larger casks as well as CONCRETE vessels are increasingly supplementing or replacing the classic 228-litre Burgundian PIÈCE for Pinots of both colours.

Vine varieties

The 1971 German wine law, with its focus on quality designations defined solely by must weight, discounted the significance of grape variety and significantly disadvantaged Riesling in the marketplace. But today the importance of grape variety and the qualitative pre-eminence of Riesling among Germany's white wine grapes (like Pinot Noir among those for red) is undisputed. Covering in 2020 just over 23% of German vineyard surface, Riesling boasts more than double the surface area of Müller-Thurgau, the next most planted white variety. SILVANER, while traditionally important, now registers just 4.5% of German vineyard surface, having been overtaken by GRAUBURGUNDER (Pinot Gris) and WEISSBURGUNDER (Pinot Blanc) at 7.1% and 5.7% respectively. Chardonnay, at 2.3%, recently edged out Kerner, one of numerous CROSSES (others include Bacchus, Huxelrebe, and Ortega) that rose to prominence after the Second World War but have since drastically declined in surface area. Among CROSSES, acid-retentive and distinctively aromatic SCHEUREBE has a special claim to excellence, though in terms of surface area it has recently been overtaken by Sauvignon Blanc. Among varieties with ancient legacies albeit 1% or less of nationwide surface are TRAMINER, GUTEDEL (Chasselas, important in Baden's Markgräflerland), and ELBLING (dominant in the Upper Mosel), while acid-retentive RIESLANER retains eloquent partisans in the Pfalz and its native Franken.

Plantings of red-wine varieties have increased dramatically since the 1990s, SPÄTBURGUNDER (Pinot Noir) having by 2020 overtaken Müller-Thurgau to become, with an 11.3% share, Germany's second most widely planted grape. Dornfelder, a cross responsible for much of Germany's red-wine boom, increased its share of surface more than fourfold between 1995 and 2020, to 7.1%. Among traditional black grapes, PORTUGIESER has slipped to 2.5%, while TROLLINGER, Lemberger (aka BLAUFRÄNKISCH) and SCHWARZRIESLING range from 1.8 to 2% each thanks to their prominence in Württemberg. Tiny shares also accrue to FRÜHBURGUNDER and ST-LAURENT, thanks primarily to

partisans in the Ahr and Pfalz respectively, as well as—predictably, given their French notoriety—to Cabernet Sauvignon, Merlot, and Syrah.

Wine labelling

The overwhelming majority of German wine is officially QUALITÄTSWEIN. A portion of this, the amount varying according to quality of vintage and subject to long-term labelling trends, is bottled unchaptalized and bears a so-called PRÄDIKAT, of which there are six: KABINETT, SPÄTLESE, AUSLESE, BEERENAUSLESE, TROCKENBEERENAUSLESE, and EISWEIN, each pegged to a minimum MUST WEIGHT. A long-term trend is towards omitting these Prädikat designations for dry wines. Whereas a Beerenauslese, Trockenbeerenauslese, or Eiswein is almost inevitably bottled with a high level of RESIDUAL SUGAR, designation of a wine as Kabinett, Spätlese, or Auslese bears no direct relation to the sweetness of the finished wine. Among wines not labelled as trocken (dry), FEINHERB, or halbtrocken (medium dry; see SWEETNESS for the official EU classification of such terms), an Auslese will generally, though not always, taste noticeably sweeter than a Spätlese, which will in turn taste sweeter than a Kabinett. All German Qualitätswein carries an AP NUMBER on its label, certifying its having passed analytical and sensory examinations.

The tradition of picking parcel by parcel and often selectively within parcels, combined with what many Germans would claim is a national passion for minutiae, can make for dozens of different bottlings at a given wine estate. And German Riesling is arguably capable of more stylistic diversity than any other combination of place and variety. The resulting multiplicity of bottlings, combined with the divided ownership of individual sites, has made it very difficult for vineyard names to have any widely recognized associations of flavour, bouquet, or style. The German wine law has in recent decades added new layers of terminology while adapting but not jettisoning the old. An obvious example is the wine law promulgated in 2021, designed to bring German regulations into conformity with EU categories and principles under the rubric of narrower geographical specifications equalling higher promised quality, yet without displacing the existing Prädikat hierarchy. What the rubric amounts to in practice could

perhaps be better expressed as: 'The higher the level of official prestige and of purported quality, the narrower the permitted degree of geographical specificity with which a wine may be labelled.' Qualitätswein falls into the categories of generic (Gutswein); communal or village designated (Ortswein); and site-specific (Lagenwein), though a producer could choose to bottle all of his or her wines under vineyard names or, for that matter, to market entirely under fantasy names. Any authorized vineyard name must be preceded on labels by the corresponding communal or village name. Authorized names include those of an official EINZELLAGE or of a *Gewann* (the smallest cadastral unit) that has been registered for label usage by a grower with holdings in that *Gewann*. Many producers are enthusiastic about the opportunity for adding geographical specificity—as of 2021, more than 300 such *Gewann* names had been registered in Rheinland-Pfalz (incorporating Mosel, Nahe, Ahr, Mittelrhein, Rheinhessen, and Pfalz). *Gewann* designation often permits the singling-out of a core vineyard whose name was co-opted for an Einzellage—e.g. Im Pitterberg (*Gewann*) as opposed to Pittersberg (Einzellage)—and can correct for the extreme heterogeneity of many a sprawling Einzellage.

A CLASSIFICATION of German estates similar to the 1855 one of the Médoc and Graves had prominent proponents among journalists and growers in the late 1980s. From the mid 1990s, momentum gathered for a system of classifying vineyards, with the sites at the apex of a qualitative pyramid being designated an ERSTES GEWÄCHS (first growth) or GROSSES GEWÄCHS (great growth), categories which entered German wine law in 2021 by analogy to 'premier cru' and 'grand cru', albeit without much specificity or any classification of vineyards (in contrast with what the VDP producers' organization has established for its members). It can scarcely be argued that this development, or the proliferation of vineyard designations, will alleviate Germany's perennial dilemma of hard-to-decipher wine labels and consumer confusion.

The 21st century has experienced a diminution of what had been a vicious cycle of over-production and depressed prices from

nugatory flatlands, and an increase in interest in excellent, steep vineyard land. The international reputation of Germany's revered Riesling is higher than at any time in almost a century. Unprecedented levels of technological sophistication are meeting their equal in quality aspirations, responsibility to the environment, and rediscovery of ancient viticultural wisdom. And a reaction appears to have set in both against the stylistic straitjacket of German consumers' and opinion-makers' fanaticism for legally dry wine and against the threat of global gustatory uniformity, promising German wines and winegrowers an opportunity to flourish with that dazzling stylistic diversity of which they, and especially the Riesling grape in their soils, are uniquely capable.

Gevrey-Chambertin , small town in the Côte de Nuits producing some of Burgundy's most famous red wines from Pinot Noir grapes. The area allowed the appellation was sharply reduced in the late 1990s to exclude some less favoured land towards the plain; but with about 400 ha/1,000 acres under vine—including an overflow of

vineyards into neighbouring Brochon, which does not have its own AOC, as well as 80 ha/198 acres of GRANDS CRUS—this is still the largest viticultural source in the Côte d'Or. In 1847, Gevrey annexed the name of its finest vineyard, Chambertin, somewhat tediously dubbed 'the king of wines and wine of kings' (although it was in fact the Emperor Napoleon's favourite wine).

Gevrey-Chambertin wines are typically deeper in colour and firmer than their rivals from Vosne-Romanée and Chambolle-Musigny. Good examples may take time to develop into perhaps the richest and most complete wines of the Côte d'Or. Given the ease with which the village name sells, there used to be plenty of under-achievers in Gevrey-Chambertin, especially at grand cru level, but the quality of wines today from producers such as Denis Bachelet, Pierre Damoy, Claude Dugat, Dugat-Py, Duroché, Sylvie Esmonin, Fourrier, Harmand-Geoffroy, Heresztyn, Henri Magnien, Denis Mortet, Rossignol-Trapet, Joseph Roty, the exceptional Armand Rousseau, and Trapet is reassuring.

In all, Gevrey boasts nine grands crus, the pick of which are Chambertin and Chambertin-Clos de Bèze. The latter, comprising 15.4 ha/38 acres, may equally be sold as Le Chambertin. It is hard to differentiate between the two qualitatively, although Clos de Bèze is slightly further up the hill than Chambertin, with a less deep soil, giving wines which are fractionally less powerful but full of sensual charm.

Le Chambertin, 12.9 ha (plus the 15.4 of Clos de Bèze), is the flagship: if not quite as sumptuous as Musigny or Richebourg, nor as divinely elegant as La Tâche or Romanée-St-Vivant, Chambertin is matched only by Romanée-Conti (see VOSNE-ROMANÉE) for its completeness and its intensity.

Two other grand cru vineyards, Mazis-Chambertin and Latricières-Chambertin, lie on the same level as Chambertin and Clos de Bèze; one, Ruchottes-Chambertin, is to be found a little higher up the slope, while Charmes-Chambertin, Mazoyères-Chambertin, Griotte-Chambertin, and Chapelle-Chambertin are further downhill.

Mazis-Chambertin (12.59 ha), also written Mazy-, is usually regarded as being next in quality to Chambertin and Clos de Bèze, especially in the upper part, Les Mazis-Haut. The flavours are just as intense, the structure perhaps just a little less firm. Latricières (6.94 ha) is less powerful, although the wines are explosively fruity when young, with an entrancingly silky texture, especially when a sunny vintage warms up the cool CLAY soil. Ruchottes (3.50 ha), thanks to a particularly thin CALCAREOUS soil, is lighter in colour, angular in style, but again impressively intense in a fine, lacy style.

Griotte-Chambertin (5.48 ha), which possibly owes its name to the grill-pan shape of the vineyard rather than the griottes cherry aromas which the wine seems to have, and Chapelle-Chambertin (5.39 ha) are also a touch lighter in style. Charmes-Chambertin covers 31.6 ha if Mazoyères-Chambertin is included, which is usually the case. Together this constitutes the largest grand cru in the village; as with Clos de Vougeot and Échezeaux, its size precludes homogeneous quality. Some of the vineyard, such as the part stretching down to the main road, the D974, should perhaps not be classified as grand cru, although a good Charmes is one of Gevrey-Chambertin's most seductive, fragrant wines when young.

Some of the grands crus are matched, if not surpassed, by the best of the premier cru vineyards, especially those with an ideal south-eastern ASPECT such as Les Cazetiers and Clos St-Jacques. Indeed, Domaine Armand Rousseau, the most famous name in Gevrey thanks to the eponymous Armand's pioneering DOMAINE BOTTLING in the 1930s, charges significantly more for Clos St-Jacques than for several grands crus in an impressive range of wines.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

Gewürztraminer, often written Gewurztraminer, is the aromatic variant of the pink-skinned SAVAGNIN, shown by DNA PROFILING to be identical to TRAMINER, and is responsible for some of the most distinctively perfumed, full-bodied white wines of all. Gewürztraminer may not be easy to spell but is blissfully easy to recognize—indeed

many wine drinkers find it is the first, possibly only, grape variety they are able to recognize from the wine's heady aroma alone. Deeply coloured, opulently aromatic, and broader than almost any other white wine, Gewürztraminer's faults are only in having too much of everything. It is easy to tire of its weight and its exotic flavour of lychees and heavily scented roses, although ALSACE's finest Gewurztraminers are extremely serious wines, with an occasional savoury note reminiscent of bacon fat in some of the most complex examples, capable of at least medium-term AGEING.

Gewürztraminer is the name adopted in the late 19th century for the dark-pink-berried aromatic or MUSQUÉ mutation of Traminer (and adopted as its official name, without the umlaut, in Alsace in 1973). Although much has been read into the direct German translation of *Gewürz* as 'spice', in this context it simply suggests 'perfume'. Traminer Musqué, Traminer Parfumé, and Traminer Aromatique were all at one time French synonyms for Gewürztraminer. It is also known as Roter Traminer in German and Traminer or Termeno Aromatico, Traminer Rosé, or Rosso in Italy. Its long history in Alsace means that it is occasionally known as some sort of KLEVNER, particularly in this case Rotclevner.

Gewürztraminer has become by far the most planted variant of Traminer. The grapes are certainly notable at harvest for their variegated but incontrovertibly pink colour, which is translated into deep golden wines, sometimes with a slight coppery tinge. Gewürztraminers also attain higher alcohol levels than most white wines, with over 14% being common, and acidities can correspondingly be precariously low. MALOLACTIC CONVERSION is almost invariably suppressed for Gewürztraminer, and steps must be taken to avoid OXIDATION.

If all goes well, the result is deep-golden, full-bodied wines with a substantial spine and concentrated heady aromas whose acidity level will preserve them while those aromas unfurl. In a lesser year or too hot a climate, the result is either an early-picked, neutral wine or an oppressively oily, flabby one that can easily taste bitter.

Viticulturally, Gewürztraminer is not exactly a dream to grow. Relative to the varieties with which it is commonly planted, it has small bunches and is not particularly productive. Its early budding leaves it prey to spring FROSTS, and it is particularly prone to VIRUS DISEASES, although the viticultural station at Colmar has developed eight virus-free CLONES, certified between 1971 and 2003.

The finest examples still come almost exclusively from Alsace, but the number of interesting examples made elsewhere has been growing.

Germany relegates its Roter Traminer to a very minor rank, well behind Riesling, with 1,119 ha/2,765 acres in total in 2021, including some plantings of the non-aromatic sort, which is very occasionally bottled separately. The variety needs relatively warm sites to avoid spring frost damage and to assure good FRUIT SET so that in northern Germany Riesling is usually a more profitable choice for growers. More than half of Germany's Roter Traminer is planted in the Pfalz and Baden, where it can produce wines of discernible character, but they can tend to flab. At Rhodt in the Pfalz, a Roter Traminer vineyard said to be more than 400 years old styles itself the world's oldest.

There were 263 ha/650 acres of Traminer planted in Austria in 2021 (the name is used to refer to pink and aromatic MUTATIONS as well), but here too it has been largely consigned to the non-modish wilderness, even though some examples—dry or slightly sweet wines from Styria and BOTRYTIZED sweet wines from Burgenland—can exhibit an exciting blend of race and aroma and can develop for many years in bottle.

The variety is grown, in no great quantity but usually distinctively, throughout Eastern Europe: called Tramini in Hungary, Dišeči Traminec in Slovenia, and Traminer or Traminer Roz in Romania. Most of the vines are the aromatic mutation and demonstrate some of Gewürztraminer's distinctive perfume but often in dilute form, typically overlaying a relatively sweet, lightish white. Hungarians are particularly proud of their Tramini grown on the shores of Lake Balaton. It is grown by the Romanians in Transylvania, by the Bulgarians in the south and east, and also, as Traminer, in Russia,

Moldova, and Ukraine, where it is sometimes used to perfume sparkling wine.

It is grown in small quantities in Switzerland and in ever smaller quantity in Luxembourg. In Iberia, Torres grow it in the High PENEDÈS for their Viña Esmeralda, and it is essentially a mountain grape even in Italy, where about 1,121 ha/2,770 acres of Traminer Aromatico are still grown, particularly in Alto Adige. The less scented and less interesting Traminer is also grown to a limited extent.

Outside of Europe, Gewürztraminer presents a challenge. Many wine regions are simply too warm to produce wine with sufficient acidity, unless the grapes are picked so early (see HARVEST, timing), as in some of Australia's irrigated vineyards, that they have developed little Gewürztraminer character. Australia's Traminer/Gew?rztraminer made a modest recovery in the decade to 2013 but has since declined to 679 ha/1,678 acres. It has become popular as a perfumed ingredient in newer wine styles such as PÉTILLANT NATUREL and SKIN-FERMENTED whites.

The variety has been more obviously successful in the cooler climate of NEW ZEALAND, although even here total plantings were 193 ha/477 acres in 2021, despite some lively examples from Gisborne on the east coast of the North Island. This, incidentally, was one of the earliest identifications of varietal/geographical matching in the southern hemisphere.

Another happy home for Gewürztraminer is in the Pacific Northwest of America, particularly in Washington and Oregon, although the variety has lost ground to Riesling in Washington and to Pinot Gris in Oregon. Washington had 164 ha/405 acres in 2017 (down from a high of 775 acres in 2011) and could demonstrate some appetizing life in several well-vinified examples, even if too many were too sweet. In Oregon, the 61 ha/150 acres in the ground in 2020 are used to make a range of styles from dry to sweet, white to ORANGE, with some contributing to multi-varietal blends, although rot can be a problem in this wetter climate.

Gewürztraminer remains a relatively minor variety in California, however, whose 1,643 ha/589 acres, almost half of them in Monterey,

too often bring forth oil rather than aroma (see CALIFORNIA for more on the wines). There are a few hectares of Traminer in Argentina and some increasingly convincing bottlings from Chile, particularly from cooler, southern vineyards, but generally South America relies on TORRONTÉS and MOSCATEL to provide aromatic whites. Limited plantings in South Africa have so far yielded sweetish wines but some of the right aromas.

It seems likely that serious Gewürztraminer will remain an Alsace speciality for some years yet.

Galet, P., *Dictionnaire encyclopédique des cépages* (2nd edn, 2015).

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Ghemme, ancient, tiny red-wine zone high up in the subalpine Novara Hills in the Alto PIEMONTE region of north-west Italy. Its promotion to DOCG in 1997 was intended to rescue its minuscule vineyard surface, which was up to 83 ha/205 acres in 2020. Like GATTINARA across the river Seisa in the Vercelli Hills and LESSONA and BRAMATERRA, Ghemme is made from the NEBBIOLO grape (minimum 85%) with the possible addition of UVA RARA (locally known as Bonarda Novarese) and/or VESPOLINA. For more details, see SPANNA, the local name for Nebbiolo.

GI. See GEOGRAPHICAL INDICATION.

gibberellins, naturally occurring plant HORMONES which regulate vine growth as for other plants. Isolated in 1941 from a rice fungus, they have been much studied since. In the vine they are formed in growing tissue in the leaves, roots, and berries. Many thousands of hectares of seedless varieties, notably Thompson Seedless (SULTANA), are treated by spraying with gibberellins during FLOWERING and shortly

afterwards, resulting in larger berries suitable as TABLE GRAPES. Since the first trials at GEISENHEIM and Oppenheim in Germany, the application of gibberellic acid to seeded grapes in the middle or at the end of full bloom has been included in the Plant Protection Act in several countries. The technique causes berry shatter (see FRUIT SET) and results in a substantial reduction in both BOTRYTIS BUNCH ROT infection and the development of SOUR ROT. Careful calculation of the dose is required since some varieties can respond with reduced fruitfulness the year following the application. R.E.S. & H.S.

Giennois, Coteaux du, small AOC which extends on both banks of the Loire from just north of POUILLY-FUMÉ in the upper Loire to the town of Gien. Although the zone is quite extensive and encompasses both CALCAREOUS and FLINT soils, it comprised just 195 ha/482 acres in 2019. Most of the wines are crisp, pale whites made exclusively from Sauvignon Blanc, mostly harvested by machine, but some light reds and rosés are also made from a blend of Gamay and Pinot Noir. Joseph Balland-Chapuis is one of the most dedicated producers in this region, where spring FROSTS are a perennial threat.

See also LOIRE, including map.

Gigondas, the first Côtes du Rhône-Villages to be promoted to CRU in the southern RHÔNE, in 1971, named for a particularly pretty village perched within the Dentelles de Montmirail, the dramatic LIMESTONE formations visible from many neighbouring appellations. The grape varieties are similar to those grown in Châteauneuf-du-Pape, but the TERROIR is very different. A proportion of the vineyard is grown at high ELEVATION, up to 500 m/1,640 ft, while the rest tumbles down slopes facing west and north-west past the village and into the flatter land below. The effects of elevation and EXPOSURE help bring freshness to the wines, as do the CALCAREOUS soils. Thanks to the action of the Nîmes Fault, soils are particularly complex here, even

for the southern Rhône, with large amounts of limestone and MARL and a band of Miocene sand and SANDSTONE underneath the village.

In 2021, wines were made from 1,225 ha/3,033 acres of vineyards, 99% red, 1% rosé. Wines must be at least half GRENACHE and must include some SYRAH and/or MOURVÈDRE; a further list of secondary grapes can make up no more than 10% of the blend (although in 2022 a move was under way to increase the allowed maximum for the more DROUGHT-resistant CINSAUT to 20%). White wines must be labelled Côtes du Rhône Blanc, but there may soon be AOC Gigondas Blanc, based on CLAIRETTE. Vines have been cultivated here since Roman times, and the village might take its name from the Latin word *jucundus*, meaning 'joyful'. The style of red wine here is concentrated and generous, with a welcome freshness. Though drinkable on release, they typically show their best after ten years in bottle. M.C.W.

Gingin. See HERITAGE CLONES.

Gippsland, vast, relatively cool Australian zone of coast and rolling hills stretching from just beyond the eastern fringe of Melbourne to the state of VICTORIA's eastern border with NEW SOUTH WALES. Some very good Pinot Noir and Chardonnay are produced, but the zone's size and scattered nature of its less than 200 ha/490 acres of vineyards renders generalizations meaningless.

girasol. See GYROPALETTE.

girdling, making an incision round a vine trunk, cane, or shoot, usually to improve FRUIT SET. For more details, see CINCTURING.

Girò, red grape used for dry, sweet, and FORTIFIED WINES on SARDINIA. It is unrelated to the aromatic, pink-skinned Giró Blanc

grown on Mallorca.

Gironde, the estuary which separates the MÉDOC from BLAYE and the south-western extreme of cognac country and gives its name to the *département* that contains the city of Bordeaux and the Bordeaux wine region. The rivers DORDOGNE and GARONNE flow into the Gironde (see map under BORDEAUX).

GIS. See GEOGRAPHICAL INFORMATION SYSTEM.

Gisborne, (Tairawhiti in Māori) in the North Island of NEW ZEALAND, is the first city to see the sun each day due to its easterly location. Its climate is warm, temperate, and very maritime. Viticultural challenges emanate from easterly low-pressure systems during late summer and early autumn which bring rainfall, humidity, and the odd tropical cyclone. BOTRYTIS BUNCH ROT is a challenge and arguably a feature of the region's wines, with rich, honeyed aromatics across all varieties.

In recent times plantings have declined due to competition from the lucrative kiwi-fruit industry, but the Gisborne GEOGRAPHICAL INDICATION remains important for both BULK WINE as well as for boutique players who produce an array of mostly white wines. Chardonnay takes podium position with 620 ha/1,532 acres, producing opulent wines with flavours of ripe pineapple and melon. Pinot Gris varies in style and sweetness, typically displaying ripe pear and spice characters, while the little GEWÜRZTRAMINER planted is distinctive for its intense aromatics and oily texture. Millton Vineyards, a leader in BIODYNAMIC VITICULTURE, is a flagship producer.

S.P.-T.

Givry, famous as the preferred wine of King Henri IV, produces mostly red wine in the Côte CHALONNAISE district of Burgundy. White wine constitutes only one-fifth of total production but is often particularly interesting with a soft bouquet reminiscent of liquorice. The reds have more structure and ability to age than those of

neighbouring RULLY but less depth than Mercurey. Nearly half the 303 ha/749 acres of productive vineyard area in 2018 is designated PREMIER CRU, but the vineyards which most merit the higher rank are those on the hillside between Clos Salomon and the Cellier aux Moines. J.T.C.M.

glass, history of. For more than 3,000 years, glass has played a unique role in the history of wine, in terms of both serving (GLASSES, DRINKING VESSELS, and DECANTERS) and storage (BOTTLES).

Glass vessels were known in the ancient world (first appearing in EGYPT *c.*1500 BCE) and became common during Roman times, when the techniques of glass-blowing spread throughout the Roman Empire. Wine was sometimes drunk from glass tumblers, and surviving examples show astonishingly intricate craftsmanship. Glass bottles were used as decanters for carrying wine to the table, but not for storage because they were too fragile.

Glass-making continued after the collapse of Roman power. By the time of the Renaissance, VENICE had become the centre of luxury production. Venetian glassware was exported throughout the known world, and Italian craftsmen settled across Europe setting up new workshops. In Tudor England, aristocrats preferred Venetian-style glasses to silver (which was considered too common), but glass was so expensive that several diners were expected to share each beaker.

The problem with glass was that it was too light and therefore too fragile to withstand either transport or storage. The most common CONTAINERS for wine were BARRELS for bulk and leather, tin, or stoneware bottles for everyday use.

A turning point in the history of glass (and the history of wine) came early in 1615, when a timber shortage led to the introduction of coal-fired furnaces in England. Hotter furnaces and open-topped clay pots made possible the production of bottles that were not only darker and heavier but also stronger. At first these dark, onion-shaped bottles were used mainly as decanters and for personal use, but by the beginning of the 18th century they were used for the long-

distance transport of wine. Initially the French had to rely on English imports, but by 1790 there were five factories around Bordeaux (still an important centre of glass production) producing 400,000 English-style bottles.

This development was revolutionary because it made possible the AGEING of wine. The necessary corollary was the CORK, whose use became common at this time. The advantages of ageing in bottle were most noticeable in PORT, a staple drink in Georgian England. As the practice of BINNING wine became more common, the shape of wine bottles evolved towards the taller cylindrical shape (*c.*1760) we know today.

Meanwhile a revolution in drinking glasses had emanated from the two southern English workshops of George Ravenscroft, who in 1675 had discovered how to make LEAD crystal. This gave rise to a whole new style of English glassware quite distinct from intricate Venetian fashions. Increasingly, different glasses were designed and produced to be used specifically for certain wines, and by the end of the 18th century the concept of a uniformly decorated glass service was well established throughout Europe. Tait, H. (ed.), *5000 Years of Glass* (new edn, 2012).

glass, wine by the. In an increasing proportion of the world's restaurants and bars, particularly in the United States, wine is served by the glass, sometimes matched to specific dishes on a menu. This is especially useful for those who want to drink less than a half or full bottle, want to taste as many different wines as possible in a FLIGHT of different small servings, or want to practise focused FOOD-AND-WINE MATCHING in a group that has ordered a wide range of different dishes. When carefully administered, with a high level of professional service and due attention to LEFTOVERS in opened bottles, possibly

using special storage systems involving INERT GAS, this is an admirable service to the consumer. See also PRESERVATION SYSTEMS.

glasses, not just the final CONTAINER for wine but an important instrument for communicating it to the human senses (see TASTING). Wine can be drunk from any DRINKING VESSEL, but clean (and only clean) GLASS has the advantage of being completely inert and, if it is clear, of allowing the taster the pleasure (or in the case of BLIND TASTING the clues) afforded by the wine's appearance: colour, clarity, and so on.

For this reason, wine professionals and keen amateurs prefer completely plain, uncoloured, unengraved, uncut glass, preferably as thin as is practicable to allow the palate to commune as closely as possible with the liquid. Thin-rimmed glasses are particularly highly valued.

The ideal wine glass also has a stem—indeed, Americans call wine glasses 'stemware'—so that the wine taster can hold the glass without necessarily affecting the wine's TEMPERATURE (a critical element in wine tasting). The stem also enables a glass to be rotated easily (although it takes a certain knack); rotation, as explained in TASTING, is essential for maximizing AROMA or BOUQUET. This rotation process also means that the ideal wine glass narrows towards the rim, to minimize the chance of spillage during rotation and to encourage the volatile FLAVOUR COMPOUNDS to collect in the space between the surface of the wine and the rim of the glass.

Individuals have their own aesthetic preferences, but any glass which fits the above criteria will serve as a wine glass, including some relatively inexpensive examples. There is a sensual thrill to be had, however, in really thin crystal. This is usually expensive, although central Europe, and BOHEMIA in particular, has a long tradition of producing fine glasses at good prices.

For many households, a single wine glass shape and size will do, traditionally supplemented by smaller glasses for FORTIFIED WINES and

an elongated one for SPARKLING WINES. Purists, however, use slightly different glasses for different sorts of wine, conventionally (although not particularly logically) a smaller glass for white wines.

In this respect there is no greater purist than Georg Riedel, an Austrian glass-maker who is unusual for his wine CONNOISSEURSHIP. His family business makes different glasses for specific wines, supposedly based on analysing how taste characteristics are optimized on the nose and palate by minute variations in glass design. Those determined to take full advantage of all Riedel permutations may need to give up a room or two to accommodate the necessary number of glasses, however, and in practice most people content themselves with just two or three possible glass types, often chosen as much on appearance as on efficacy.

Over the centuries, various specific glasses have come to be associated with different wine types.

CHAMPAGNE and other sparkling wines were long drunk in a flat, saucer-like glass called a coupe, but this was abandoned in favour of the tall flute, which preserves the wine's MOUSSE though suppresses the aroma. Because of this, an increasing number of sparkling wine producers prefer a shape more closely resembling a regular wine glass.

In Spain, SHERRY has traditionally been served in the COPITA, and it tastes infinitely better in a part-filled glass in this elongated tulip shape than it does brimming over a cut-glass thimble sometimes favoured elsewhere. But some of the more fastidious sherry producers also prefer (a smaller pour in) a regular wine glass, as do some PORT producers.

The ideal port glass is not so very different from the copita, although it is usually rather bigger in order to allow maximum appreciation of the complex bouquet of a vintage port.

BURGUNDY, particularly red burgundy, has come to be served in glass balloons, sometimes so large they resemble fishbowls. The idea, apart from lusty exhibitionism, is that a good burgundy can offer such a rich panoply of aromas that they should be given every

chance to escape the wine and titillate the taster. Most wine connoisseurs use the shape on a reduced scale.

The wines of ALSACE and GERMANY are sometimes served in particular forms of glass such as the Rohmer, often with green or brown glass stems, mainly for traditional reasons.

See also SERVING WINE.

glassy-winged sharpshooter, LEAFHOPPER insect (*Homalodisca vitripennis*) of great significance in some southern California wine regions since the 1990s as it is a vector of PIERCE'S DISEASE. It is able to fly longer distances than other leafhoppers and feed on both soft and hardwood stems, allowing the disease to spread more rapidly. It has been detected in Australia but has not become established and poses no immediate threat to vineyards as the Pierce's disease bacterium is not present. R.E.S. & M.A.W.

Glenrowan, warm, historic Australian wine region in the North East Victoria Zone (see VICTORIA), famous for Ned Kelly, FORTIFIED WINES, and full-bodied reds from its 13 growers in 2022. See TOPAQUE AND MUSCAT.

Glera. The PROSECCO grape was renamed Glera in 2009 so that Prosecco could attain (greatly expanded) geographically protected status. Total plantings in Italy, almost exclusively in the Veneto, had reached 19,730 ha/48,754 acres by 2015. Recent DNA PROFILING revealed that Glera is a natural offspring of the obscure and no longer cultivated Austrian variety Vulpea. J.V.

globalization of the world's wine markets continues to accelerate. There was always some trade in wine between Mediterranean countries, and a degree of trade expansion in the five decades prior to the First World War, but until the late 20th century intercontinental interactions involved little more than the exporting of CUTTINGS and

traditional production expertise. Most wine was consumed in the country of production, and those countries were mostly in Europe. But since the 1980s, with the fall in TRANSPORT and communication costs and the rise of E-COMMERCE, the wine industry has embraced new modes of internationalization. They include a greater export focus by the main producers, mergers and acquisitions of what are becoming multinational wine companies (see below), the not-unrelated growth of supermarket chains operating internationally as wine retailers, and the increase in OENOLOGISTS and VITICULTURISTS employed in multiple countries and, often, in both the northern and southern hemispheres.

Globalization has brought significant changes in demand. Gradual deregulation of wine retailing in Britain and elsewhere from the 1970s allowed rapidly expanding supermarket chains to compete with traditional sellers of wine and attract new consumers. Those chains responded to new consumers' preferences by sourcing robust, fruity wines that are more approachable and affordable than FINE WINE but better than traditional basic European wine. For national advertising to be profitable for those chains, and for wineries (and in some cases the supermarket chains themselves) seeking to build BRANDS, large quantities of homogeneous wine are needed year after year. New World producers were initially more adept at responding to this new demand, and one of the consequences was *la* CRISE VITICOLE.

The share of global wine production volume exported, which had previously been well below 15% and mostly Mediterranean or intra-European, grew dramatically from the late 1980s and by 2015 had reached 40%. Meanwhile the NEW WORLD's share of global wine exports has risen from 3% in the late 1980s to almost one-third (if sparkling wine is excluded). Recognizing their poor performance, Europe's producers began belatedly in the mid 2000s to adapt their practices to compete. The world's three leading wine-exporting countries, Italy, Spain, and France, as a group now export about 40% of their production volume, up from just 20% a generation ago. Between 2002 and 2015 the share of wine that is exported from the New World in BULK rose from less than 15% to more than 50%.

Bottling in the country of destination can reduce both transport costs and wine's CARBON FOOTPRINT. It also reflects the growth of supermarkets' own brands, as well as their demands for prompt delivery of those and other branded wines. The new bulk container shipping technology offers greater opportunities to blend wines from any region of the world and so may add to the commoditization of the most popular wine category.

The dramatic expansion in international wine trade is part of a general tendency for global trade to grow faster than production, fuelled in part by the lowering of trade restrictions and the freeing up of markets for foreign currency exchange. This greater openness means winemakers and hence grape-growers are far more exposed now than pre-1990 to exchange-rate volatility and also to greater import competition in their domestic market as consumers seek an ever-broader range of wine varieties, qualities, and styles. Wide fluctuations in exchange rates after the global financial crisis of 2008 substantially altered national shares in key markets, as did CHINA's emergence as a significant player in global wine markets.

Greater openness and international travel also alter tastes and preferences. This has been very clear in the EU, where shares of beer, spirits, and wine in national alcohol consumption have gradually converged. But nowhere has the emergence of wine consumption been more striking than in ASIA, albeit from a low base. Between 2001 and 2017, Chinese wine imports grew from 30 to 750 million litres. Initially they were of low- to medium-quality (often bulk) wines, but more recently they have been of wines that are more expensive than average wine imports elsewhere. Further large increases in wine consumption and probably imports are expected as China's middle class grows, since Chinese per capita consumption of grape wine is still around 1 litre per year (less than 3% of China's total alcohol consumption). Mergers and acquisitions accelerated from the mid 1980s when Louis Vuitton bonded with Moët-Hennessy to form LVMH. At about the same time, UK-based Grand Metropolitan (now DIAGEO) invested in California wineries, and Paris-based Pernod Ricard added Jacob's Creek to its portfolio of brands via Orlando

Wyndham in Australia. Global drinks company interest rests mainly with sparkling wines, brandies, and vermouths, however, which have lent themselves much more easily to global branding than weather-dependent still wines produced just once a year. Pernod had entered the mass market before, only to leave it to wine-focused operators such as CONSTELLATION BRANDS, GALLO, and CASTEL; Diageo did the same in the mid 1990s. Pernod Ricard signalled a return to the fray by acquiring Montana (renamed Brancott Estate) and other significant wine brands when Allied Domecq broke up in 2005.

A second phase of international consolidation drew Australian producers closer to the American market with the merger of California's Beringer with the Mildara Blass subsidiary of Australian brewers Foster's in 2001 and with the acquisition of Hardys of Australia by Constellation in 2003. Foster's subsequently separated its wine business from beer to form Treasury Wine Estates, and Constellation sold their Australian arm, now called Accolade, to a private-equity firm in 2011. When in late 2020 China imposed punitive tariffs on imports of Australian wine, Treasury sourced non-Australian wine for their Australian brands that had been so lucrative in China.

Companies such as ANTINORI, Gallo, and MONDAVI have also been involved in a changing roster of JOINT VENTURES and acquistions which have helped to globalize wine. A more recent development has been Chinese investment in vineyards and wineries, often for distribution reasons, particularly in France.

The emergence of large international wine companies and brands, built on economies of scale, and the ease with which technology and know-how can now be transferred have led to significant shifts of wine-grape production from western Europe to the globe's cheapest vine-growing regions. But globalization is bound by TERROIR and the need for companies to offer differentiated wines of place—one of the main reasons the largest wine companies have a much smaller global market share than do the largest beer, spirits, and soft-drink companies. See also BRANDS.

global navigation satellite system (GNSS), the collective name for the various satellite-based navigation systems (including the original US-owned global positioning system or GPS) which allow detailed mapping of specific vineyard features to a positional accuracy of 1 m/3 ft or less through the use of differential corrections. Differential GNSS (dGNSS or, more commonly, dGPS) is an essential component of PRECISION VITICULTURE. R.G.V.B.

global warming. See CLIMATE CHANGE.

glou-glou, term for a wine, usually red, that is especially easy to drink—*glou* is French for 'glug'. Such wines are typically fairly light in colour and BODY, are low in TANNINS and ALCOHOL, have relatively high ACIDITY, and have an emphasis on the wine's FRUIT. They are often part of the NATURAL WINE movement, and many are made with WHOLE-BUNCH FERMENTATION and little if any SULFUR DIOXIDE or other ADDITIONS. Often served lightly chilled, they may also be called *vins de soif*.

SEE WEB LINKS

Ayscough, A., 'A brief history of glou-glou' (2018). www.wine.sprudge.com/2018/01/30/a-brief-history-of-glou-glou.

gluconobacter, a genus within the acetic acid bacteria family associated more with grapes than wine because of its high sugar tolerance. Like ACETOBACTER species, gluconobacter species are capable of spoiling wine by converting it into vinegar.

glucose is with fructose one of the two principal SUGARS of the grape and of sweet wines. Like fructose, it is a six-carbon-atom sugar, or a hexose.

The two major sugars that accumulate in grapes occur in about equal amounts; at the beginning of RIPENING, glucose exceeds fructose (up to fivefold), but in wines made with overripe grapes there is less glucose than fructose at the end of FERMENTATION. Glucose also serves a very important function as the major sugar used by the vine for forming GLYCOSIDES (see also FLAVOUR PRECURSORS). Common table sugar, sucrose, is made up of one molecule of glucose and one of fructose. See FRUCTOSE for details of the unusual relationship between these sugars and the grape.

B.G.C. & A.D.W.

glutathione, or glutathion, sulfur-containing compound (tripeptide) found in grape juice and an important antioxidant which has been shown to play a significant part in the AGEING of wines and in protecting them from PREMATURE OXIDATION. It also has an important role in the formation of some precursors of VOLATILE SULFUR COMPOUNDS and in stabilizing the THIOLS which characterize the aroma of Sauvignon Blanc and possibly some other white grape varieties.

Glutathione also plays a major role in GRAPE COMPOSITION AND WINE QUALITY: higher levels of glutathione lead to higher levels of FLAVOUR PRECURSORS and lower levels of PHENOLICS.

V.L.

glycerol, or glycerine, member of the chemical class of polyols and a minor product of alcoholic fermentation. The name derives from the Greek word for ‘sweet’, and glycerol does indeed taste slightly sweet,

as well as oily and heavy. It is present in most wines in concentrations ranging from about 4–6 g/l, although BOTRYTIZED wines may have concentrations of around 10 g/l.

While glycerol does have a slight effect on the apparent sweetness of a wine, contrary to popular conception it makes only a very minor contribution to a wine's apparent VISCOSITY and bears no relation to the TEARS observed on the inside of many a wine glass. Whereas sensory tests have demonstrated that glycerol imparts sweetness at a threshold of about 5.2 g/l in white wine, a level of more than 28 g/l would be needed before any difference in viscosity were noted.

A.D.W. & T.H.L.

glycolysis. See YEAST.

glycosidase. See ENZYMES.

glycosides are naturally occurring molecules made up of two parts joined by a glycosidic linkage; one of the parts is a sugar, frequently GLUCOSE, and the other may be a non-sugar, called an aglycone. Common aglycones are phenolic compounds, for example ANTHOCYANINS, although TERPENOIDS and a number of other compound types are found glycosylated in many plant tissues, including fruits. Glycosides present in wines come from the grape, and here the sugar is usually glucose, although it too may be connected to a second, non-glucose sugar residue. Formation of a glycoside changes the physical and chemical properties of molecules that are glycosylated. Glycosides are usually more water soluble and invariably much less volatile than the aglycones from which they were derived. It is still not clear why they form in plants, but glycosylation is presumed to aid detoxification and the transport of aglycones, or to make plant tissues rigid. Plants and fruits often have a higher concentration of glycosides than of aglycones. The sensory properties of flavour-active aglycones are profoundly diminished by glycosylation, and such glycosides, known as FLAVOUR PRECURSORS, are a reserve of FLAVOUR

and contributors to VARIETAL flavour expression of some grape varieties such as MUSCAT (as opposed to aspects of flavour that arise from vinification) and BOUQUET in wines. Following the recognition of glycosides as flavour precursors, a development in the mid 1990s was the determination of this class of compound in grapes and wines through measures of glycosyl-glucose. See also INFRARED SPECTROSCOPY. P.J.W.

glycosyl-glucose assay, or G-G assay, an experimental measure of grape and wine composition, developed in the mid 1990s, based on the recognition of the role of GLYCOSIDES as FLAVOUR PRECURSORS of varietal wine flavour. The assay as applied to a grape, juice, or wine sample involves (*a*) isolation of the glycosides, (*b*) their complete hydrolysis to yield glucose, and (*c*) quantification of the glucose. The G-G assay has been applied to both light- and dark-skinned grape varieties, at early stages of berry development through to harvest; to MUSTS and juices during fermentation; and to wines before, during, and after AGEING. The assay is particularly important for white varieties, where there are few alternative ways of analysing secondary metabolites. With red varieties, most of the glycosides are ANTHOCYANINS. The assay allows the viticulturist and oenologist to relate the glycoside component of grape composition, obtained before harvest, to the glycoside concentration of a wine, irrespective of its style, years after its vinification. It has revealed the decrease in G-G in wines with ageing as glycoside HYDROLYSIS progresses, the range in glycoside concentration in juices of the same varieties grown in different regions, and the different rates of increase in glycoside concentration in fruit grown under different conditions. In the late 1990s, the assay was advocated as a valuable new tool to viticulturists wishing to investigate the influence of vine-growing practices on grape composition. As such it holds promise of an objective measure of fruit composition pertinent to wine quality. However, the assay is relatively complex and time consuming, requiring specialized skill. For this reason there has been little uptake

by commercial wineries, and new methods utilizing INFRARED SPECTROSCOPY that offer rapid analysis of G-G in grapes are more popular. R.D.

GM and GMO. See GENETIC MODIFICATION.

GM 6494–5. See RONDO.

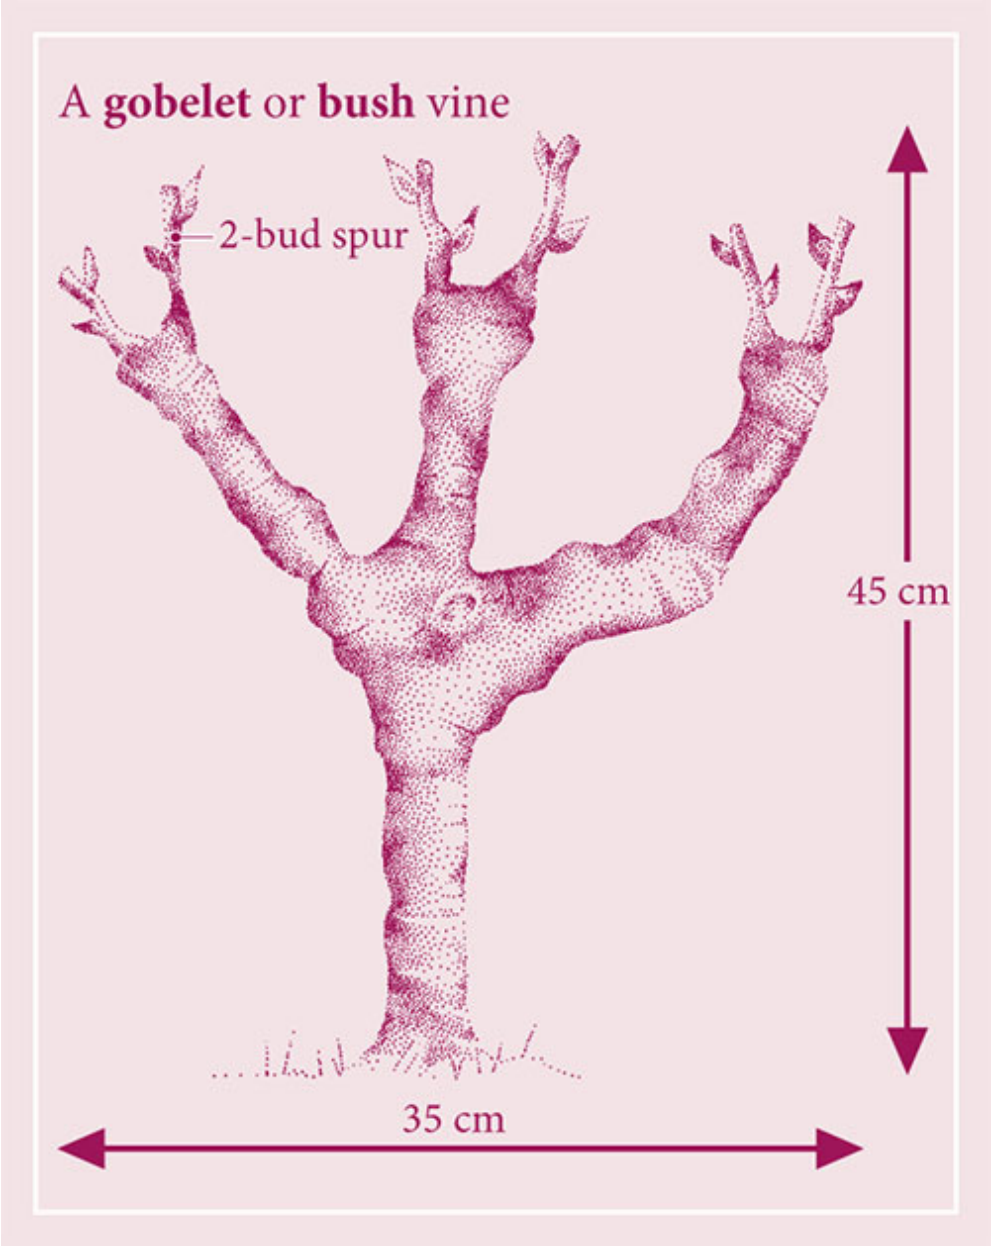
gneiss, a dense, tough, coarse-grained rock (pronounced 'nice') in which distinct bands have developed, distinguishing it from other metamorphic rocks. These irregular bands, typically of paler feldspar and QUARTZ alternating with darker biotite or amphibole, range in thickness over a few millimetres to centimetres with an irregularity that distinguishes the appearance of gneiss from the layers seen in some sedimentary rocks (see GEOLOGY). It is resistant to weathering and usually yields thin, rather acid soils. It occurs, for example, in AUSTRIA's Kamptal and Wachau regions, in MUSCADET, ROUSSILLON, and CÔTE RÔTIE in France, in parts of the US state of VIRGINIA, and in CANADA's Okanagan Valley. A.J.M.

GNSS. See GLOBAL NAVIGATION SATELLITE SYSTEM.

gobelet, or goblet, a form of vine-TRAINING SYSTEM, used since Roman times, whereby the SPURS are arranged on short ARMS in an

approximate circle at the top of a short TRUNK, making the vine look something like a goblet drinking vessel. The vines are free-standing (apart from a small supporting STAKE when young), and the system is best suited to low-VIGOUR vineyards in drier climates. This is a form of HEAD TRAINING and is generally subject to SPUR PRUNING. The trunk is short, typically 30–50 cm/12–19 in, and the foliage is unsupported by WIRES.

The gobelet is widespread in France, from Beaujolais southwards, although it is now less common than it was because it is generally more economical to train vines on trellis systems rather than have them free-standing. The traditional spacing was 1.5 by 1.5 m (5 ft), but the distance has been increased to allow tractor access. With low-vigour vineyards the foliage can be relatively erect, but shoots may trail on the ground in high-vigour vineyards, and there can be substantial SHADE. Grape yield and quality may suffer as a result. The system is used widely in many Mediterranean countries. In Italy, the system is called *alberelli a vaso*, in Spain *en vaso*, and in Portugal *en taça*. In many NEW WORLD countries such as Australia and South Africa, the traditional, low-vigour gobelet-trained vines are often called BUSH VINES; in California, viticulturists tend to refer to them as head-trained, spur-pruned vines. Many have been replaced by vines with some form of trellising to accommodate the improved VIGOUR of newer vineyards, even if OLD VINES are increasingly valued by some winegrowers. R.E.S.



Galet, P., *General Viticulture* (2000).

goblets. See DRINKING VESSELS.

Godello, fine white grape variety native to north-west Spain and northern Portugal rescued from near extinction in the 1980s and grown on more than 1,400 ha/3,459 acres of north-west Spanish vineyard by 2020. As Godello it is responsible for well-structured,

tense dry whites in VALDEORRAS. DNA PROFILING shows it to be identical to a Portuguese variety known as Gouveio in the Douro and also in Dão (where it used to be known as Verdelho do Dão), and it is therefore a sibling of VERDEJO, their parents being SAVAGNIN and Castellana Blanca. Total plantings in Portugal were 1,045 ha/2,582 acres in 2020, rather more than of the distinct GOUVEIO REAL.

Goldburger, bland Austrian gold-skinned CROSS of WELSCHRIESLING and Orangetraube. Just 39 ha/96 acres of this vine remained in 2020, almost all of them in BURGENLAND, mainly used for sweet wines.

Goldkapsel, unregulated term of approbation referring to German Rieslings. Use of gold capsules to signify superior quality was a response, initially and still primarily in the MOSEL, to the 1971 German wine law's prohibition on labels of traditional terms such as CABINET, *feine*, *feinste*, or *hochfeinste*. Because the band of permissible MUST WEIGHT for AUSLESE is especially broad and Auslesen are the products of selective picking, usually in very small volumes, there is ample room for gradations. Some growers even designated really fine examples *lange* Goldkapsel (long gold capsule), and the abbreviations GKA and LGKA became established. From the 1990s the designations spread to wines of all possible PRÄDIKATS including, at some estates, dry wines, the standards employed being entirely estate-specific. Wines referred to in this way on price lists sometimes lack a physical gold capsule, and in recent years some growers have snuck the tiny letters GKA or LGKA on to a label without the authorities finding grounds to object. D.S.

Goldmuskateller, German name for the golden-berried MOSCATO Giallo grape speciality in ALTO ADIGE.

gold rushes have played a significant role in the development of NEW WORLD wine production through their influence both on demand for alcoholic beverages and on LABOUR supply. In CALIFORNIA, commercial viticulture had emerged during the 1830s, and with the discovery of gold in 1848 there was a massive increase in demand for all types of alcohol in the gold-mining counties of Amador, Calaveras, El Dorado, Nevada, Placer, and Tuolumne. However, by the 1850s, once the first flush of gold fever was over, a number of the immigrants, seeking to profit from the rising price of wine, turned to grape-growing and winemaking as a more reliable source of income. By 1857 it is estimated that there were some 1.5 million vines in California, and only three years later, after the enactment of legislation in 1859 which exempted vineyards from taxation, this total had risen to some 6 million.

Viticulture had been introduced into Australia on the establishment of the new colony in New South Wales in 1788. Its subsequent spread followed the increasing pace of colonization and settlement, with new vines being planted almost as soon as each new colony was founded. During the first half of the 19th century, however, despite the activities of proponents such as James BUSBY, winemaking remained a minority interest. The gold rush of 1851 changed this by attracting numerous immigrants to VICTORIA, with large numbers coming from France, Switzerland, Italy, and Germany, countries which had long traditions of viticulture and winemaking. Many, failing to make a success of prospecting, turned to farming, and in particular to viticulture, with the result that the pattern of vineyards in Victoria closely reflected the scattered distribution of the gold. In particular, during the 1870s and 1880s, the gold-mining areas of Ballarat, Bendigo, Great Western (now Grampians), and the Murray river all became important wine regions.

In New Zealand, the Otago gold rush of the 1860s likewise led to the gold mines, now long since abandoned, that are still a feature of wine country in this part of New Zealand. In 1864, for example, the Frenchman John Désiré Feraud used some of the fortune he made from a gold claim at Frenchman's Point to plant a vineyard on the

Dunstan Flats. His wines won prizes in Sydney and Melbourne in the late 1870s and early 1880s. P.T.H.U.

González Byass, the largest producer of SHERRY, still run by the family that founded the house. In 1835, 23-year-old Manuel María González Angel set up business as a shipper in JEREZ in southern Spain. Within months he had joined forces with D. Juan Dubosc to make their first large shipment to London: 48 hogsheads and a quarter cask, sent to Robert Blake Byass, who was to become their UK agent. The FINO brand Tío Pepe was born in the mid 1800s, named after Manuel's uncle José Angel y Vargas (*tío* being Spanish for 'uncle'), who helped his nephew establish the SOLERA. In 1855, Robert Blake Byass became a shareholder in the business, and in 1870 his sons and the sons of the founder entered the firm that became González Byass & Co.

In the mid 1980s, González Byass started to expand outside Jerez and now owns Bodegas Beronia (Rioja and Rueda), Cavas Vilarnau (Barcelona), Finca Constancia (Vino de la Tierra de Castilla), Finca Moncloa (Vino de la Tierra de Cádiz), Viñas del Vero (Somontano), Pazo de Lusco (Rías Baixas), and Dominio Fournier (Ribera del Duero). In 2016 the company expanded outside Spain to include Viñedos Veramonte and Neyen Apalta Estate in Chile. This was followed by the acquisition of Pedro Domecq (Mexico), and by 2022 the company owned a total of 2,143 ha/5.295 acres of vineyard in Spain, Chile, and Mexico.

Fifth-generation Mauricio González Gordon has been at the helm since 2006 during a period of change and expansion which has also

included the development of a premium spirits portfolio, built on the success of its range of Jerez brandies, including the renowned Lepanto.

González Gordon, M., *Sherry: The Noble Wine* (3rd edn, 1990).

Gorbachev, Mikhail (1931–2022), last President of the Soviet Union (1985–91) and significant in the history of wine because of his 1985–8 national campaign against alcohol abuse. Measures were energetically directed not just against vodka consumption but also against the production and importation of wine. The immediate domestic effect was that the total vineyard area in the SOVIET UNION fell by one-third between 1980 and 1990.

The anti-alcohol campaign had equally dramatic consequences in countries from which the Soviet Union had been importing huge quantities of wine; see for example, BULGARIA, ROMANIA, HUNGARY, GEORGIA, and CYPRUS. These countries suddenly had to find new customers for an important proportion of their annual grape harvest —customers who would certainly be more demanding than their Soviet predecessors—or simply abandon vines and wine production to a significant degree.

Gordo, or Muscat Gordo Blanco, originally Spanish synonyms for MUSCAT OF ALEXANDRIA since adopted by Australia.

Gouais Blanc, genetically important, light-skinned grape variety commonly planted in central and north-eastern France in the Middle Ages which produced rather ordinary, acid wine, while the more highly valued Pinots were planted on more favoured sites. DNA PROFILING has shown that Gouais Blanc and Pinot had a great number of important progeny in northern France (see PINOT). Following that discovery, researchers became more interested in this ancient variety and realized that, besides its numerous synonyms in France, Gouais Blanc is also identical to Belina Drobna, Štajerska Belina, and

Heunisch Weiss or Weisser Heunisch in Eastern Europe, as well as to Liseiret and Preveiral in Italy. Moreover, more than 60 additional possible parent–offspring relationships have been suggested between Gouais Blanc and French or European varieties, including RIESLING, BLAUFRÄNKISCH, and FURMINT. Gouais Blanc has been called a 'key variety' for grape diversity in Europe by some researchers, and some others have even nicknamed it the 'Casanova of grapes'. Despite its relative scarcity in France, in 2021 it was added to the official catalogue of varieties permitted there. VARIETAL Gouais Blanc is produced by Josef-Marie Chanton of Visp in Switzerland's Valais under the name Gwäss, by Georg Breuer in the RHEINGAU, and some is also grown in Australia, where it has been known as Best's No 4. J.V.

Goulburn Valley, long-established temperate wine region with some two dozen producers in Australia's Central Victoria Zone. Nagambie Lakes is a subregion with Tahbilk and Mitchelton its leading wineries. See VICTORIA.

goût, French noun for TASTE in all its senses. Some wines, particularly old CHAMPAGNES, are described as suiting the goût anglais, or English taste (supposedly for wine necrophiliacs). Sweet champagne was described as satisfying the goût russe in the days of the imperial court. (The late 19th century Champenois defined champagne sweetened to satisfy the *goût russe* as one with 273–330 g/l of RESIDUAL SUGAR, as opposed to the *goût anglais* of 22–66 g/l.)

A wine made from fruit adversely affected by HAIL, for example, might be described in French as having a goût de grêle. Another much discussed and loosely applied TASTING TERM is goût de terroir, sometimes used about those aspects of flavour deemed to derive from the TERROIR rather than from the grape variety but sometimes erroneously and pejoratively used as a synonym for the term 'earthy'.

Gouveio Real, minor pale-skinned vine variety of which 110 ha/272 acres remained in northern Portugal in 2020, mainly in the Douro, where it makes full-bodied whites. It is distinct from Gouveio, a Portuguese synonym for the GODELLO of north-west Spain.

governo, also known as *governo all'uso toscano*, since it is most closely associated with TUSCANY, is a winemaking technique once widely used in the various CHIANTI production zones and occasionally in UMBRIA and the MARCHE. The technique consisted of setting aside and drying grapes from the September and October harvest, pressing them in mid to late November, and introducing the resulting unfermented grape juice into young wines which had just completed their alcoholic FERMENTATION, thereby restarting a slow fermentation. This practice led to a slight increase in the ALCOHOLIC STRENGTH of the wines and an increase in the level of CARBON DIOXIDE in the wine, some of which inevitably remained in young Chianti, bottled and marketed in the spring after the harvest. One of the precise purposes of the *governo* was to make the wines marketable at an earlier date by accelerating the malolactic conversion. Occasionally a second addition (*rigoverno*) is made in spring, producing a deeply coloured, fragrant wine with low acidity.

Today *governo* is much less widely used as producers have striven to transform Chianti's image from a quaffing wine to a serious candidate for AGEING, although producers of NATURAL WINE as well as researchers at the universities of Pisa and Tuscia are showing renewed interest in this ancient method. The technique was also used in the VERDICCHIO production zone in the Marche, to add fizz and a slight sweetness—from the high sugar content of the dried grapes—to counteract Verdicchio's occasionally bitter finish. It has virtually disappeared there now. W.S.

GPS. See GLOBAL NAVIGATION SATELLITE SYSTEM.

Graciano, sometimes called Graciana, is a richly perfumed black grape variety once widely grown in Rioja in northern Spain. It had fallen from favour because of its inconveniently low yields, thereby depriving modern Rioja of an important flavour ingredient with considerable freshness, but by 2020 plantings had grown to 2,570 ha/6,351 acres, from which some increasingly interesting VARIETAL bottlings are made in Rioja and Navarra, and there were experimental plantings as far afield as Toledo. This is Portugal's TINTA MIÚDA, France's Morrastel, the Tintilla de Rota grape of Jerez, and BOVALE Sardo, Muristellu, and Cagnulari on Sardinia.

The vine buds very late and is prone to DOWNY MILDEW but can produce wine of great character and EXTRACT, albeit notably acidic in youth. As Morrastel, it was popular in the Languedoc and Roussillon until the mid 19th century, when Henri BOUSCHET stepped in to provide growers with a more productive, more disease-resistant, but wildly inferior CROSS of Morrastel with Petit Bouschet, Morrastel-Bouschet, which in time replaced virtually all of the original Morrastel in French vineyards. True Morrastel, or Graciano, is still grown in southern France in minute quantities.

The variety known as Xeres in California, which has also been planted on a similarly limited scale in Australia, is probably Graciano, as is Graciana, the variety of which there are small plantings in Mendoza, Argentina.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Graciosa, island in the AZORES and DOC for its dry white wine made from VERDELHO (mostly), Arinto dos Açores, and Terrantez do Pico. With just 14.3 ha/35.3 acres in 2021, small quantities are made. The CO-OPERATIVE also makes LICOROSO (fortified) and *espumante* (sparkling) styles. S.A.

grafted vine, a vine consisting of a SCION grafted to a ROOTSTOCK, typically produced by a grapevine NURSERY or a vine grafter (see FIELD GRAFTING). The vines may be sold by the nursery as a growing plant soon after GRAFTING, with limited root and shoot growth and ready for planting in early summer, or, more conventionally, as a dormant one-year-old vine. The latter are grown in a field nursery for around six months, then removed, trimmed of shoots and roots, and bundled and cool-stored. They are prepared for despatch for planting the following spring.

Most countries in the world have PHYLLOXERA infestation, and therefore grafted vines are common. Countries such as Chile, where phylloxera is not present, or Australia, where phylloxera is largely contained by QUARANTINE, may use UNGRAFTED VINES, which are not resistant to phylloxera but grow satisfactorily in most situations and are cheaper. R.E.S.

grafting, the connection of two pieces of living plant tissue so that they unite and grow as one plant, has been a particularly important element in growing vines since the end of the 19th century, when it was discovered that grafting on to resistant ROOTSTOCKS was the only effective weapon against PHYLLOXERA.

History

The grafting of vines as a means of PROPAGATION was well known in ancient ROME, and it is referred to as early as the 2nd century BCE by CATO in his treatise *De agri cultura*. Knowledge of grafting survived through the medieval period, but it was in the 19th century that it came into particular prominence as the only method of satisfactorily ensuring the continued production of wine in the face of the threat posed by phylloxera. European varieties of VITIS VINIFERA had little resistance to phylloxera. It was only through the grafting of *vinifera* cuttings on to American species of VITIS, which had sufficient phylloxera resistance, that traditional European grape varieties could continue to be cultivated, and thus wine with the commercially acceptable taste thereof could still be made. Early experiments to counter phylloxera had generally centred on chemical treatments or flooding, but during the 1870s, those, such as Laliman, who had been advocating the use of AMERICAN VINE SPECIES as rootstocks gained increasing support. Eventually, at the 1881 International Phylloxera Congress in Bordeaux, it became generally accepted that grafting of French scions on to American rootstock was the best solution, and this led to much experimentation to identify the best rootstocks for particular soil types. On a regional scale, however, widespread adoption of grafting awaited the efforts of people such as Gustave Foëx, director of the agricultural school at MONTPELLIER, who in 1882 produced a small booklet recommending the use of American vines, written in a clear style specifically designed for the small wine producers of the Languedoc. Traditionally grafting was done by hand in the field (FIELD GRAFTING). Today, however, most grafting in Europe is done by machines which join together SCION and rootstock, usually in an omega-shaped cut (see BENCH GRAFTING). In California and to a lesser extent South Africa, field grafting is still common.

Modern viticultural practices

Vines are grafted or budded to take advantage of the desirable properties of the rootstock variety. Foremost is resistance or tolerance to soil-borne pests and diseases, especially phylloxera and NEMATODES. Other properties are tolerance to soil SALINITY, to high LIME levels, and to soil waterlogging or DROUGHT, as well as an ability to modify VIGOUR or to hasten or delay RIPENING. If conducted in the vineyard, as FIELD GRAFTING, the practice offers a method of changing a VINE VARIETY. If conducted indoors, before planting, it is called BENCH GRAFTING, which may in warm climates be complemented by NURSERY grafting.

The uniting of the scion with the rootstock is achieved by a slow growth process: a mass of undifferentiated cells, the CALLUS, develops at each cut edge of the respective CAMBIUMS (zones of dividing cells), so it is important to position the two cambiums opposite each other and close together. Thereafter, the scion piece is part of the whole plant vascular system.

A number of factors determine success or failure in grafting, in addition to the skill involved in cutting and matching of cambiums. The first is that the graft needs specific environmental conditions such as warm temperatures (24–30 °C/75–86 °F) and high humidities (90–100%) around the union. The second is the compatibility of the scion/stock combination. The third, and probably the most serious, is that some rootstocks are difficult to root (see ROOTLING), which can affect the overall success of grafting. It has been shown that grafting success is reduced if the scion or rootstock is infected by any of the fungi involved in TRUNK DISEASES.

Particular forms of graft include CLEFT GRAFTING, NOTCH GRAFTING, and WHIP GRAFT. See also GRAFTED VINE and GREEN GRAFTING.

B.G.C. & R.E.S.

grafting machine, a device used in GRAFTING by making cuts through the vine ROOTSTOCK and SCION pieces with mirror-image shapes that permit snug fitting. Shapes used include castellate and

omega. Grafting machines are an essential part of the factory-like methods used for BENCH GRAFTING, but innovative growers have used modified machines for NURSERY grafting and FIELD GRAFTING. B.G.C.

Graham, important port shipper. See SYMINGTONS.

Grahm, Randall (1953–), California winegrower arguably more famous for his words than for his wines. After a stint at DAVIS he founded Bonny Doon winery in the SANTA CRUZ MOUNTAINS intending to make great Pinot Noir. He never did. But his debut, 1984 vintage of a Rhône blend Le Cigare Volant, sowed the seeds for the entire RHÔNE RANGERS movement in California.

For someone with such a quirky—nay, goofy—image (his winemaking experiments included macerating rocks in his wines to achieve MINERALITY), he proved exceptionally good at creating popular wine BRANDS. He successfully sold his Big House and Cardinal Zin brands in 2006 and Pacific Rim in 2010 before selling Bonny Doon Vineyard in its entirety in 2019 in order to concentrate on a 400-acre property near San Juan Bautista he calls Popelouchum. His lofty plan there is to breed no fewer than 10,000 new grape varieties from seed 'and perhaps produce a true *vin de terroir* in the New World', he has written.

His wines may not have thrilled connoisseurs, but his words did. His exceptionally erudite and playful newsletters did consistently and were eventually compiled into the book cited below. Journalists know that he can be relied upon for a quote more entertaining than anyone else's.

Grahm, R., *Been Doon So Long: A Randall Grahm Vinthology* (2009).

grain is visible on the end of a barrel STAVE at the bevelled edge, which is also known as the chime. Since staves are split along the radial plane, it can be seen across the width of the stave end. Each

light and then dark alternation represents a one-year growth ring for the oak tree. The average width of each annual growth ring is called the grain by coopers and barrel users.

Every year, the tree forms a new growth ring in the CAMBIUM layer under the bark. Seen under a microscope, a ring can be broken down as a succession of spring wood (or early wood) and summer wood (late wood). Vessels in spring wood are more numerous and wider than in summer wood. Summer wood therefore has a higher density of fibres and parenchyma and fewer vessels.

Grain can be measured in two ways: either by the number of growth rings per centimetre/inch or by the average width of these rings. Grain is generally considered tight if there are 4–5 rings per cm or if the rings are narrower than 2–3 mm.

Many factors affect grain size. In addition to the work of the forester, who selects and raises the trees in each plot year after year, thereby regulating tree growth and therefore grain, different soil and climate conditions in oak forests produce different types of grain. Trees growing in dry areas, with a high population density and on poor soil, tend to have tight grains. But grain also varies through the life of the same tree. The older the tree, the more slowly its diameter grows and the tighter its grain. Similarly, the grain at the foot of a tree will be wider than at the top.

It is acknowledged that grain is wider for *Quercus robur* and tighter for *Quercus petraea* (see OAK). This is due to the effect of differences in the ecological behaviour of each species. In general, *Quercus robur* requires more water and light and hence exhibits faster growth and wider grains where it tends to be grown. *Quercus petraea*, which better withstands dry soils and a lack of light, tends to be located on top of hills. But these species frequently co-exist in the same forest plots, in which case individuals of either species will rarely show significant differences in grain size. These species are sold together by forest managers. Sorting by grain, coopers tend to find a larger percentage of *Quercus robur* with wide grain than with tight grain, although this empirical approach is in no way systematic. *Quercus alba*, or American white oak, shows a wide range of ring

widths, depending on the growing conditions, but because it is dense and has a high number of tyloses (see OAK) the grain may have little influence on wine during BARREL AGEING. Nevertheless, some coopers do grade white oak according to grain size.

Contrary to popular belief, tight grain is more porous than wide grain. Indeed, a slowing down in oak growth primarily affects summer wood, and the proportion of early wood in the ring (the large vessels) is greater. Tight grain therefore has more spring wood per centimetre and thus has more void than wide grain, which has more summer wood and therefore more fibre and parenchyma. This explains why there are differences in wines aged in barrels with wide grain compared with those aged in ones with tight grain. However, it is important to distinguish between total porosity (the void in the wood) and active porosity, which is connected to the exterior environment and allows OXYGEN diffusion. Studies show that active porosity varies significantly with no direct relationship to grain. Barrel permeability is therefore more complex and less influenced by grain than by other anatomical factors of wood, particularly the number of tyloses, which block the vessels (see OAK), or by coopering practices such as assembling the staves and the intensity of TOASTING.

Comparisons of barrels made from tight-grain versus wide-grain French oak showed that tight grain released more aromatic compounds (e.g. eugenol, whisky lactones) over time than wide grain, and wide grain released more wood TANNINS (ellagitannins). It was also observed that the release of various compounds from the wood differed from one grain type to another. Since porosity is higher for tight grain, it is easier for the wood to interact with wine, which releases the most accessible compounds in the wood more quickly.

Grampians, temperate wine region in Australia's Western Victoria Zone, somewhat cooled by ELEVATION and Southern Ocean influences,

producing smooth, medium-bodied Shiraz and Cabernet Sauvignon. Great Western, the historic heart of the region and home to 1860s-founded Best's and Seppelt, is now a subregion of Grampians. See VICTORIA.

Granada, province and DOP in ANDALUCÍA between the high Sierra Nevada mountain range and the Mediterranean with an old viticultural tradition and 300 ha/741 acres of vines in 2020. Average vineyard ELEVATION is 1,200 m/3,937 ft, including some of continental Europe's highest vineyards. The elevation and humidity provide a much cooler growing environment than the LATITUDE would suggest. There is one VINO DE LA TIERRA, Cumbres del Guadalfeo, 79 ha in the south of the DOP. INTERNATIONAL VARIETIES dominate, although Moscatel de Alejandría (MUSCAT OF ALEXANDRIA) and GARNACHA often appear in blends. F.C.

Gran Canaria, CANARY ISLAND with its own DO and 245 ha/605 acres of vines planted up to 1,300 m/4,265 ft in ELEVATION in VOLCANIC soils. LISTÁN Bianco dominates plantings, with MARMAJUELO and MALVASIA; reds are mainly made from LISTÁN NEGRO.

grand cru means literally 'great growth' in French. In Burgundy's CÔTE D'OR a grand cru is one of 33 particularly favoured vineyards (see BURGUNDY for list), a decided notch above PREMIER CRU. In CHABLIS and ALSACE, grand cru is a separate, elevated AOC accorded to specific vineyards listed in the relevant entries. In Bordeaux, the words 'grand cru' usually apply to a specific property or château and depend on the region in which it is located (see CLASSIFICATION). See also QUARTS DE CHAUME and CHAMPAGNE, geography and climate.

Grande Rue, La, red burgundy GRAND CRU vineyard in VOSNE-ROMANÉE.

grandes marques, obsolete, self-imposed term for some of the major houses or BRANDS of CHAMPAGNE. The original Syndicat des Grandes Marques was founded in 1882 but was disbanded in 1997. The term means literally 'big brand' in French and is still used informally.

grand format. See LARGE FORMAT.

Grand Noir de la Calmette hardly deserves a name that suggests it is the great black grape variety of the BOUSCHET experimental vine-breeding station, Domaine de la Calmette. Bred from Petit Bouschet and the common ARAMON, it has a very high yield and, from its TEINTURIER parent, red flesh (although not as red as Alicante Bouschet's). Often known simply as Grand Noir, it was widely planted in France until the 1920s and is now almost extinct there. See also GRAN NEGRO.

Grand Roussillon, little-used VIN DOUX NATUREL appellation in ROUSSILLON used effectively for declassified RIVESALTES. It may be any of the three colours and also comes in RANCIO form.

Grands Échezeaux, red GRAND CRU in Burgundy's CÔTE D'OR. For more details, see ÉCHEZEAUX.

grand vin, name current in BORDEAUX for the main wine produced by a CHÂTEAU (as opposed to a SECOND WINE or *second vin*).

granite, a coarse-grained, pale-coloured igneous rock of plutonic origin (see GEOLOGY). Feldspars are the dominant constituent, especially potassium feldspar, with lesser amounts of QUARTZ and minerals such as mica and amphibole. The potassium feldspar tends

to weather to kaolinite (see CLAY) and release POTASSIUM, which can affect juice ACIDITY. In parts of the northern RHÔNE and South Africa's WESTERN CAPE, the granite bedrock has weathered into kaolinite (china clay) to the extent it is mined for pottery. Granite soils tend to be acid, poorly fertile, and, because the quartz grains resist weathering, sandy and well-drained. Granite is widespread in vineyards: examples include DÃO, the Granite Belt of QUEENSLAND, parts of BEAUJOLAIS, coastal CHILE, and the SIERRA FOOTHILLS. A.J.M.

Granite Belt, wine region and GEOGRAPHICAL INDICATION in the extreme south of QUEENSLAND, Australia, about three hours' drive south-west of Brisbane, on the border with NEW SOUTH WALES, with more than 305 ha/754 acres of vineyards. On the tableland of the Great Dividing Range at ELEVATIONS of 700–1,000 m/2,297–3,281 ft, the region experiences warm days and cold nights. Here humidity and summer rainfall are less of an issue than spring FROST. Although the region is dominated by GRANITE and coarse SANDS from weathered granite (indeed granite boulders are readily visible across the district and in nearby Girraween National Park), the terrain is diverse, from the arid, windy, rocky landscape of the Eukey Road high country to the deeper, wetter soil of the Ballandean area, the flat, exposed Summit, Severnlea with deeper soil and wind protection, and sunny Pyramids Road.

The Granite Belt Strange Bird marketing initiative has encouraged planting of Spanish and Italian grape varieties, and warm-climate ALTERNATIVE VARIETIES are expected to be increasingly important. In the colder, rocky subregions, a 'Syrah' style of Shiraz, with spicy red-berry aromas, complexity from WHOLE-BUNCH FERMENTATION, and limited oak influence, is a common premium style. A.C.

Granja-Amareleja, subregion of the southern part of the ALENTEJO adjacent to the Spanish border in one of the most arid parts of southern Portugal. Ungrafted MORETO vines thrive on the SANDY left

bank of the Guadiana river; the red grape is a traditional component of VINHO DE TALHA. S.A.

Gran Negro, or Grão Negro, local name for GRAND NOIR DE LA CALMETTE in Galicia, particularly in Valdeorras, where there were still 545 ha/1,347 acres in 2020. It was introduced here after the PHYLLOXERA invasion. As Grão Negro it is also grown in southern Portugal.

Gran Reserva, Spanish term for a wine supposedly from an outstanding VINTAGE which has been subject to lengthy BARREL AGEING, the exact period varying from DO to DO, before release. Rioja produces the great majority of all Gran Reservas. For much of the 20th century, Gran Reservas represented Spain's finest and most expensive wines, but many of the country's most celebrated winemakers are nowadays concerned to preserve more FRUIT in their top bottlings and do not necessarily equate quality with time spent in wood.

See also RESERVA.

Gran Selezione, controversial category of supposedly superior CHIANTI CLASSICO introduced in 2014.

grape, the berry or fruit of the grapevine, or VINE, whose juice is the essential ingredient for making WINE. A grape is *raisin* in French, *uva* in Italian and Spanish, and *Rebe* in German. The grapes produced by commercial viticulture are sold either as TABLE GRAPES or RAISINS, or they are crushed and processed into wine or GRAPE JUICE, GRAPE CONCENTRATE, or RECTIFIED GRAPE MUST. Wine production is, however, the most important use, accounting for some 80% of the world's grape production. The solids, including stems, skins, seeds, and pulp, left after these juicing processes are called grape POMACE.

There are usually less than 100 grapes to a BUNCH for wine-grape varieties, and berries are individually relatively small.

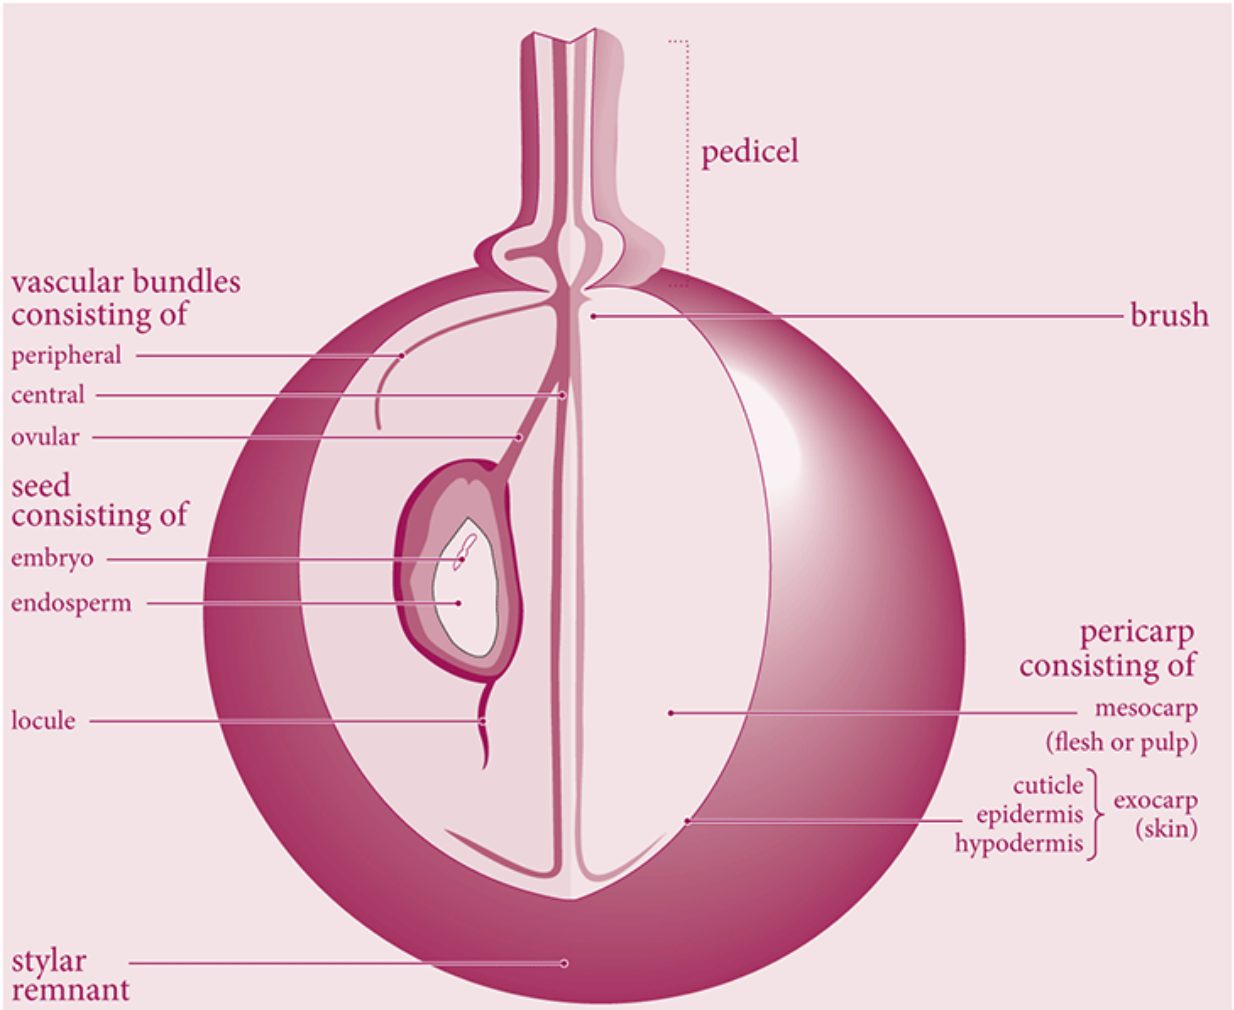
The form and appearance of grape berries varies hugely between VINE VARIETIES. Their shape varies from flattened through to spherical and oval through to elongated and finger-like; colour from green to yellow, pink, crimson, dark blue, and black; and size from as small as a pea (as in CURRANT, for example) to the huge, egg-like berries of some recently bred table-grape varieties which may weigh as much as 15 g/0.5 oz each. The majority of wine grapes, however, are spherical to short oval, 1–2 g in weight, and are coloured yellow (called 'white' by vine-growers) or very dark purple (called 'black' or 'red').

Grape berries are borne on the end of a short stalk called the PEDICEL, which is in turn attached to the RACHIS or STEM. The peduncle is the stem where it connects to the SHOOT. At the end of the berry opposite the pedicel is a small stub of dead tissue which is the remnant of the style and stigma (see FLOWER). Some varieties, for example Riesling, have corky lenticels scattered over the skin. When cut open, the grape is seen to have two units (carpels) side by side, each enclosing a space (a locule) in which are the seeds. When the berry enlarges, the space becomes compressed by encroaching flesh. The significant parts of a berry are the flesh, skin, and seeds. The pericarp tissue is formed from the wall of a ripened ovary, which creates three layers as it grows and develops. These are the endocarp, surrounding the seed, the middle juicy part called the mesocarp, and the outer layer (i.e. the skin) called the exocarp.

Flesh or pulp

The mesocarp (i.e. the flesh or pulp) is the bulk of the PERICARP. The pulp contains the juice in the VACUOLES of pericarp cells. A section across the flesh (see diagram) shows that there are about 40 large parenchyma cells from beneath the skin to the single cell layer that is the inner lining. A central core of vascular strands connects to a mesh of veins that encircles the outer edge of the flesh like a chicken-wire cage and provides the vascular connection with the rest of the vine; the veins contain the XYLEM, which transports water and minerals from the roots, and PHLOEM, which is the all-important pathway for sugar from the leaves. Another zone with a different texture is the so-called BRUSH, which is the lighter-coloured part of the flesh near the junction with the pedicel.

The pulp and the juice are the most important part of the grape to the winemaker and to the wine drinker, for they contain the main components of the finished wine. Because the juice of all grapes (apart from the specialist TEINTURIER varieties) is a pale grey, white wine can be made from grapes of all colours, so long as the juice is not left in contact with dark skins. Red wines can be made only by leaching colour from such skins, while pink wines can be made either from short contact with dark skins or more prolonged contact with pink or red skins.



Grape berry

Skin

The grape's exocarp or skin is the tough, enveloping layer around the grape that holds it together. The outside layer, or BLOOM, forms the grape's typically whitish surface. It consists of wax plates and cutin, both of which resist water diffusion and hence water loss from the berry. They also impede penetration of fungal spore growths and other biological infections. The fatty acids and sterols from the bloom supply important nutrients for the growth of YEAST during FERMENTATION.

Below the wax and cutin are the cell layers that form the skin; the first is the true epidermis, and below this are about seven cell layers forming the hypodermis, in which are concentrated most of the berry PIGMENTS, yellow CAROTENOIDS, and xanthophylls, and the red and blue ANTHOCYANINS important in the making of red wine. As well as some TANNINS, a significant amount of a grape's FLAVOUR COMPOUNDS are also associated with the skin layers.

There are other differences in the chemical composition of skin compared with the underlying flesh: besides phenolics, they are rich in POTASSIUM. Skins constitute 5–12% by weight of a mature grape berry, depending on the vine variety. The thickness of grape skin can vary from about 3 to 8 μm.

Seeds

Seeds of grapes vary in size and shape between varieties; for example, those in MUSCAT BLANC À PETITS GRAINS are about 5 mm long, while those in the table grape Waltham Cross are nearly 10 mm. Their number per berry, typically one or two, tends to be a characteristic for each variety. Four is possible since each carpel bears two ovules. However, some abnoraml Alphonse Lavallée (Ribier) berries with double the number of carpels may have eight seeds. Often, incompletely developed seed structures, called stenospermic (thin-seeded), occur alongside fully developed seeds. The greater the number and amount of seed development, the larger the berry; this relationship is mostly a reflection of differences in amount of cell division in the pericarp mediated by the plant hormone GIBBERELLIN.

Seeds are only of minor importance in winemaking although if they are crushed, bitter tannins are released. Unlike the stems, they are not easily separated from the berry, but in WHITE WINEMAKING the contact time between juice and seeds and the absorption of tannins from the seeds is minimal. In RED WINEMAKING, on the other hand, the prolonged contact between the seeds and an increasingly alcoholic solution means that tannins are very likely to be dissolved. Grape seeds have served as a source of edible or industrial oil.

See also GRAPE COMPOSITION AND WINE QUALITY and RIPENING. (For other parts of the vine plant, see VINE MORPHOLOGY.)

Coombe, B. G., 'Research on development and ripening of the grape berry', *American Journal of Enology & Viticulture*, 43 (1992), 101–10.

grape composition and wine quality. Grape composition is the essential basis of wine quality, and knowledge of grape composition is critical for those winemakers interested in making the appropriate wine style, although the significant impact of winemaking practices cannot be denied. The concentrations of component

chemical groups play a part. Grape SUGARS, for example (see MUST WEIGHT), determine the possible potential ALCOHOLIC STRENGTH of the wine. ACIDS and nitrogenous compounds (see NITROGEN) affect the course of FERMENTATION and exert their own effects on flavour. POTASSIUM salts have effects on PH and thus on microbiological activity and oxidative STABILITY. PHENOLICS contribute to levels of COLOUR and TANNINS. A multitude of volatile compounds alter aroma (see ACIDITY, AMINO ACIDS, FLAVOUR COMPOUNDS, and SUGARS).

Grape composition is constantly changing during RIPENING. A central factor in grape ripening is the steady increase in sugar concentration after sugar accumulation has been triggered at VERAISON. Another feature is that acidity declines, due mainly to the RESPIRATION of malate but also to dilution by berry growth and the formation of salts, especially with potassium, which increases concurrently with sugar. Colour and tannins increase in skins early during ripening. Less is known about the timing of the increase in aroma compounds and FLAVOUR PRECURSORS because until recently they have been difficult to measure, but in some varieties intensity appears to develop late in the ripening process, after sugar concentration has levelled (see GRAPE QUALITY ASSESSMENT). Wine quality depends on the integration of these chemical groups in such a way that there is a balance between components, coupled with an intensity of VARIETAL character. R.D. & R.E.S.

Boss, P. K., 'Towards the prediction [sic] wine outcomes from grape compositional measures', *Proceedings of the ASVO Workshop on Assessing Grape Quality* (2011).

grape concentrate is what is left when the volatile elements are removed from fresh grape juice. Rarely used to produce really fine wine, it can provide a useful supply of grape SOLUBLE SOLIDS for use long after the HARVEST. Grape concentrate is the main ingredient, for example, in so-called MADE-WINES produced without the benefit of

freshly picked grapes (see BRITISH WINE and HOME WINEMAKING). Grape concentrate can also be used in BLENDING to soften and sweeten dry wines of everyday commercial standard made in cooler regions. It was once widely used in Germany, for example (see SÜSSRESERVE). For more details of grape concentrate used for sweetening purposes, see SWEET RESERVE.

Grape concentrate is also in some circumstances used for ENRICHMENT, increasing the eventual alcohol content of a wine (it is a permitted pre-fermentation ADDITIVE in Australia, for instance, although sugar is not). It is also used to sweeten some other fruit juices and foodstuffs. Concentrate is also used to produce a small category of high-intensity red and purple colourants, used to enhance colour and add body to wines.

Historically, winemakers made a form of grape concentrate by simply boiling grape juice until the volume was reduced by at least one-half. This resulted in a liquid with a strong cooked, caramel flavour, however, and such an additive is used exclusively for sweet, dark, strong wines such as rich SHERRY, MÁLAGA, and MARSALA. In Spain it is known as *arrope*.

Today the caramelizing effect is avoided by CONCENTRATION of the grape juice under very low temperatures in vacuum evaporators. Modern low-pressure concentrators are expensive and therefore tend to be operated by specialists who may use them to concentrate other fruit juices at other times of year. Most grape juice is subject to CLARIFICATION and is reduced in TARTRATES before concentration so that the solids precipitated are minimal when water is removed. See also RECTIFIED GRAPE MUST.

Red grape concentrate may be made by first heating the grapes to extract PIGMENTS into the juice before concentration. A.D.W.

grape juice is a sweet, clear, non-alcoholic liquid. Winemakers generally use the term to refer to liquid from grapes at any stage after DRAINING or PRESSING up to the point when FERMENTATION occurs.

It is thus quite different from MUST, though the term 'must' is often used for both. If grape juice is preserved by holding it at temperatures so low that any YEAST or BACTERIA are inhibited, it can be used in commercial winemaking to soften or sweeten new, dry wines. However, since the development of efficient juice concentrators, it has generally been supplanted in winemaking by GRAPE CONCENTRATE, which can be stored much more cheaply, is inherently stable against microbiological attack, and dilutes the wine much less.

A certain amount of grape juice is bottled and sold as a drink, but since it so readily ferments it needs to be protected from yeast contamination. This is usually done by PASTEURIZATION and/or ULTRAFILTRATION and heavy additions of SULFUR DIOXIDE. Many VITIS VINIFERA varieties lose their pleasant, fresh taste after pasteurization, and the American grape-juice industry uses the non-*vinifera* CONCORD variety. It is very difficult to distinguish VARIETAL character in most grape juices, other than such conspicuous flavours as those associated with MUSCAT and Concord grapes. Wine drinkers generally find grape juice bears disappointingly little relation to wine.

grape juice composition. The relative proportions of the compounds that make up grape juice are constantly changing as the berries ripen, so the time of HARVEST greatly affects composition. Most of the sugary solution that results when grapes are squeezed or crushed derives from the contents of the VACUOLES of the cells of the PULP, although heavy CRUSHING and PRESSING add further solution from vacuoles of the skin and vascular strands, thereby mixing many different compounds into the must. Thus the composition of the juice that issues when berries are crushed changes with the pressure and time of crushing; the first, FREE-RUN juice has fewest suspended solids and skin extracts; further pressing yields juice with more PHENOLICS and POTASSIUM salts, and hence lower TOTAL ACIDITY.

Fermentation of juice with the skins, as in red winemaking and SKIN-FERMENTED whites, yields still more FLAVOUR COMPOUNDS and PIGMENTS that are enriched in the cells of the skin. See GRAPE.

See also ACIDITY, AMINO ACIDS, ANTHOCYANINS, ASCORBIC ACID, CAROTENOIDS, CITRIC ACID, FLAVOUR PRECURSORS, FRUCTOSE, GLUCOSE, GLYCOSIDES, LIPIDS, MALIC ACID, MINERALS, PECTINS, PROTEINS, SOLUBLE SOLIDS, STARCH, SUCROSE, TANNINS, TERPENOIDS, VARIETAL character, VITAMINS, and the all-important SUGAR IN GRAPES. B.G.C.

grape quality assessment is needed by winemakers for long-term strategic planning and, in the short term, for the planning of each vintage, especially in fixing HARVEST dates.

Assessment is often a matter of combined judgement by grape-growers and winemakers, using experience of the performance of previous vintages as the main guide, supplemented by visual inspection, tasting of berries, and by measurements of GRAPE COMPOSITION (see SAMPLING and ANALYSIS). Previous experience with the variety, the region, and the vineyard contribute to such assessments. Ultimately it is a trade-off between continuing improvements in grape composition and any deterioration in the quality of the berries.

All commercial wineries measure at least the sugar content of the juice (see MUST WEIGHT) since this determines the POTENTIAL ALCOHOL of the wine, which is important for BODY and BALANCE; and in some regions ENRICHMENT may be prohibited or limited. If the sugar level becomes too high, it is very difficult to reduce the alcohol legally except through BLENDING. In some regions, sugar content is sufficient to indicate forthcoming wine quality, especially in cool regions (unless, of course, major catastrophes such as disease or extreme weather intervene). In warm to hot regions, sugar alone is an unreliable guide to quality.

Most wineries will also measure the ACIDITY and the PH of the maturing grapes, bearing in mind that ACIDIFICATION is not permitted

in some regions.

To be able to monitor other changes in grape composition during RIPENING requires specialized fruit-sampling techniques, expensive analytical equipment, and trained personnel, beyond the means of small and even many large wineries.

Research by Deloire has shown that measuring grams of sugar per berry allows the easy determination of when sugar accumulation in the berry has stopped, thereby making it possible to predict optimal harvest dates for any given wine style. Studies by Antalick et al. have demonstrated the commercial usefulness of this approach although the differences in berry development make such approaches less precise.

Another recent proposal has been to assess white grape skin colour as a guide to harvest date and aroma dominance (Deloire 2013).

The importance of aroma and so-called 'aromatic maturity' is increasingly recognized, as discussed by van Leeuwen et al., but it is difficult to measure. Valuable information can be obtained by collecting and storing juice samples at intervals during grape development and running comparative 'sniffing tests' using gas chromatotography-olfactometry, but these are costly and difficult because of their subjective nature. INFRARED SPECTROSCOPY can be used to measure many different grape constituents, including red grape colour, expressed as the concentration of total ANTHOCYANINS. This is quicker and simpler than the GLYCOSYL-GLUCOSE ASSAY, an experimental technique developed in the mid 1990s.

Many other characteristics of the harvest contribute to the assessment of its quality, including the amount and type of berry ROT, the presence of broken skins due to heavy RAINFALL, HAIL, or physical damage. The extent of BERRY SHRIVEL, SUNBURN, evenness of ripening, and BERRY SIZE are other important factors. Mechanically harvested fruit will also be assessed for contamination with material other than grapes (MOG).

grape sorting (*triage* in French) is the sorting of grapes according to quality prior to winemaking, typically involving the removal of unripe, overripe/shrivelled or diseased grapes, leaves, stem fragments, PETIOLES, or any other undesirable components from harvested grapes. Sorting may begin in the vineyards at harvest if the pickers are trained to do so, but grapes may also be sorted by hand on a vibrating table or conveyor belt known as a sorting table (*table de tri* in French) when they arrive at the winery. This is a labour-intensive and therefore expensive process.

Many automated sorting systems have been developed since the early 2000s. These machines use various separation techniques and combinations of techniques, including image analysis (optical sorting), vibrating screens, roller screens, air-knives that blow light material away, and density baths in which ripe grapes sink while unripe grapes float. While hand-sorting can be performed before and/or after DESTEMMING, automated sorting equipment generally works on destemmed grapes—although some vibrating bunch conveyors with screens may perform a degree of sorting. New styles of shaking destemmer often have an integrated roller sorting system, and this has enabled more wineries to implement some level of sorting.

There is also a growing trend to integrate automated destemming and sorting systems with MECHANICAL HARVESTERS. The current on-

harvester sorting systems can require the use of slower harvesting speeds in high-yielding vineyards, making them less practical, but there are ongoing developments and compromises that will make sorting on harvesters even more common. S.N.

grape varieties. This term is often used interchangeably with 'vine varieties', since different varieties of vine have predictably different grapes or berries. The effect of grape varieties on wine quality is discussed under VINE VARIETIES. Different varieties of vine produce grapes with very different and distinct characteristics, as outlined in this book under thenames of individual varieties. Wines made predominantly from a single grape variety, usually specified on the label, are called VARIETAL wines.

See TABLE GRAPES and RAISINS for examples of these specialized varieties.

grapevine, an alternative name for the plant on which most of the world's wine trade depends. It is known by most wine producers and consumers as the VINE, although botanically there are many other plant species which are vines. See also BOTANICAL CLASSIFICATION.

grapevine Pinot Gris virus. See VIRUS DISEASES.

grapevine red blotch virus, or grapevine red blotch disease, a new circular DNA geminivirus first described by scientists at CORNELL and UC DAVIS in 2012 and now recognized as a serious problem in the US. Two strains have been identified. The virus is known to seriously impair the RIPENING potential of the fruit in infected vines. Symptoms include red blotchy leaves in red-wine varieties and yellow leaves in whites, although infected symptomless vines have also been seen.

The origin of this emerging disease is unknown, but the primary source to growers is infected plant material that was previously certified free of known viral pathogens. In addition, the virus is

spread from sick to healthy vines via insect vectors, including a treehopper.

By the end of 2014, the presence of this virus had been recorded in NURSERY plants in California. Nurseries in the US, as well as their clients, are now testing for red blotch in the hope of eliminating it from the plant-material stream.

It has spread throughout the US and is also reported in Mexico, India, Italy, Korea, Switzerland, Argentina, Canada, and France, linked to imported plant material originating from California. In California and Oregon, this virus has been found in *Vitis californica* and in VITIS RIPARIA as well as in naturalized hybrids of these with VITIS VINIFERA, often in riparian habitats. L.T.M.

grapevine yellows, generic term for a group of related PHYTOPLASMA diseases of grapevines which pose a serious threat to vineyards in many wine regions of the world because there is no known control. The best-known is FLAVESCENCE DORÉE. Variants, which have been shown by a form of DNA PROFILING called polymerase chain reaction to be related, include *bois noir* in north-eastern France, Bordeaux, and Switzerland, *Vergilbungskrankeit* in Germany, leaf curl and berry shrivel in New York State, and Australian grapevine yellows. A similar disease has been described in Romania, Israel, Chile, Italy, and, more recently, Slovenia, Croatia, Hungary, and Spain. These diseases can kill young vines and makes old vines

uneconomical. They are spread by infected plants from the NURSERY and further spread by insects called LEAFHOPPERS, to which many common vineyard WEEDS and COVER CROPS are alternative hosts. The diseases occur sporadically in epidemics, and varieties vary in their sensitivity.

The first sign of grapevine yellows can be delayed BUDBREAK and very slow SHOOT growth until FLOWERING. Later, shoots on infected vines stop growing while leaves yellow and curl downwards. Later in the season, shoots droop as though made of rubber. When affected early in the season, bunches fall off. Otherwise, the berries shrivel and taste bitter. Symptoms seem to vary from year to year, and crop levels fluctuate. During epidemics, as for example in the PROSECCO region in northern Italy in 1995, yields of some vineyards dropped to one-tenth of a normal crop. The Australian experience is that vineyards with well-established infections yield at about half the rate of healthy vineyards.

Different species of leafhopper seem to be associated with the spread of different forms of grapevine yellows. Flavescence dorée is transmitted in the field by *Scaphoideus titanus*. *Vergilbungskrankheit* and *bois noir* are spread by the leafhopper *Hyalesthes obsoletus*, and in Australia the vector for some strains of the phytoplasma is *Zeoliarus atkinsonii*.

Other plants can furthermore act as reservoirs of the disease in that insects spread the disease to and from them and grapevines. These so-called host plants include many broadleaf weeds and cover crops such as nettles, mallow, chicory, dandelion, thistles, bindweed, deadly nightshade, and many clovers. The infection spreads rapidly when the appropriate insect vector and host plants are also present in or around the vineyards, which is becoming more common as vineyard TILLAGE is practised less frequently. Disease epidemics in France and Italy have been associated with the natural fluctuations in leafhopper populations, and this is probably the case everywhere.

There is no effective control of grapevine yellows diseases. Insecticide sprays (see PESTICIDES) can reduce the leafhopper populations—especially of *Scaphoideus*—and reduce the spread of

the disease. The removal of broad-leaf cover crops and weeds reduces insect levels and opportunities for feeding on host plants. However, if the vineyards are small and are surrounded by native vegetation, this can be impractical. The spread of these diseases by infected planting material can be reduced if young plants are treated by hot water before they leave the nursery (typically 50 °C/120 °F for 30–45 minutes when fully dormant). This will kill phytoplasma as well as some other diseases, but regrettably not all nurseries follow this practice.

Chardonnay and Riesling are among the most susceptible VITIS VINIFERA varieties, followed by Grenache, Tannat, Pinot Noir, and Pinot Gris. Some AMERICAN VINE SPECIES are tolerant. Grapevine yellows diseases may eventually be as destructive to the world's viticulture as was PHYLLOXERA, because they are widespread, they are spreading even further due to CLIMATE CHANGE effects on insect distribution, and they cannot be controlled with resistant ROOTSTOCKS. Wine quality does not appear to be affected, but the supply of grapes, especially of Chardonnay and other sensitive varieties, can be. R.E.S.

Wilcox, W. F., et al., *Compendium of Grape Diseases, Disorders, and Pests* (2nd edn, 2015).

Grasa˘, or Grasa˘ de Cotnari, the 'fat' white grape of COTNARI in ROMANIA, where it is grown exclusively. Total plantings stood at 549 ha/1,357 acres in 2021. It can reach extremely high MUST WEIGHTS—in 1958, Grasa˘ grapes in Cotnari reached a sugar concentration of 520 g/l—but needs the balancing acidity of grapes such as Tămâioasă Românească˘ in a blend. The vine is usefully sensitive to NOBLE ROT and may be the same as Hungary's Kövérszőlő.

Graševina, Croatian name for the republic's most planted vine variety, WELSCHRIESLING, whose origins may well be Croatian.

grasshoppers, insects of the families *Acrididae* and *Tettigoniidae* which can feed on the vine. Reductions in vineyard leaf area impair grape RIPENING, with potentially severe effects on wine quality. In California, for example, the devastating grasshopper (*Melanoplus devastator* Scudder) is particularly harmful to vineyards, causing damage by defoliation, usually in mid to late summer. In eastern Australia, the Australian plague locust (*Chortoicetes terminifera*) can be a major pest. Dense swarms can descend very quickly on vineyard areas, especially when pastures dry out. Control where necessary is usually by insecticides (see PESTICIDES). M.J.E.

Buchanan, G. A., and Amos, T. G., 'Grape pests', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

grassy, TASTING TERM usually used synonymously with HERBACEOUS.

Grau, German for 'grey' or *gris*.

Grauburgunder, or Grauer Burgunder, German synonym for PINOT GRIS used for the increasingly popular dry wines made from this grape in Germany. (Sweeter wines are sometimes labelled RULÄNDER.) Its success in producing spicy, full-bodied dry wine accounts for the marked increase in total area planted with the variety in Germany: its 7,356 ha/18,177 acres by 2020, an increase of 90% since 2000, make it the country's fourth most planted white wine grape and considerably more popular than WEISSBURGUNDER (Pinot Blanc). Only Italy grows more of this grape variety (see PINOT GRIGIO) than Germany. It needs a good site with deep, heavy soils to maximize the impressive level of EXTRACT of which it is capable. It is a particularly popular speciality of the warm BADEN region, although there are around 2,000 ha in both RHEINHESSEN and the PFALZ, too.

Grave del Friuli. See FRIULI GRAVE.

gravel consists of rock fragments greater than 2 mm/0.08 in in diameter, referred to as pebbles if they have been worn smooth by running water. Known in French as *graves*, gravel is key to the names of the two appellations below, for example. Gravelly soils are the most distinctive soil type of Bordeaux's LEFT BANK wine region. During the Ice Ages, beginning some 2 million years ago, glaciers moved slowly to the Atlantic coast from the Massif Central and the Pyrenees, following the course of the Garonne and Gironde rivers and pushing back the high right bank. When the glaciers melted and retreated, their vigorous outwash streams spread gravel far and wide. The vineyards of the GRAVES are characterized by their gravelly surface, and gravel is nowhere so prevalent as at Ch HAUT-BRION, where in places it is 16–20 m/50–65 ft deep. Such soils offer excellent DRAINAGE, imposing on the vine the moderate WATER STRESS favoured for wine quality. See VINE PHYSIOLOGY and SOIL AND WINE QUALITY.

Gravel soils are also highly prized for quality wine production on the plateau of ST-ÉMILION, in CHÂTEAUNEUF-DU-PAPE, in FRIULI GRAVE, and in the Gimblett Gravels region of HAWKE'S BAY and MARLBOROUGH in New Zealand. Such soils are also widespread in the Ningxia region of CHINA, near the Helan Mountains. Chx Haut-Brion and La Mission-Haut-Brion are now viticultural oases in the southern suburbs of Bordeaux, indicating that the land is more valuable for housing than for vines. R.E.S. & R.E.W.

Anson, J., *Inside Bordeaux* (2021).

White, R. E., and Krstic, M. P., *Healthy Soils for Healthy Vines* (2019).

Graves, French for 'gravelly terrain', and a term at one time used for many of Bordeaux's wine districts, but now the name of one large region extending 50 km/30 miles south-east of the city along the left bank of the river GARONNE (see map under BORDEAUX). Graves is Bordeaux's only region famous for both red and white wines, although its aristocratic, mineral-scented, Cabernet-dominated red

wines are made in much greater quantity than its dry whites. In the early 1990s, about 1,800 ha/4,500 acres were planted with red wine grapes, while about 950 ha produced dry white Graves. By 2020 the areas were 2,613 and 659 ha respectively. Graves Supérieures is an AOC for sweet wines, to which 136 ha were dedicated in 2020, producing wines very similar to, but generally slightly drier and coarser than, those from the enclave entitled to the CÉRONS appellation.

The Graves, and in particular the outskirts of Bordeaux, the Grabas de Burdeus, is the birthplace of CLARET. In the Middle Ages, much of the light CLAIRET dispatched in such quantity to England was grown in these vineyards within easy distance of the quayside; the Médoc was largely marshland (see BORDEAUX, history). Ch Pape-Clément is Bordeaux's first named château, while HAUT-BRION was the first New French Claret noted in London, by Samuel Pepys, in 1663. Thomas JEFFERSON noted that late 18th century 'Grave' wines were considered the finest Bordeaux had to offer. It was presumably this historic fame which had Ch Haut-Brion, Graves's most famous property, included with the finest Médoc châteaux in the famous CLASSIFICATION in 1855.

For centuries Graves encompassed all the vineyards south of the border with the MÉDOC in a great sweep around the city and upstream along the Garonne as far as Langon, with the exception of the enclaves for sweet-white-wine appellations BARSAC, CÉRONS, and SAUTERNES. In 1987, the appellation of PESSAC-LÉOGNAN was formed, a northern slice of the original Graves appellation which includes all its most famous properties, as well as the southern suburbs of Bordeaux itself.

The creation of this new premium appellation had the effect of somewhat declassifying the historic name Graves, although some excellent wines are conscientiously made within the modern Graves appellation on the varied GRAVEL terraces which have been deposited there over ALLUVIAL deposits with the occasional sandy outcrop over the millennia. The reds, which can taste like country cousins of their

more urbane neighbours in Pessac-Léognan, can often be good value and mature earlier than their Médoc counterparts. It is in this area that some serious barrel-fermented, or at least oak-aged, dry whites are made, from Sauvignon and Sémillon grapes in varying proportions. J.R. & J.L.

Graves de Vayres, a small BORDEAUX district, named after the historic town of Vayres, which has nothing to do with GRAVES but is just across the river DORDOGNE from the town of Libourne. From a total of 337 ha/832 acres in 2020 of, not surprisingly, gravelly soil, with patches of SAND, the appellation produces light red wines made substantially from Merlot grapes, although many of them are sold under the simple BORDEAUX AOC. White wines are usually dry, often based on Sémillon, occasionally given BARREL MATURATION, and were produced from just 64 ha in 2020.

gravity-fed, describes a WINERY that is constructed on different levels, often into a hillside, or uses lifts, so that grapes, MUST, juice or wine are moved by gravity rather than by PUMPS in the belief that wine quality is improved by more gentle handling.

Great Southern, high-quality, COOL-CLIMATE wine region encompassing 2,545 ha/6,289 acres of vines in the extreme south-west of Australia, including subregions Albany, Denmark, Frankland River, Mount Barker, and Porongurup. See WESTERN AUSTRALIA for more detail.

Great Western. See GRAMPIANS.

Grecanico Dorato, white grape variety grown on Sicily shown by DNA PROFILING in 2007 to be the GARGANEGA of the Veneto. The wines currently made may not be maximizing its full potential.

Grechetto, strictly Grechetto di Orvieto, sometimes Greghetto, characterful central Italian white grape variety most closely associated with UMBRIA. It is an ingredient in ORVIETO and in the whites of TORGIANO and the Colli Martani DOC, typically blended with Trebbiano Toscano and Verdello. The grapes' thick skins provide good resistance to DOWNY MILDEW. Grechetto Gentile is a synonym for PIGNOLETTO, and DNA PROFILING suggests a parent–offspring relationship between the two Grechettos. Several DOC regulations specify simply 'Grechetto'. There were 1,824 ha/4,507 acres of Grechetto di Orvieto in Italy in 2015 (and 1,174 ha of Pignoletto).

Greco, or Greco di Tufo (which has its own DOCG for the zone around the village of Tufo), is a late-ripening Campanian white wine grape that has been shown by DNA PROFILING to be identical to Asprinio, under which name it often appears as a lightly sparkling wine. The variety also grows in northern Puglia, Lazio, and Tuscany and is genetically distinct from GRECO BIANCO. Wines tend to be dry and assertive, with more BODY than aroma. J.V.

Greco Bianco is a CALABRIAN vine variety best known for its sweet whites made from semi-dried grapes grown around the town of Bianco on the south coast. There were 2,050 ha/5,066 acres planted in Italy in 2015. It is not related to the Campanian GRECO (di Tufo) nor to Greco Bianco di Gerace, which has been shown by DNA PROFILING to be identical to MALVASIA di Lipari.

At least four other varieties have a synonym that begins 'Greco Bianco'. The popularity of the name shows how widely Greek origins were assumed. J.V.

Greco Nero, name for at least five dark-berried CALABRIAN vine varieties.

Greece, renascent Mediterranean wine producer with a particularly rich history of wine made in classical times from the 7th century BCE and on in the Roman era (see ancient ROME). Early Greek colonization led to the vine being taken to all parts of the Mediterranean. In modern Greece, vineyards covered around 109,000 ha/269,345 acres in 2021, with only about 61,000 ha producing grapes for wine. RAISINS and TABLE GRAPES are important to the agricultural economy. About 60% of annual wine production of 2.5–3 million hl/79,251,600 million gal is of white wine. More than 85% of Greek wine is consumed within the country, though the financial turmoil of the early 2010s encouraged many top wineries to invest in exports.

Ancient Greece

Origins Wine was important in Greek society from the earliest times, forming part of the Greek cultural identity. The ancient Greeks were aware that other societies, such as the Babylonians in MESOPOTAMIA and the inhabitants of ancient EGYPT, made and drank wine, but for them it was a luxury, and they normally drank beer (a drink disparaged by Greek writers as inferior and fit only for foreigners) or else 'wine' made from dates or lotus. Complete ignorance of viticulture was the mark of savages; so too was the drinking of undiluted wine, which was associated with northern BARBARIANS such as the Scythians (in modern CRIMEA).

There is evidence of winemaking in Neolithic Greece (at Dikili Tash *c.*4300 BCE), and the vine was widely cultivated by the early Bronze Age. Wine was clearly a significant element in the culture of Minoan CRETE before 2000 BCE: remains of grapes and of installations for wine production (treading floors and spouted vats) have been found by archaeologists at palaces and villas, and some of the large storage jars found in the palace complexes surely contained wine rather than olive oil; an ideogram for 'wine' has been identified in the early script Linear A, and artistic evidence suggests the use of wine in ritual contexts. Given the links between Crete and Egypt in this period, the Minoans might be expected to have been influenced by their neighbours and to have exported to supply the demand there and elsewhere in the Near East, though much trade was evidently more local. In turn, Crete will have influenced contemporary Thíra (modern SANTORINI), where vines and grapes are depicted on painted pottery.

Mycenae There is no doubt of the importance of wine in Mycenaean culture (*c.*1600–1150 BCE), which followed and developed on the mainland from Minoan culture: evidence from Mycenae, Tiryns, and Sparta includes grape pips and residues of wine, as well as the seal of a jar bearing the impression of vine leaves, while the palaces have revealed many storage jars, including a complete cellar at Pílos which contained at least 35 large jars, some labelled as containing wine. The evidence of the Linear B script, preserved on clay tablets fired hard in the destruction of the palaces, confirms that wine was important: the palace records contain many references to it and include words for 'wine', 'vineyard', and, apparently, 'wine merchant', not to mention allusions to the god DIONYSUS. Finds of Mycenaean pottery abroad imply that they were exporting wine and oil to Syria, Palestine, Egypt, Cyprus, Sicily, and southern Italy, while the discovery of a few small CANAANITE jars (the earliest AMPHORAE) at Mycenae may suggest that connoisseurs were also importing foreign wines; certainly wine appears to have been a luxury item largely restricted to the elite.

Early Greek literature In the poetry of HOMER and HESIOD, the earliest Greek literature, wine is an essential part of life. It is naturally drunk by Greek and Trojan heroes at their feasts, but it is also used in the rituals of sacrifice, prayer, and burial, to solemnize agreements, and for therapeutic purposes; it is also the human drink, whereas gods drink nectar. A depiction of the vintage, in an enclosed vineyard, is part of the encapsulation of human life on the shield which Hephaestus makes for Achilles (*Iliad* 18. 561 ff.). Wine is the touchstone of civilization: even the Cyclopes in the *Odyssey* drink it, but without cultivating the vine, unlike the pleasure-loving Phaeacians, and, when offered the fine wine of Maron, Polyphemus swigs it neat until he falls into a stupor. Homer implies that the vine was widespread in Greece in his time, describing several places as 'rich in vines' (including Phrygia; in this as in other respects the Trojans are as civilized as the Greeks), and he gives us our earliest reference to specific wines, Pramnian and Ismarian, while Hesiod mentions Bibline. Advice on viticulture forms part of Hesiod's *Works and Days*: he mentions pruning and the harvest, including drying the grapes before vinification to make early forms of DRIED-GRAPE WINES.

The extent of viticulture In the classical period, vines were grown throughout Greece, and, through colonization, the Greeks carried viticulture to Sicily and southern Italy (which the Greeks called OENOTRIA, 'land of trained vines'), southern France, and the Black Sea. Some producers operated on a large scale, with extensive estates: we can infer the existence of vineyards of 8–10 ha and 30 ha/74 acres on the island of Thásos in the northern Aegean in the late 5th century BCE and of one of about 12 ha in Attica in the middle of the 4th century, and Diodorus records a cellar at Acragas in Sicily with a storage capacity of 12,000 hl/317,000 gal and a vat holding 400 hl/10,500 gal (*Library of History* 13. 83). Viticulture was also probably part of the normal system of polyculture, which in Greece was founded on grain, vines, and olives.

Trade Viticulture was important to the economy of many cities, as is shown by the number of states whose coinage bears wine-related designs. Greek wine was traded within Greece—with Athens, the largest and richest city, offering the best market—and exported throughout the Mediterranean world, especially to Egypt, the Black Sea, Scythia, and Etruria (modern TUSCANY). Soon the colonial cities began to produce and export their own wine. (See CELTS for archaeological evidence of the geographical extent to which Greek wine and drinking rituals were adopted.) Amphorae from Marseilles are found along the southern coast of France and up the RHÔNE Valley, while in the CRIMEA archaeology has revealed extensive estates, their vineyards protected from the prevailing winds by low walls and planted with indigenous vines which were gradually domesticated, rather than with imported varieties.

The scale of the Greek wine trade can be inferred from the widespread finds of amphorae and the seals which indicate their origin. The richest evidence is from the island of Thasos, which took elaborate precautions to regulate its wine trade, both to maximize tax revenues and to prevent fraud which would damage its reputation; amphorae were required to be of standard sizes and were sealed with

the name of an annual magistrate, which acted as a guarantee of authenticity; other states, notably Rhodes, also used this system. Thasos also protected its commerce by forbidding citizens to import foreign wine.

Viticultural practices No vine grown today can be confidently traced back to any ancient Greek variety, although we know the names of 50 or more, some of which were cultivated in Italy in Roman times, and names such as GRECO, GRECHETTO, and AGLIANICO (i.e. Helleniko) reflect popular traditions of continuity (although DNA PROFILING suggests that these are more romance than reality). Roman writers noted that the YIELDS of Greek varieties were low, although their quality was good. In the 4th century BCE, the botanically expert THEOPHRASTUS was aware of the need to match varieties to soil type and MESOCLIMATE and recommended PROPAGATION by cuttings or suckering. A variety of vine-training systems was used: often vines were supported by forked props or trained up trees (see ARBOREAL VITICULTURE), but a few varieties naturally formed bushes, and sometimes plants were simply left to trail on the ground; training on trees meant climbing up, or using trestles, to pick the grapes. PRUNING was known to have an important effect on YIELDS and quality, and land leases sometimes specify that the lessors be allowed to oversee it towards the end of a lease, as well as regulating the use of manure as FERTILIZER.

Vinification The HARVEST was early by European standards: Hesiod recommends early September. Vase paintings suggest that, in many cases, PRESSING took place near the vineyard: the grapes were trodden inside a handled wicker basket which stood in a wooden trough with low legs, from which the juice ran through a spout into an earthenware vat sunk in a hole in the ground; sometimes a sieve was placed over the mouth of the vat. As pickers brought grapes in, they were added to the basket, while the treader held on to the basket handles or a ring or rope overhead (or a convenient vine) to keep his balance and worked at CRUSHING in time to a flute. There are also scenes of treading in the vat itself, in which case the skins and pips will not have been strained out, and the wine will have taken colour from the skins, an early form of PUNCHING DOWN. In either case,

the vats will then have been covered and the juice taken for FERMENTATION in larger-capacity *pithoi* (see PITHARI); these could be 3 m/10 ft high, with a mouth measuring 1 metre across. Larger, more specialized establishments had permanent stone treading floors rather than wooden ones, but otherwise the process was the same; although the beam PRESS was normally used for olives, there is little evidence for its use in wine production in classical Greece, and the screw press probably appeared only in Roman republican times. Small-scale producers may well have employed more primitive forms of pressing, such as torsion in a fabric container, but no evidence for these survives.

References to the drying of grapes in Hesiod and the *Odyssey* (see DRIED-GRAPE WINES) suggest that this was the early norm, but in later times practices varied: a Lesbian wine, Protropon, was made from FREE-RUN juice, while in other cases grapes were deliberately harvested unripe to produce a wine with high ACIDITY (Omphakias); fresh MUST itself was sometimes drunk, as was boiled must. Finally, the solids left after treading could be moistened with water and trodden again to yield a low-quality PIQUETTE called Deuterias or Stemphulites.

Although wine was often transferred from the fermentation vessels once fermentation was over, it is clear that it had not been subjected to proper RACKING or FINING since a sieve or strainer through which to pour the wine is a standard feature of the SYMPOSIUM; although Theophrastus may refer to the addition of gypsum, which was later used for the purposes of both CLARIFICATION and ACIDIFICATION, he describes this as an Italian practice. References to 'strained wine' suggest that it was unusual, and the straining may have been done at the point of sale rather than during production.

Common additives The basic wine could be 'improved' by various additives: the use of a small percentage of seawater or brine seems to have begun in the 4th century BCE, apparently as a flavouring, although it probably also had preservative qualities, and the technique was associated with particular areas of production, notably the island of Kos, and marked a shift in taste during antiquity. We also hear of the addition of aromatic herbs, to produce a sort of VERMOUTH, and of perfume being added both in production and by the consumer, as well as of the use of boiled must and, on Thasos, the addition of a mixture of dough and honey to produce a special CUVÉE for consumption on state occasions. BLENDING of different wines was also practised: Theophrastus gives one example, a mixture of hard but aromatic wine from Heraclea with soft Erythraean (a salted wine) which lacks BOUQUET, and says that there are many other blends known to experts (see TASTING, ancient history). There is some evidence, mainly in the Bronze Age, for the deliberate addition of pine or terebinth resin, but it is likely that storage (see below) was normally a more significant cause of such flavours.

Containers for wine Finished wine was normally stored in AMPHORAE lined with resin or pitch (see RESINATED WINES) to limit porosity, which will have affected the taste to some extent, and pitch was also used to secure the stopper, which was usually of pottery, although the use of cork was known. Amphorae of the classical period held 20–75 l/5–20 gal, depending on their origin, and added 5–15 kg/11–33 lbs to the total load. These commercial amphorae are, of course, to be distinguished from the much smaller painted pots, also called amphorae, used to present the wine when it was drunk. In the *Odyssey* (2. 340 ff.), Telemachus had wine drawn off from the big *pithoi* in which it had been ageing into amphorae for his journey abroad. Homer also refers quite frequently to wine kept in wineskins, but in classical times skin bags were probably mainly filled for rapid consumption; despite being lighter and, perhaps, less fragile, they

will have flavoured the wine, being usually made from the skin of a sheep or goat.

Selling wine In Athens, wine was bought mainly from wine sellers for immediate consumption: after the purchaser had sampled the wine, the required amount was ladled or siphoned from the amphora into a jug or small amphora which the purchaser usually provided; wealthier customers, however, and those holding parties will have bought an amphora at a time. Evidence on price is scanty, but for imported wine of good quality, such as Chian or Mendean, in Athens in the 4th century BCE a *chous* of about 3.25 l cost between one-quarter of a drachma and 2 drachmas (a drachma being a day's wage for a craftsman). Of course, these were luxury wines, with prices to match. One Athenian, urged to improve his morals by the Areopagus, the Council of Elders, cited drinking Chian, along with keeping a mistress, as evidence of a life of blameless hedonism appropriate to a gentleman. See also MERCHANTS, ancient history.

Specific wines Some idea of the leading wines of classical Greece can be obtained from references in literature, particularly lyric poetry and the Athenian comic poets; these make it clear that in Athens, at least, there was a degree of CONNOISSEURSHIP, different poets singing the praises of different wines while disparaging their rivals. The most frequently praised wines are those of Thasos, Lesvos, Mende, and Khios (especially one called Ariousian), while those of Ismaros (in Thrace), Naxos, Peparethos (modern Skopelos), Acanthos, and, from the 4th century, Kos were also admired.

This makes it clear that, although other areas had their admirers, the regions which produced the best wines were, by general consent, the AEGEAN ISLANDS, particularly to the east, and Chalkidike (modern Halkidiki, see below) and Thrace on the northern mainland.

Two other much-praised wines, Pramnian and Bibline, are problematic. Pramnian, whose name goes back to Homer, is associated with a number of places—Lesvos, Smyrna, and the island of Ikaros (modern Ikaria, in the Dodecanese)—and indeed, according

to ATHENAEUS, some considered it a generic name for dark wine, or long-lived wine. However, there was also a vine variety called Pramnian, and it seems most likely that Pramnian, which perhaps originated on Ikaria, came to be used as the name of wine of the style of the original, 'neither sweet nor rich, but dry, hard and unusually strong', whether or not made from the original vine.

In the case of Bibline, the problem is a confusion of names, since there was also Bybline wine, from Byblos in PHOENICIA, which is highly praised for fragrance by the 4th century BCE gastronome Archestratus. Bibline, however, took its name from a region in Thrace, where it originated, and came from a vine called Bibline, which was apparently subsequently introduced elsewhere. Since scribes were prone to confuse the two, allusions cannot always be reliably attributed to one or the other, but both evidently had excellent reputations. On these interpretations, both Pramnian and Bibline will also fall within the top zone outlined above. In all cases, wines are praised in terms of their origins; we never hear of particular estates or producers as being superior.

What was Greek wine like? First, it could be of three colours, white, black or red, and tawny, the last being less frequently mentioned; Homer's wine is always dark. Greeks were sensitive to aromas and often speak of wines being fragrant; more specifically, they refer to wine as 'smelling of flowers', an expression often almost equivalent to our BOUQUET, although the way in which the comic poet Hermippus talks of a mature wine 'smelling of violets, roses and hyacinth' shows that it was not always metaphorical; the same passage attributes a scent of apples to Thasian wine. The sweetest wines were said to lack bouquet, which could, according to Theophrastus, be supplied by blending, spicing, or perfuming.

In taste, wine is often praised as sweet, honeyed, ripe, and soft, and this must have appealed to the Greek palate, to judge from the production of PASSITO, or dried-grape wine, and even sweet wine further concentrated by boiling. Given the likely ripeness of the grapes, the limitations of natural YEASTS, and, perhaps, the risk of STUCK FERMENTATION without TEMPERATURE CONTROL, sweetness must

have been the most frequent outcome and is often assumed by Greek writers: Aristotle distinguishes among heavy drinkers between drunkards and the sweet-toothed. However, this was not always the case. As noted earlier, grapes were sometimes picked unripe, and some varieties, like Pramnian, were naturally more austere; one vine was allegedly called 'smoky' (*Kapnios oenos*) because the wine was so sharp as to bring tears to the eyes, like smoke. Medical writers discussing the qualities of wines class them as dry or sweet white; and dry, sweet, or medium red/black—there was obviously a wide range of styles.

Wine ageing Given the vagaries of vinification, much Greek wine will not have lasted long, succumbing either to OXIDATION, which medical and scientific writers discussed as a form of decomposition, or to spoilage, the risk of which was noted by Aristotle. It is not surprising that the people of Thasos traded in VINEGAR as well as wine and that sour wine was a regular cheap drink, especially since the risk of oxidation must have increased as a large jar was emptied.

Nevertheless, some wines clearly aged, since old wine was highly regarded by the Greeks: 'praise old wine, but the flowers of new songs', said the poet Pindar, and comic poets noted that women preferred old wine but young men. The old wine praised by Hermippus (above) was described as *sapros*: literally, 'rotten' or 'decomposed', but obviously referring in the case of wine to the production of secondary flavours through AGEING; older wine was also described as having 'lost its bite'. We never find discussion of particular VINTAGES (unlike Roman wines and specific vintages such as OPIMIAN wine mentioned by Roman writers), and there is little reliable evidence as to how long good wine might keep. Theocritus speaks of drinking four-year-old wine, perhaps from Kos, in the early 3rd century BCE, and in the same era Peparethian wine was regarded as a slow developer in requiring six years to reach maturity, while the elder PLINY (in the 1st century CE) considered all foreign wines middle-aged at seven years old; comparisons with the wines of ancient ROME, which evidently matured more slowly, might allow one to guess that few Greek wines lasted more than ten years, a good age for a wine in the heroic age (*Odyssey* 3. 390–2) but not a very long time by modern standards, especially given that the CONTAINERS were very much larger than modern ones, so that the rate of development should have been proportionately reduced.

The uses of wine Wine had many uses for the Greeks. It was of course important as a food and drink (it was doubtless often safer than water), and the SYMPOSIUM, which centred around the drinking of wine, was one of the most important Greek social forms. Wine was almost always drunk diluted with water: the ratio varied, normally ranging between 2 : 3 and 1 : 3, which would give a range in ALCOHOLIC STRENGTH of about 3–6% and generally at the lower end of this range (roughly the same as British draught beer). This dilution should be viewed under the light that ancient Greeks consumed every pour of wine in one sip, since the kylix, a round-bottomed drinking vessel, would spill the wine if set down. Weaker mixtures are disparaged in comedy (and even 1 : 3 called for a good wine), but 1 : 1 was considered by some dangerous to the HEALTH, and the regular drinking of unmixed wine a habit confined to barbarians. The mixed wine was also normally cooled, sometimes in special pottery coolers; the very rich added snow.

The medical uses of wine were numerous and much discussed by medical writers. Its advantages as a pick-me-up, tonic, and analgesic were obvious, and by experience it became clear that certain wines were nourishing, diuretic, good for the digestion, and so on, but the qualities of different types were also discussed in terms of the four essential qualities (hot, cold, wet, dry) in order to decide how they should be used to correct imbalances in the bodily humours.

There are occasional references to procedures for making wine-based medicines, either by adding drugs to the wine or by treating the vines with an appropriate agent. Certain wines also had the reputation of producing medical side-effects: those of Troizen (just across the Saronic Gulf from Athens), for example, were said to render the drinker sterile. The Greeks were also well aware of the hazards of consuming wine to excess, and Athenaeus mentions popular remedies for a HANGOVER.

After social aspects, however, the most important aspect of wine was its place in religion. A LIBATION (*sponde*) of wine was offered as a sort of first fruit whenever wine was drunk (at the symposium

different gods were invoked for each bowlful), and drink offerings were part of the formula for prayers; hence treaties and truces were referred to as *spondai*, because they were sanctified by prayers and libations. Wine was used to quench the burning offerings on the altar at a sacrifice and was one of the liquids poured on the ground as an offering to the dead.

More than this, however, wine was directly associated with a particular divinity: Dionysus was the patron god and the symbol of wine, as Demeter was of cereals, and one of the 12 major divinities (a further indication of the basic importance of wine to the Greeks).

R.B.

Wine festivals

For the Athenian of the 5th century BCE, festival days in honour of the gods at set times of year gave the sort of relaxation now provided by weekends. Many of them were associated with wine drinking, vine-growing, and the HARVEST. The most important of these, the Anthesteria, in honour of Dionysus, celebrated the opening of wine jars in February to test the new wine. It included processions and ritual wine-drinking contests and was probably closest to the modern idea of a wine festival. Nonetheless, at the heart of the festival was the serious business of the dedication of the new wine to Dionysus.

Other festivals included the Oschophoria, a vintage celebration in September which seems to have been restricted to aristocratic families: two young men led a procession carrying vine branches with the grapes still on them (*oschoi*) in honour of Dionysus. The Apatouria in the same month was the festival when young males were registered in their *phratries*, or clans, and there was much associated pouring of wine. The last day of this festival was called Epibda and came to mean 'the morning after'. Strangely, there does not seem to have been a particularly important festival at the time of the grape harvest. At the Dionysia celebrated in the countryside around Athens, a jar of wine and a vine headed the procession.

The great festivals of Athens, the Panathenaia and the City Dionysia, were less dominated by the vine (perhaps because they were held further from the vineyards), but there is no doubt that wine was enjoyed at them. H.H.A.

Bibliographical note: There is no modern book in English specifically on Greek wine, and works on ancient wine (cited under ancient ROME) tend to pass rapidly on to Rome, where the evidence is much fuller; however, Roman sources are not necessarily reliable evidence for Greek practice 500 years earlier. Of the ancient sources, ATHENAEUS' *Deipnosophistae* collects much classical literary material (especially Books 1–2, 25e–40f), and Theophrastus' *Enquiry into Plants and On the Causes of Plants* (especially 3. 11–

16) contains a lot of botanical lore; all are accessible in translation in the Loeb Classical Library. On Athenaeus, see Brock, R., and Wilson, H., 'Athenaeus on Greek wine', in D. Braund and J. Wilkins (eds.), *Athenaeus and His World* (2000), 455–65, 587–8 with further general bibliography. On the Minoan and Mycenaean periods see Pratt, C. E., *Oil, Wine and the Cultural Economy of Ancient Greece* (2021). Grace, V., *Amphoras and the Ancient Wine Trade* (2nd edn, 1979), is a good general introduction to AMPHORAE; see also Koehler, C., in P. E. McGovern, et al. (eds.), *The Origins and Ancient History of Wine* (1995), ch. 20. Sparkes, B. A., 'Treading the Grapes', *Bulletin Antieke Beschaving*, 51 (1976), 47–64, collects and discusses the pictorial evidence for the vintage. Wilson, H., *Wine and Words in Classical Antiquity and the Middle Ages* (2003), is mainly concerned with the literary, social, and religious uses of wine but also deals with AGEING; Boulay, T. 'Wine appreciation in ancient Greece' in J. Wilkins & R. Naudeau (eds.), *A Companion to Food in the Ancient World* (2015), 273–82 is stimulating, though based substantially on late sources. On festivals, see Parker, R., *Polytheism and Society at Athens* (2005), ch.14.

Medieval history

In the medieval Greece that was part of the Byzantine empire, wine was grown by private individuals and by monasteries (see MONKS AND MONASTERIES). Monasteries were foremost among the great landowners because, as in western Europe, they received donations and bequests from the laity. In the 8th and 9th centuries, agriculture was exceptionally profitable; its chief products were wine, fruits, cotton, and medicinal herbs. As in antiquity, the best wines came from the AEGEAN ISLANDS, Chios first of all, and Thasos and Crete. The wines of THRACE and ANATOLIA (Cappadocia in particular) were ranked second to these. Evidence from shipwrecks shows that wine was still transported in amphorae in the 7th century, whereas wooden BARRELS were commonly used in western Europe from the 3rd century CE. After the 7th century, the Greeks, too, started using wooden casks, which are lighter and easier to handle than amphorae.

In the 12th century, Constantinople (on the site of modern Istanbul) was the centre of the Byzantine empire's wine trade. Wines were shipped to Constantinople from the Aegean Islands, from Thebes, and also from near Monemvasia, a port on the southern Peloponnese, which gave its name to MALVASIA and its English corruption MALMSEY. Monasteries were exempted from customs duties and were therefore at an advantage compared with private growers and traders: the monasteries of Patmos and Mount Athos, for instance, made large profits from selling their wines in Constantinople.

But the private growers and wine merchants of Greece faced a much greater problem than unfair competition from monks. In 1082, the Emperor Alexius I Comnenus had granted VENICE trading facilities at Constantinople and in 32 towns without payment of taxes of any kind. As a result so much money disappeared to the west that Byzantium was economically ruined. Wine producers and wine merchants suffered badly. With no duties to pay, the Venetians were able to sell wine much more cheaply than any Greek could. Often this

was imported Italian wine, but most of the wine came from Crete, known then as Candia, which was a colony of Venice (and remained so until the mid 17th century). Worse still, many taverns in Constantinople were owned by Venetians so, in Constantinople at least, they controlled the retail trade as well.

It took until the middle of the 14th century for the Byzantine government at least to try to protect the empire's own trade. The Venetians agreed in 1361 to accept a distinction between wholesale and retail trade and to impose a tax of their own, with the proceeds of course going to Venice, on taverns run by Venetians. In the 15th century, tax was finally levied on wine imported by Venetians, but by then it was too late, for Byzantium's wine trade was no longer viable. Crete and CYPRUS, under Venetian ownership, continued to produce the strong, sweet wines that were capable of surviving the long sea voyage to western Europe, but the harbour of Monemvasia, close to Byzantium's own supply of Malvasia wines, was now too small to take the larger ships that the west had increasingly come to adopt. From the late 14th century onwards, it lost out to Cyprus and Crete as a port, and the south-west Peloponnese declined as a producer of export-quality wine. All trade in Greek wine ceased in the late 15th century, when, after the fall of Byzantium, the Ottoman Turks occupied the Peloponnesian shore and drove out its inhabitants.

Modern history

The centuries of domination by the Ottoman Turks were to blight Greek viticulture and winemaking until well into the 20th century. Winemaking was not normally forbidden to the Christian population, but communication difficulties resulted in a localized peasant industry viewed by the Turkish rulers as a useful means of raising revenue through TAXATION. Thus, while France, for example, was developing fine-wine regions and their markets, Greece remained in what might be termed the vinous Dark Ages.

The battle for independence was prolonged and tortuous, and the exhausted and impoverished modern Greek state, founded in 1830, had preoccupations more important than the creation of a fine-wine industry. It was not until well after the two World Wars and the subsequent bitter civil war that Greece began to modernize its fragmented wine industry. Two kinds of aristocracy are needed to produce fine wine: one able to afford quality-oriented viticulture and production and another able to afford buying high-quality wine. Greece had neither.

The Vine Institute of Athens, which experiments with winemaking techniques and advises winemakers, was founded in 1937, and some major wine companies were established in the late 19th century, but they were chiefly concerned with DISTILLATION and, later, BULK WINE sales. CO-OPERATIVES were established mainly in the 1930s, providing much-needed stability to vine-growers. Only in the 1960s was any significant proportion of Greek wine sold in bottle rather than directly from the barrel.

The 1960s, however, saw considerable investment in modern technology, and the 1970s ushered in Greece's first generation of trained OENOLOGISTS. The 1980s signalled a new era for Greek wines. A number of oenologists moved out of the large companies to start their own projects, while other Greeks established small, quality-oriented estates. By the early 21st century the mavericks of the 1980s had commercially successful mid-sized wineries, and an increasing number of small ventures appeared across the country.

Geography and climate

At latitudes of 34–42° N, Greek vineyards are commonly but mistakenly thought to be some of the world's warmest. In fact, the diverse TOPOGRAPHY and the mountainous landscape create mild or even cool MESOCLIMATES, though largely unsuspected by summer tourists enjoying the Greek sun in a coastal resort.

The climate is generally predictably MEDITERRANEAN, although there can be considerable variation between the CONTINENTAL-influenced vineyards in the mountains of Epirus and Macedonia, where grapes may not even reach full RIPENESS, and the intense heat of Patras, Crete or Rhodes, where harvest may start in July. ELEVATION plays a major role, too: while vines can be found growing on flat land near sea level, such as at Ankhialos, high-elevation vineyards are increasingly sought-after.

Most vineyards are sufficiently close to the sea for maritime breezes to moderate temperatures, but lack of water, particularly on the islands and in the south, is a major challenge. The first three months of the year are generally the wet months, and many wine areas have no rain at all for six months, which can make the establishment of young vines extremely difficult. IRRIGATION is considered an annual necessity in many areas.

As the country experiences much seismic activity, it is rare to find an area with a single prevailing soil profile. However, the soils devoted to vines or olives are generally of low fertility, since the few high-fertility regions tend to be devoted to more lucrative or essential crops. Subsoils on the mainland tend to be LIMESTONE, while on the islands they are mainly VOLCANIC. CLAY, LOAM, SCHIST, and MARL are all found, as well as sandy clay and CHALK.

Viticulture

The Greek land-tenure system means that much of the vineyard area is in the hands of smallholders. Little by little, the large companies which buy in many grapes have been working more closely with these vine-growers and promulgating more modern viticultural techniques. Grape PRICES were long determined by sugar levels, which too often resulted in dangerously low levels of ACIDITY, but these problems have been largely resolved by the big commercial concerns and the more modern co-operatives. The more ambitious of the small estates now practise thoroughly modern viticultural techniques.

Traditionally most vines were left to grow as BUSH VINES, but almost all new vineyards have been designed with TRELLIS SYSTEMS on wires. However, in certain areas, unique trellis and pruning systems have been adapted, after centuries of trial and error, to local conditions. Pre-eminent examples are the basket-trained vines (see TRAINING SYSTEMS) on the windy sites of SANTORINI, *aplotaries* on Paros (see APLOTARIA), where vine canes are left to grow on the ground, or even the vines trained around olive trees in Messinia. CORDON systems of pruning and training are more common than GUYOT.

Viticultural CONSULTANTS have been instrumental in improving Greek vineyards. Vine VIRUS DISEASES are common in some vineyards and certain grape varieties. The most common ROOTSTOCKS are 110 R or 41 B, which offer much-needed DROUGHT resistance.

Vine varieties

Greece remains a largely unexplored source of ancient INDIGENOUS VARIETIES, of which more than 300 have been identified. Many of them are used solely for the TABLE GRAPE or dried-fruit industries, however, and others are used in tiny quantities on a purely local basis. There is still considerable work to be undertaken in VINE IDENTIFICATION, not just in rediscovering classical varieties but in discovering the relationships between Greek varieties and those grown in neighbouring countries such as Italy and Albania. The success of varieties such as MALAGOUSIA (virtually unheard of in 1993 but currently responsible for top-quality wines from no fewer than 150 producers), VIDIANO, Limniona, KYDONITSA, and many more suggests it will take decades for Greek viticulture to fully capitalize on the potential of its native grapes. There is also a growing interest in Greek varieties from other countries such as Australia, South Africa, Italy, and the US, inspired in part by CLIMATE CHANGE concerns that have winegrowers searching for more drought- and heat-resilient varieties.

Greek wine-grape varieties can offer unique characters and flavours. The mild climate and the tradition of consuming wine with food has favoured varieties that are relatively low in alcohol and based more on acidity and freshness than softness and body. Many varieties are grown in regions where attaining full ripeness is difficult, resulting in wines with distinctively COOL-CLIMATE characteristics. Many grapes are very specific to place, as well. For example, Debina is a speciality of Epirus, and Xinomavro of Macedonia, but Greek vine-growers are increasingly experimenting with varieties such as ASSYRTIKO and AGIORGITIKO in areas far from their traditional homes.

The most important white wine grapes in Greece are Assyrtiko, RODITIS, ROBOLA, SAVATIANO, MOSCHOFILERO, VILANA, DEBINA, and both MUSCAT BLANC À PETITS GRAINS and MUSCAT OF ALEXANDRIA. The Greek port of Monemvasia also gave its name to the MALVASIA grape. Among Greek red grape varieties, the most important to the modern Greek

wine industry have been Agiorgitiko, LIMNIO, MANDILARIA, and XINOMAVRO. See regional details below for more local grape varieties.

In addition to these native varieties, INTERNATIONAL VARIETIES make up around 10% of total plantings. These include Chardonnay and Sauvignon Blanc among whites and Cabernets Sauvignon and Franc, Merlot, Grenache Noir, Cinsaut, and Syrah among red grape varieties. These appear sometimes in VARIETAL versions but more often in blends with Greek varieties.

Winemaking

While Greece was behind the curve in modernizing its wineries, with refrigeration and stainless-steel tanks coming into widespread use only in the 1980s, today winemaking technology is as modern as anywhere, although the trend is a return to traditional methods such as fermentation using AMBIENT YEASTS and reduced SULFUR DIOXIDE additions.

Better-quality red wines have traditionally been matured in large, old casks. After a couple of decades of over-using French, mainly new, BARRIQUES for the BARREL MATURATION of reds and even some whites, the pendulum is swinging back to more subtle oaking or even the use of CONCRETE vessels or clay AMPHORAE.

Wine laws

Greek wine laws were drawn up in the early 1970s and refined in the early 1980s as Greece prepared to join the EU. Since 2009 the top quality category is designated PDO or Protected Designation of Origin, of which there were 33 in 2021. The words Réserve or Grande Réserve indicate PDO wines with extended AGEING.

Protected Geographical Indication wines (PGI), which constitute the next tier and of which there were 120 in 2021, may be made in a wide variety of specified areas, nearly always from a range of vine varieties that includes both Greek and foreign grape varieties. The term 'Kava' is sometimes used to indicate high-quality PGI wines made only in small quantities and subjected to prolonged ageing.

The large category of WINE WITHOUT GEOGRAPHICAL INDICATION, known now simply as 'Wine from Greece' but formerly as table wine, includes some of Greece's most successful GENERIC brands as well as some more interesting wines made outside appellation regulations.

Wine regions

Wine is made all over Greece, often on a very small scale. The following includes those quality wine regions which have established their own identity within Greece and sometimes abroad; see map.

Northern Greece The regions of Macedonia and Thrace are noted mainly for their red wines, although wines of all hues are made there today. Xinomavro is arguably the most important grape variety with no less than four PDOs dedicated to it. The wines of NAOUSSA and AMYNDEO must be pure Xinomavro; to the north-east, in the slightly warmer PDO Goumenissa, it is blended with NEGOSKA grapes. Rapsani also favours Xinomavro but belongs to Thessaly in Central Greece (see below).

Côtes de Meliton on the slopes of Mount Meliton on the Halkidiki peninsula is the appellation specially created by Domaine Carras, a wine estate developed with the well-publicized assistance of Professor Émile PEYNAUD of Bordeaux. Its wines are made with a mixture of Greek and international vine varieties, notably Cabernet Sauvignon. The estate also pioneered the rediscovered elegant indigenous white variety MALAGOUSIA.

Since at least 1990, the coastal area of Kavala and its landlocked neighbour Drama have been enormously influential in introducing a particularly modern style of Greek wine, with exceptional red BORDEAUX BLENDS and Assyrtiko/Sauvignon Blanc white blends.

Thrace, famous for its wines in antiquity, is slowly reclaiming its past glory, mainly around Mount Ismaros and in Avdira, using the local MAVROUDI red grape, as well as blends of Greek and international varieties.

In the mountains of Epirus, not far from the town of Ioánnina and near the border with ALBANIA lies PDO Zitsa, which is most famous for lightly sparkling white wines from the local DEBINA grape, which is able to achieve full flavour ripeness at only 11% alcohol. To the immediate south-west, in the mountains around Ioánnina, are Greece's highest vineyards at Metsovo: the PGI starts at 500 m and soars to 1,200 m/4,000 ft. Cabernet Sauvignon and the local Vlahiko dominate reds; Debina and GEWÜRZTRAMINER provide fresh white wines.

Central Greece Thessaly, on the north-east coast of Central Greece, was not particularly important for quality wine production in past decades, but its combination of steep SCHIST slopes, ELEVATIONS reaching 900 m/3,000 ft, and OLD VINES yield small quantities of ageworthy reds. Rapsani is its most important PDO, produced on the foothills of Mount Olympus from Xinomavro (here grown at its most southerly point) blended with Krassato and Stavroto grapes and given CASK AGEING.

Further south-west, Messanikola is Greece's smallest PDO, 95 ha/234 acres focused on red wines made from the grape of the same name. High-quality wines are also being made in Tyrnavos (especially reds made from the indigenous Limniona) and the high elevations of Meteora.

Attica, together with Viotia, form the most important vine-growing area of Greece. Mainly planted with SAVATIANO, the region was once looked down on for its role in producing low-quality RETSINA, but in the 2010s the tables turned: by focusing on old vines and high-elevation areas, producers have proved Savatiano's potential for producing high-quality and even ageworthy white wines.

Other areas such as the island of Evvia, and Atalanti in Fthiotida, have produced excellent wines since at least the 2000s from a wide range of grape varieties, from Syrah and Cabernet Sauvignon to Assyrtiko, Agiorgitiko, and indigenous varieties Mavrokoundoura and Asprokoundoura.

Peloponnese This large southern peninsula has the greatest number of Greek wine PDOs, as well as some interesting PGI wines. On the plateau of Mantinia in Arcadia, at elevations of about 600 m/2,000 ft, the pink-skinned Moschofilero grape produces fresh, dry, aromatic, slightly spicy, sometimes sparkling whites; with extended SKIN CONTACT, it can also yield interesting rosés. In Nemea, not far from the Corinth Canal that separates the Peloponnese from mainland Greece, the Agiorgitiko grape is grown on MARL and deep red soil. It can produce fruity, simple, dry or sweet red wines in the region's lower elevations; at 450–900 m/1,476–3,000 ft, the wines become more structured and intense, capable of AGEING. As in Naoussa, the 2000s saw a trend in new French BARRIQUES, but gentler oaking is becoming the norm. Since the late 1990s, Nemea has seen more investment in high-tech wineries than any other Greek region, resulting in some outstanding bottlings. Leading vineyards have been replanted with a higher VINE DENSITY.

The vineyards around Patras on the north coast are responsible for four PDOs. The Patras PDO is for dry white wines made from Roditis grapes grown on the slopes around the town. Muscat of Patras is a strong, sweet VIN DOUX NATUREL-style dessert wine from Muscat Blanc à Petits Grains grapes, as is Rion of Patras, which is almost extinct owing to the encroachment of buildings on the vineyard area. Mavrodaphne of Patras is a popular appellation for sweet reds, made from at least 51% Mavrodaphne and supplemented by the locally grown Korinthiaki (Corinth or CURRANT). Fermentation is arrested when ALCOHOLIC STRENGTH has reached about 4% (as in making PORT), and the wine, like tawny port, is then aged in wood. Examples aged 10–12 years in cask can be delicious. Wines falling outside of the PDO regulations may be bottled under the PGI Achaia.

In the far south-east of the peninsula is the medieval city of Monemvasia, which lends its name to the PDO Monemvassia-Malvasia, a barrel-aged sweet white wine made from several varieties of sun-dried grapes, including Monemvassia (at least 51%), Assyrtiko, and the rare Kydonitsa. Other significant viticultural areas include Ilia

in the western Peloponnese, where REFOSCO has been grown by Mercouri for more than a century, and Messinia in the south-west, where, interestingly, Cabernet Sauvignon excels.

The islands Of the Ionian Islands off Greece's west coast, Kefalonia is best known for its wine, particularly the powerful, dry white ROBOLA. Vines here were individually trained on high, stony land, and mainly UNGRAFTED, leading Venetians to call Robola a *vino di sasso*, or wine of stone. Some dry, unfortified red wines from MAVRODAPHNE are also made, possibly the finest examples of this genre. Rarer are Mavrodaphne and Muscat dessert wines similar to those of Patras.

The Cyclades may be best known for the structured whites of SANTORINI, but wine is made on several of its islands. The PDO Paros red is a powerful, quite tannic wine made from a curious blend of the deeply coloured MANDILARIA lightened by the addition of half as much of the white grape called Monemvassia (see MALVASIA). PDO Malvasia of Paros is a sweet white, from sun-dried Monemvassia and a small percentage of Assyrtiko. Vines are trained along the ground using the APLOTARIA system as protection against the strong winds. Strong winds are also a characteristic of SANTORINI as well as Tinos, the home of a small group of top-quality producers working with Assyrtiko, Mavrotragano, and local varieties such as Potamisi. Small amounts of wines are also made on Mykonos, Naxos, Serifos, and Syros.

Of the Dodecanese islands, Rhodes has been an important producer of wine since classical times. Today PDO Rhodes includes dry whites based on ATHIRI and rosés and reds based on MANDILARIA, here known as Amorgiano. Sparkling wines, for decades a local tradition, now have their own PDO, including white and red versions. Only grapes grown on the higher reaches of the north or north-eastern slopes qualify for appellation wines. The PDO Muscat of Rhodes applies to both late-harvest and fortified sweet Muscat wines. Some wines are also made on the island of Kos.

The AEGEAN ISLANDS claim two of Greece's most famous sweet Muscat wines. On Samos, Muscat Blanc à Petits Grains is grown up to 800 m/2,600 ft above sea level, often on TERRACES on the island's steep hillsides, and the vintage can last a full two months, depending

on vineyard ELEVATION. Muscat of Samos comes in several forms: Samos Doux is a MISTELA, while Samos Vin Doux Naturel is made by stopping the fermentation slightly later. Anthemis is an outstanding barrel-aged example. Potentially finest of all, however, is Samos Nectar, an unfortified wine made from sun-dried grapes capable of being fermented into a wine of 14% alcohol, which is then given three years in cask. Old vintages of the top bottlings can be sublime and great value for money. France is the single largest market, importing in BULK more than half of the island's annual production.

Limnos was the original home of the LIMNIO grape, which is still grown there, producing the PDO Limnos (also spelt Lemnos) red wine. But the island is more famous for Muscat wines, both dry and sweet. The PDO Muscat of Limnos, a sweet wine made from Muscat of Alexandria, is widely admired, being surprisingly delicate in both LATE HARVEST and VIN DE LIQUEUR forms.

The last of the appellation wines of commercial importance come from Crete, an island so large and diverse it is covered in detail under CRETE.

winesofgreece.org

green, tasting term often used for a wine made from grapes that did not reach full RIPENESS; as popular taste has evolved towards wines with higher acidity, however, it is no longer necessarily pejorative and may be used for wines that remind the taster of green vegetation.

green grafting, viticultural term for BUDDING and GRAFTING in the vineyard or nursery using green stem tissue. Green grafting offers less flexibility in timing than CHIP BUDDING and T-BUDDING because the

ROOTSTOCK shoots must be green, and so it must take place in late spring or early summer. As with T-budding, the SCION pieces to be inserted may be from stored winter cuttings or the current season's green shoots. B.G.C.

green harvest. See CROP THINNING.

greenhouse effect. See CLIMATE CHANGE.

Green Valley of Russian River Valley is a cool, foggy California AVA in SONOMA best known for Pinot Noir and sparkling wines.

Grenache Blanc, the white-berried form of GRENACHE NOIR, was once important in France but now ranks eleventh among white grape varieties. However, there has been a modest revival in the last 15 years and the variety was grown on a total of 5,896 ha/14,569 acres of France in 2019, throughout the Languedoc and Roussillon, where it produces full-bodied whites that vary from fat and soft to nervy, floral, terroir-driven cellar candidates. In unfortified wines it is typically blended with the likes of Grenache Gris, Clairette, Bourboulenc, Marsanne, Roussanne, Viognier, Macabeo, and Rolle, adding supple fruit if not necessarily longevity. It need not necessarily be consigned to the blending vat, however. If carefully pruned and vinified, it can produce richly flavoured, full-bodied VARIETALS that share some characteristics with Marsanne and can be worthy of ageing in small oak barrels. It is also an ingredient in white Châteauneuf-du-Pape and is a significant ingredient in Roussillon's VINS DOUX NATURELS. The variety is also found in varietal form in California and occasionally in South Africa.

See GARNACHA BLANCA for details of the variety in Spain.

Grenache Gris, the least significant of the three Grenaches is a pink-skinned MUTATION of GRENACHE NOIR and is most important in Roussillon, where two-thirds of France's 2,190 ha/5,412 acres in 2019 were grown. It is more perfumed than GRENACHE BLANC and can add interest to unfortified wines. A small amount of Garnacha Roja is grown in northern Spain.

Grenache Noir, increasingly fashionable vine variety that in the late 20th century was the world's second most widely planted, sprawling all over Spain and southern France, but by 2016 had slumped to eighth place, thanks largely to the EU VINE PULL SCHEME. It probably owes its early dispersal around the western Mediterranean to the strength and extent of the ARAGÓN kingdom. As GARNACHA, it probably originated in Spain in the northern province of Aragón before colonizing extensive vineyard land both north and south of the Pyrenees, notably in Roussillon, which was ruled by Spain, and more particularly by the kingdom of Aragón, for four centuries until 1659. From here Grenache presumably made its way east and was certainly well established in the southern Rhône by the 19th century. Although Grenache was not planted in Rioja before PHYLLOXERA struck in 1901, this productive, resistant variety then practically replaced native vines in what is now Rioja Oriental and made significant inroads in Alta and Alavesa. Grenache is undoubtedly, however, the same grape variety as Sardinia's CANNONAU, which the Sardinians claim as their own, advancing the theory that the variety made its way from this island off Italy (where it is also known as Granaccia or Tai Rosso and, confusingly, as Gamay del Trasimeno in Umbria) to Spain when Sardinia was under Aragón rule, from 1297 until 1713.

Whatever its origins, Grenache has been uprooted to such an extent in Spain (see GARNACHA) that France has the world's largest Grenache presence, 84,745 ha/209,409 acres in 2019—more than any variety other than Merlot. For a vine that covers so much terrain, until recently its name has been rarely encountered by the wine drinker, much of it being blended with other varieties with more

colour and backbone. Grenache produces essentially very fruity, rich, sweet-tasting wine, with varying degrees of tannin depending on the degree of WATER STRESS.

With its strong wood and upright growth, Grenache Noir is well suited to traditional BUSH VINE viticulture in hot, dry, windy vineyards. It buds early, can be prone to COULURE, and ripens relatively late (after Cabernet Sauvignon). In regions allowing a relatively long growing cycle, it can achieve heady sugar levels and indeed does not achieve full PHYSIOLOGICAL RIPENESS without them. The wine produced is, typically, paler than most reds (although low yields tend to concentrate the pigments, and tannins, in Spain and some Châteauneuf-du-Pape vineyards), with a tendency to oxidize early, a certain rusticity, and more than a hint of sweetness. If the vine is irrigated, as it has tended to be in the NEW WORLD, it may lose even these taste characteristics. If, however, as by the most punctilious Châteauneuf-du-Pape producers, it is pruned severely on the poorest of soils and allowed to reach full maturity of both vine and grape, it can result in excitingly dense reds that demand several decades' cellaring. The rediscovery of Rhône reds in the late 1980s (see RHÔNE RANGERS, for example) encouraged some New World producers to invest more effort in their own Grenache, even though its sturdy trunk has made it less widely popular in the modern era of MECHANICAL HARVESTING.

See GARNACHA for details of the variety in Spain.

In France, the majority of Grenache is planted in the southern RHÔNE Valley. Here seas of Côtes du Rhône of varying degrees of distinction are produced alongside smaller quantities of CHÂTEAUNEUF-DU-PAPE, GIGONDAS, and the like. Although blending has been the watchword here, notably with the more structured Syrah, older vintages of such monoliths as the famously concentrated Châteauneuf-du-Pape Ch Rayas show what can be done by Grenache and determination alone. The variety's kingdom spreads north to the Drôme *département*, where it also dominates, on nearly 7,000 ha. Grenache is responsible for much of southern France's fruitiest, fullest

rosé, most obviously and traditionally in TAVEL and in neighbouring LIRAC but also much further eastwards into Provence proper, where Grenache is strongly identified with its significant rosé production. In the Languedoc and Roussillon, Grenache plays a generally unsung supporting role, together with its downy-leaved close relative LLEDONER PELUT, which is also habitually cited in the AOC regulations for red wines. In Roussillon, Grenaches of all three colours (see also GRENACHE BLANC and GRENACHE GRIS) are valued not only for their dry wines but as the vital ingredient in the region's distinctive VINS DOUX NATURELS.

Grenache Noir is being uprooted on Corsica in favour of local varieties, but on SARDINIA, as Cannonau, it still plays a dominant role in the island's reds and dessert wines. The vine is also grown around the Mediterranean, for example in Croatia.

Grenache's ability to withstand DROUGHT and heat made it a popular choice with New World growers when FASHION had little effect on market forces. Extensive historic acreage in the central San Joaquin Valley, and some in Mendocino, constituted the majority of the 1,780 ha/4,399 acres that remained in California in 2020. The wine typically made from these OLD VINES—cheap, sweet, gimmicky Grenache Rosé or 'White Grenache'—had done little for Grenache's image in California, but the state's RHÔNE RANGERS have rejuvenated the variety's image with new plant material imported straight from the Rhône Valley in their Central Coast vineyards. Grenache has benefited from Washington State's love affair with Rhône wines although only 86 ha/212 acres were recorded there in 2017, less than one-twentieth as much as Syrah.

Grenache was Australia's most planted black grape variety until the mid 1960s. Shiraz (Syrah) overtook it in the late 1970s, but it was not until the early 1990s that Australia's Cabernet Sauvignon output overtook that of Grenache. By 2022 the total area planted with Grenache in Australia had fallen to 1,801 ha/4,450 acres, high-yielding vines in Riverland having been pulled out while more cosseted vines have been planted in McLaren Vale and the Barossa

Valley, and old-vine Grenache is increasingly treasured. VARIETAL Grenache has been less popular in Australia than GSM blends and has not featured much in South America.

Robinson, J., et al., *Wine Grapes, A Complete guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

grès, French term for SANDSTONE.

Grés de Montpellier, named CRU within the LANGUEDOC AOC in southern France created in 2003 for red wines made mainly from Syrah and Mourvèdre with Grenache Noir. The region encompasses 46 communes a broad sweep of hinterland of the city of Montpellier, generally cooled by breezes from the nearby Mediterranean.

grey rot, sometimes known as grey mould and sometimes just bunch rot, the malevolent form of BOTRYTIS BUNCH ROT and one of the most harmful of the FUNGAL DISEASES that attack vines. In this undesirable bunch-rot form, the *Botrytis cinerea* fungus rapidly spreads throughout the berry flesh and the skin breaks down. Other fungi and bacteria then also invade the berry and the grapes become rotten. Badly infected fruit develops off-flavours, ACIDITY is significantly reduced, and PHENOLICS are oxidized by LACCASE; badly infected vineyards themselves have a characteristic mouldy and often vinegary smell. Wines produced from such fruit smell mouldy, and red wines look pale and grey-brown. Research in Champagne has shown that botrytis can have a negative effect on the foaming properties of champagne. When the *Botrytis cinerea* fungus attacks healthy, ripe, white wine grapes and the weather conditions are favourable, it results in so-called NOBLE ROT, which can produce some of the world's finest sweet wines.

greywacke, pronounced 'graywacky', from the German *Grauwacke*, is a tough, dark-grey SANDSTONE, with a high CLAY content. Most sedimentary rocks (see GEOLOGY) show a fairly uniform grain size, whereas greywacke, formed in turbid deep-sea water, shows characteristically jumbled grain sizes, with thick accumulations of coarse material (typically of QUARTZ, feldspar, and rock fragments) closely intermixed with fine clay. On land it weathers slowly, giving stony, free-draining soils.

Greywacke is found in South Africa's Western Cape, in California's RUSSIAN RIVER VALLEY, and in Germany's MOSEL, AHR, and MITTELRHEIN, but perhaps most famously it is found in NEW ZEALAND, where it constitutes much of the bedrock spine of both islands. Detritus derived from it dominates the GRAVELS of regions such as Hawke's Bay, Marlborough, and Waipara. A.J.M.

Grignan-les-Adhémar, name adopted in 2010 for an extensive appellation on the northern fringes of the southern RHÔNE for mainly red wines. (Its original name, Coteaux du Tricastin, was abandoned because it was too readily associated with a nearby nuclear power plant.) In 2020, wines were produced from 1,270 ha/3,138 acres of vineyards; 74% red, 16% rosé, 10% white. Although the climate here is definitively MEDITERRANEAN, the higher vineyards and more exposed terrain produce slightly lighter wines than those of the Côtes du Rhône, which they resemble. Grenache and Syrah are the principal varieties for reds and rosés, Grenache Blanc and Viognier for whites. M.C.W.

Grignolino, ancient grape variety of the PIEMONTE region in north-west Italy already documented in 1249 as Berbexinis (the synonym Berbesino is still used). Native of the MONFERRATO hills between Asti and Casale and vinified almost invariably as a pale red VARIETAL wine with an almost alpine scent and a tangy ACIDITY, it has naturally high TANNINS thanks to having three-to-four times more seeds (*grignole*

means 'pips' in the Monferrato dialect) than most varieties. But these tannins were seen as a disadvantage and avoided by short MACERATION times, thus stripping the wine of its ageing potential and depth and creating the misconception that it must be drunk young.

The growing appreciation for Nebbiolo and its tannic structure has helped Grignolino's fortunes, as has the foundation in 2016 of Monferace, a private association of 12 Grignolino producers who choose to adhere to strict production rules requiring 100% Grignolino and ageing for at least 40 months, including 24 in CASK. This harks back to the variety's historic reputation as an ageworthy wine and aims to eradicate the early-drinking image.

Grignolino has its own DOC areas, Grignolino Monferrato Casalese (270 ha/667 acres) and Grignolino d'Asti (308 ha), slightly overlapping with the DOCG of ASTI, and is allowed in a further five DOCs. Total plantings in Italy in 2021 were 645 ha/1,593 acres, compared with 743 ha in 2011, practically all in Piemonte. W.S.

www.viniastimonferrato.it

Grillet, Château. See CHÂTEAU-GRILLET.

Grillo, Sicily's second most planted white grape variety, was once used as the base for the best MARSALA. Grown as BUSH VINES, it produced potent, full-bodied base wines that were supplemented by a proportion of the more aromatic INZOLIA. DNA PROFILING established that Grillo is a natural CROSS of Sicily's CATARRATTO with MUSCAT OF ALEXANDRIA and that Rossese Bianco of Liguria is identical to Grillo. At its best, it gives full-bodied wines of real interest, although they lack the aromatic intensity that has made Inzolia's transformation from FORTIFIED WINE to dry white wine variety so much easier. Plantings have grown substantially and had reached 8,444 ha/20,866 acres on the island by 2020. See SICILY for more details.

Gringet, not, as was long thought, a synonym for SAVAGNIN but a distinct variety used mainly for full-bodied, floral, still and sparkling wines in AYSE in SAVOIE.

Groenekloof, cool, predominantly white-wine ward in the Darling district in SOUTH AFRICA.

Grolleau Noir, sometimes known as Groslot and one of the numerous natural progenies of GOUAIS BLANC, is the everyday red grape variety of TOURAINE. It produces extremely high yields of relatively thin, acid wine, and it is to the benefit of wine drinkers that it is so systematically being replaced with Gamay and, more recently, Cabernet Franc. It was once much more important, but total French plantings have been steady this century at around 2,000 ha/4,942 acres. The status of the variety is such that it is allowed into the rosé but not red versions of AOC wines such as SAUMUR and Touraine. It has played a major part only in Rosé d'Anjou, in which it is commonly blended with Gamay, which ripens just before it. Plantings of the pink-skinned mutation Grolleau Gris, in much the same part of France, totalled 573 ha/1,416 acres in 2019.

Groppello Gentile, red grape variety grown to a limited extent on about 78 ha/193 acres, mainly in the Italian wine region of LOMBARDY. It is the most important of the Groppellos.

Groslot is a common synonym for the Loire's red vine variety GROLLEAU.

Gros Manseng, assertive and increasingly popular Basque white grape grown on about 3,965 ha/79,798 acres of SOUTH WEST FRANCE in 2019 to produce drier versions of Jurançon and various Béarn wines, as well as being one of the more characterful ingredients in Gascon

dry whites. It is known as Iskiriota Zuri Handia over the border in Spain's Basque country (see TXAKOLI). DNA PROFILING established a parent–offspring relationship with the rarer, thinner-skinned PETIT MANSENG. It yields more generously and produces discernibly less elegant, less rich, but still powerful wine. Unlike the smaller-berried Petit Manseng, it is not sensitive to COULURE. Gros Manseng, unlike Petit Manseng, is rarely used for sweet wines. J.E.H. & J.V.

Gros Plant du Pays Nantais is an AOC overlapping that of MUSCADET. The wines are from FOLLE BLANCHE, called Gros Plant here, with the rare Colombard and Montils permitted. The area comprises a wide, ocean-influenced arc south-east of the city of Nantes, with the well-drained igneous and metamorphic hillsides of Grandlieu and Vallet the best for taming Gros Plant's VIGOUR. Tart by nature, the variety can make bracingly acidic, austere wines when overcropped, but quality winegrowers can produce examples that combine ripeness and salty freshness, building TEXTURE and aromatic complexity with LEES CONTACT. The Folle Blanche vine was introduced to this region by the DUTCH WINE TRADE for DISTILLATION purposes and outnumbered the MELON vine until the ravages of PHYLLOXERA in the late 19th century. Gros Plant was promoted from VDQS to AOC in 2011. The decreasing production represents one-tenth of the Muscadet output, with a large proportion enjoyed locally. P. Le.

Gros Rhin, Swiss synonym for SILVANER, to distinguish it from Petit Rhin, or Riesling.

Grosse Lage, term adopted in 2012 by Germany's VDP for those vineyards classified by its members as their best and hence capable of generating a GROSSES GEWÄCHS. Prior to that, the term ERSTE LAGE was used for such vineyards, but it is now used for an ostensibly lesser tier of vineyards (effectively the PREMIERS CRUS, with Grosse Lagen being the GRANDS CRUS). D.S.

Grosser Ring, the Mosel branch of the VDP growers' association in GERMANY. Founded in 1908 in Trier, where its annual September AUCTIONS are still a prestigious feature of the country's wine calendar as well as an indicator of vintage quality and market health, the group comprises around 30 growers. D.S.

Grosses Gewächs (pronounced 'guh-*vex*') is a prestige dry wine category devised by the VDP growers' association in GERMANY and in use (though no longer exclusively by its members) since 2002. Within the VDP, wines so designated originate in vineyard sites classified by the VDP as a GROSSE LAGE. Such a site is typically an EINZELLAGE, but increasingly many producers make use of a provision permitting the registration of any cadastral site name for labelling purposes. Grosse Gewächse (plural) must be cropped at YIELDS of no more than 50 hl/ha, be hand-harvested, at no less than the MUST WEIGHT required for SPÄTLESE (though CHAPTALIZATION is permitted, and the wines are nowadays labelled without PRÄDIKAT), and be subjected to sensory review. Grosses Gewächs wines are typically bottled in glass embossed with a logo featuring a grape cluster and the numeral 1 and (since vintage 2007) are labelled with the initials GG. In imitation of Burgundian GRAND CRU practice, VDP members typically promote Grosse Gewächse without reference to their commune (village) of origin, with the result that some names—Herrenberg, for example—can be found on wines from several different sites. A 2021 German wine law recognizes Grosses Gewächs (together with an effectively PREMIER CRU counterpart, ERSTES GEWÄCHS) and sets parameters for yield, minimum ALCOHOLIC STRENGTH, and release date. D.S.

Grosslage designates a collective vineyard site as delimited by Austrian or German wine law (and under no circumstances should it be confused with the superior class of single-vineyard sites defined by the VDP as GROSSE LAGEN). Generally co-opting a traditional place name with cachet (but sometimes made up), Germany's Grosslage

designations must be conjoined to the name of a particular wine village but typically cover vineyards (each officially known as an EINZELLAGE) in far-flung and far less prestigious villages, the thinly disguised intent being, by means of the German labelling template village+vineyard, to trade on the prestige earned by sites outside the Grosslage. Thus, Niersteiner Gutes Domtal refers to vast acreage spread across 15 disparate villages and 32 Einzellagen of which only one—obscure—falls within the communal limits of the Rheinhessen's justly famous wine village Nierstein. Another notorious example is Piesporter Michelsberg in the Mosel. By the 1990s, use of Grosslage designations had greatly diminished. A very few German Grosslage names—most notably Bernkasteler Badstube—remain widely used even by the most quality-conscious growers because they incorporate sites within the designated village that are high quality but lesser known. However, a 2021 revision to the German wine law stipulates that from 2026 any Grosslage designation—or any newly minted collective site designations—must be preceded by the word 'Region' and eliminate reference to commune (village); for example, no longer Piesporter Michelsberg but Region Michelsberg. However, this change was still being hotly disputed in 2022.

The word 'Grosslage' remains an officially recognized term in Austria but is not used on labels. D.S.

Gros Verdot, an unusual Bordeaux variety without the concentration or interest of PETIT VERDOT. It is grown to a limited extent in California and possibly also in South America.

grower, the all-important producer of the raw material for winemaking. These individuals may be called grape-growers, more precisely vine-growers, possibly even winegrowers (or wine-growers) if they also vinify. Terms in other languages include *vigneron* and *viticulteur* in French and *vignaiolo* in Italian. Wine producers who grow their own grapes and vinify them into wine but on a limited scale are often referred to somewhat carelessly and often

inaccurately as small growers. A significant proportion of all vine-growers produce only grapes, however, which they sell to CO-OPERATIVES, merchant-bottlers (see NÉGOCIANT), or larger wine operations.

growler, a resealable jug commonly used in the United States for the sale of beer and kombucha; more recently, growlers are sometimes used for wine, for off-site consumption. While Europeans have long been allowed to bring refillable vessels to a winery to have them filled with wine, the practice has been complicated in the US by the arcane rules of the TTB and remains rare. Growlers are gaining traction in other countries such as Argentina, which began allowing the sale of wine in growlers in 2021 as a more environmentally friendly option to bottled wine, saving on glass, labels, and transportation.

growth cycle. See VINE GROWTH CYCLE.

growth regulators, synthetic substances which act on vines like HORMONES to regulate their growth and development. A synthetic AUXIN, 4-CPA, has for example been used to improve FRUIT SET. Synthetic GIBBERELLINS have been used to increase berry size, especially for the seedless SULTANA, and a synthetic ethylene-releasing compound termed 'ethephon' can be used to hasten grape maturity and enhance coloration in particularly cool climates. More recently applied to viticulture, hydrogen cyanamide encourages early and complete BUDBREAK, which can be useful for TROPICAL VITICULTURE. These chemicals are mostly used for TABLE GRAPES, and their application to both table grapes and wine grapes is regulated by rules governing the use of AGROCHEMICALS. R.E.S.

grubbing up vines is known as *arrachage* in France, where it became a common practice as part of the EU's various VINE-PULL SCHEMES aimed at reducing the European WINE LAKE, notably in the 1980s and 1990s. Outside Europe the practice is generally referred to as 'ripping out'.

The more traditional reason for grubbing up a vineyard is that the VINE AGE is so high and the average YIELD so low that the vineyard is no longer economic (although the prestige associated with OLD VINES may retard this process). Weak demand for wine grapes, signalled by wineries failing to renew contracts with growers and/or continued periods of low prices, sometimes below production costs, may also lead to vineyard removal.

A vineyard may be grubbed up because its owner wishes to change VINE VARIETY or CLONE, although this may be achieved by TOP GRAFTING, or field grafting on to the existing TRUNKS and root systems. Vineyards are normally grubbed up when invaded by a pest as deadly as PHYLLOXERA (as thousands of acres were in northern California in the late 1980s), and a disease such as LEAFROLL VIRUS, ESCA, or GRAPEVINE YELLOWS may damage production to such an extent that grubbing up is the only option. In the early 2010s, TRUNK DISEASE infection had become a major reason for vineyard removal in California and around the world, as the proportion of dead and missing vines increases with age.

If the vineyard is to be replanted, care must be taken that the soil is free of pests and diseases. FUMIGATION may be necessary; see also NEMATODES.

Grumello, one of five subzones of VALTELLINA in the far north of Italy.

Grüner Veltliner. The most commonly planted vine variety in AUSTRIA is grown elsewhere in Eastern Europe and is increasingly respected worldwide. This well-adapted variety was planted on

14,612 ha/36,107 acres of Austria in 2020, almost 50% of the country's white wine grape area, and is particularly dominant in Lower Austria. DNA PROFILING in Austria has shown that Grüner Veltliner is a spontaneous CROSS between SAVAGNIN and the obscure St Georgener from Eisenstadt but is not genetically related to ROTER VELTLINER or FRÜHROTER VELTLINER.

The vine can be productive and is relatively hardy but ripens too late for much of northern Europe. Yields of 100 hl/ha (5.7 tons/acre) are possible in the least distinguished vineyards and the resulting wine is inoffensive if unexciting. However, at its best, arguably in the Wachau, Kamptal, Kremstal, Weinviertel, and Wagram and in the hands of some of the most ambitious growers in Vienna, Grüner Veltliner can produce wines which combine perfume and substance. The wine is typically dry, full-bodied, peppery, or spicy, and with time in bottle it can start to taste positively Burgundian. Grüner Veltliner can produce a variety of wine styles, from base wines for Austrian SEKT, simple wines served at HEURIGER, popular medium-bodied peppery wines to very opulent, concentrated wines. Grüner Veltliner may be regarded as Austria's biggest asset and adorns restaurant wine lists around the globe. It can be difficult for non-German speakers to pronounce so is often abbreviated to 'Gruner' or 'GV'.

The variety has long been grown just over Lower Austria's northern border in CZECHIA—where it is known as Veltlin or Veltlínské Zelené and is the country's most widely planted variety—and in the Sopron vineyards of HUNGARY as Zöldveltelini. It is also known in Germany's Rheinhessen and Pfalz regions and is proving successful and versatile in Australia, New Zealand, and North America.

GSM on a wine label indicates the popular, southern-Rhône-inspired blend of Grenache, Syrah/Shiraz, and Mourvèdre. GSM is particularly common in Australia but also made in California and Washington State.

GST. See CLIMATE CLASSIFICATION.

guaiacol. See BRETTANOMYCES, FLAVOUR COMPOUNDS, OAK FLAVOUR, and SMOKE TAINT.

Guarnaccia, Calabrian synonym used for CODA DI VOLPE BIANCA. Guarnaccia Nera is a Campanian synonym for MAGLIOCCO Dolce.

Guenoc Valley, California AVA. See LAKE COUNTY.

Guigal, family-owned merchant-grower based at Ampuis, CÔTE RÔTIE, in the northern Rhône. Although established as recently as 1946 by Étienne Guigal, Maison Guigal is the most famous of any of the Rhône Valley's merchants or growers with collectors and investors. This is very largely due to the efforts of its manager since 1961, Étienne's only son Marcel, a man of exceptional modesty and a gifted, meticulous winemaker. Marcel's son Philippe, OENOLOGIST and chief winemaker, joined the estate in 1997 and is a worthy successor. Guigal owns more than 150 ha/370 acres, of which slightly more than 30 ha/75 acres is prime vineyard in Côte Rôtie. It was the wines made from three of its best PARCELS, extravagantly praised by influential American wine writer Robert PARKER in the early to mid 1980s, that first drew international attention to Guigal. It would be fair to say that the quality of Guigal's top wines, along with Parker's persistent enthusiasm for them among many other Rhône wines, spearheaded a resurgence of interest in the whole region.

Guigal's so-called 'LaLa' wines (La Mouline, La Landonne, and La Turque) are dark, dense, mouth-fillingly rich and oaky expressions of the SYRAH grape (supplemented by up to 11% of co-planted VIOGNIER in the case of La Mouline, 7% for La Turque); they are made from low yields of very ripe, late-picked fruit aged for three-and-a-half years in 100% new OAK and bottled without FINING or FILTRATION. They are particularly impressive when young and their quality is beyond question, but opinions are divided about their style; Côte Rôtie purists seek transparency. Reputation and rarity combined (only 400–

700 cases of each are made each year) have also made them extremely expensive and therefore game for criticism, fair or not. From the 1990s offerings have included the more plentiful Côte Rôtie Ch d'Ampuis, La Doriane, a special CONDRIEU, and, from the 2001 vintage, Ermitage Ex Voto.

In 1984 Guigal bought and revitalized the firm of Vidal Fleury, the company where Étienne Guigal worked at the age of 14 (from 1923 until 1940) before founding his own. The former Jean-Louis Grippat and de Vallouit estates were absorbed by Guigal in 2001 followed by the Bonserine estate in 2006. In 2017 the Guigal family moved into the southern Rhône with the purchase of Ch de Nalys's well-situated 77 ha/190 acres of vines, although they had long (meticulously) sourced wine in the south for their NÉGOCIANT bottlings such as their great-value Côtes-du-Rhône. M.W.E.S. & J.R.

Gumpoldskirchen, wine centre in the THERMENREGION district of Austria famous for white wines made from ZIERFANDLER (or Spätrot) and ROTGIPFLER grapes.

Gundagai, small, hilly wine region in southern NEW SOUTH WALES comprising low-lying warm areas and cooler vineyard sites at higher ELEVATIONS in the foothills of the Australian Alps. It is known for ripe, vibrant Shiraz, full-flavoured Cabernet Sauvignon, and diverse styles of Chardonnay. A.R.P.

Gutedel, meaning 'good and noble' in German, is not the most obvious synonym for CHASSELAS but is still used in Germany, particularly in the Markgräflerland, southern BADEN, which—along with neighbouring areas of Alsace and Switzerland—is sometimes referred to as the Gutedel Triangle on account of this variety's ubiquity and continued popularity. The wines, generally juicy and straightforward, may have notes of almond and hay in the better examples, and particularly old vines in CALCAREOUS sites can evince both distinction

and MINERALITY. A dark-berried form, Roter Gutedel, is also known in Baden.

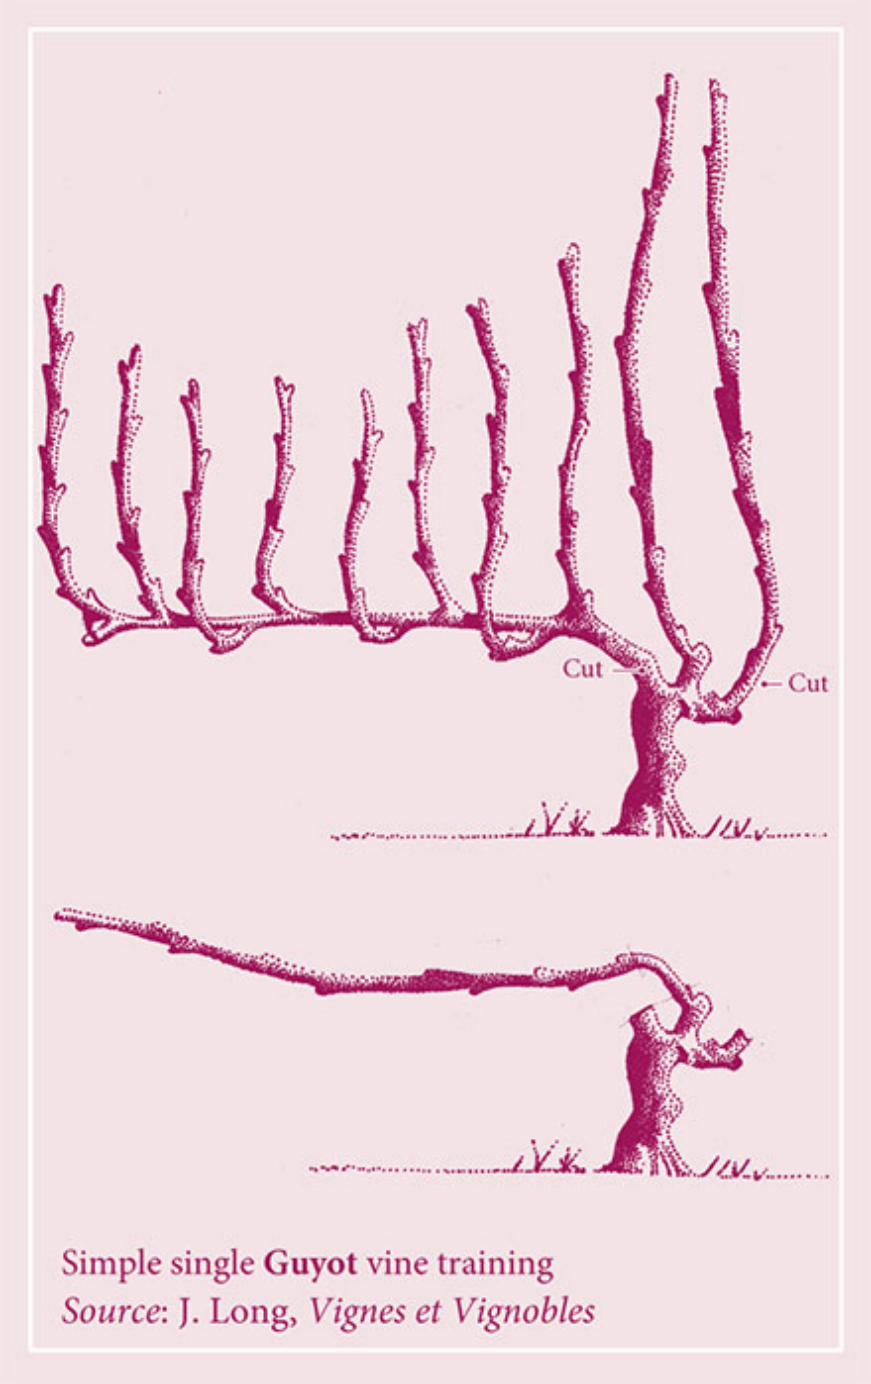
Gutsabfüllung. See ERZEUGERABFÜLLUNG.

guttation, botanical term applied to vines losing water through small pores at the leaf margin, due to root pressure. It can be seen early in the morning for vines in wet soil under cool conditions. See also BLEEDING.

Gutturnio, red wine from EMILIA-ROMAGNA in Italy, overwhelmingly produced as FRIZZANTE (8.5 million bottles in 2020) but potentially more interesting in its still form.

Guyot, Jules , respected 19th-century French scientist with a particular interest in viticulture and winemaking whose name lives on in the system of CANE PRUNING which had been in use in France for a long time but which he promulgated in the 1860s. His practical treatises on growing vines and making wine were translated into English in the second half of the 19th century and are enthusiastically followed by vignerons around the world.

The basic principle of Guyot pruning is to leave six- to ten-bud CANES and for each a single two-bud SPUR at the base; shoots from this spur form the cane the following year (see PRUNING). The Guyot simple form, also known as single Guyot, has one cane and one spur. Guyot double, or double Guyot, the most common vine-TRAINING SYSTEM in Bordeaux, has two canes and two spurs, and the canes are trained to each side. Sometimes the canes are arched, as in the Jura. Galet lists regional variations of the Guyot. See PRUNING for more details. R.E.S.



Simple single **Guyot** vine training

Galet, P., *General Viticulture* (2000).

gyropalette, or girasol, special metal crate holding many dozen inverted bottles of TRADITIONAL METHOD sparkling wine in a remote-controlled, movable frame. This is the mechanized form of RIDDLING

and was developed in CATALUÑA in the 1970s. They are now widely used in CHAMPAGNE, ITALY, and elsewhere. *Girasol* is Spanish for 'sunflower', which also turns during a 24-hour period.

For more details, see SPARKLING WINEMAKING.

H

HACCP. See QUALITY ASSURANCE.

hail, frozen raindrops or ice bodies built up by accretion, typically falling in thunderstorms. To the normal ill effects of heavy summer RAINFALL is added direct physical damage to the vines and fruit. Impact on the vines ranges from ripping and stripping of the leaves to bruising and breaking of the young stems—effects which can carry over to the following season. Damage to young bunches may destroy or at least reduce the crop, although compensatory growth of the remaining berries may minimize the effects on final YIELD. Hail damage while berries are ripening, on the other hand, is invariably more serious. Smashed berries are prone to ROT and ferment on the vine, rendering even undamaged parts of the bunches unusable. BURGUNDY is particularly and apparently increasingly prone to hail damage, as is Mendoza in ARGENTINA. Hail is said to cost French agriculture more than €500 million a year.

Hailstorms characteristically follow irregular but well-defined pathways through an area, sometimes devastating parts of a vineyard but leaving other parts untouched. Local TOPOGRAPHY may result in a tendency for the storms to follow preferred pathways, but largely their incidence and route is unpredictable. Various prevention techniques have been tried, including seeding the clouds with silver iodide or dry ice, from planes or cannon, and using hail cannon that generate shock waves intended to disrupt the formation of hail. Covering the vines with netting is another laborious and expensive option which reduces the impact of hailstones but may also reduce the amount of SUNLIGHT reaching the vines—desirable only in the hottest wine regions. The technologies can hardly be described as

proven, but they have found supporters among vine-growers understandably desperate to protect their hard-won crops. Insurance against hail is rarely cost-effective. J.E.H. & R.E.S.

hail disease. See WHITE ROT.

halbtrocken designates German wines that have 5–18 g/l of RESIDUAL SUGAR depending on the TOTAL ACIDITY. Levels above 12 g/l are permitted—governed by the formula: maximum residual sugar equals total g/l of acidity plus 10—up to an absolute limit of 18. Halbtrocken wines falling within 12–18 g/l are almost entirely from acid-endowed RIESLING.

Among the top German producers in the 21st century there has been a tendency to bottle fewer wines that fit the criteria for halbtrocken, as well as labelling those that do as FEINHERB or without any reference to degree of SWEETNESS. In Austria, any wine is officially halbtrocken (and then labelled as such, albeit in tiny print) if it exceeds the maximum residual sugar set for TROCKEN (which varies with total acidity) but does not exceed 12 g/l. D.S.

haloanisoles, group of related compounds including chloroanisoles such as trichloroanisole (TCA) and 2,3,4,6-tetrachloroanisole (TECA) as well as bromoanisoles such as tribromoanisoles (TBA) responsible for the musty odour of CORK TAINT and some instances of winery contamination. TCA was the first identified and is the most prevalent contributor to the problem.

The formation of chloroanisoles in cork bark is not yet fully elucidated, but the first step occurs when chlorine reacts with phenol to produce compounds such as trichlorophenol (TCP). This may occur for several reasons, including formation during chlorine bleaching of cork bark (no longer used in the production of CORKS) or perhaps even direct biosynthesis in cork tissue before the bark has been removed from the tree. In addition, there is the direct application of

organochlorine biocides such as chlorophenol fungicides used on cork trees in the forests. Although these fungicides have been banned in Europe since 1995, chlorophenols are very stable and still present in groundwater.

If this first step remains unclear, the final step is well understood: the chlorophenols are degraded by fungi in the presence of moisture, a reaction catalyzed by the enzyme methylase, yielding the haloanisoles.

Research has not yet provided a definitive understanding of the important origins of chlorophenols in cork bark, so the presence of chloroanisoles remains a problem in cork production. In addition, similar precursor phenols are present in all wood-related material found in a typical winery, including corks, BARRELS, wooden pallets, structural wood, and wood-treatment products.

See TCA, TBA, and TECA. J.E.H. & A.L.W.

Hammurabi (end of 18th century BCE), king of BABYLONIA, responsible for uniting MESOPOTAMIA with its capital Babylon. His law code survives on baked clay tablets and contains the earliest references to wine shops and wine sellers.

Hanepoot, traditional Afrikaans name for South Africa's most planted Muscat vine variety, MUSCAT OF ALEXANDRIA.

hangover, one of wine's least welcome effects, normally following some DRUNKENNESS or certainly excessive consumption. Drinking wine with or after food and drinking at least as much WATER as wine can lessen the likelihood of a hangover. Homeopathic prophylactics include milk thistle extract (silymarin) and nux vomica. There is no evidence that wine hangovers are different from those caused by any other form of ALCOHOL, although inexpensive wine, non-organic wine, wine consumed with grain-based alcholic drinks, and bottle-aged PORT

have all been accused of increasing the risk of hangover. The only indisputably effective control is moderation.

hang time, American expression that has come to be associated with the controversial practice of postponing the harvest beyond traditional ripeness. This can result in partly shrivelled and dehydrated berries that yield overripe flavours and such high ALCOHOLIC STRENGTH that MUSTS may need dilution with water. Proponents of long hang time argue that wines made from such grapes have better aroma and flavour and softer TANNINS. The practice appears to have become less popular in the second decade of the 21st century than it was in the last decade of the 20th. Very ripe, dehydrated grapes shrivel as a result of BERRY CELL DEATH and weigh less than those picked at conventional ripeness, generally resulting in lower payments for growers paid by weight. See also BERRY SHRIVEL and RIPENING. R.E.S.

Happy Canyon of Santa Barbara, warmest, easternmost AVA of SANTA BARBARA, south of the San Rafael Mountains and north-west of Lake Cachuma. A protected valley with clay, loam, and some sandy soils and dramatic DIURNAL TEMPERATURE RANGE, it is planted mainly to Bordeaux and Rhône varieties. The name comes from the region's popularity with moonshiners during PROHIBITION. M.D.K.

Haraszthy, Agoston (1812–69), early CALIFORNIA winegrower and promoter, frequently but wrongly identified as the 'father of California wine'. Born in Austro-Hungary, he went to the United States in 1842 and to California in 1849, where he engaged in multifarious activities, including politics, horticulture, and gold-refining. In 1856, he bought a SONOMA County vineyard and established the Buena Vista winery, still extant today. In 1861, as a member of the state commission on viticulture, he travelled to Europe and sent back many thousands of vine cuttings to California. His account of this trip and of

his work as a winegrower in California—*Grape Culture, Wines, and Wine-Making* (1862)—first brought California as a wine state to the attention of the nation and is Haraszthy's main claim to importance in the history of wine in America.

After losing control of the Buena Vista winery he migrated to Nicaragua, where he died in mysterious circumstances. In the years after his death it came to be believed that Haraszthy was the first to show the possibilities of winegrowing in California, the first to introduce superior grape varieties into the state, and in particular the first to introduce the ZINFANDEL vine. None of these is true, but the story has become legendary and difficult to dislodge. T.P.

McGinty, B., *Strong Wine: the Life and Legend of Agoston Haraszthy* (1998).

Pinney, T., *A History of Wine in America* (1989).

hard, TASTING TERM applied to wine that is high in astringent TANNINS and apparently lacking in FRUIT. See TEXTURE.

Harlan, name synonymous with quality, ambition, and the long term in the NAPA Valley. H. William (Bill) Harlan scouted for land there from the early 1970s, put Meadowood country club and resort on the wine map as the site of the famous wine AUCTION from 1981, founded Merryvale Vineyards soon after, and then acquired land on the west side of the valley that would in 1987 produce the first vintage of the meticulously managed Harlan Estate. The first vintage to be released commercially was 1990, in 1996, when Merryvale was sold and BOND, a group of single-vineyard wines from around the valley, was founded. Since then Harlan Estate, usually 75% Cabernet Sauvignon, has been established as a peer, certainly in terms of PRICE, of Bordeaux's FIRST GROWTHS. Next up was a decidedly upmarket members' club Napa Valley Reserve with its own winery next to Meadowood and the acquisition of the sprawling site for Promontory, also in the foothills of the Mayacamas Mountains, managed by Bill's

son Will, who took over as managing director of Harlan Estate, BOND, and The Mascot, Harlan's SECOND WINE, in 2021.

harmony, TASTING TERM for a component of wine QUALITY related to BALANCE, but encompassing FLAVOUR as well as structure. A wine is harmonious if all its aromatic and structural elements are in proportion, with no individual element being too prominent, and if they complement each other to form a coherent whole. For example, a wine with herbaceous, barely ripe aromas but, in contrast, full BODY and low ACID on the palate might be said to lack harmony. A.H.

Harriague, name for TANNAT in Uruguay, inspired by a Basque viticultural pioneer there.

Hárslevelű, white grape variety, whose name means 'linden leaf', most widely grown in the Tokaj region of Hungary where it produces elegant, spicy, aromatic dry white wines with good ageing potential. It also brings perfume to FURMINT, the variety that has been shown by DNA PROFILING to be its parent and with which it is often blended in the famous dessert wine TOKAJI. It can also make very good sparkling wine.

Hárslevelű is widely planted elsewhere in Hungary, to a national total of 1,445 ha/3,571 acres in 2021, and produces a varied range of VARIETAL wines. Good Hárslevelű is typically full-bodied yet fresh, with a honey-sweet character when very ripe. In Somló, it produces a leaner and less aromatic wine. The wines labelled Debrő Hárslevelű, an appellation in the Eger region, are usually bottled with some RESIDUAL SUGAR. Dry and sweet wines are produced around Villány-Siklós.

The variety is also grown over the border from Hungary's Tokaj region in SLOVAKIA, in Austria's Burgenland, and in South Africa.

harvest, the process of picking ripe grapes from the vine and transferring them to the winery (or field pressing station), as well as its occasionally festive, if frenetic, duration.

This transition period in the winemaking cycle from vineyard to cellar is also known as VINTAGE or crush in much of the NEW WORLD, RÉCOLTE or *vendange* in France, *vendemmia* in Italy, *Ernte* in Germany, COSECHA in Spain, *vindima* in the DOURO, and *colheita* in the rest of Portugal.

Timing

A critical aspect of harvest is its timing, choosing a point during the grape RIPENING process when the balance between its natural accumulation of SUGARS and its decreasing amount of natural plant ACIDS is optimal (see SAMPLING). In all but the rare ideal vintages, it is a compromise involving multiple factors: target alcohol level, ideal flavour/aroma profiles, tannin profile (for red wines), acidity, PH, disease levels, health of the vines, and the weather forecast. However, logistical considerations to do with the harvesting operation, or the capacity to receive and process grapes, may constrain these decisions.

Typically this is a frenzied period, especially in hotter climates where warm, dry weather can rapidly accelerate ripening, causing different varieties to ripen at the same time. In cooler climates, an orderly harvest can be disrupted by humid and wet weather and possible ROT, by heavy RAINFALL making vineyard access difficult, by HAIL damage, or even by FROST. ACIDIFICATION and ENRICHMENT are respectively the most common rescue operations in the case of grapes picked slightly after or before ideal maturity if they are permitted by local wine regulations. MICRO-OXYGENATION may also help reduce the HERBACEOUSNESS resulting from slightly unripe fruit.

Timing of the harvest is additionally complicated by the fact that the fruit in different parts of a single vineyard may vary in ripeness, and the picking may need to be done in several stages (see PRECISION VITICULTURE).

Although the timing of harvest depends on fruit RIPENESS, it also depends on the region, the grape variety, and the type of wine required (Pinot Noir grapes destined for sparkling white wine are invariably picked much earlier than they would be for a still red wine, for example). Harvest can theoretically take place somewhere in the world in every month of the year but typically takes place in autumn (see VINE GROWTH CYCLE): September and October in the northern hemisphere and March and April in the southern hemisphere. In very

hot climates, harvest may start earlier in the summer, while at the coolest limits of vine cultivation grapes may be picked when all the leaves have fallen from the vine and there is snow on the ground. Some German EISWEIN is not picked until the January following the official year of harvest (which it must by law carry on the label, no matter when it was picked).

The effects of CLIMATE CHANGE are increasingly seen in earlier harvest dates and HARVEST COMPRESSION. In Australia, for example, picking in the HUNTER VALLEY can start in December and in 2020 the Champagne harvest began in mid August. Most wine regions around the world are on average harvesting around two to three weeks earlier than they were 30 years ago.

Manual harvesting

The traditional method of harvesting, by hand, consists of cutting the STEM of individual bunches and putting the bunches into a suitable container. This method, as opposed to MECHANICAL HARVESTING, can be employed regardless of terrain, row spacing (see VINE DENSITY), and precise vine-TRAINING SYSTEM. It also allows pickers to select individual bunches according to their ripeness and to eliminate unhealthy fruit affected by ROT or DISEASE. Very occasionally pickers may be instructed to leave unripe fruit on the vine, although this is not always easy to determine by the time of harvest.

Occasionally individual berries are harvested, in the case of bunches affected by BOTRYTIS, an operation that is possible only with a very high LABOUR input. This is most famously practised at Ch d'YQUEM and other properties in Sauternes as well as in other vineyards specializing in botrytized sweet wines in SOUTH WEST FRANCE, Austria, Germany (see AUSLESE, BEERENAUSLESE, and TROCKENBEERENAUSLESE), and Hungary, but the technique may also be employed in the production of (necessarily expensive) dry wines when the vineyard has been attacked by less noble rot.

The cost of manual harvesting increases dramatically when yields are low, for particularly widely spaced vines, or on particularly steep vineyards as in the MOSEL.

The efficiency of hand-picking depends on vineyard conditions. If the fruit is at a convenient height and the crop heavy, an experienced picker can harvest up to 2 tonnes/4,400 lbs a day. Output is reduced by worker fatigue or when the fruit is at a less convenient height—close to the ground as in traditional Bordeaux vineyards, for example, or trained on the overhead TRELLIS SYSTEMS of southern Italy, northern Portugal, Argentina, and Chile. Light crops are also particularly expensive to pick by hand, where bunches are small because of the grape variety (GEWÜRZTRAMINER, for example) or because of poor fruit

set (see COULURE). In such circumstances, even an experienced picker may have less than 500 kg/1,100 lb to show for a day's work.

Manual harvesting requires little equipment. The stems are cut by small secateurs or hooked-tip knives. The fruit is put into a small container holding perhaps 5 or 10 kg of fruit. This was traditionally (and still is in parts of Europe) a wooden trug, cane basket, or leather hod strapped on to the pickers' backs, but nowadays it is most likely to be an unromantic but lighter and easier-to-clean plastic container which may be emptied at intervals into a larger container for transport to the winery, or field pressing station, typically by tractor. These larger containers, often called 'gondolas' in the New World and holding between 500 kg and 2 tonnes, are passed down the row before being towed to the winery. In many vineyards, the fruit is simply emptied into the back of a trailer, although the shallower the depth of fruit, the less damage it will suffer, and so containers full of grapes are increasingly stacked on trailers for transport to the grape reception area.

The harvest workforce varies from region to region. In much of Europe, picking teams include both experienced locals and casual workers, often students and itinerant workers, even members of the family. Iberia traditionally supplied picking teams that would systematically work their way northwards through Europe from region to region as they successively reached ripeness. Similarly, Australian vineyards of the 1950s and 1960s were traditionally picked by the large numbers of itinerants who moved between the sugar-cane fields of northern Australia and the vineyards of the south. But increased mechanization in the sugar-cane industry has necessitated increased mechanization of the Australian wine industry. In the western United States, the typical grape-picker is Mexican. Wine farms in South Africa enjoy access to relatively inexpensive labour, although since 1994 regulatory protection for rural employees has been strengthened. When in the late 1980s the Iron Curtain was torn down and EU membership raised wages in Spain and Portugal, eastern Europe became an important source of itinerant labour for vineyard owners in northern Europe.

However, finding and employing seasonal workers has become more difficult, due partly to increasing prosperity in these countries and partly to bureaucracy and restrictions on freedom of movement; in Burgundy, for example, some producers are following the example of their counterparts in the New World and turning to companies set up to manage and hire out harvest crews. While this is more expensive, it means a domaine can employ pickers on the days they are needed rather than right through harvest.

Providing this annual influx of workers with accommodation, sustenance, and, often, transport is an increasingly onerous task each harvest. It is said that in many wine regions mechanical harvesting is the direct result of protest by the spouses and children of vineyard owners, to whom much of this annual workload has traditionally fallen.

harvest compression is a feature of many vineyard regions around the world, especially with the pronounced climate warming of the last three decades (see CLIMATE CHANGE). In warm to hot regions in particular, HARVEST starts earlier and is over more quickly. This is a consequence of more varieties having more similar maturity dates, making the task of harvest scheduling more difficult. These problems are exacerbated in the winery, with more fruit being processed in shorter periods, creating pressure on the allocation of appropriate FERMENTATION VESSELS. Detailed phenology studies in Australia have shown that advancement in maturity is related more to earlier VERAISON than to accelerated ripening. R.E.S.

harvest traditions celebrate the culmination of a year's hard work in the vineyard and, in areas which have not yet succumbed to MECHANIZATION, encourage the pickers in their back-breaking task.

France

Harvest traditions are at their strongest in France. The church plays a role in many European villages, where a symbolic bunch of grapes is blessed before the harvest and a thanksgiving service held at the end (see also RELIGION). (New World producers such as Robert MONDAVI of California have emulated this tradition.)

Vineyard owners and other members of their families try to be present for the harvest even if they usually work in a distant city. At the end of the harvest a certain amount of horseplay almost inevitably accompanies the picking of the last rows, and one or two pickers end up being thrown into the sticky mass of grapes (a tradition endangered by the increasing use of shallow plastic containers to transport grapes to the cellar).

Traditionally the tractor pulling the final load is decorated with flowers before it drives, horn blaring, to the cellar. On some estates the pickers still offer a bouquet of flowers to the owner and speeches are made. Large or small, almost all estates celebrate the end of harvest with a party, and some regions have their own name for this: *la PAULÉE* in BURGUNDY, *la gerbebaude* in BORDEAUX, and *le cochelet* in CHAMPAGNE.

Most harvest traditions are gastronomic, however, and the major events in a picker's day are the three meals which punctuate it (or four if the *casse-croute*, a second breakfast normally taken in the vines, is counted). In France, the kitchens during the harvest are usually run by women who are part of a family team, helped by other local women who may work in the vines during the rest of the year. For 11 months they cook only for their families and friends, but for one month they must turn themselves into restaurateurs of a special kind. Working in often rudimentary kitchens, they must feed demanding pickers both well and economically. Soups, rabbit dishes, and dishes such as *pot-au-feu*, *coq au vin*, and *blanquettes* are often requested by pickers nostalgic for an era when long, slow cooking was the norm. A harvest would not be a harvest in Burgundy without a *bœuf bourguignon*, for example, and in Bordeaux the bonfires of

sarments, or vine shoots, on which are grilled steaks and sausages may be kept blazing to form the focus of informal dancing and singing after dinner.

The harvest cook's work is regularly interrupted to administer first aid, and when the cook's long day ends, she (and it is still usually she) is likely to be kept awake by pickers at play. Small wonder that there is something of a revolt among the younger generation of vine-growers' spouses, who may anyway have full-time jobs elsewhere. Caterers are increasingly used, and high unemployment has in some cases substituted, for students in search of a good time, local people who would rather increase their earnings by forgoing lunch. Bureaucratic regulations are creating increasingly onerous paperwork; stricter standards may soon be enforced in respect of the lodgings provided for pickers. These developments are contributing substantially to the substitution of MECHANICAL HARVESTERS for human pickers and, therefore, to the death of harvest traditions.

The menus for each day, handwritten in notebooks every year, enlivened by anecdotal remarks, may, together with the photograph albums kept on many estates, eventually be the only record of harvest traditions. R.H.

Rest of Europe

Harvest traditions are most likely to survive where vineyards are picked by approximately the same people each year, which is why few survive in Italy and Germany, where grapes are increasingly picked by immigrants with no tradition of grape-picking in their families. As mechanization invades a wine region, so harvest traditions retreat, presumably until revived as a public-relations exercise. This means that harvest traditions are more likely to survive where LABOUR costs are relatively low.

A prime example of this has been the DOURO Valley, where PORT is made, although even here rural labour shortages are having an effect. Even in the early 21st century, however, it was still just possible to associate a genuine sense of folk tradition and celebration with the harvest, as some local pickers invade the QUINTAS at which they and their families have traditionally worked every autumn for decades. The increasingly depopulated TRÁS-OS-MONTES region has supplied many of the teams, or *rogas*, of pickers who brought noise, chatter, and traffic to a region marked by its silence the rest of the year.

At a few properties in the Douro, pickers' feet were still expected to provide a more bucolic, gentler, and more effective alternative to the mechanical CRUSHER, or robotic lagar (see FOOT TREADING). Members of the *roga*, or sometimes only its male members, are expected not only to pick the grapes but to make the wine as well. Donning shorts, and with their arms around each others' shoulders, they march methodically backwards and forwards across the granite LAGARES, often thigh-high in sticky purple grapes, to a chant or beat of a drum. Once a floating CAP of skins has visibly been separated from the juice beneath, *liberdade* (liberty) is declared and the march evolves into dancing, traditionally to the sound of an accordion but nowadays, more often than not, to recorded music from a stereo system. Traditionally the leader of the *roga* would present the owner

of the farm or winery, the *patrão*, with a decorated vine branch at a final celebratory vintage feast.

New World

Such traditions as have evolved around the harvest, or crush, in the New World tend to be the direct result of having large numbers of people—often from very different backgrounds, doing work unfamiliar to many of them—come together in the open air. The weather conditions, especially the temperature and sunshine, have greatest effect on worker comfort and, thereby, on the development of traditions. In many parts of the New World, harvest can be a time of heavy physical work for moderately low pay under trying conditions. Where the weather is hot, the harvest can start very early in the morning, and meal breaks are short as there is often little opportunity to relax in a hot, dusty, vineyard with little available shade.

Many of the social aspects of harvest are changing with use of the mechanical harvester. One harvester and operator can pick as much in three shifts during the 24 hours as could hundreds of human pickers during the day.

Hanson, R., *Recipes from the French Wine Harvest* (1995).

Hastings River, a warm and humid wine region on the north coast of NEW SOUTH WALES about 400 km/250 miles up the coast from Sydney, has a history of viticulture dating back to 1837, though production restarted only in 1980 after a significant decline. With average annual rainfall of 944 mm/37 in, disease pressure is significant, making mildew-resistant hybrid CHAMBOURCIN an important red variety. In the driest years, Chardonnay, Sémillon, Verdelho, and Cabernet–Merlot blends can be successful. A.R.P.

Haut, French for 'high'. See the rest of the name if there is no relevant entry under H.

Haut-Brion, Château, the most famous property in the GRAVES district in BORDEAUX producing both red and white wines; today, after

years of fierce competition, it is run in tandem with Ch La MISSION HAUT-BRION. Manuscripts from the beginning of the 15th century mention extensive vineyards around the LIEU-DIT Aubrion. In 1521 Ch Haut-Brion became the first Bordeaux wine to be named after its TERROIR rather than its owner or parish, and thus it could claim to be the world's first luxury wine BRAND. Jean de Pontac was one of the most important owners of Haut-Brion: as early as 1525, he defined the vineyard as it is today, and he built the château in 1549. His great-nephew Arnaud III de Pontac, Président of the Bordeaux Parliament, invented the 'New French Claret Haut-Brion', a new type of red wine benefiting from ageing, which laid the foundations of great bordeaux. In 1660, the cellar records of the British King Charles II mention that no fewer than 169 bottles of the 'wine of Hobriono' (*sic*) were served at the royal table. The wine was praised by Samuel Pepys, the London diarist, who recorded on 10 April 1663 that he 'drank a sort of French wine called Ho Bryan that hath a good and most particular taste I never met with'. In 1666, the son of Arnaud III de Pontac, François-Auguste, opened a tavern in London called Pontack's Head which soon became 'the most fashionable place in all of London' where luminaries such as Locke, Swift, Defoe, Dryden, and the members of the Royal Society came to dine or buy Haut-Brion.

Thomas JEFFERSON also praised it on his visit to Bordeaux in 1787 as American minister in France. In 1801, Charles-Maurice de Talleyrand Périgord, Minister of Foreign Affairs to Emperor Napoleon I, bought Ch Haut-Brion and used its wines and the talent of the famous chef Antonin Carême, 'king of chefs and chef of kings', to diplomatic ends. In 1855, on the occasion of the Exposition Universelle held in Paris, Ch Haut-Brion was listed as one of four first growths in the famous CLASSIFICATION of Bordeaux wines.

After a further series of not very successful owners in a very difficult time, the château was bought in 1935 by Clarence Dillon, an American banker. Today the property is run by his grandson Prince Robert of Luxembourg, President and CEO since 2008, with his mother, the Duchesse de Mouchy. In 2004, Jean-Philippe Delmas

became deputy managing director when his innovative father, Jean-Bernard, retired.

The 49.9 ha/123.3 acres of vineyard are planted with just 42% Cabernet Sauvignon, 46% Merlot, 11% Cabernet Franc, and 1% Petit Verdot. The SECOND WINE was renamed Le Clarence de Haut-Brion (from Ch Bahans-Haut-Brion) in 2007 in honour of Clarence Dillon. About 500 cases of the property's rare dry white Ch Haut-Brion Blanc are produced from a 2.9 ha vineyard planted with 52% Sémillon and 48% Sauvignon Blanc. About 1,000 cases of a second white wine, La Clarté de Haut-Brion, common to both Chx Haut-Brion and La Mission Haut-Brion, are also produced.

In early summer 2011 family-owned Domaine Clarence Dillon purchased Ch Tertre Daugay in St-Émilion and renamed it Ch Quintus. Two years later the neighbouring property, Ch L'Arrosée, was also acquired with the intention of restoring the united properties to their former glory. In 2021 Ch Grand-Pontet was added to Ch Quintus, and a visitor centre and wine shop were opened at Ch Haut-Brion in Bordeaux.

Hautes-Alpes, a rugged region and IGP extending 130 ha/321 acres in the southern foothills of the French Alps. The high ELEVATION (600–1,300 m/2,000–4,265 ft) makes it cooler than neighbouring PROVENCE yet drier than SAVOIE to its other side. While the IGP allows a great number of grape varieties, it is perhaps best known as the homeland of Mollard, a grape making light, fresh reds that was saved from extinction by Marc Allemand, who has been making a varietal example since 1984.

Hautes-Côtes de Beaune and Hautes-Côtes de Nuits, sometimes known collectively as the Hautes-Côtes, vineyards dispersed in the hills above the escarpment of the Côte d'Or in Burgundy. Most of the production is red wine from Pinot Noir, with some white wine made from Chardonnay or occasionally Pinot Blanc or Pinot Gris, but at ELEVATIONS reaching 500 m/1,640 ft the grapes

do not ripen easily. This is also suitable ground for BOURGOGNE ALIGOTÉ, especially as the blackcurrant bushes needed for the production of CASSIS can often be seen growing alongside.

Forty-seven communes are included in the Hautes-Côtes appellations. The most prolific villages include Meloisey, Nantoux, and Échevronne above the Côte de Beaune; and Villars-Fontaine, Magny-lès-Villars, and Marey-lès-Fussey above the Côte de Nuits. There is a good CO-OPERATIVE for the Hautes-Côtes wines located just outside Beaune. Many leading growers in the Côte de Nuits such as the Gros family now also offer affordable wines from the Hautes-Côtes.

See also CÔTE D'OR and map under BURGUNDY. J.T.C.M.

Haut-Médoc, the higher, southern part of the Médoc district of Bordeaux which includes the world-famous communes of MARGAUX, PAUILLAC, ST-ESTÈPHE, and ST-JULIEN, as well as the less glamorous LISTRAC and MOULIS. The Haut-Médoc AOC applies only to red wines made within its 4,682 ha/11,569 acres. For more details, see MÉDOC.

Haut-Pays, French term meaning 'high country' which was used in the Middle Ages to describe the area upstream of BORDEAUX which produced wine (and had done so for longer than Bordeaux, since at the beginning of the Christian era winemaking spread north-west from Narbonne towards the Atlantic). This included GAILLAC, BERGERAC, Quercy (modern CAHORS), and Nérac (BUZET). The more dependable climate here often produced wines stronger than the light, thin wines then made in the Bordeaux region itself and were seen as a serious commercial threat. The port of Bordeaux penalized them by taxing them heavily and barring them from the port until the region had exported its own wines. See also HUNDRED YEARS WAR.

Haut-Poitou, AOC zone almost due south of SAUMUR in which 90 ha/222 acres of vines on calcareous clay produce crisp red, white,

and rosé wines. Whites are mainly Sauvignon Blanc, although up to 40% FIÉ (Sauvignon Gris) is permitted. Reds and rosés are mainly Cabernet Franc with various Gamays and Pinot Noir allowed to make up the rest; Merlot is allowed in red wines. The CO-OPERATIVE at Neuville dominates production.

Hawaii, chain of islands in the Pacific and one of the 50 United States. Owing to the humidity, which encourages FUNGAL DISEASES, the state produces mainly FRUIT WINES, including a pineapple sparkling wine. However, fast-draining VOLCANIC soils and temperate higher ELEVATIONS allow vine-growers some success with CROSSES such as SYMPHONY, as well as VITIS VINIFERA such as Grenache, Syrah, and Malbec. In 2021 the state was awarded its first AVA, Ulupalakua, 29 ha/70 acres ranging from 475 m/1,560 ft to 564 m/1,850 ft in ELEVATION on the south-west slopes of Mount Haleakala on Maui.

Hawke's Bay, first planted by Catholic missionaries in 1851, is the second-largest wine region in NEW ZEALAND, with 4,643 ha/11,473 acres under vine in 2021.

Situated on the east coast of the North Island, it vies with both Marlborough and Nelson each year in the battle for the country's highest sunshine hours. With its temperate MARITIME CLIMATE, the region's growing season accumulates more degree days (see CLIMATE CLASSIFICATION) than any other main winegrowing region, which is why it is one of the few regions that hangs its hat on red Bordeaux blends as well as rich, textural expressions of Chardonnay.

Its complex soils can be simplified down to two main types: CLAYS and GRAVELS. From the 1980s, pockets of less fertile and more free-draining soils across the region's river plains were sought out for viticulture. More recently the cooler inland LIMESTONE-based hills of Central Hawke's Bay have shown potential for Sauvignon Blanc, Pinot Noir, and Pinot Gris.

The subregions of Hawke's Bay can largely be grouped by soil type and MESOCLIMATE. Coastal areas such as Bay View in the northern Esk Valley area and Te Awanga to the south benefit from the cool maritime conditions allowing a long growing season for Chardonnay and Pinot Noir. The free-draining alluvial gravels and stony terraces across the region's four river valleys and plains accommodate the earliest viticultural areas of Meeanee and Taradale as well as premium areas such as Bridge Pa and the country's only trademarked subregion, the Gimblett Gravels. The latter is an 800-ha/1,977-acre area of gravel soils on an ancient riverbed comprising 90% red varieties—primarily Merlot with some Syrah and Cabernet Sauvignon. Its eponymous association of producers formed in 2001 and collaboratively promotes their wines.

While Cabernet Sauvignon has been an important part of Hawke's Bay's history, plantings have declined in recent times to just under 200 ha, from a peak of over 500 ha 20 years ago. It can be challenging to ripen but was lauded as a star performer in the warmer years of 2013, 2014, 2019, and 2020.

Chardonnay and Merlot are the most planted Hawke's Bay varieties with 1,049 ha and 981 ha respectively, while Sauvignon Blanc comes close behind at 886 ha. Historically the top Hawke's Bay reds were Bordeaux-style blends; however, Syrah is now challenging their exalted status. There is arguably still no consistent style, with producers pursuing both perfumed northern RHÔNE-esque examples with little oak influence as well as richer, riper iterations closer to Australian Shiraz. Hawke's Bay Chardonnay tends towards ripe stone fruit and sometimes tropical nuances thanks to the plenitude of the Mendoza CLONE, while Sauvignon Blanc is a softer, fleshier wine than its Marlborough counterpart. It often has a nectarine or stone-fruit character, a useful indicator of regional identity. S.P.-T.

head, or crown, of a vine is the top of the TRUNK where CORDONS branch, or where some SPURS are retained to produce new CANES in cane pruning.

head space, that space in a container holding a liquid that is not taken up by that liquid. In wine containers it is often called the ULLAGE, or ullage space. In large, modern wineries, the head space of stainless-steel tanks is often deliberately filled by an INERT GAS as a preservative measure. Similarly, many BOTTLING lines use inert gas to exclude oxygen from the head space.

head training, a form of VINE TRAINING whereby the trunk has a definite head, or roughly circular knob, consisting of old wood rather than arms of a CORDON. **Head-trained** vines may be subject to CANE PRUNING or SPUR PRUNING (see GOBELET). The head may be anywhere between 40 cm/1.25 ft and 1 m/3.3 ft from the ground. The GUYOT system is a common cane-pruned form of head training. R.E.S.

health, effects of wine consumption on. Until the 18th century, wine played a central role in medical practice, not least because it was safer to drink than most available water, as outlined in MEDICINE. But wine of course contains ALCOHOL, and it and its primary breakdown product ACETALDEHYDE are toxic to the body's tissues. Its contribution to damage to the liver, pancreas, and brain, and to accidents, is well known. Less well known is that the incidence of certain cancers, wasting of nerves and muscles, blood disorders, infections, psoriasis, raised blood pressure, strokes, and infertility increases with heavy consumption. Alcohol consumption during pregnancy can affect the developing foetus, stunting its growth and causing birth defects and behavioural and intellectual problems (termed 'foetal alcohol spectrum disorder'). This has resulted in a proliferation of health warning labels on wine bottles in many countries (see LABELLING).

Since the early 1990s, however, a substantial and increasing body of research has shown that modest consumers have lower mortality than heavy consumers or non-drinkers, suggesting that alcohol consumption (and perhaps especially wine consumption) can have a

net beneficial effect on health. The clinical, experimental, and medical evidence to date continues to be so convincing that the link between moderate consumption and reduced risk of heart disease is acknowledged by the World Health Organization in its commentaries on alcohol. Moderate consumption is very generally considered to be 20–30 g/0.7–1 oz alcohol per day for men and 10–20 g/0.35?0.7 oz alcohol per day for women.

Coronary heart disease

The most beneficial effect of wine is its contribution to reduced mortality from coronary heart disease, the western world's major killer. This develops when plaques of cholesterol build up in the arteries supplying the heart muscle. These furred-up arteries cannot supply the heart muscle with enough oxygen, resulting in the pain of angina. Heart attacks happen when blood clots block these narrowed arteries completely, cutting off the oxygen supply. Heavy drinkers develop increased cholesterol levels as well as raised blood pressure, weakened heart muscle, and a susceptibility to potentially fatal abnormal heart rhythms. Given this record, it was not just the temperance movement which believed that moderate consumption must surely be doing some harm. Yet there is now a mass of evidence that those who drink moderately are less likely to develop coronary heart disease and to die from it than either those who drink heavily or those who have never drunk alcohol. Furthermore, it is the alcohol in alcoholic drinks which has been identified as the single most important ingredient in prevention of coronary heart disease.

Alcohol, it seems, moderates the level of inflammatory blood chemicals called cytokines which adversely affect blood cholesterol and blood-clotting proteins. Blood carries LDL (low-density lipoprotein) cholesterol, which forms the plaques which block arteries, and HDL (high-density lipoprotein) cholesterol, which mops them up. Moderate alcohol consumption improves the balance between the harmful and beneficial forms of cholesterol. Blood clots are formed by platelets—small shards of old cells which float harmlessly in the blood until they are chemically triggered to stick together in a tangle of threads of fibrin protein. Alcohol has two anticoagulant effects which make blood less likely to clot in the wrong place. It makes the platelets slightly less sticky, and it reduces the level of fibrin available to form a clot. An added benefit for moderate consumers, and particularly moderate wine consumers, is increased vascular elasticity, enabling a more rapid flow of blood through the arteries and lowering risk of heart and blood pressure problems.

The anticoagulant effect of alcohol lasts less than 24 hours. This may explain why the risk of a heart attack is reduced during the day following a couple of drinks. The traditional wine drinker's glass or two with the evening meal provides a steady, safe level of alcohol. In contrast, the beer or spirit drinker's Saturday night binge leaves him or her temporarily over-anticoagulated (and at increased risk of a stroke due to bleeding) until he or she has metabolized the alcohol, then at increased risk of heart attack until the next night out. Binge drinking of wine carries the same health risk as any other alcoholic drink taken to excess.

Alcohol is not the only compound of cardiovascular significance in wine. Red wine, much more than white, is rich in PHENOLICS, which have antioxidant, anti-blood-clotting, and anti-inflammatory properties. There are hundreds of phenolic compounds in wine, but attention has focused on RESVERATROL. Like alcohol, resveratrol modulates the breakdown of LDL cholesterol in the laboratory and so may help to reduce the formation of plaques in the body. Heart attacks are not the only problem caused by furred-up arteries. They cause peripheral vascular disease, which leads to angina-type pain in the leg muscles when their activity exceeds the ability of the arteries to the legs to provide oxygen. Most strokes are caused by blockages of blood vessels, so it is not surprising that moderate alcohol consumption reduces the risk of strokes. However, the anticoagulant effects of alcohol, which are beneficial if the stroke is caused by a blood clot, are likely to make the stroke worse if it is due to bleeding into the brain.

A growing number of studies conclude that the way alcohol is consumed—the pattern of drinking—is key to potential health benefits. Studies show that regular moderate consumption, predominantly with meals, significantly reduces the risk of a heart attack.

It is therefore likely that it is the combination of alcohol, its phenolic compounds, and the usual consumption pattern of wine (versus that of other alcoholic drinks) that makes wine the most

beneficial alcoholic beverage for cardiovascular health. These factors may explain the FRENCH PARADOX. See also FLAVONOLS.

Cancers

Awareness of the influence of lifestyle on cancer risks has stimulated research into the relationship between drinking and cancers. Alcohol consumption increases the risk of cancers of all parts of the digestive tract except the stomach. The link becomes progressively weaker from mouth to rectum. The risk is tripled for cancer of the mouth and throat, and doubled for cancer of the oesophagus. The mucosal surfaces of these organs come into direct contact with imbibed alcohol, and it has been suggested that the risk of developing these cancers is less if the alcohol is consumed with food.

Food and drink passes from the oesophagus to the stomach, and there is good news about alcohol and stomach cancer. Ulcer sufferers were traditionally advised to avoid alcohol lest it irritate the lining of the stomach. However, gastritis, peptic ulcers, and stomach cancer are now known to be strongly associated with infection by the bacterium *Helicobacter pylori*, and a short course of treatment designed to eradicate *H. pylori* is saving many former sufferers a lifetime of treatment and abstinence. Furthermore, studies have shown that moderate wine and beer drinkers are significantly less likely to be infected with *H. pylori* than non-drinkers, possibly due to the anti-microbial effects of alcohol. If moderate consumers are less likely to have *H. pylori* infection, they should have fewer ulcers, a deduction supported by evidence from the US. Recent studies suggest that regular moderate consumption may reduce the chances of infection with *H. pylori* more than occasional consumption of heavier amounts of alcohol. St Paul's advice to 'use a little wine for thy stomach's sake' proves to have been wise.

Drinking alcohol is associated with a modest increase of the risk of cancer of the bowel (colon and rectum). As with cancers of the upper digestive tract, the risk is greater with high consumption of alcohol.

Studies of the incidence of breast cancer show that even the moderate consumption of alcohol is associated with an increase in risk. Four to five drinks per day increase the risk by 50% compared with only one drink per day.

Preliminary studies suggest that moderate alcohol consumption may offer some protection from cancer of the prostate and the kidney and non-Hodgkin's lymphoma, but more evidence is needed to confirm this.

Respiratory problems

SULFITES are produced naturally by FERMENTATION and so occur at low levels (10–50 mg/l) in all wines. Small amounts are also routinely added to most wines as a preservative. Asthmatics who are sensitive to sulfites may experience respiratory problems after drinking wine with concentrations of sulfur dioxide above 45 mg/l. So in most countries, wines containing more than 10 mg/l are labelled accordingly. BIOGENIC AMINES such as HISTAMINE are generally present in low concentrations in wine, but they can contribute to respiratory problems in histamine-allergic or sensitive individuals (see ALLERGIES AND INTOLERANCES), especially if they consume wine together with foods high in histamine such as some cheeses. Wine also contains salicylates that can trigger respiratory problems in salicylate-allergic individuals.

Headaches

Biogenic amines in wine, such as histamine and tyramine, can trigger migraines for some migraine sufferers. Red wine generally contains more biogenic amines that white. It has also been suggested that PHENOLIC compounds could be a trigger. In the test tube phenolics liberate serotonin (5-hydroxytryptamine) from cells; this is the chemical messenger that plays a part in the initiation of migraine.

Additionally, the alcohol in wine and its breakdown product, ACETALDEHYDE, act on the brain. The pain of headaches is referred via pain receptors to the surface of the head from deep structures such as the brain and its related tissues. The headache experienced after consuming alcohol is generally related to blood alcohol concentration (BAC). Alcohol and acetaldehyde readily diffuse from the blood into the fluids of the brain and spinal cord where they directly irritate the brain's cells and tissues, causing pain at the front surface of the head. The more wine consumed, the higher the BAC, the more the brain will be irritated, and the more severe the headache.

Dementia

The intoxified brain does not function well (whatever its owner may temporarily believe), and the deleterious effect on intellectual function of long-term assault with heavy alcohol is well known. It comes as a pleasant relief to find that moderate wine consumers have improved cognitive function compared with both heavy wine consumers and non-drinkers, and they are less likely to develop dementias such as Alzheimer's disease. Studies suggest that RESVERATROL may additionally be 'dementia-protective' by increasing the brain's blood flow as well as directly benefiting the cells and tissues of the brain.

Musculo-skeletal problems

Excessively heavy drinkers are prone to fracture their bones such as the hips and vertebrae; a consequence of the effects of too much alcohol on their bone density and structure in addition to an increased rate of falls. Alcohol has been shown to have directly damaging effects on cellular bone formation as well as indirectly affecting the pancreas and cytokine and endocrine systems, which also influence cellular bone formation. However, studies show an association between moderate consumption of alcohol, and in particular wine, and improvement in bone density. Men and post-menopausal women at risk of osteoporosis may find one or two glasses of wine a day beneficial rather than harmful.

Rheumatoid arthritis has been shown to be less common in those who take moderate alcohol in any form, potentially from alcohol's anti-inflammatory actions, although any improvement in sufferers' symptoms may be due to the pleasure of a glass of wine rather than its physiological effects.

Diabetes mellitus

Although diabetics are obliged to watch carefully what they eat and drink, alcohol taken with a meal does not substantially alter their blood sugar level and is therefore an appropriate element in a diabetic's diet. As the World Health Organization acknowledges, moderate consumers of alcohol, and particularly wine drinkers, have a significantly lower risk of developing Type-2 diabetes mellitus than heavy drinkers and non-drinkers. Type-2 diabetes is the form of diabetes which typically develops in middle age and is usually treatable with diet and tablets. Type-2 diabetes is due not so much to lack of insulin but to decreased response to it. Research shows that moderate drinkers are more sensitive to insulin than non-drinkers, probably because alcohol moderates the effect of the cytokines, which appear to contribute to the development of Type-2 diabetes.

Gastrointestinal problems

As already described, alcohol is associated with an increase in the incidence of all gastrointestinal cancers except those of the stomach. But wine is more active against the bacteria that cause travellers' diarrhoea than bismuth, another traditional and distinctly less palatable remedy. More encouraging news: moderate drinkers are at reduced risk of developing gallstones.

Sensible drinking

Health authorities in many countries have disseminated 'low risk' or 'sensible drinking levels'; these suggested maxima for personal consumption of alcohol are usually expressed in 'units', or STANDARD DRINKS, of alcohol, though there is wide variation between what constitutes a unit and how many of them may safely be consumed.

These limits are at best only a rough guide as individuals' reactions to alcohol must always be taken into consideration when assessing recommended consumption levels. Sex, age, build, genetic make-up, state of health, drinking with or without food, and drug intake all affect the way alcohol is metabolized. For instance, women, regardless of their weight or size, absorb relatively more alcohol glass for glass than men because of differences in levels of stomach enzymes, their lower body water content meaning that alcohol is more concentrated in their tissues. They also break down alcohol relatively more slowly than men because of differences in levels of liver enzymes and, if they are also taking the contraceptive pill and/or other breakdown competing medications, they eliminate alcohol more slowly. This may explain why women who drink in excess of the recommended daily units experience significantly greater risks of poor health outcomes than men who do likewise. Additionally, women's tissues are more susceptible to the damaging effects of alcohol. Conversely, it appears that the relationship between moderate consumption and better general health is stronger for women.

Aside from any specific health benefits, it emerges that self-reported health—a good predictor of all-cause mortality—is best for moderate consumers, and especially for moderate wine consumers. Indeed, in 2011 the US Center for Disease Control and Prevention proposed that moderate alcohol consumption was one of four healthy lifestyle behaviours related to a lower mortality risk, along with not smoking, eating a healthy diet, and physical activity. The mortality risk for those who also consumed alcohol was significantly lower than for those exhibiting only the three other behaviours. This observation

has subsequently been seen in many more countries. And there is a benefit that the studies of mortality cannot identify. A final word which won't appear in studies of mortality: the healthy can enjoy a drink, but for those whose lives are restricted by chronic disease a glass of wine may be one of the few pleasures left. That is a substantial health benefit. J.H.H. & C.S.S.

Heathcote, temperate Australian wine region in the Central Victoria Zone, cooled somewhat by the Mount Camel Range. This expanding region continues to diversify beyond the rich, earthy Shiraz upon which its reputation is built and which lured the likes of northern Rhône growers Alain Graillot and CHAPOUTIER. See VICTORIA.

heat stress affects vines when air temperatures are high. Very high daytime temperatures, of more than 40 °C/104 °F, cause the vine to 'shut down', or virtually cease PHOTOSYNTHESIS, as the ENZYMES responsible can no longer work. High temperatures also lead to WATER STRESS, especially when accompanied by bright sunshine, low humidity, and strong, dry winds. High temperatures cause fast RESPIRATION in vines, and this leads to, for example, low levels of MALIC ACID in mature fruit in hot regions. VARIETAL character and red COLOUR in grapes are also depressed by high temperatures. Australian research into the physiological impact of CLIMATE CHANGE has shown that, in a biochemical sense, sugar and ANTHOCYANIN accumulation in ripening berries is 'decoupled' by elevated temperatures. Some researchers claim that even more moderate daytime temperatures, in excess of only 25 °C, can depress colour formation and varietal flavour expression. R.E.S.

heat summation, a computation involving addition of mean temperatures over the growing season that forms part of many systems of CLIMATE CLASSIFICATION.

heat-treated vines, vines which have undergone heat treatment, or THERMOTHERAPY, to eliminate virus disease. Not to be confused with HOT-WATER TREATMENT.

heatwave, a period of two or more consecutive days of abnormally hot weather. Such conditions can have severe and adverse effects on grapevines and field workers. For the former, WATER STRESS dominates the plant's physiology: leaves wilt and STOMATA close as the vine is unable to take up sufficient water to meet TRANSPIRATION needs. Leaves and fruit experience high and damaging temperatures, especially if also exposed to direct SUNLIGHT. Where possible and permitted, the grower should provide adequate water by irrigation when a heatwave is imminent. See also SUNBURN. R.E.S.

hectare, common agricultural measurement of area equivalent to 100 ares, 10,000 sq m, or 2.47 acres.

hedging. See TRIMMING.

Heida, Swiss-German synonym for SAVAGNIN BLANC and a speciality of Visperterminen.

Helfensteiner is famous principally as a parent of DORNFELDER, the more successful German red-wine CROSS. The cross of FRÜHBURGUNDER × TROLLINGER has all but disappeared, even from WÜRTTEMBERG.

helicopters are more expensive than fixed-wing aircraft, which limits their application to viticulture. Their manœuvrability is a bonus, however. They are particularly useful for crop SPRAYING, and the turbulence created by the rotors helps the spray to penetrate, although there may be complications where individual landholdings are small. They are commonly used as airborne WIND MACHINES in New Zealand and very occasionally in Europe to stir up cold, dense air just above the vineyard surface with warmer air above to prevent spring FROST DAMAGE. It is not uncommon, for instance, to have helicopters on standby when the risk of frost is high. On occasion they have been used in an attempt to dry excess moisture off vine leaves and bunches immediately after heavy RAINFALL at HARVEST.

Henderson, Dr Alexander (1780–1863), Scotsman who qualified as a doctor and then moved to London and contributed to a wide range of publications, including the *Encyclopaedia Britannica*. After visiting the wine regions of France, Germany, and Italy, he wrote *The History of Ancient and Modern Wines*, which was published in 1824 (eight years after JULLIEN but nine years before REDDING). Some of the most useful aspects of his book reflect some aspects of his medical training: his observations on the art of wine TASTING.

Henkell Freixenet, world's biggest producer of sparkling wine since the German-based company Henkell acquired Freixenet, the

largest producer of TRADITIONAL METHOD sparkling wine and most significant exporter of CAVA from Spain. Freixenet has four production centres in San Sadurní d'Anoia—Freixenet SA, Segura Viudas SA, Castellblanch SA, and Torrelavit SA—as well as wineries in a number of DOP regions around Spain: Solar Viejo in Rioja, Morlanda in Priorat, Garbó in Montsant, Valdubón in Ribera del Duero, and Vionta in Rías Baixas. The combined production of Cava alone is now more than 140 million bottles per year. Best-known brands are the medium-dry Carta Nevada, launched in 1941, and Cordon Negro, a brut Cava in a distinctive, frosted black bottle. Freixenet's overseas interests include the Bordeaux NÉGOCIANT Yvon Mau, Henri Abelé in Champagne, the Wingara Wine Group and Katnook Estate in Australia, Gloria Ferrer in the CARNEROS district of California, Finca Doña Dolores, a sparkling wine estate in MEXICO, and Finca Ferrer in the Uco Valley of Mendoza in Argentina.

Henriques, Justino . See JUSTINO'S.

Henty, particularly cool Australian wine region in the Western Victoria Zone (see VICTORIA) with only about a dozen wineries. Pioneered as a source for sparkling wine grapes, it also produces fine TABLE WINES, especially Riesling from the likes of Crawford River.

herbaceous, TASTING TERM for the leafy or grassy aroma of crushed green leaves or freshly cut grass. Herbaceousness is generally considered a defect only when present in excess (although American tasters tend to be much less tolerant of it than, for example, the British). Wines made from the produce of SAUVIGNON BLANC, SÉMILLON, CABERNET SAUVIGNON, CABERNET FRANC, or MERLOT vines which failed to ripen fully are often excessively herbaceous. In general, the younger the vines, the greater their VIGOUR; and the earlier the grapes are picked, the more pronounced the herbaceousness. One cause of vegetative herbaceous aromas, particularly in wines of Sauvignon

Blanc and Cabernet Sauvignon, is the presence of METHOXYPYRAZINES originating from the grape; see also FLAVOUR COMPOUNDS. Another source of herbaceousness is six-carbon-atom leaf aldehydes.

Numerous investigations have shown that they, and the corresponding six-carbon-atom ALCOHOLS, derive from linoleic and linolenic, which are both fatty acids found in plant leaves and in the fruit. These decompose rapidly once the grape berry is crushed to yield hexanal, hexenal, and the related unsaturated alcohols, all six-carbon-atom compounds which can react further during FERMENTATION to produce a wide range of flavour compounds which are responsible for the aroma called herbaceous. Another reason a wine may taste herbaceous is from vine leaves inadvertently crushed with the grapes (see MOG). Early MECHANICAL HARVESTERS were particularly prone to do this, and the grapes were often so mangled that it was impossible to separate the wet leaves from them. Wines made from such a blend would also not surprisingly be high in leaf aldehydes and taste distinctly leafy or herbaceous, a problem accentuated when such mechanical harvesters are used on relatively young vineyards. More sophisticated machine harvesters have reduced leaf contamination considerably. P.J.W.

Herbemont, dark-skinned *Vitis aestivalis* × *Vitis cinerea* HYBRID grown in Brazil because of its resistance to FUNGAL DISEASES.

herbicides, AGROCHEMICALS applied to vineyards to control the growth of WEEDS. They may be either pre-emergent (or residual) or post-emergent (knockdown). The latter group comprises two types, contact and systemic herbicides. Residual herbicides act against germinating seedlings of the weeds, while post-emergent herbicides damage growing weeds. Typically, herbicides are applied only to the strip of ground directly under the vine, and weeds or COVER CROPS growing between the rows are controlled by TILLAGE or mowing. Herbicides are used even between rows in some vineyard regions,

though there can be risks of soil erosion or loss of water infiltration without the ORGANIC MATTER produced by plant growth in this zone.

In areas of winter rainfall, a contact or systemic spray is typically applied in late autumn to early winter, followed by a pre-emergent herbicide in the early spring. In regions with summer rainfall, or for irrigated areas, further contact or systemic sprays may be needed to control weeds that grow during the growing season. Most herbicides used in vineyards are low-hazard chemicals which present no danger to the operator (see AGROCHEMICALS). Many of the knockdown chemicals are inactivated by soil and so leave no soil RESIDUES.

Continued use of some herbicides leads to resistance by some weed species, so-called 'escape' weeds, which were previously suppressed by the herbicide. Although herbicides are relatively inexpensive, their use can cause high soil surface temperatures, preventing vine root growth near the surface, and loss of organic matter, so that there may be fewer EARTHWORMS and a loss of soil biodiversity. Some herbicides can even damage vines, either by wetting vine leaves inadvertently or when herbicides are leached into the rootzone, as can happen with young vines, sandy soils, and irrigation.

Concern about environmental pollution as a result of herbicide use has been growing, and vine-growers are more frequently substituting undervine ploughing for herbicide use—helped by the increasing sophistication of machinery for this type of tillage (see WEED CONTROL). Glyphosate, one of the most controversial herbicides, has been widely used in vineyards for many years but is being banned for some uses in some regions, for example inter-row use in France from 2022. Alternative control methods such as the use of electric currents, heat or hot foam are not yet proven. R.E.S.

heritage clones, term used particularly in parts of the New World with a relatively long history of vine-growing, such as California and Australia, for CUTTINGS from particularly historic vines. Examples in Australia are those from century-old UNGRAFTED VINES which may be

traced back to early imports into the colony from pre-PHYLLOXERA Europe. They are typically virus-free, having been exported from Europe before the introduction of the GRAFTING that is known to spread VIRUS DISEASE. In California such selections as Calera, Mt. Eden, Swan Pinot Noir, and Rudd and Wente Chardonnay CLONES are regarded as part of the state's viticultural heritage. The Abel Pinot Noir clone, said to have been imported illegally from DOMAINE DE LA ROMANÉE-CONTI in Burgundy, was planted in New Zealand in the 1970s, having been confiscated by Malcolm Abel, who happened to be both a customs officer and a winemaker. In Western Australia, the complex history of the revered Gingin Chardonnay clone, imported into Australia in 1957 from an old block at DAVIS, has only recently been elucidated thanks to the identification of clonal genetic markers.

Roach, M. J., et al., 'Origin of Chardonnay clones with historical significance in Australia and California', *Australian Journal of Grape and Wine Research*, 26/4 (2020).

heritage varieties. See INDIGENOUS VARIETIES.

Hermitage, the most famous northern RHÔNE appellation of all, producing extremely limited quantities of seriously long-lived reds and about one-third as much full-bodied dry white wine, which some believe is even more distinguished. Although the appellation is only the size of a large Bordeaux estate, Hermitage was one of France's most famous wines in the 18th and 19th centuries when the name alone was sufficient to justify prices higher than any wine other than a FIRST GROWTH bordeaux (which were sometimes strengthened by the addition of some Hermitage until the mid 19th century). The origin of the name 'Hermitage' is not so much shrouded in mystery as obscured by many conflicting legends, most of them concerning a hermit, *ermite* in French. Not least of the puzzles is how and when Ermitage acquired its H (dropped for some modern bottlings, notably by CHAPOUTIER), although there was no shortage of English-speaking

enthusiasts of the wine in the 18th century (including Thomas JEFFERSON). The first recorded mention of Hermitage in English was in Thomas Shadwell's 1680 play *The Woman-Captain*, 'Vin de Bon, Vin Celestine, and Hermitage, and all the Wines upon the fruitful Rhône'. These wines were also a great favourite with the Russian imperial court, but the economic upheavals of the first half of the 20th century affected Hermitage as much as any Rhône appellation. While the surrounding appellation CROZES-HERMITAGE has, like most of the Rhône Valley, seen considerable changes and extension over the last 50 years, Hermitage is a constant, give or take a winemaking tweak or two.

There are 138 ha/341 acres of vines on the hill of Hermitage, which almost pushes the town of Tain l'Hermitage below into the Rhône (see map under RHÔNE). The hill itself is built around a section of granite that was once shorn from the Massif Central by the Rhône, which now constitutes around 25% of its mass (its western flank) on to which other types of rock have fused and bonded during successive geological ages. This steep, south-facing slope exists thanks to a brief kink in the river when the Rhône flows briefly west to east. SOIL EROSION is a frequent problem here, and TERRACES are necessary in the steepest sections.

It is not surprising that such a celebrated vineyard has long been divided into various LIEUX-DITS, all with their own soil types and reputations for wine types. There are 20 officially recognized, the most famous of which are at the western granitic end of the hill. Les Bessards has a topsoil of sandy gravel on GRANITE and produces some of the most linear and intense wines. Le Méal produces richer wines from a soil with more LIMESTONE and bigger stones towards the top of the slope, where L'Hermite is crowned with a small stone chapel owned by Paul Jaboulet Aîné and has more SAND and fine LOESS over granite. CLAY and large stones predominate in the lower *lieux-dits* of Les Gréffieux and Les Dionnières. Other famous CLIMATS include Les Beaumes, Maison Blanche, Péléat, Les Murets, and Les Rocoules.

Although white and red grapes are planted all over the hill, some of the finest white Hermitage comes from higher vineyards.

Producers such as Jean-Louis Chave, the modest master of Hermitage, delight in blending the produce of holdings all over the hill to produce a complex, well-balanced expression of each vintage. Other producers such as Chapoutier and Ferraton prefer to bottle *lieux-dits* separately in order to illustrate their individual characters.

Unlike CÔTE RÔTIE upriver, red Hermitage is in practice made from pure Syrah (although the AOC regulations permit the addition of up to 15% white grapes). The wine is typically very deeply coloured, full-bodied, and concentrated, with a robust tannic structure. They usually start to show their best at around 20 years after vintage, and the best can age for 50 years or more.

White Hermitage, made from the MARSANNE and/or ROUSSANNE, is typically very full in BODY, and some of the more serious examples such as Chave's and Chapoutier L'Ermite or De l'Orée are among the world's longest-living dry white wines. Both red and white are typically matured in small and medium-sized oak barrels, usually with at least some new oak, and whites typically undergo MALOLACTIC CONVERSION.

In very ripe years, a few producers, notably Jean-Louis Chave, Paul Jaboulet Ainé, and Cave de Tain, still make tiny amounts of sweet white VIN DE PAILLE.

Hermitage has also been used as a synonym for SHIRAZ in Australia, where, for example, PENFOLDS Grange was originally called Penfolds Grange Hermitage. Hermitage was also the historic South African synonym for CINSAUT and is sometimes used in Switzerland for Marsanne. M.C.W.

Herodotus, prolific ancient Greek writer. The *Histories* of Herodotus (490/480–425 BCE), a native of Halicarnassus in Asia Minor, are not a history in the modern sense: the Greek word *historia* means 'an investigation'. Herodotus' main subject is the conflict between the Greeks and the Persians, and as such his book is

history; but it is also an investigation into the geography and anthropology of the east in Herodotus' own day, for as a young man he had travelled widely in the Greek-speaking world and in Egypt and Africa.

Forming part of Herodotus' descriptions of the customs of foreign nations are some intriguing observations about wine and DRUNKENNESS. He says that the Assyrians use palm-wood casks to transport wine, in boats built in Armenia, down the Euphrates (1. 194). In fact, Herodotus' curiosity concerns the construction of the boats: their cargo is mentioned in an aside and he expresses no surprise at the Assyrians' use of palm-wood BARRELS instead of AMPHORAE. He has just told us that the date palm supplies the people with food, honey, and wine and that Assyria is the world's largest producer of grain. The country does not grow vines (1. 193) but, as we know from other sources, Babylon imported wine from ARMENIA. This is probably what the casks contained: with date palms growing all around, transporting fermented date juice would not have made sense. See also MESOPOTAMIA.

All of Book 2 and the beginning of Book 3 are taken up with Herodotus' description of Egypt before he goes on to relate the Persian conquest of that country. He states that the Egyptians have no wine made of grapes but drink one made from barley (2. 81). This cannot be true, for we know that the vine was grown there in the 5th century BCE. Egyptian wine may have been too scarce, however, for Herodotus to have come across it on his travels. Egypt certainly imported wine from Greece and PHOENICIA, as Herodotus mentions (3. 8). He says that it came in earthenware jars and that, when the wine had been finished, the mayor of the town had to collect the empty jars and send them to Memphis, where they would be filled with water and sent to the Syrian desert. This system was devised by the Persians immediately after they had conquered Egypt so that they could reach Egypt through the Syrian desert without risking death through thirst.

When the Persians have subjugated the Egyptians, the king, the megalomaniac Cambyses, marches against the Ethiopians. The

expedition is a disaster, and the Ethiopians recognize the Persians' superiority in one respect only: they have wine, and that is the reason for their longevity (3. 23). But Cambyses is too fond of it, and when he is told so by a court official he wrongly deduces that the Persians regard this as the cause of his madness (3. 35), which, along with his cruelty, seems to have been congenital (3. 38). Wine can cause madness, though: Cleomenes, king of Sparta, went mad and died as a result of drinking wine unmixed with WATER, a nasty habit he had picked up from those notorious drunkards the Scythians (6. 85). Only a barbarian would drink unmixed wine. The Persians are all great drinkers of wine, and their frequent drunkenness explains one of the strangest of their customs. The sensible part is that any decision they take when they are drunk they reconsider when they are sober. But the opposite also holds: any decision taken when they are sober has to be reconsidered when they are drunk (1. 135). Far from regarding drunkenness as undesirable and immoderate behaviour, the Persians, if Herodotus is to be trusted, viewed it as an altered state of consciousness that is as valuable as sobriety.

Wilson, H., *Wine and Words in Classical Antiquity and the Middle Ages* (2003).

Heroldrebe is the marginal dark-berried GERMAN CROSS to which the prolific breeder August Herold put his name. This PORTUGIESER × LEMBERGER cross yields regularly and prolifically, about 140 hl/ha (8 tons/acre), but ripens so late that it is suitable only for Germany's warmer regions, particularly the Pfalz. Total plantings had fallen to 90 ha/222 acres by 2020. It spawned DORNFELDER.

Herzegovina. See BOSNIA AND HERZEGOVINA.

Hesiod (*c.*700 BCE), the earliest agricultural writer of ancient GREECE, wrote *Works and Days*. Most of this is homely advice for the farmer: 'Be sparing of the middle of the cask, but when you open it, and at the end drink all you want; it's not worth saving dregs.' He is the first writer to tell of simple rustic pleasures: 'I love a shady rock and Bibline wine [from BYBLOS], a cake of cheese, and goat's milk, and some meat of heifers pastured in the woods, uncalved, of first-born kids. Then I may sit in the shade and drink the shining wine, and eat my fill, and turn my face to meet the fresh west wind, and pour three times an offering from the spring which always flows, unmuddied, streaming down, and make my fourth LIBATION one of wine.' Hesiod gives the time for the grape HARVEST as 'when Orion and the dog star [Sirius] move into the mid sky'. H.H.A.

Hessische Bergstrasse. The northern vineyards on the western slopes of Germany's Odenwald constitute Germany's smallest official wine region, comprising 463 ha/1,100 acres. As of 2019, 40% was planted with RIESLING and can yield impressive dry wines. The largest and most prestigious estate is the Hessische Staatsweingüter (known nowadays for their fabled headquarters as KLOSTER EBERBACH) while a majority of the region's growers deliver their crops to the CO-OPERATIVE in Heppenheim known as Bergsträsser Winzer. D.S.

Heuriger, derived from the word for 'today' but signifying by implication 'this season', or 'the latest', is an AUSTRIAN institution whose social dimensions extend far beyond the only weeks-old wine so described. Emperor Josef II in 1784 formally established the right of Austrian winegrowers to dispense their young wines by the glass (along with a rudimentary repast) at establishments whose function was signified by the hanging of bush-like bundles of evergreens over the door, for which reason such an establishment is still referred to within Austria as a *Buschenschank*. The still-cloudy, often only partially fermented young wine is variously known as Staubiger

('dusty one'), FEDERWEISSER, or Sturm ('storm'). Groups of Heurigen with their rows of tiny press houses at the edge of a village or its vineyards are prevalent throughout the former Hapsburg Empire, and within Austria many of these still double as dispensaries. Many top Austrian wine estates dispense tavern-style year-round, at least on weekends, out of economic necessity. The Heurigen of Austria's thirsty capital Vienna (WIEN) and of the adjacent THERMENREGION are especially numerous and seasonally frenetic. D.S.

higher alcohols. See FUSEL OIL.

High Valley. California AVA. See LAKE COUNTY.

hillside vineyards. Even in ancient ROME it was said *Bacchus amat colles*, or BACCHUS loves the hills, suggesting that hillside vineyards have long been regarded as a source of high-quality wine.

This is partly because hillside soils are typically shallow, so that vineyard VIGOUR is relatively low, a factor commonly associated with higher wine quality. Over millennia, topsoil tends to be washed down the hillsides and accumulates on the valley floors. Vines planted there will typically be more vigorous, as the soils are deeper and the roots will be able to reach more water and nutrients.

Vines may also be planted on hillsides for reasons of MESOCLIMATE. Hillsides are less prone to FROST because cold air can drain freely away at night (see AIR DRAINAGE and TOPOGRAPHY). If the slopes face the equator, they receive more sunshine during the day and are warmer. In hotter regions, vineyards may be planted on hillsides to take advantage of cooler temperatures at higher ELEVATIONS.

Hillside vineyard sites have their drawbacks, including SOIL EROSION, and in California's NAPA Valley there are strict regulations to avoid erosion. Working on steep slopes is particularly tiring: productivity is affected, and the costs are higher. In most vineyards of the world, rows run up and down the slopes. Where the slopes are

too steep for tractors, as in the CÔTE RÔTIE, parts of the MOSEL Valley, and SWITZERLAND, everything must be done by hand or by machines winched down into the vineyards. Where rows run across the slopes, the vineyard is normally laid out in TERRACES, as in Portugal's DOURO Valley or France's hill of HERMITAGE, to both protect against erosion and facilitate mechanization. R.E.S.

Hillside vineyards: the warmth received by direct radiation on the vineyard depends on the elevation of the sun combined with the inclination of the vineyard towards the sun. The elevation of the sun controls the thickness of the atmosphere (an absorbing medium) through which the radiation passes. The inclination of the vineyard is independent of this variation.

$I = k \sin \alpha + q \sin \beta$

Where I = Intensity of radiation received in vineyard
k and q = constants
α = angular elevation of sun
β = angle of inclination of the vineyard to the horizontal along a meridian

Hilltops, moderately cool, high-ELEVATION wine region situated at 450 m/1,476 ft in the south-western slopes of the Great Dividing Range in NEW SOUTH WALES. With red wine grapes covering 80% of its 591 ha/1,460 acres in 2020, Hilltops is best known for fragrant,

elegant, spicy Shiraz and classic, well-structured Cabernet Sauvignon. A host of other red varieties including Nebbiolo, Barbera, Corvina, Sangiovese, Grenache, and Tempranillo are also gaining traction.

A.R.P.

hippocras, popular medieval FLAVOURED WINE.

histamine, a small organic nitrogenous molecule responsible for ALLERGIC and allergy-like reactions, is thought to play a central role in certain people's reactions to wine. A better-known example involving this mechanism is scombroidosis, a type of food poisoning due to fish spoilage. Histamine in wine is chiefly produced by the decarboxylation of histidine (an amino acid) to histamine by certain microbes, particularly some strains of LACTIC ACID BACTERIA such as *Pedioccocus* and *Lactobacillus*.

Wine ANALYSIS has demonstrated that typical histamine concentration in wine is <5 mg/l in whites and <10 mg/l in reds, though some styles, such as wines with no added (or late-added) SULFUR DIOXIDE, may contain higher concentrations. Low levels or reduced function of diamine oxidase, the enzyme which breaks down histamine, in some individuals may result in intolerance of wine containing even these levels of histamine. Ethanol itself inhibits amine metabolism, thus higher alcohol content might worsen this effect. See also BIOGENIC AMINES and ALLERGIES AND INTOLERANCES.

Historic Vineyard Society was formed in CALIFORNIA in 2011 to preserve the state's rich heritage of old vines by carefully assembling a registry of those 50 years old and older. In 2022, the non-profit organization listed 159 vineyards, including many dating to the late 1800s, such as Bechthold in LODI and Bedrock in SONOMA.

Hochgewächs, an ancient but little-used approbation for German wines meeting higher standards than the minima set for QUALITÄTSWEIN but not qualifying for a PRÄDIKAT.

Hochschule Geisenheim University. See GEISENHEIM UNIVERSITY.

hock, traditional generic English term for (white) Rhenish wines, from the RHINE regions of GERMANY, sometimes for the wines of Germany in general. In 20th-century Britain it typically referred to a simple QUALITÄTSWEIN, and it was by no means uncommon for the same wine to be offered as Hock to a gentlemen's club and LIEBFRAUMILCH to a supermarket buyer.

The term is a contraction of 'hockamore', an English rendering of the adjective 'Hochheimer', denoting wines from the important wine centre of Hochheim on the river Main just west of Frankfurt (see RHEINGAU).

The earliest firm reference in English occurs in Thomas D'Urfey's play *Madam Fickle; or, The Witty False One* in 1676: 'Here's a glass of excellent old Hock.' The *Oxford English Dictionary* gives a first

reference in 1625 in John Fletcher's play *The Chances*, but this depends on a corrupt reading of 'hock' for 'hollock', a light red wine. However, it is likely that the term was already current in England by the 17th century, for its use is closely linked to the growth in popularity of Rhenish and Main wines, which began to supplant the wines of ALSACE in export markets after 1500 (see GERMAN HISTORY).

At the outset, 'hock' appears to have described only wines from the middle Rhine: in an address to the Royal Society in 1680, Anthony van Leeuwenhoeck, the inventor of the microscope, spoke of 'vinum Mosellanicum, vinum Rijncoviense and vinum Rhenanum, quod vulgo hogmer dicitur' (called 'hogmer' in the vernacular). In 1703, Johann Valentin Kauppers in his *De natura…vini Rhenani* could still distinguish between 'Rhine wines' and wines from the Rheingau, but in the course of the 18th century hock became the general designation of German wines sold in Britain. T.S.

Holland . See NETHERLANDS.

Homer, writer(s) in ancient GREECE of the epic poems the *Iliad* and the *Odyssey*. Homeric poems are usually dated to the 8th century BCE, and wine features regularly in both. See also CLASSICAL TEXTS.

home winemaking, small-scale domestic activity indulged in for fun, to save money, or both. Because such wine attracts no DUTY, it is especially popular in countries with high excise duties. Some countries with no or limited viticulture such as Britain have a long tradition of making FRUIT WINES and wines based on plants, flowers, or even root vegetables. The term 'country wines' is used to cover wines made from anything but grapes.

Home winemaking became popular in the United States during PROHIBITION, when making an annual allowance of 100 gal/3.75 hl of wine per adult, up to a maximum of 200 gal/7.5 hl per household (a limit that still applies in the US), was the only legal way the average

American household could procure alcoholic drink. Technology was primitive, and tales of exploding bottles were common, but the pursuit was so popular that vineyard acreage in California doubled between 1919 and 1926.

After Repeal, home winemaking continued, mostly in the hands of European immigrants with strong winemaking traditions. However, by the early 1990s the growth in home winemaking had slowed, with fewer than half a million Americans making roughly 2.5 million cases of wine a year, mainly from grapes grown in California and shipped by rail to the rest of the country but also from juice or GRAPE CONCENTRATE. Today, home winemakers have access to juice and grapes grown not only in California but also in Oregon and New York State, for example, as well as from other major grape-growing countries such as Italy, Chile, Argentina, and South Africa. In Great Britain the hobby peaked in the late 1980s, with grape concentrate the usual raw material, producing MADE-WINE, which lacks the fresh fruitiness of wine made from the juice of freshly picked grapes.

It was Canada that popularized home winemaking. Kits based on canned grape-juice concentrate had been introduced in the 1950s, but a new type of kit made by Canada's Brew King, using a combination of concentrates and flash-PASTEURIZED fresh grape juice and including much of the necessary equipment, encouraged many new recruits.

In addition, the introduction in the Canadian provinces of Ontario and British Columbia of 'wine on premise' shops, and of *centres de vinification* in Quebec, where customers could vinify an unlimited amount of wine for personal use, free of any tax, led to a huge increase in home-made wine.

Today the world's major wine-kit manufacturers are all based in Canada but distribute throughout the world. D.P.

homoclime, or 'analogue climate', is a geographical term meaning 'similar climate'. It remains a common approach to VINEYARD SITE SELECTION in the NEW WORLD to search for homoclimes of established

wine regions, implicitly assuming that CLIMATE is the primary determinant of wine quality. Homoclimes can be found with digitized maps and GEOGRAPHICAL INFORMATION SYSTEMS, using temperature and rainfall data but also considering SUNLIGHT, HUMIDITY, and EVAPORATION. For example, Tamar Ridge Vineyards used this approach to identify new vineyard regions in Tasmania with the same climate as that of New Zealand's MARLBOROUGH region. R.E.S.

Hondarrabi Beltza, rare Spanish BASQUE red wine grape related to Cabernet Franc and grown to produce red and rosé TXAKOLI. The pale-skinned grapes making white Txakoli are called Hondarrabi Zuri, of which Spain's total plantings had grown to 741 ha/1,831 acres by 2020. But these vines are probably a mix of COURBU BLANC, CROUCHEN, and, according to one reference sample for DNA PROFILING, the American hybrid NOAH. Hondarrabi is also spelt Hondarribi or Ondarrabi.

Hong Kong has been the hub of ASIAN wine markets since 2008, when duty on wine was slashed to zero with this very intention. Duties on wine imported to the rest of CHINA are substantial and therefore many Chinese wine collectors continue to buy and store their FINE WINES in this special administrative region. The number of wine STORAGE FACILITIES, wine MERCHANTS, wine AUCTIONS, and wine trade fairs in Hong Kong subsequently soared. By the second decade of the 21st century, auction totals in Hong Kong had overtaken those in Europe and the United States (though the latter has since reclaimed the lead), and virtually every fine-wine trader had a Hong Kong outpost. Reliable statistics are not available but, on top of official re-exports of several million litres annually, a considerable quantity of fine wine is thought to cross the border into China from Hong Kong. Beyond fine wine, the city is a significant regional base for wine competitions, wine media, and wine education, to the extent that the WSET chose Hong Kong for its first international office in

2016. A few URBAN WINERIES vinifying imported grapes opened in the region in the late 2000s and early 2010s but have since closed down.

S.K.H.

Horace (Quintus Horatius Flaccus) (65–8 BCE), the Latin poet, did not write a systematic guide to viticulture, although wine does figure prominently in his work and reflects his Epicurean philosophy of enjoying its pleasures in moderation. He tells us that at the Sabine farm which his patron Maecenas gave him he does not grow wine (*Epistles* 1. 14), but as a token of his gratitude he serves Maecenas the local wine, laid down by the poet himself in the year that his patron had recovered from a serious illness (*Odes* 1. 20). This matching of the wine to the guest and the occasion is a constant feature of Horace's invitation poems and other poems about drinking: see also *Odes* 1. 9 and 4. 2 (simple wines for intimate occasions), 3. 21 (a wine from the year of the poet's birth for an honoured guest), 1. 37 (a grand old CAECUBAN to celebrate the defeat of the monstrous Cleopatra), 3. 14 (a wine that goes back to the Social War, 91–88 BCE, to celebrate Augustus' return), and 3. 28 (Caecuban of Bibulus' consular year, 59 BCE, in honour of Neptune).

Horace cannot afford the very best wine, old FALERNIAN; to spend a feast day drinking that would be the greatest happiness (*Odes* 2. 3). Note that to Horace good wine is always old wine: the Romans (and the Greeks) preferred old wine to the wine of the current vintage. *Epistles* 1. 19 is Horace's contribution to the debate about poetic inspiration. Callimachus (*c*.310/05–*c*.240 BCE) first raised the question of whether water, symbol of the purity of poetic labour, or wine, which brings poetic frenzy, is the better drink for a poet. On the authority of Cratinus (*c*.520–*c*.423 BCE), Horace sides with the wine drinkers, for were not Homer and Ennius (see ancient GREECE), the fathers of Greek and Latin epic respectively, wine bibbers? 'Laudibus arguitur vini vinosus Homerus', Horace asserts: 'in his praises of wine, wine-bibbing Homer betrays himself.' To the modern reader, Horace seems to have more in common with today's civilized wine enthusiast than does any other classical writer.

hormones, natural substances present in trace concentrations in vines and other plants which move from one organ or part of the plant to another to regulate growth and development. Synthetic GROWTH REGULATORS may have similar chemical structures and a similar mode of action. Three groups of hormones promote growth: AUXINS, GIBBERELLINS, and CYTOKININS. Two groups inhibit growth: ABSCISIC ACID and ethylene. R.E.S.

horses are making a return to vineyards as an alternative to TRACTORS in response to concerns about SOIL COMPACTION. See also BIODYNAMIC VITICULTURE, TILLAGE, LABOUR, and SUSTAINABLE VITICULTURE.

Hospices de Beaune, charity auction which has taken place in BEAUNE annually since 1859 on the third Sunday in November, a key feature of the Burgundian calendar. The beneficiaries are the combined charitable organizations of the Hôtel Dieu, founded in 1443 by Nicolas Rolin, chancellor of the duchy of Burgundy, and the Hôpital de la Charité.

The produce of vineyard holdings donated by benefactors over the centuries is auctioned at prices usually well in excess of current commercial values. Nevertheless, the results serve as some indication of the trend in bulk wine prices for the new vintage.

The cuvées sold are named to commemorate original benefactors such as Nicolas Rolin and his wife Guigone de Salins or more recent

ones such as de Bahèzre de Lanlay, an inspector of aerial telegraphs. The Hospices de Beaune also provides the occasion for 'Les Trois Glorieuses', the three great feasts held over the weekend at CLOS DE VOUGEOT on Saturday night, in Beaune on Sunday night, and in MEURSAULT for the extended lunchtime bottle party that is the Paulée de Meursault on Monday.

The Hospices de Nuits also holds a charity wine auction; see NUITS-ST-GEORGES.

hot bottling. See PASTEURIZATION.

hot-water treatment is used by QUARANTINE authorities and vine NURSERIES to sterilize dormant grapevine CUTTINGS or nursery plants. These are immersed in hot water at around 50 °C/122 °F, or slightly warmer, for a few minutes to destroy surface contaminants and for up to 30 minutes for internal diseases such as FUNGI and PHYTOPLASMA. Hot-water treatment is also used to control CROWN GALL bacteria, NEMATODES, and PHYLLOXERA and other insects. The process is used in nurseries to control TRUNK DISEASES. There should be no damage to the plants if the temperature is accurately regulated and storage protocols followed. Not to be confused with THERMOTHERAPY. R.E.S.

Howell Mountain, CALIFORNIA wine region and AVA defined by ELEVATION. See NAPA Valley.

Hrvatska. See CROATIA.

Hugel, one of the best-known and oldest wine producers in ALSACE, having been established in 1639. The family business is run today by the 12th and 13th generations. The Hugels, based in Riquewihr, make fine wines from their own 30 ha/74 acres of vineyard around the

village planted mainly with Riesling and Gewurztraminer, together with a little Pinot Gris and Pinot Noir. Their Estate (once Tradition) range can be excitingly full and the Grossi Laüe (once Jubilee) range masterful. The Hugel family also pioneered the resurrection of Alsace's late-harvest wines and were instrumental in drawing up the rigorous requirements for these VENDANGES TARDIVES and SÉLECTION DE GRAINS NOBLES wines. They are arch exponents of these styles themselves and produce them, along with the Grossi Laüe range, exclusively from their own GRAND CRU and Pflostig vineyards. The Hugel family, of which three family members work in the Riquewihr wine business, have long been champions of maximizing quality in Alsace's finest wines but do not recognize the Alsace Grand Cru appellation, which they feel is no guarantee of quality. The Hugels buy in grapes, never wine, for their basic range of bottlings from about 55 ha/135 acres of vineyard under contract from more than 60 growers. Marc Hugel and his nephew Marc-André are in charge of winemaking.

Humagne Blanche, Swiss Valais white grape which, unexpectedly, is not related to HUMAGNE ROUGE. The wine produced is elegant, though less expressive than ARVINE. DNA PROFILING has shown that Humagne Blanche is the parent of LAFNETSCHA and that it is also found in south-west France as MIOUSAT. J.V.

Humagne Rouge, relatively rare red wine grape of the Swiss Valais region whose wines are wild and rustic, with unusual aromas of dried vine leaves and relatively soft TANNINS. DNA PROFILING at CHANGINS and Aosta showed that this variety is identical to CORNALIN of the Valle d'AOSTA and confirmed that it is not related to HUMAGNE BLANCHE. J.V.

humidification, euphemism for the (usually illegal but increasingly common) winemaking operation of adding water to

reduce ALCOHOLIC STRENGTH. Lack of regulation and transparency concerning the amount of water that is allowed for the purposes of incorporating any oenological substances, for example ADDITIVES and PROCESSING AIDS, makes this an even more grey area.

humidity, or moisture content, of the atmosphere has considerable implications both for vine growth and for STORING barrels and wine, whether in bulk or bottle. Humidity is normally measured as per cent relative humidity (% RH): the amount of water vapour a given volume of air holds, as a percentage of the maximum it could hold at the same temperature. The latter amount increases with temperature, so the RH of air containing a constant amount of water vapour falls as temperature rises, and vice versa. Humidity can also be expressed as saturation deficit, which is a direct measure of the evaporative power of the atmosphere. Actual EVAPORATION is further influenced by WIND and SUNLIGHT.

Relative humidity follows a regular daily cycle, normally being highest in the early morning, when temperature is lowest, and lowest in the early to mid afternoon, when temperature is highest. High humidity is conducive to the spread of FUNGAL DISEASES, especially when combined with high temperatures after rainfall, for example. High morning humidity creates DEW, which is also important for some diseases. The afternoon humidity, together with sunshine, temperature, and wind, dominates in determining evaporation rate and therefore the likelihood of WATER STRESS. The contrast between morning and afternoon RH tends to be greatest inland and least near coasts.

Gladstones argues that high humidity levels, critically those in the afternoon, are conducive to high wine quality, but it is difficult to separate this influence from that of lower temperatures.

Viticultural regions of the world with high afternoon RH during the fruiting period, and lower daytime temperature, include those mentioned in COOL-CLIMATE VITICULTURE. See WARM-CLIMATE VITICULTURE

for wine regions where there is also an inverse general relationship between afternoon summer temperatures and RH.

Typical areas of intermediate humidity include the southern Rhône Valley of France; most inland areas of Portugal producing table wine, such as Dão, and of Spain; Bulgaria; intermediate and warmer parts of the coastal valleys of California, such as the Napa and Santa Clara Valleys; Stellenbosch and Paarl in South Africa; the Western Australian west coast and hills; Barossa, Adelaide Hills, Langhorne Creek, and Coonawarra in South Australia; Grampians and other parts of the Great Dividing Range in Victoria; and the Hunter Valley and, marginally, Mudgee in New South Wales.

For details of humidity and barrels, see EVAPORATION. For details of humidity and wine storage, see STORING WINE. R.E.S.

humus. See ORGANIC MATTER.

Hundred Years War. The sporadic fighting between the kings of England and France known as the Hundred Years War (1337–1453) changed both the political map of Europe and the nature and volume of the medieval wine trade. Both crowns claimed ownership of the wine regions of western France, which, through the wealthy port of BORDEAUX, supplied England with almost all its wine.

The hostilities had a marked effect on the wine trade. First, the large and commercially successful vineyards of the HAUT PAYS, or 'high country', upstream from Bordeaux (GAILLAC, BERGERAC, BUZET, CAHORS) were for the most part under French control. This increased English reliance on the lesser vineyards of Bordeaux and its environs, encouraging their expansion.

Second, the ships carrying wine back to England faced the risk of greater piracy. Convoys organized for their protection proved expensive. Reduced supplies and greater freight costs led to a dramatic rise in the price of wine in England.

After Bordeaux's surrender at CASTILLON in 1453, England remained a major market for its wines, although the overall volume of this

trade was not to reach the pre-war peak for many centuries. English merchants became more willing to look beyond western France for their wine imports, while Bordeaux attracted a wider clientele of merchants from northern Europe.

Hungary , central European wine-producing country with a distinctive range of vine varieties and wines. Hungary usually produces less wine than its eastern neighbour ROMANIA but considerably more than, for example, AUSTRIA and BULGARIA. Some 64,000 ha/158,147 acres were devoted to vines in 2021, and almost 70% of them produced white wines. Total Hungarian wine production has been decreasing and is now usually below 4 million hl/105 million gal a year, of which about one-fifth is exported.

Wine-growing regions

History

Vine-growing and winemaking have been practised in what is now modern Hungary since at least Roman times, when it was part of the Roman province of Pannonia. The Magyar tribes who arrived here at the end of the 9th century found flourishing vineyards and familiarity with winemaking techniques. Under Bela IV (1235–70), the king who rebuilt Hungary after the Mongol invasion of 1241, wine production was given such priority that immigrants from areas with particular expertise in vine-growing and winemaking were invited to rebuild the devastated areas, and by the end of his reign wines from the towns of SOPRON and EGER were being exported in relatively large quantities. Hungary's most famous wine, TOKAJI, is first mentioned in records in the late 15th century, although it was almost certainly dry at this time.

Following the defeat and death of Louis II at the battle of Mohács in 1529, much of the country was under Muslim rule for a century and a half, during which wine production survived but did not thrive (see ISLAM).

The most important development in the 17th century was the emergence of sweet, rich Tokaji Aszú. As early as 1641, a Vine Law for the entire Tokaj-Hegyalja district was drawn up which regulated VINEYARD SITE SELECTION, the construction of TERRACES, IRRIGATION, manuring, and harvesting. By 1570, NOBLE ROT was recognized, and the laws for Aszú formulated. For more details, see TOKAJ.

In 1686 the city of Buda was liberated from the Turks, followed within the next few years by the rest of Hungary, which then became part of the vast Habsburg empire. In 1711 a bid for independence led by Ferenc Rákóczi failed, but it had the effect of spreading the fame of Tokaj wines to the court of the French king, Louis XIV, to whom Rákóczi had sent sample bottles as gifts. This was the beginning of Tokaj's formidable international reputation.

The vineyards of Tokaj were some of the first to be submitted to CLASSIFICATION, in 1700; the first national vineyard classification

anywhere, a five-level rating, was undertaken in Hungary in 1707–8 as part of general appraisal of the country's resources.

PHYLLOXERA struck Hungary in the 1870s, devastating the southern vineyards at Pancsova initially and eventually spreading to the Northern Massif and Tokaj-Hegyalja. Replanting on phylloxera-resistant ROOTSTOCKS began in 1881, but scientific proof that phylloxera could not thrive in sandy soils had just been published, encouraging the planting of new vineyards in the Great Plain, between the Danube and Tisza rivers, where vines were also discovered to be helpful for stabilizing the shifting sands.

Zsigmond Teleki (1854–1910) bred the famous 5 BB Teleki rootstock which proved perfectly suited to producing high-quality grapes even when planted in the desolate, intensely CALCAREOUS hillsides of Villány. When Teleki died in 1910, his sons Andor and Sándor continued the NURSERY business with great success, maintaining subsidiaries in six countries, until the Second World War. Ironically, Franz Kober in Oppenheim eventually collected most of the recognition by subjecting Teleki's CLONES to further selection, and indeed the rootstock is more commonly known today as 5 BB Kober. Móricz Preysz (1829–77) was the pioneer of PASTEURIZATION, publishing his work on the technique, then needed to stabilize Tokaji, in 1861, two years before Louis PASTEUR developed pasteurization.

In 1947, the National Association of Hungarian Vine-Growers, Wine Trades, and Wine-Growing Communities was forced to suspend its activities when the communist state monopoly took control. An era of state farms and state wineries followed, during which all wine exports were funnelled through the state-controlled trading company Monimpex. Half of all production was at one point handled by just two wineries designed to export huge quantities of very ordinary wine to the SOVIET UNION. Unlike the similarly organized BULGARIAN wine industry, that of Hungary suffered a period of stagnation and generally low technology that stultified the development of Hungarian wine until the return of a free-market economy and private enterprise in the late 1980s. However, because a considerable proportion of Hungarian vines had remained in private hands in the communist era,

Hungary was able to adapt production to the more stringent requirements of Western importers more quickly than other ex-Comecon countries.

In the post-communist division of vinicultural spoils, there was no shortage of Western interest in the unique Tokaji wines, and the influx of foreign winemakers, western European capital, and EU finance enabled much-needed investment in modern winery equipment, resulting in a marked improvement in wine quality. And the early 21st century saw a marked increase in the number of ambitious, quality-focused wineries—many Hungarian-owned—with improved VINEYARD site selections and plant material, respect for TERROIR, and better winemaking, especially for dry white wines. The best winegrowers have come to realize that their high-acid wines do not require the same barrel regimes as wines from warmer regions and have drastically reduced the amount of new wood used in the winemaking process, switching out the once-popular 225-l barrels for larger formats. So-called NATURAL WINES are also on the rise.

Geography and climate

Hungary, which lies between latitudes 45° and 50° N, is landlocked, but the River Danube (called Duna in Hungary) flows through it from north to south, dividing it in almost equal halves. To the west lies Transdanubia, which includes Central Europe's largest lake, Balaton. Here, complex soils of BASALT with CLAY and sandstone dominate. Other soils include LIMESTONE and SLATE, particularly around Balatonfüred. (See map.) East of the Danube is the Great Plain, an area of mainly SAND and LOESS, except in the volcanic hills of the Northern Massif north-east of the capital Budapest. In the extreme north-east, bordering SLOVAKIA, is the Tokaj (formerly Tokaj-Hegyalja) region.

See below and separate entries for EGER, SZEKSZÁRD, TOKAJ, and VILLÁNY for details of individual wine regions.

Hungary's climate is essentially CONTINENTAL and Central European, involving cold winters and warm summers. The sun shines for an average of about 2,600 hours a year, and annual rainfall averages 500–800 mm/20–31 in.

Wine regions

Hungarian law in the 21st century established 22 wine regions. In 2009, in keeping with the EU reforms of CONTROLLED APPELLATION terminology, these were replaced by 36 PDOs (*Oltalom alatt álló eredet megjelöléssel* in Hungarian, or OEM) and 13 PGIs (*Oltalom alatt álló földrajzi jelzéssel*, or OFJ). The following PDOs may be considered pre-eminent: Badacsony, Balatonboglár, EGER, Etyek-Buda, Somló, SOPRON, SZEKSZÁRD, TOKAJ, and VILLÁNY. Names such as Mátra, Neszmély, and Pannonhalma may also be familiar from export labels. The wine regions fall into three major geographical groups, as outlined below.

Transdanubia The wine regions in this western part of Hungary, between the Austrian border and the Danube, are strongly influenced by the waters of Lake Balaton, Lake Fertö (called NEUSIEDLERSEE in Austria), and the Danube itself. Wines from this area may be labelled by the PGI **Dunántúl** and its variations Dél-, Észak-, and Nyugat-dunántúl (South, North, and West Dunántúl).

Traditionally the northern side of Lake Balaton was the vine-growing area, with the famous Badacsony Hill on the volcanic slopes at the south-west end. The surface area of water in the lake has a considerable ameliorating effect on the MESOCLIMATE (see TOPOGRAPHY) and the wines tend to be full and powerful. This is home to the ancient KÉKNYELŰ grape variety, and it also grows fine Pinot Gris (Szürkebarát) and Olaszrizling (WELSCHRIESLING). **Balatonfüred-Csopak** also lies on the northern shore, on sandstone, slate, and marl, and is known for its Olaszrizling, a speciality upheld by the Csopak Kódex, an independent association devoted to maintaining its reputation through strict regulations for viticulture and vinification.

On the slopes of an extinct volcano north-west of Lake Balaton is the small PDO region of **Nagy-Somló** and the even smaller PDO **Somló**, whose wood-aged, blended wines once enjoyed a reputation similar to those of Tokaj. JUHFARK is prized here, along with Furmint, but Olaszrizling, Hárslevelű, and Traminer have been in the ascendant. Somló has been attracting increasing investment as its potential for elegant, ageworthy wines with a distinctive mineral character becomes evident.

Sümeg is just 40 km/25 miles south-west, in the Balaton Highlands (Balaton-Felvidék), and grows a wide variety of grape varieties in its heavy calcareous clay soils. What sets the PDO apart is its focus on natural winemaking, requiring extremely low yields and vine-growing without any AGROCHEMICALS as well as LOW-INTERVENTION WINEMAKING.

On the south shore of the lake is **Balatonboglár**, where the fertile soils include SAND and LOESS. Important grapes grown here are Olaszrizling, KIRÁLYLEÁNYKA, Zöldveltelini, IRSAI OLIVÉR, Chardonnay,

Muscat, Merlot, and Pinot Noir. Base wines for excellent sparkling wines are also produced here.

Sopron, the most westerly wine region of northern Transdanubia and effectively a continuation of NEUSIEDLERSEE, Austria's most revered source of sweet white wine, is dominated by ambitious growers of Austro-German extraction. Today Sopron is mainly devoted to red wines made from Kékfrankos (BLAUFRÄNKISCH), Cabernet Sauvignon, Cabernet Franc, Merlot, Pinot Noir, and Syrah, which can be particularly elegant when grown on the SCHIST soils here.

Further south, in the southernmost end of the Alps, is the PDO Kőszeg, where Kékfrankos excels, just as it does just across the border from Austria's MITTELBURGENLAND.

In the north are two increasingly important white wine areas: **Neszmély** and **Mór**, between Sopron and Budapest, which are best known for crisp but well-balanced Olaszrizling and Sauvignon Blanc, tart EZERJÓ, LEÁNYKA, and aromatic GEWÜRZTRAMINER. Some thrilling red wines from Kékfrankos and Pinot Noir are also produced. Etyek stands out for its TRADITIONAL METHOD sparkling wine, bottled under the PDO Etyeki Pezsgő and made in white and rosé versions from Chardonnay and Pinots Blanc, Noir, or Gris grown in the region's LIMESTONE soils.

Southern Transdanubia has three important wine regions. **Villány** is most famous for the saddle of land in the Villány Hills which manages to produce highly prized reds even in difficult years. Cabernet Franc is most successful here, although Kékfrankos, Merlot, Syrah, and Zweigelt are also good.

Szekszárd has traditionally been associated with KADARKA, which it has managed to ripen more healthily than most regions, owing to its long, warm summers, but plantings total barely 100 ha/250 acres. This native red variety has been supplanted by vigorous Merlot and Cabernet, but Szekszárd producers tend to achieve a higher average quality with their Kadarka, Kékfrankos, and BIKAVÉR wines. The cooler area around Bátaszék, 15 km/9 miles to the south, can produce some

particularly good Sauvignon Blanc and Grüner Veltliner. ANTINORI own a winery in Tolna, the neighbouring region.

Pécs, Hungary's warmest wine region, is at constant risk of DROUGHT. A wide range of white and red vine varieties is cultivated here.

The Northern Massif This range of hills running north-east from Budapest along the border with Slovakia contains four wine regions: Mátra, EGER, Bükk, and TOKAJ.

In the foothills of the Mátra Mountains, the soils are mainly VOLCANIC, and most of the wine produced is white, mainly from Olaszrizling, Muscat, and Királyleányka. The region also produces some elegant, fruity reds, especially from Kékfrankos and Pinot Noir. Quality is growing rapidly here, with an influx of talented young winemakers.

Just east of the Mátra foothills, in the foothills of the Bükk Mountains, is the wine region named after the historic town of EGER. Spring often comes late here and rainfall is low. Some white wines are made, principally from local varieties such as Olaszrizling, Leányka, Királyleányka, and Irsai Olivér. Some of the region's finest white wines are bottled as Egri Csillag ('Star of Eger'), a blend of at least four local varieties. Yet the region's reputation is for ageworthy red wine, notably Egri Bikavér, once known on export markets as Bull's Blood. At one time the blend depended heavily on Kadarka, but as elsewhere this challenging native variety was replaced by Kékfrankos and Zweigelt, supplemented by Cabernet, Merlot, and Syrah.

North-east of Eger lies the Bükk region. With the mountains at its back, the region's 1,011 ha/2,498 acres of vines are largely protected from the cold north winds as well as rain. The diverse soils support a range of varieties, generally favouring whites—Leányka, Chardonnay, and CSERSZEGI FŰSZERES—with some fruity, elegant reds made from Kékfrankos and Zweigelt.

Tokaj is even further north-east, into the foothills of the Zemplén Mountains. See TOKAJ for more detail.

The Great Plain This vast, flat expanse (known as Alföld in Hungary) south of Budapest and between the Danube and Hungary's second river, the Tisza, accounts for nearly half the country's vineyards. The plain was heavily planted after the PHYLLOXERA invasion because of phylloxera's intolerance of sandy soils and because vines were better at stabilizing the soil than the fruit trees planted earlier.

MECHANIZATION is easy on this flat land, but the DROUGHT in summer and FROST in both late spring and autumn are a perennial threat, and the combination of sandy soil and high summer temperatures means that soil temperatures can be very high indeed.

INDIGENOUS and INTERNATIONAL VARIETIES or Olaszrizling, Rajnai Rizling (RIESLING), Kékfrankos, Kadarka, Cserszegi Fűszeres, and Ezerjó are planted here. The Great Plain encompasses the PGI Duna-Tisza Közi and the PDOs Csongrád, Hajós-Baja, and Kunság, but wine quality is generally indifferent. The more recent PDO Duna may be used for wines from those three more specific and well-established regions.

Vine varieties

Wine labelling is mostly VARIETAL. Hungary had a particularly rich selection of INDIGENOUS VARIETIES, many of which were largely abandoned after PHYLLOXERA invaded in the late 19th century. A potentially exciting selection of localized white grape varieties can still be found, such as KÉKNYELŰ, found almost exclusively in Badacsony on the north shore of Lake Balaton, and JUHFARK, known mainly in Somló.

Indigenous varieties which are relatively widely planted include EZERJÓ, a light speciality of the Mór region west of Budapest; FURMINT, the most characteristic ingredient of Tokaji; and HÁRSLEVELŰ, which is usually a lesser Tokaji ingredient and is also widely grown throughout Hungary. The indigenous Leányka and Királyleányka are used for light-bodied aromatic wines. Efforts are being made to replant old Hungarian grapes such as Bakator, BUDAI ZÖLD, Szerémi Zöld, KÖVIDINKA, and Sárfehér. Newer crosses such as the Muscat-like IRSAI OLIVÉR and the grapey cross CSERSZEGI FŰSZERES are now being more widely planted for their own intrinsic character and quality. Other light-berried crosses include ZÉTA, ZENGŐ, ZEFIR, and ZENIT. Hungary's most characteristic red grape variety is KADARKA, although Csókaszőlő is making a comeback, and PORTUGIESER (once known as Kékoportó) can also make some appetizing wines here.

A range of central European vine varieties is grown: Olaszrizling (WELSCHRIESLING), Zöldveltelini (Austria's GRÜNER VELTLINER), Cirfandli (Austria's ZIERFANDLER, a speciality of Pécs); and, for red-wine production, KÉKFRANKOS (along with Nagyburgundi, the Hungarian name for BLAUFRÄNKISCH), and Austria's ZWEIGELT.

A wide range of vine varieties have been imported into Hungary from western Europe, however, including Chardonnay, Sauvignon Blanc, Riesling (generally called Rajnai Rizling or Rheinriesling), Gewürztraminer (Tramini), Muscat Ottonel and Yellow Muscat, the deeper-hued Muscat Blanc à Petits Grains (both of which are

sometimes called Sárga Muskotály), and Pinot Gris, whose distinctively Hungarian synonym is Szürkebarát. Red-wine varieties imported from the West include Merlot and, to a much lesser extent, Cabernet Sauvignon and Cabernet Franc, as well as a smaller amount of Pinot Noir and Syrah.

Hunter Valley Zone, historic warm, humid NEW SOUTH WALES wine zone two hours north of Sydney in which Hunter is a region and Broke Fordwich, Pokolbin, and Upper Hunter are subregions. The region is best known for its distinctive, long-lived dry SÉMILLON wines.

Chardonnay and Shiraz are also well-regarded.

Huxelrebe is an early 21st century German vine CROSS that enjoys some popularity both in Germany and, on a much smaller scale, in ENGLAND. Although like SCHEUREBE and FABERREBE it was actually bred by Georg Scheu at Alzey, this cross takes its name from its chief propagator, nurseryman Fritz Huxel. It was bred in 1927 from ELBLING (not Chasselas as the breeder originally indicated) and Courtillier Musqué, as confirmed by DNA PROFILING. The cross is capable of producing enormous quantities of rather ordinary wine—so enormous in fact that the vines can collapse under the strain of the grapes. If pruned carefully, however, and planted on an average to good site, it can easily reach Auslese MUST WEIGHTS even in an ordinary year and produce a fulsome if not exactly subtle wine redolent of honey, musk, and raisins for reasonably early consumption. In England, its ripeness is a useful counterbalance to naturally high acidity. In Germany, it is grown almost exclusively in Rheinhessen and the Pfalz; although it continues to lose ground, there were still 396 ha/979 acres in 2019. Gysler and Seehof manage to spin gold from it.

HVE, abbreviation for *Haute Valeur Environnementale*, a French certification system for SUSTAINABLE VITICULTURE.

hybrids, in common viticultural terms, the offspring of two varieties of different species, as distinct from a CROSS between two varieties of the same species, which is also known as an intraspecific cross. (See VITIS for details of the various species of the vine genus.) EU authorities prefer the somewhat cumbersome term 'interspecific cross' to the word 'hybrid', which has pejorative connotations within Europe.

Hybrids can occur naturally by cross-pollination, as happened, for example, in early American viticulture (see AMERICAN HYBRIDS). More commonly, however, hybrids have been deliberately produced by people (see NEW VARIETIES and VINE BREEDING) to combine in the progeny some of the desirable characteristics of the parents. This viticultural activity was particularly important in the late 19th century, when European, and especially French, breeders tried to combine the desirable wine quality of European VITIS VINIFERA varieties with AMERICAN VINE SPECIES' resistance to introduced American pests and diseases, especially PHYLLOXERA, which was devastating European vineyards (see FRENCH HYBRIDS).

Grafting European vines on to American ROOTSTOCKS proved the eventual solution to phylloxera, and many of today's commercially important rootstocks are hybrids. Early rootstocks were often pure varieties of a single American vine species chosen for their resistance to phylloxera. It was subsequently found, however, that hybrid rootstocks with combinations of genes from several American vine species allowing tolerance of various soil conditions and diseases were more successful in the nursery.

Different species of *Vitis* contain genes with natural tolerance or resistance to winter cold, lime-induced CHLOROSIS, SALINITY, DOWNY MILDEW, POWDERY MILDEW, BOTRYTIS BUNCH ROT, CROWN GALL, PIERCE'S DISEASE, NEMATODES, WINTER FREEZE injury, and phylloxera. It is logical,

therefore, to explore the possibilities of new hybrid varieties for wine production in an age of increasing concern about the AGROCHEMICALS which are used to control some of these. Vine breeders such as those at Geilweilerhof, DAVIS, and MONTPELLIER have proved that new hybrids, now called DISEASE-RESISTANT VARIETIES, may, without recourse to agrochemicals, produce good wine with no recognizably non-*vinifera* characteristics which, in controlled tests, cannot be distinguished from that of their pure *vinifera* counterparts. As a result, EU authorities allow hybrids such as RONDO, REGENT, PHOENIX, and ORION, as well as the more recent French hybrids Artaban, Vidoc, Floréal, Voltis, Coliris, Lilaro, Sirano, Selenor, and Opalor, into wines with GEOGRAPHICAL INDICATION.

The pedigree of many modern hybrids can involve seven or eight generations of crosses so that their ancestry is typically complex and includes *vinifera*, American varieties, possibly Asian varieties, and also early released French hybrids. R.E.S & J.E.H.

Mullins, M. G., et al., *Biology of the Grapevine* (1992).

hydrogen sulfide, or H_2S, is the foul-smelling gas, reminiscent of rotten eggs, which even at very low concentrations (parts per billion) is easily recognized in wine because it is highly volatile and has a very low sensory detection threshold. Although it can form at any stage of wine production, hydrogen sulfide is produced most commonly during alcoholic FERMENTATION. Hydrogen sulfide production during fermentation is associated with a deficiency in the amount of NITROGEN (often referred to as yeast-assimilable/available nitrogen, or YAN) in the grape must or juice. The nitrogen content of grapes is highly variable and depends on many factors, including grape variety, soil type and NUTRIENT status, climate, and vineyard management practices, such as type and amount of nutrient application, IRRIGATION, and use of COVER CROPS. Nitrogen-deficient grape musts are often supplemented with nitrogen, typically in the form of DIAMMONIUM PHOSPHATE (DAP), which usually suppresses the

appearance of hydrogen sulfide, although not all yeast strains respond equally well to DAP.

Because grape must does not have sufficient sulfur-containing AMINO ACIDS, which are essential for yeast protein synthesis and cell growth, yeast use inorganic sulfur sources—sulfate and, when added, sulfite—present in the must. The inorganic sulfur is metabolically reduced to hydrogen sulfide, which is immediately incorporated into a nitrogen precursor molecule (*o*-acetylhomoserine) to synthesize the sulfur amino acids cysteine and methionine. However, if a deficiency of nitrogen occurs, the cell is unable to synthesize the nitrogen precursor molecule and, consequently, hydrogen sulfide escapes into the wine. The addition of nitrogen (i.e. DAP) decreases the accumulation of hydrogen sulfide in the wine, not by stopping its formation in the yeast cell but by allowing the yeast to make the amino acid precursor. Novel strains of wine yeast that are not capable of producing significant amounts of hydrogen sulfide have recently been developed, for example at both the AWRI and at DAVIS using conventional breeding and selection techniques.

Residual sulfur in the must from vineyard fungicide can easily be reduced to hydrogen sulfide by the highly REDUCTIVE conditions generated by fermenting yeast. Decreasing or eliminating sulfur residues by ceasing sulfur applications to the fruit zone soon after VERAISON can help. (Elemental sulfur is used to control powdery mildew, which is no longer an issue on the grapes once they reach 12 ºBRIX, but it may still be necessary to spray the foliage.)

When present at low levels, hydrogen sulfide may add complexity to wine aroma (see VOLATILE SULFUR COMPOUNDS), but at concentrations above its odour threshold, hydrogen sulfide imparts the smell of rotten eggs, which is considered a FAULT. Fortunately, hydrogen sulfide is very volatile and can usually be removed by the SPARGING action of CARBON DIOXIDE produced during fermentation. However, hydrogen sulfide formed or released towards the end of fermentation, or after fermentation is completed, is of concern to the winemaker. If allowed to remain in the wine, it can react with other wine components to form MERCAPTANS, disulfides (see SULFIDES), which

have pungent garlic, onion, or rubber aromas, and polysulfanes, which may act as latent sources of hydrogen sulfide in wines post-bottling.

Hydrogen sulfide can usually be removed from the new wine by a small addition of copper sulfate, and it is also effectively eliminated during RACKING, where it is carried along with released carbon dioxide. Unfortunately, copper sulfate may react not only with off-flavours but also with desirable varietal aromas. In the case of robust wines (especially reds), sulfur compounds can also be removed by AERATION thanks to two mechanisms. Firstly, the oxygen uptake by the yeast allows them to make cell-wall sterols, which improves the ability of the yeast to absorb nitrogen from the must. Secondly, the various techniques of PUMPING OVER, RACK AND RETURN or direct introduction of air to the tank all serve to blow off any hydrogen sulfide that may have formed. This practical strategy has been shown to suppress the formation of hydrogen sulfide in red ferments with the added benefit of enhancing positive red-fruit attributes.

If a winemaker notices that a fermentation has produced high levels of hydrogen sulfide, they will usually rack the wine from the yeast lees early as the lees will continue to release hydrogen sulfide during ÉLEVAGE.

Finally, the type of CLOSURE and PACKAGING can also influence the development of sulfidic odours. Closure selection affects oxygen ingress, which may protect against hydrogen sulfide formation. Similarly, packaging material can either protect against the formation of hydrogen sulfide or be directly involved in the formation of sulfidic odours. For example, REDUCTIVE faults associated with hydrogen sulfide have been reported in some canned wines, which may be due to the reaction of SO_2 with the aluminium. M.B. & M.J.T

hydrolysis, a chemical reaction with, or involving, water and often catalysed by the hydrogen ions of acids. Hydrolysis is the reaction whereby an ESTER is split into its acid and alcohol components and GLYCOSIDES into their sugar and aglycone parts. The reaction is of great importance to the AGEING of wine when slow hydrolysis affects the FLAVOUR PRECURSORS, releasing aroma-active aglycones from their flavourless glycosides. P.J.W.

hydrometer, an instrument used for measuring the SOLUBLE SOLIDS, sugar content, or MUST WEIGHT of juice and wine before and/or during fermentation, consisting of a closed glass tube with a bulbous base, weighted so that it floats upright. The floating depth is inversely proportional to the DENSITY of the solution and is read by matching the bottom of the meniscus against a scale within the stem.

This scale may be calibrated as for BAUMÉ, BRIX/Balling, OECHSLE, or % alcohol by volume (see ALCOHOLIC STRENGTH). As with all such density measurements, correction for the temperature of the solution is necessary. B.G.C.

hygiene, an essential discipline in modern cellar management, involving cleanliness of winemaking premises and equipment and a great deal of WATER.

History

Winery hygiene was clearly already regarded as important in ancient ROME, as suggested by writers such as CATO and references in classical literature to SULFUR.

At the heart of the transformation from traditional mouldy cellars to their spotlessly clean modern counterparts has been a desire by winemakers to obtain much greater control over the processes of vinification and the maturation of wine, primarily through an emphasis on hygiene. While the pace of scientific research on the microbiology and biochemistry of winemaking has quickened appreciably since 1945, its origins lie in the middle of the 19th century with the experimental work of Louis PASTEUR. Until then, the precise reasons why pressed grapes would ferment into wine—and then become unpalatable if left open to the air for any length of time—were unknown. Practical experience had convinced Roman winemakers of the need to use chemicals such as sulfur to help prevent spoilage, and by the late 15th century in Germany it was recognized that wine kept in large barrels that were subjected to regular TOPPING UP would last longer than wine kept in small barrels which were left on ULLAGE. However, it was Pasteur who first reported in western Europe that wine deteriorated mainly as a result of the actions of microorganisms and that these could be killed by heating the wine in the absence of oxygen (although see HUNGARY, history).

Much of the impetus for the changes in winery hygiene in the late 20th century came from the New World, in particular from institutions such as the Department of Viticulture and Enology at the University of California, DAVIS, where the driving mentality during the 1950s and 1960s was towards the eradication of poor-quality wine. This, it was argued, could best be achieved through tight control of the FERMENTATION process, excluding the chance interference of a range of microorganisms. More recently, innovative research at the AWRI has also played a significant part in advancing the importance of winery hygiene. Above all, greater hygiene has enabled the adverse effects

of ACETOBACTER and other spoilage microorganisms such as BRETTANOMCYES to be avoided. P.T.H.U.

Current practice

Hygiene is regarded as vital by modern winemakers (although it is still ignored by some of the more traditional ones, several of whom somehow manage to produce top-quality wine). Old cellars, while usually more picturesque, are almost impossible to keep clean and free of BACTERIA and YEASTS.

Most modern wineries, on the other hand, are designed with sanitation and hygiene in mind. STAINLESS STEEL and POLYETHYLENE tanks can be easily cleaned and sanitized; hard floors are designed to drain dry; and all equipment is sited and mounted so that it can be cleaned thoroughly around, above, and below the unit. Vast quantities of water are used, together with non-foaming detergents and sterilizing agents, by carefully trained staff. Research at Stanford University into the use of hydrogels could be a promising alternative that reduces water consumption and loss of wine when pipes and hoses are cleaned. In many wineries, all places where finished wine is exposed to the atmosphere are in separate, aseptic rooms, and care is taken particularly during BOTTLING, to its limit in STERILE BOTTLING. See also BARREL MAINTENANCE and WINERY WASTE.

Some local winemaking traditions supposedly rely on cellar moulds (see TOKAJ in Hungary, for example).

Hygiene, or sanitation, is also important where the grapes are received, as overripe and damaged fruit can easily attract insects, particularly DROSOPHILA and other fruit flies. Piles of POMACE and stems should also be distanced from the winery as these can become a breeding ground for insects. A.D.W.

hyperoxidation. See OXIDATION.

I

IBMP, or 2-isobutyl-3-methoxypyrazine. See ISOBUTYL-METHOXYPYRAZINE.

ice wine, direct Anglicization of the German EISWEIN, sweet wine made from ripe, healthy grapes picked when frozen on the vine and pressed so that water crystals remain in the PRESS and the sugar content of the resulting wine is increased. This sort of true ice wine is a speciality of CANADA, where it is written ICEWINE. It is also increasingly made elsewhere, including AUSTRIA, CHINA, LUXEMBOURG, OREGON, and MICHIGAN. The term has also been used in other English-speaking wine-producing countries for wines made by artificial freeze CONCENTRATION, or CRYOEXTRACTION.

Icewine is CANADA's version of EISWEIN. While Canada is the world's largest producer of ice wine, it comprises less than 5% of the country's total wine production by volume. It is made predominantly in ONTARIO, as well as in BRITISH COLUMBIA, QUEBEC, and NOVA SCOTIA. In 2014, a Government of Canada standard of identity was created stipulating that only wine made exclusively from grapes naturally frozen on the vine can be called 'icewine', 'ice wine' or 'ice-wine', whether made in or imported into Canada. The word 'Icewine', one word with a capital I, is trademarked by Wine Growers Canada, a national trade association. Grapes for VQA Icewine in Ontario and British Columbia must be harvested and pressed in a continuous process while the air temperature is −8 °C/17.6 °F or lower (compared to −7°C/19.5 °F for German Eiswein) with an average minimum sugar level of all grapes used in the final blend not less

than 35 °Brix (around 154 °Oechsle, considerably higher than the minimum in Germany and Austria). Residual sugar at bottling must be at least 100 g/l in Ontario and British Columbia. Wineries must be registered with the delegated provincial authority and indicate their intention to make Icewine prior to harvest and advise when they have harvested. All Icewine must be VARIETAL and made from VITIS VINIFERA grapes or the French hybrid VIDAL, grown and pressed within a recognized Viticultural Area. Canadian wineries were the first to make sparkling Icewine and Icewine from red wine grapes. J.D.

Schreiner, J., *Icewine: The Complete Story* (2002).

icon wine, an expression favoured by marketing people for highly priced, often heavily oaked, wine. Icons are generally regarded as ultra-premium wines, which cost more than super-premium wines, which are in turn more expensive than premium wines. The rest is all but undrinkable.

Idaho, a Pacific Northwest state of the United States with a distinctly CONTINENTAL CLIMATE and three large AVAs. Most of the state's 65 wineries are found in the south-western part of the state where the Snake River Valley AVA and, within it, Eagle Foothills AVA lie on VOLCANIC ash and SANDY loam over ancient deposits from the long-extinct Lake Idaho. Much of Idaho's wine country is described as 'high desert', though the vineyards of Eagle Foothills, at about 762–1,067 m/2,500–3,500 ft in ELEVATION, particularly benefit from proximity to Prospect Peak and the airflow from the hills around it. Those GRANITIC slopes also add pebbly material to the vineyards.

A newer, lower-elevation AVA to the north, Lewis-Clark Valley, is engendering enthusiasm for its VITIS VINIFERA wines, including Bordeaux and Rhône varieties. The AVA shares many characteristics with the Walla Walla Valley AVA of OREGON and WASHINGTON, just 160 km/99 miles west—not only its LOESS soils but also that it drapes

across the state line; about one-quarter of the AVA is in Washington State. D.F.

IFOAM, International Federation of Organic Agriculture Movements. See ORGANIC VITICULTURE.

IGP, short for *indication géographique protégée*, France's PGI category, which has replaced the old VIN DE PAYS and represents about 30% of all wine produced in France. Regulations for an IGP wine are much less strict than for an AOC wine. To qualify as an IGP, a wine must come from a specified area, be made of certain specified grape varieties (usually a much longer list than for an AOC wine), reach a certain minimum ALCOHOLIC STRENGTH, and be submitted to a tasting panel. Each IGP has its own specification, known as a *cahier des charges* (available on the INAO website, along with a map).

French wine producers who farm vineyards within an area that qualifies as an AOC have a choice between making an AOC/AOP (PDO) wine or an IGP wine, or even a wine without geographical indication (VSIG) that will be labelled VIN DE FRANCE, either because yields are too high to qualify for an AOC, or because the grape or mix of varieties used is not permitted by the AOC regulations, or because the tasting panel judges that the style does not conform to that outlined in the *cahier des charges*. In general, IGP wines may be produced from grapes which yield up to 90 hl/ha (5 tons/acre), while 50 hl/ha or so is a more likely maximum YIELD permitted by AOC regulations.

Some of France's 76 IGPs (as of 2022) are regional, for example Pays d'Oc (for wines from the LANGUEDOC and ROUSSILLON) or Val de LOIRE; some are departmental, named after one of France's *départements*, such as Aude, Gard, or Gers. Some are more locally specific, named after some historical or geographical phenomenon such as Cité de Carcassonne and Alpilles. Some IGP names represent strokes of genius. The image of Corsica is transformed in the name

Île de Beauté. Le Pays Cathare recalls the colourful history of this part of the western Languedoc, while one of Roussillon's most popular IGPs rightly emphasizes the region's ethnic origins in Côtes Catalanes. The most important single IGP by far is Pays d'Oc, France's prime source of VARIETAL wine. About 85% of all IGPs are grown in the Languedoc, Roussillon, Provence, or the southern Rhône. This category has also provided a useful way of selling the surplus produce of vines grown in regions specializing in brandy production. Crisp, dry white IGP Côtes de Gascogne has been the commercial saviour of vignerons in Armagnac country since the early 1980s, while the Cognac counterpart is now named Charentais.

IGT, or IGP, stands for Indicazione Geografica Tipica/Indicazione Geografia Protetta, corresponding to the EU denomination PGI. Either IGT or IGP may appear on labels. This category of wines was created in ITALY by law 164 in 1992 as an approximate equivalent of the French VIN DE PAYS. It officially enabled producers to give more information on the labels of their myriad esteemed, and often extremely expensive, wines than selling them as a VINO DA TAVOLA. IGT was created as the basis of a quality pyramid with DOC in the middle and DOCG at the top. Many producers are unable or unwilling to opt for any denomination higher than IGT, either because they produce wines from vine varieties and/or use winemaking techniques not permitted by the local DOC regulations, or because the quality control system, which must establish a wine's TYPICALITY, is unable or unwilling to adapt to changes in viticulture and winemaking resulting in different styles. Wines produced and bottled without SULFUR DIOXIDE, unfiltered wines, and SKIN-FERMENTED white wines fall victim to this. Particularly popular IGTs include Trevenezie, Puglia, Terre Siciliane, Toscana, and Veneto. W.S.

Île de Beauté is a nickname for CORSICA as well as the IGP zone covering the entire island. Many producers opt for this denomination

—or forgo appellations completely, choosing the VIN DE FRANCE designation—to have more freedom, especially as most Corsican INDIGENOUS VARIETIES are not permitted by AOC regulations. The same goes for the recent revival of the historical LIMESTONE terroir of Bonifacio, spearheaded by Clos Canarelli from nearby Figari. Not yet recognized by any of Corsica's AOCs, these wines must be labelled as IGP or Vin de France. A.L.

Île-de-France. IGP approved in 2020 for still red, white, and rosé wines produced in and around PARIS. Five subregions may appear on wine labels: Paris, Guérard, Coteaux de Provins, Coteaux de Suresnes-Mont-Valérien, and Coteaux de Blunay.

imbottigliato is Italian for 'bottled'.

impériale. See BOTTLE SIZES.

Imperial Tokay, historical name used for wine produced on the vineyard properties of the Austrian Habsburg emperors in the TOKAJ-Hegyalja region of Hungary, especially during the 19th century. The Habsburg holdings were concentrated in the village of Tarcal, particularly the highly respected Szarvas vineyard that had been confiscated from the rebellious Prince Ferenc Rákóczi II in 1711. The term became widely known in western Europe following the creation of the Austro-Hungarian Monarchy in 1867. However, Imperial Tokay was usually misunderstood as either necessarily far superior to all other Tokaji wines or an alternative term for Eszencia. M.L.-G.

INAO, the Institut National de l'Origine et de la Qualité (formerly the Institut National des Appellations d'Origine), is the public organization in charge of recognizing, granting, administering, regulating, and protecting the French *appellations contrôlées*, or AOC,

now known as *appellation d'origine protégée* or AOP (see PDO), and the other official *signes* such as IGP that identify quality and origin for agricultural products, including not just wines and spirits but also other alcoholic drinks, dairy products, olive oil, meat, honey, fruit and vegetables, etc. In 2020 there were more than 360 AOC/AOPs for wine (including the 51 separate ALSACE grand cru appellations) and 75 IGPs for wine, as well as 50 AOPs for dairy products and 45 for meat, poultry, olive oil, etc.

Now that IGP wines also come under the INAO umbrella, the INAO supervises more than 90% of French wine production. Nearly 75,000 vine-growers therefore are bound by its rules and depend on its protection—as well as its efforts to continue France's reliance on geographically based wine names rather than VARIETAL wines, known in French as *vins de cépage*. The headquarters are in Paris, but its decision-making structure operates through regional committees of wine professionals.

The INAO was founded in 1935; because France's leading role in the world of wine was undisputed for much of the 20th century, it provided a role model for the administration of more embryonic GEOGRAPHICAL INDICATION schemes being developed in other countries. During the 1980s, however, increasing competition on the domestic and export markets encouraged a re-examination of the role of the INAO. The result was an even stronger INAO, given additional powers in 1990, dedicated to defending and promoting the notion of controlled, geographically determined appellations for products that owe their characteristics to their place of origin and a prescribed mode of production. It is empowered to protect them against imitation both in France and abroad, convinced that France's viticultural future depends on its ability to trade on its uniquely well-established wine names.

Any group of wine producers can apply to the INAO to establish an AOP or an IGP. They have to prepare a dossier by giving reasons for the request, proof of the traditional use of the name of the proposed appellation, full details of the terroir and how it affects production, and economic details concerning added value, markets, sales, prices,

and comparative prices of similar products. Once an application has been agreed by the INAO, it has to be approved by the EU and published in the *Journal Officiel de l'Union Européenne*.

The INAO is also concerned about the sustainability of AOPs and IGPs, reviewing regulations relating to methods of production, defending appellations against the effects of urbanization, and supporting them in anticipating and adapting to CLIMATE CHANGE (see, for example, VIFA) as well as in finding ways to reduce inputs such as fertilizers, irrigation, pesticides, and herbicides.

incrocio, Italian for 'vine CROSS'. A wine made from Incrocio Manzoni grapes, for example, is made from one of Signor Manzoni's many crosses of one VITIS VINIFERA variety with another. His Incrocio Manzoni 6.0.13, Riesling × Pinot Blanc, often known simply as Manzoni Bianco, is the most widely planted with 339 ha/838 acres in 2015, throughout Italy but especially in the south. Incrocio Manzoni 2.15 is Prosecco (now GLERA) × Cabernet Sauvignon. Incrocio Terzi No 1 is a Barbera × Cabernet Franc cross grown in Lombardy.

indexing, method of testing vines for VIRUS DISEASES, PHYTOPLASMA diseases, and their like by GRAFTING buds from an indicator vine—one which shows typical symptoms of the disease—on to the vines being tested. Cabernet Franc, for example, is used as an indicator vine variety to test for LEAFROLL VIRUS. Indexing tests have been replaced by serological methods; see ELISA. R.E.S.

India, large Asian country where wine consumption, production, and quality are increasing steadily. A growing middle class should maintain this trend, despite high taxes, licensing fees, discriminatory inter-state policies, and several dry states.

History

The vine was probably introduced into north-west India from Persia during the Indus civilization in the fourth millennium BCE, but wine may not have been made from its fruit for many centuries. The gradual invasion of Aryan tribes from central Asia during the second millennium BCE produced the Vedic period (*c.*2000–800 BCE), a blossoming of culture in north-west India. The Aryans enjoyed gambling, music, and intoxicating drink, and in the four Vedas, the world's oldest religious texts, two drinks are mentioned: *soma*, a milky drink ceremoniously prepared immediately before a sacrifice and probably containing hallucinatory hemp; and *sura*, a potent secular drink made from either barley or paddy (rice) fermented with honey.

While praising the fierce and hard-drinking Aryan warrior god Indra, the Vedas clearly condemn the effects of drinking. Later, Hindu, Buddhist, and Jain texts reveal similar dichotomies. Kautilya, chief minister under the Mauryan King Chandragupta (ruled *c.*324–300 BCE), was the author of the Arthasastra, a remarkable text on statecraft in which he condemns alcohol and yet chronicles the king's drinking bouts and mentions *madhu* (wine) of various varieties and qualities. This is the first documentation of wine made from grapes in India.

Down the centuries, wine has maintained its status in India as a drink of the Kshatriya caste of aristocrats and warriors rather than of the masses, who have preferred more potent alcohol prepared from the staple local agricultural cereal crops.

The contradictory attitudes towards intoxicating drinks continue into modern times. The Muslim (see ISLAM) Mughal emperors' royal vineyards were in the Deccan; the alcoholic emperor Jehangir (who ruled 1605–27) would drink himself insensible on double- and triple-distilled wine (brandy), violating the Qurʾān's command not to lose one's sensibilities through intoxication.

Secular independent India's Constitution, adopted on 26 January 1950, recommends total PROHIBITION of alcohol among its aims (in

deference to Mahatma Gandhi, the father of the nation) but remains a state subject. Only a few states such as Gujarat, Tamil Nadu, Andhra Pradesh, and Haryana ever enforced, variously, limited or total prohibition. Today Gujarat (Mahatma Gandhi's home state) is the only major state that still has prohibition.

Although the orthodox of all faiths may abstain, Indians everywhere (except Gujarat) are free to consume wine and other alcohol if they choose.

Indian viticulture was encouraged in the 19th century as the Victorian British upper classes enjoyed drinking wine. Vineyards were established in Kashmīr, Bārāmati, Surat, and Golkonda. A number of Indian wines were exhibited at the Great Calcutta Exhibition of 1884 and elicited favourable comment. But in the 1890s, Indian vineyards, like their European counterparts, succumbed to PHYLLOXERA.

Since Independence in 1947, wine production has increased very slowly as it requires long-term investment and, ideally, a strong local market. Goa continued to produce low-quality fortified wines made in the image of PORT, an industry initiated by Portuguese colonists in the 16th century.

Until the 1990s, the small Indian wine industry went virtually unnoticed outside the country, partly because of the quality of the wine, made by rudimentary village operations, excepting a large winery and distillery established in Hyderābād and Bangalore in 1966 by the Shaw Wallace group, producing Golconda and Bosca wines.

Viticulture

India's 111,000 ha/274,287 acres of vineyards produce around 3.5 million tons of grapes a year, of which less than 2.5% are used as TABLE GRAPES and RAISINS. Established vineyards of mainly table grapes are found in the temperate north-west and as far south as the state of Tamil Nadu. Two-thirds of the country's area under vine, however, is in the south-central states of Mahārāshtra (86,000 ha/212,510 acres), Karnataka (18,100 ha/44,726 acres), and Tamil Nadu (2,700 ha/6,672 acres). In Mahārāshtra, cultivation is concentrated around Pune, Nāshik, Bārāmati, Sangali, and Sholhāpur on the west of the Deccan Plateau, about 300 km/180 miles in length and 60 km in width, 135 km inland from Mumbai. The remainder of southern India's plantings are near Bangalore and around Hyderābād.

Plantings range from ELEVATIONS of 300 m/984 ft on the Deccan in Mahārāshtra to over 500 m in Karnataka and a few at 800 m on the slopes of Sahyadri. With India's hot summer and heavy monsoon, temperatures in growing areas range from 8 °C/46 °F in winter to 45 °C/113 °F in summer, 625–1,500 mm/25–60 in of rain falling between June and August depending on the region. There is little unseasonal rain. Humidity levels are high, particularly during the monsoon, moderated only by afternoon winds. Eastern regions suffer most from humidity and extreme heat.

Over half the total vineyard area is planted to SULTANA, although INTERNATIONAL VARIETIES are increasingly planted by the leading wine companies. Indigenous TABLE GRAPES such as Anab-e-shahi are grown along with Bangalore Blue (ISABELLA) and Bangalore Purple, which are the major varieties in Tamil Nadu, Telengana, and Karnataka along with some Gulabi (MUSCAT OF HAMBURG) and small amounts of Perlette. These varieties account for less than 10% of Indian grapes, however.

Vines are trained high on wire and bamboo with wide ROW SPACING to retain SOIL WATER, prevent SUNBURN, and maximize aeration of the vines, minimizing the risk of FUNGAL DISEASES. Since the early 1980s, DRIP IRRIGATION has been used throughout the growing season.

Pruning takes place in April and October with harvest (always manual in India) in February and March. Average YIELDS are 32 tons/ha. In warmer regions, particularly Andhra, Karnataka, and Tamil Nadu, two harvests a year are possible. See TROPICAL VITICULTURE.

The contemporary wine industry

The current renaissance of Indian viticulture began with pioneers Chateau Indage (known later as Indage Vintners) in 1984 near Pune in Mahārāshtra and Grover Vineyards in 1988 north of Bangalore in Karnataka, both of which set themselves the goal of exporting. Indage produced an impressively elegant sparkling wine for the international market. A short-sighted and aggressive overseas expansion programme and diversification in 2007/08 resulted in its collapse soon afterwards. Grover Vineyards trialled 33 vine varieties initially and settled principally on Cabernet Sauvignon and Clairette, which grow on PERGOLAS. Its first wine was released in 1992. With French oenologist Michel ROLLAND as its wine CONSULTANT, Grover's quality and reputation grew steadily. The company, merged with Nāshik-based Vallée de Vin (whose main brand is Zampa) to form Grover Zampa Vineyards in 2012, has grown considerably with new acquisitions.

Sula Vineyards, founded by former Silicon Valley engineer Rajeev Samant, set up its winery in Nāshik in Mahārāshtra in 1999 with the help of Californian wine consultant Kerry Damskey. Sula produced India's first varietal Chenin Blanc, Sauvignon Blanc, Riesling, and Zinfandel. In 2005 Sula overtook Grover to become India's largest wine producer following the demise of Indage Vintners. Today Sula's market share is around 70%, with sales of around 11 million bottles in 2020. The company also imports and distributes wine and has spearheaded wine TOURISM in India.

India's wine industry has also attracted significant outside investment: DIAGEO is a major shareholder in Four Seasons; LVMH launched Chandon India in 2014; Jean-Charles BOISSET is a partner in J'Noon, and Fratelli Wines is India's first Indo-Italian collaboration.

KRSMA Estates, a boutique winery near the UNESCO heritage site of Hampi in Karnataka, became India's first winery to be voted among the World's 50 Best Vineyards in 2020. R.K.S.

www.karnatakawineboard.com

Indiana, midwestern state in the UNITED STATES with more than 120 vineyards and wineries, many residing within the Indiana Uplands AVA, an area of 1,530 square miles (396,268 ha) next to the massive Ohio River Valley AVA (6,733,969 ha/16,640,000 acres) in 2022. Indiana Uplands wineries include Oliver Winery, established more than half a century ago and among the Midwest's largest wineries. Most Indiana wines are based upon fruits, HYBRIDS, and AMERICAN VINE SPECIES though a significant amount of VITIS VINIFERA-based wines are produced as well. The state was the site of some early vinous efforts by Swiss vineyardists, particularly Jean Jacques Dufour, author of *The American Vine-Dresser's Guide* (1826), which remained the dominant treatise far into the 19th century. D.F.

indicator. See INDEXING.

indigenous varieties, VINE VARIETIES that are intensely local to a particular area and have a relatively long tradition of being grown there. Researchers in SWITZERLAND and GASCONY were some of the first to rescue near-extinct local varieties in the 1980s, but they have been followed by a host of others in the early 21st century, particularly but not exclusively in Italy. A discernible FASHION for indigenous varieties emerged as a reaction to an earlier one for INTERNATIONAL VARIETIES.

Indonesia had six wineries by 2022, all on the resort island of Bali, and around 400 ha/988 acres of grapevines. The industry pioneer, Hatten Wines, is by far the largest winemaking enterprise, turning out 1.3 million bottles a year. It began making wines from locally grown grapes in 1994, operating from an old rice wine factory at Sanur Beach in the south-east of the island, but its vineyards are in the Buleleng region in the island's north-west (latitude 8° S). Here, ELEVATION provides some modest respite from the relentless TROPICAL heat and humidity, but climatic conditions are such that the vines crop almost continuously.

Indonesia's original vineyards were planted by European settlers with the French VITIS VINIFERA varieties Alphonse Lavallée (Ribier) and Belgia. Both remain the major varieties, grown on overhead PERGOLAS to better manage the humidity, and are now used extensively for winemaking. Probolinggo Biru, a white-berried variety likely introduced from India, is being cultivated by Hatten for sparkling wines. Hatten also grow Syrah, MALVASIA NERA, SOLARIS, CHENIN BLANC, COLOMBARD, and Swiss HYBRIDS Muscat Bleu and Cabernet Blanc, PRUNING twice to force DORMANCY, allowing just one harvest per year (see TROPICAL VITICULTURE). Sababay, Bali's second largest producer, supplements domestically grown grapes with imported concentrates for its wines. Using imported grapes or MUST is popular because it allows consumers access to 'imported' wine without the onerous taxes. D.G.

inert gas, a gas used to protect wine from OXIDATION, including CARBON DIOXIDE, NITROGEN, and argon. Of these, the only truly inert gas is argon. Carbon dioxide is ideal for removing oxygen from storage vessels because it is heavier than air. Inert gas mixtures are often used because carbon dioxide dissolves in wine, possibly giving a higher-than-desirable residual concentration of this gas. Argon, like nitrogen, has a very low solubility in wine, and inert gas mixtures of either or both of these two with carbon dioxide can, with modern metering equipment, be selected to leave a residual level of dissolved

carbon dioxide that is optimal for the style of wine under storage. Inert gases are also used to flush the oxygen from hoses and pumps, as well as during BOTTLING. D.B.

Inferno, one of five subzones of the VALTELLINA Superiore DOCG in the far north of Italy.

inflorescence, the structure that bears the flowers (see BUNCH for more details). At FLOWERING, the grape flower becomes a BERRY and the inflorescence a bunch.

influencers have an increasing effect on FASHION and sales of wine, thanks to their presence in SOCIAL MEDIA. As in other spheres, some write what they are paid to while others have much higher ethical standards and enrich WINE WRITING (and imagery) in general. For newcomers, social media is the obvious gateway to a wine-related career.

information technology (IT) has revolutionized the world of wine as much as any other. Computers are now used throughout the production process. In the vineyard they can schedule and control IRRIGATION, for example, or measure weather and predict and even control SPRAYING regimes. They can assist VINEYARD SITE SELECTION by analysing and mapping data on CLIMATE, SOIL, VIGOUR, and TOPOGRAPHY. By monitoring, for example, WATER STRESS or FERTILIZATION needs in different parts of a vineyard, IT and ARTIFICIAL INTELLIGENCE can help control wine quality (see QUALITY IN WINE) and BERRY SIZE and in the long term can contribute towards SUSTAINABILITY. In the winery, IT can weigh and SAMPLE grapes, sort them (see GRAPE SORTING) sort control CRUSHING and PRESSING operations, ensure the most vigilant TEMPERATURE CONTROL, and eventually oversee BOTTLING.

Thanks to information technology, wine ANALYSIS is today much more sophisticated than could have been imagined even a decade ago, and there have even been attempts to mechanize the process of TASTING. During fermentation, IT-integrated tanks provide temperature and wine composition data for each tank, not just in the winery but for a CONSULTANT who may be thousands of miles away. During ÉLEVAGE, the content and history of individual tanks, barrels, and pallets can also be tracked.

Information technology has greatly assisted such techniques as DNA PROFILING in vine-variety identification and the possible new technique of 'fingerprinting' a vineyard by analysis of its MINERALS.

Those who sell wine, whether to consumers or in BULK to the trade, can use information technology to administer all aspects of TRANSPORT, STORAGE, stock control, and retailing, as well as being able to present their wares directly to potential customers via the internet —which can be an advantage when selling a commodity as tightly regulated, heavy, and fragile as bottles of wine (see E-COMMERCE). The internet has spawned a new generation of independent, often very small, online wine merchants, and has greatly widened the appeal of wine AUCTIONS.

As well as offering wine consumers a new market place, for both buying and selling, and a new medium for wine information, opinion, and EDUCATION via myriad websites, blogs, and online posts, the internet has provided them with an unprecedented forum for discussion, not just about the wines themselves but also about WINE WRITERS, a new sort of consumer power, even if one that tends to attract wine BORES. Platforms such as Twitter, Facebook, and Instagram (see SOCIAL MEDIA) are spreading the diversity of wine to a much less specialized, more democratic readership, encouraging the discovery of wines from a broader range of countries and sources. These tools have helped wine producers, retailers, and regions to find new routes to the consumer.

Those who keep and wish to share detailed cellar records and TASTING NOTES have reason to be grateful for the flexibility and sorting

ability of IT (see CELLARTRACKER). And price-comparison websites such as Wine-Searcher.com have revolutionized wine retailing and encouraged fair PRICING on a global scale.

As online technologies develop, the international wine market is being revolutionized. For example, our mobile phones can now provide us with more information than we could have dreamt of simply by being pointed at a wine label or QR code. Microchips inserted in cases of wine provide fine-wine lovers with myriad data on shipping TEMPERATURES. They are expected to play an increasing part in fighting COUNTERFEIT WINE and much else besides.

infrared spectroscopy is fast becoming a routine ANALYSIS method in wine laboratories. This ground-breaking technique relies on the fact that all organic compounds have a unique spectral fingerprint in the Near Infrared (NIR) and Mid Infrared (MIR) regions of the electromagnetic spectrum. In the past it has been difficult to interpret these fingerprints on grape or wine samples, but by the 2010s the availability of cheap instrumentation, computing power, and software development meant that it had become a standard method of analysis in food and agriculture, including the wine industry.

The critical advantages of IR spectroscopy are that very little sample preparation is required, no dangerous laboratory chemicals are needed, multiple analyses can be tested simultaneously, and, once the methods have been developed and programmed into the instrument, very little user training is required. NIR is less sensitive than MIR, but the lower absorbance makes it more penetrating, capable of analysis of grape must, whole grapes, grapevine tissue, and soil. The penetrating power of NIR can also be utilized to analyse packaged wine non-destructively, by scanning through the bottle. MIR is more sensitive and is better suited to the analysis of clarified grape juice and wine.

IR spectroscopy may be used to analyse, for example, SUGAR, PH, ACIDITY, moisture content, TANNINS, ANTHOCYANINS, and GLYCOSYL-

GLUCOSE. Grapes can also be analysed for negative quality indicators, such as fungal spoilage by BOTRYTIS and POWDERY MILDEW. Water potential of grapevine leaves is used as an indicator of WATER STRESS and can be analysed non-destructively by IR spectroscopy to aid IRRIGATION scheduling. Grapevine wood (see CANE and TRUNK) can be analysed for starch and sugar, to determine over-wintering vine storage reserves. Wines can be analysed for most routine measures such as DENSITY, ALCOHOL, pH, total acidity, sugar, VOLATILE ACIDITY, anthocyanins, tannins, and organic ACIDS. In addition to quantitative methods, with appropriate software qualitative methods such as classification of growing region and grape variety can be performed with the IR fingerprint, allowing the possibility of rapid wine AUTHENTICATION. IR spectroscopy can also be used to uncover ADULTERATION of wine. R.D.

Gishen, M., et al., 'The analysis of grapes, wine, and other alcoholic beverages by infrared spectroscopy', in E. C. Y. Li-Chan et al. (eds.), *Applications of Vibrational Spectroscopy in Food Science* (2010), 539–56.

ingredient labelling. Since detailed specification on labels of ingredients in foodstuffs is mandatory in most major markets, the EU has proposed that wine should also be subject to this requirement, and the US looks set to follow. By 2021 the EU producers' association, the CEEV, had made considerable progress towards this development, which will be mandatory for all wine sold in the EU by the end of 2023. Since all ingredients (not PROCESSING AIDS as defined by the OIV) will have to be listed, as well as nutritional information, in the language of each country in which the wine is sold, this could be extremely difficult on traditional printed LABELS. Even some of the most lauded wines in the world may have to cite yeast (unless AMBIENT), sugar (if CHAPTALIZED), and TARTARIC ACID (if acidified), together with any other ADDITIVES. Mindful of this, the CEEV has developed a global platform for digital U-labels, an alternative to

printed labels whereby all this can be communicated by a QR code on the bottle, with automatic translations. Producers of NATURAL WINE presumably welcome any public airing of the wide array of additives used by their more industrial rivals, but smartphones may become an essential accessory for curious wine drinkers. See also LABELLING INFORMATION.

initiation, botanical term for the start of the vine's fruiting when the first signs of bunches are evident as small pieces of tissue in the developing bud. These buds are themselves developing beside the leaf stalk on the shoots as they grow in spring. Initiation starts simultaneously with the FLOWERING stage of the growing season. Warm, sunny weather conditions at this time favour initiation, with one, two, occasionally three, or very rarely four bunches per bud initiated. When this bud bursts the following year, it will be termed FRUITFUL. Cold, cloudy weather depresses fruit bud initiation, and varieties vary in fruitfulness.

Part of the annual variation in vineyard YIELD is thus due to weather conditions affecting initiation during the year previous to the crop being harvested. The time when the vines are flowering is the most critical period for bunch initiation. Warm sunny weather encourages both the flowering of the year's crop and, in the buds developing in the leaf axil on the developing shoot, the initiation of next year's crop. R.E.S.

Keller, M., 'Phenology and growth cycle', in *The Science of Grapevines* (3rd edn, 2020).

injection, alternative name for CARBONATION, the cheapest and least effective method of SPARKLING WINEMAKING involving the simple pumping of CARBON DIOXIDE into a tank of wine.

inner staves, or inserts, planks of wood, usually OAK (exclusively oak in the EU), placed in a stainless-steel tank and held in position by

a metal framework, are a way of imparting oak flavour and other attributes such as STRUCTURE, roundness, and LENGTH to wine more cheaply than by fermenting or ageing in BARRELS since the staves are easily replaced. Tank staves are sometimes used in conjunction with MICRO-OXYGENATION to mimic the use of barrels for fermentation or maturation without the cost of barrels, a barrel cellar, and barrel cellar workers. Staves may also be used in oxygen-permeable tanks made of food-grade POLYETHYLENE. See also BARREL INSERTS.

INRAE (l'Institut National de la Recherche pour l'Agriculture, l'Alimentation et l'Environnement). The National Research Institute for Agriculture, Food and the Environment was created in 2020 by merging INRA, the National Research Institute for Agricultural Research, and IRSTEA, the National Research Institute of Science and Technology for the Environment and Agriculture. It is under the control of both the Ministry for Scientific Research and the Ministry of Agriculture.

INRAE brings together a community of 12,000 people, with just over 200 research units and around 40 experimental units in 18 centres across France, three of which specialize in grapevines and wine. A world leader in agricultural and food sciences, plant and animal sciences, and ecological and environmental research, the institute's ambition is to be a key player in responding to major global challenges such as population growth, CLIMATE CHANGE, the scarcity of resources, and the decline in biodiversity by building solutions that promote both yield and quality as well as sustainable management of resources and ecosystems.

INRAE Bordeaux, part of the ISVV, specializes in grapevine ecophysiology, genetics, ROOTSTOCKS, pest and diseases, OENOLOGY, and experimental economics.

INRAE Montpellier focuses on ecophysiology and 3D plant modelling, taking into account WATER and HEAT STRESS; genetic diversity; oenology; PRECISION VITICULTURE; water management; viticulture systems under Mediterranean conditions; and the socio-

economics and institutional management of the wine industry. The Montpellier Pôle Vigne-Vin brings together the various research and technology departments involved in the vine and wine industry in Montpellier and the Institut des Hautes Études de la Vigne et du Vin to disseminate technological innovation and to train agronomists and oenologists.

At Colmar, research focuses on genetic breeding, berry composition, and FUNGAL and VIRUS DISEASES. Researchers have identified innovative solutions that meet the challenges of SUSTAINABLE VITICULTURE, including new varieties resistant to DOWNY MILDEW and POWDERY MILDEW.

INRA's most significant contributions to advances in viticulture since its foundation in 1946 include the introduction of CLONAL SELECTION in France to help combat virus diseases and thus improve quality and YIELDS; the development of LOW-INPUT VITICULTURE (often referred to as *lutte raisonnée*), establishing the best use of fertilizers on high-quality vineyards, reducing the use of FUNGICIDES, and breeding DISEASE-RESISTANT VARIETIES; and understanding the influence on wine quality of different vine-TRAINING SYSTEMS and the condition of grapes at HARVEST. Other research priorities have included grape RIPENING, the organoleptic properties of PHENOLIC compounds, wine stability, biology of wine YEASTS, and control of FERMENTATIONS.

IRSTEA's historical contributions are related to water management (developing IRRIGATION systems, for example) and, in collaboration with Montpellier SupAgro, precision viticulture.

INRA's collection of 7,000 VITIS VINIFERA varieties and HYBRIDS, held at the Domaine de Vassal on the Mediterranean coast, is now managed by INRAE and known as the Centre de Ressources Biologiques de la Vigne (CRB-Vigne). It works in partnership with the Institut Français de la Vigne et du Vin (IFV) and other professional bodies and has been a centre for the analysis, preservation, and management of biodiversity, especially with regard to pest and disease resistance and wine quality. The sandy soils are free of both PHYLLOXERA and the nematode *Xiphinema index*. Some NEW VARIETIES,

MARSELAN, for example, have also been developed here; thanks to the work of AMPELOGRAPHERS such as Paul Truel and, later, Jean-Michel Boursiquot and Thierry Lacombe, Domaine de Vassal is a worldwide focus for vine identification. Work began in 2014 to move the collection to INRAE's experimental unit Pech Rouge near Narbonne.

www.inrae.fr/en

insecticides. See PESTICIDES.

insect pests. A wide variety of insects attack grapevines. Injury may occur as a result of direct feeding action, where reductions in leaf amount or leaf health can delay RIPENING with serious implications for wine quality, or as a result of carrying (vectoring) a particular VIRUS DISEASE or PHYTOPLASMA disease.

Alternatively the vine root system can be attacked, which leads to development of WATER STRESS and restricted VINE NUTRITION. While minor stress may enhance wine quality (see VINE PHYSIOLOGY), the more likely outcome of root damage by insects such as PHYLLOXERA (the most destructive of all insect pests) is severe stress or vine death. Insect pests such as phylloxera attack only grapevines, while many others attack a range of different plants.

Different insect pests attack grapes and vines in different parts of the world and in different districts, and what may be an important pest in one area may be unimportant or non-existent in another. The most important in European vineyards are the BEETLES *écrivain* and *cigarier*, the MOTHS cochylis, eudemis, and eulia, and MITES. The MEDITERRANEAN FRUIT FLY can be a pest in some areas of Australia but is not present in the United States, while LEAFHOPPERS are serious pests in California but not Australia. Other insects, such as CUTWORM and GRASSHOPPERS, are general agricultural pests worldwide.

Insect pests which affect only the appearance of grapes concern growers of TABLE GRAPES but not growers of wine grapes, who are more likely to be concerned with effects on YIELD or wine quality. Grape RIPENING can be seriously delayed, for example, when the WESTERN GRAPELEAF SKELETONIZER reduces leaf area and thus reduces PHOTOSYNTHESIS; vineyards can be destroyed as young plantings by cutworms or when mature by MARGARODES and phylloxera. Perhaps more insidiously, insects such as the fruit fly (see DROSOPHILA) can carry spores associated with BUNCH ROTS, and the MEALYBUG can transmit LEAFROLL virus. Leafhoppers spread the serious GRAPEVINE YELLOWS and PIERCE'S DISEASE and make such disease notoriously difficult to control. The larvae of some insect BORERS, such as the fig longicorn borer (*Acalolepta vastator*) in the Hunter Valley, can live inside grapevines and cause damage to the trunk.

Over recent decades, insects have also been found to cause wine taints when they are present on the fruit at harvesting and crushing. See LADYBUG TAINT and BROWN MARMORATED STINK BUG.

In general, insect pests are relatively easy to control in vineyards, although insecticides (see PESTICIDES) are among the more dangerous AGROCHEMICALS for operators to apply. Modern approaches to viticulture are more environmentally aware than previously, and so persistent chemicals such as DDT are no longer used, and INTEGRATED PEST MANAGEMENT, designed to reduce insecticide use, is becoming increasingly common, as are ORGANIC and BIODYNAMIC VITICULTURE. For example, predatory mites are encouraged, to control levels of damaging mites.

See also entries for the specific pests ANTS, APHIDS, BEETLES, BORERS, BROWN MARMORATED STINK BUG, CUTWORMS, DROSOPHILA, ERINOSE MITE, GRASSHOPPERS, LEAFHOPPERS, LOCUSTS, MARGARODES, MEALYBUGS, MITES, MOTHS, PHYLLOXERA, SCALE, SPOTTED LANTERNFLY, THRIPS, and WESTERN GRAPELEAF SKELETONIZER. R.E.S.

Buchanan, G. A., and Amos, T. G., 'Grape pests', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

integrated pest management, or IPM, a term which dates back to the mid 1970s in Europe. Initially developed for INSECT PESTS, IPM now encompasses the control of diseases, weeds, and physiological vine disorders and has the potential to increase economic returns for the grower and improve environmental and human safety by reducing, limiting or even eliminating the use of AGROCHEMICALS.

IPM is considered by conventional growers as a form of SUSTAINABLE VITICULTURE, but most IPM management systems differ from ORGANIC VITICULTURE because they tolerate the use of industrially synthesized products such as HERBICIDES, PESTICIDES, and FERTILIZERS. However, IPM aims to stop the regular, calendar-based spraying of chemicals in a potentially wasteful manner and instead to apply such treatments in a more accurately timed way and targeted to specific threats.

Thus IPM takes account of the environment, particularly weather phenomena recorded in VINEYARD WEATHER STATIONS, the occurrence and life cycles of pests, and the incidence of natural enemies and alternative host plants. It requires a knowledge of the biology of the pest and, monitoring of the occurrences of the pest and any natural predators. All this information is integrated into a decision-making process, often involving computer applications based on disease modelling and, increasingly, using ARTIFICIAL INTELLIGENCE.

A number of VINE PESTS and diseases have been studied under the aegis of IPM philosophy. For example, the European grapevine MOTHS *Lobesia botrana* and *Eupoecilia ambiguella* can cause extensive damage, and studies have shown that their population levels can be limited naturally by VIRUS DISEASES and protozoan diseases. Similarly, MITES which damage vines can be controlled by other species of predatory mites, but sometimes the latter's beneficial effect can actually be limited by the application of pesticides, in particular some

FUNGICIDES. Indeed, the increased use of some agrochemicals has altered the balance of predator to pest mites. M.W. & R.E.S.

integrated production, or IP, European system of viticulture, developed in the 1970s, aimed at reducing environmental degradation in vineyards while at the same time maintaining economic viability of viticulture. It is similar in philosophy to SUSTAINABLE VITICULTURE. As the name suggests, it has its roots in INTEGRATED PEST MANAGEMENT, or IPM.

South Africa's INTEGRATED PRODUCTION OF WINE (IPW) is a voluntary scheme established in 1998 and emphasizes the importance of balancing the needs of the natural habitat with those of winegrowers. See also ORGANIC and BIODYNAMIC VITICULTURE.

Integrated Production of Wine (IPW) in SOUTH AFRICA is a voluntary environmental SUSTAINABILITY scheme established in 1998. The scheme's criteria are based on international standards and were drafted taking account of International Federation of Wines and Spirits (FIVS) and the OIV's guidelines for sustainable viti-viniculture. For grape production these include SOIL PREPARATION, VINE NUTRITION, IRRIGATION, CANOPY MANAGEMENT, GROWTH REGULATORS, INTEGRATED PEST

MANAGEMENT, and handling of AGROCHEMICALS. Only grapes that qualify for IPW may be used for IPW wines. The cellar and wine-production guidelines cover issues such as SULFUR DIOXIDE levels as well as WINERY WASTE management. The production practices of members and aspirant members of the scheme are evaluated and audited by the Wine and Spirit Board. Wines which have achieved an appropriate level of IPW compliance are marketed with an IPW certification seal. The World Wildlife Fund (WWF) Biodiversity & Wine Initiative operates with the IPW certification scheme and aims to minimize the loss of natural habitat by working with producers who commit to set aside protected areas for long-term conservation. M.F.

International Grape Genome Program (IGGP), a framework for multinational collaborative grapevine research, with an emphasis on grapevine genomics. This project fosters efforts to characterize grape genes responsible for resistance to pests and diseases, vine growth, and fruit quality. These efforts result in the identification of genetic markers capable of expediting and optimizing classical VINE BREEDING. They also lead to the identification of grape genes that could be used to genetically modify and improve grapevines while having limited impact on variety integrity, a process known as cisgenics. See GENETIC MODIFICATION and PIERCE'S DISEASE.

www.vitaceae.org

international varieties, loose term for those VINE VARIETIES with an international reputation for their VARIETAL wines. They are planted in almost every major wine region in which they stand a chance of ripening. Foremost among them are the red-wine variety CABERNET SAUVIGNON and the white-wine variety CHARDONNAY (which many consumers take to be either a place or, more usually, a BRAND). Other strong candidates as international varieties are MERLOT, PINOT NOIR,

and, especially, SYRAH/SHIRAZ among reds and SAUVIGNON BLANC, RIESLING, MUSCAT, GEWÜRZTRAMINER, VIOGNIER, PINOT BLANC, and PINOT GRIS among whites. As winemakers and wine consumers constantly search for new excitement, the list of possibilities grows longer. MOURVÈDRE, TEMPRANILLO, SANGIOVESE, and NEBBIOLO could already be said to have joined this elite with all manner of others in the wings. But the second decade of this century, as part of a reaction to GLOBALIZATION, saw a certain backlash against international varieties in favour of INDIGENOUS VARIETIES and ALTERNATIVE VARIETIES.

International Wine & Food Society (IWFS), the oldest and most cosmopolitan of the gastronomic societies for consumers rather than professionals. Initially simply the Wine & Food Society, it was founded in London in 1933 by André SIMON and like-minded friends. Its aim, other than providing a readership for a journal *Wine and Food* which Simon planned to edit, was to promote the highest quality of raw materials and an appreciation of how they could best be served and consumed. An early motto was 'Not much, but the best'. Launched in full economic depression (partly as a reaction to the culinary decline which resulted from it), the society attracted its fair share of criticism initially and might well have withered had not the Repeal of PROHIBITION opened up North America to the proselytizing of M. Simon. Soon there were branches all over the United States, where it is most important today, although the IWFS remains based in London. André Simon and his early colleague A. J. A. Symons launched the first pocket VINTAGE CHART in 1935, and it is annually revised by a special committee of the IWFS to this day, providing useful income through sales to publishers of diaries and the like. The journal, abandoned in 2000, was at one stage edited by Hugh JOHNSON.

internet. See INFORMATION TECHNOLOGY.

internode, the part of the stem between NODES. The internode length varies between different VINE VARIETIES and with growing conditions. It is shorter with weak shoots, low temperatures, WATER STRESS, mineral deficiencies (especially of NITROGEN), and the position along the shoot (with the nodes closest together at the base and the tip). Shoots on vigorous vines have long internodes and are large in diameter. Measured lengths vary from about 1 mm to 350 mm/13.6 in, but commercially used cuttings usually have internode lengths between 50 and 150 mm. B.G.C.

interspecific hybrid denotes the result of sexually crossing more than one grapevine species, while a CROSS of varieties of the same species is intraspecific. See HYBRID and VITIS for some background.

intolerance of wine. See ALLERGIES AND INTOLERANCES.

invecchiato, Italian for 'aged', although *affinato* is more frequently used.

invertase, a very important ENZYME in the grape berry for converting the larger molecule SUCROSE to its constituent molecules of GLUCOSE and FRUCTOSE in the ripening fruit so that sugar develops (see SUGAR IN GRAPES). The name 'invertase' comes from the so-called 'invert' sugars of glucose and fructose. The reaction of this enzyme differs from that of other enzymes in that it is not reversible. This is one of the most widespread enzymes in the plant kingdom and, indeed, one of the most efficient. It can metabolize 1 million times its own weight of sucrose with no loss of activity. The enzyme is located in the VACUOLE of berry cells, where it functions readily in the acidic environment. R.E.S.

investment in wine is the acquisition of wine for gain, whether as a means of making money, financing consumption, or a combination of the two.

The principal object of wine investment is to make a profit on wine which has increased in value as it matures. The essential premise on which wine investment is based is that demand for the wine in question exceeds supply, a premise that is often hard to gauge with accuracy, although it can help to secure wines of limited availability or high FASHION that may not appear again on the market.

Buying 'earliest, cheapest, lowest' is usually available to those in the know or with solid contacts. Indeed, historically the wine trade itself, with its inside knowledge, has been known to 'take a position' on a vintage, buying grapes on a speculative hunch. This practice, known as buying *sur souches* (i.e. while the grapes are still on the vine) was referred to in Roman times by PLINY the Younger (8. 2) and became part of the folklore of the BORDEAUX TRADE, as discussed below.

Speculation and buying for consumption need not be mutually exclusive. Indeed, spreading the risk by buying mixed portfolios of wine with both disposal and consumption in mind makes sound sense and is normally advised by companies dealing in wine investment. In times of economic uncertainty, a tangible asset such as wine can bring with it comfort and prestige, and with a life expectancy for tax purposes of less than 50 years, it does not generally attract capital gains tax in the UK, unlike in the US, where the higher, collectible capital gains tax is charged when collectors sell wine. There may, however, be circumstances in which even UK tax officials would regard wine investment as a business and tax it accordingly. Vintage PORT, in particular, with a life expectancy of 50 years or more, is liable not to be regarded as a wasting asset for tax purposes.

The popularity of wine as an investment has led to the creation of a number of investment schemes, or wine FUNDS, based in the UK, some of which are regulated by the Financial Services Authority (FSA), unlike those of wine merchants whose main aim is to move

stock. Since 2012, the FSA has attempted to tighten the rules to prevent consumers from being sold risky investments.

But wine investment is inevitably a gamble, especially for anyone under the mistaken impression that making money from it is simply a question of holding on long enough to one's stock. Speculation in wine tends to be especially risky because wine is subject to the unpredictable fluctuations of market forces. Buyers' and sellers' markets come and go, and wine PRICES are as liable to go down as up. BORDEAUX, for reasons discussed below, has been the principal medium of wine investment. The name Bordeaux is virtually synonymous with wine investment, and its turbulent past bears witness to fortunes made and unmade in the name of wine.

In more recent years, the wine-investment scene has embraced a wider portfolio of wine regions, notably Burgundy, as well as Champagne, Italy, Spain, and California. It has also attracted unscrupulous individuals who have manipulated secondary wine market data and extrapolated media reports to build a case for wine investment. Because fine wine is held in distant warehouses for many years, it is the perfect vehicle for unscrupulous traders. Promises of high returns have often not been fulfilled because of fat broker margins, high storage costs, weakening currency-exchange markets, company failure, and shady dealings. COUNTERFEIT WINE accounts for a small proportion of the fine and rare wine market, but in periods of high speculation and expectations some fraudsters have attempted to circulate wines of questionable provenance, especially in emerging and particularly buoyant markets.

Bordeaux: cyclical history

The first great boom in Bordeaux resulted from a period of prosperity which coincided with shortages caused by POWDERY MILDEW in the 1850s. The canny merchant Hermann Cruse had struck the first speculative blow already, when in 1848 he had bought up vast quantities of the 1847 vintage, only to release his hoard at undisclosed prices following Napoleon III's imperial accession. British Chancellor of the Exchequer (later to be Prime Minister) Gladstone's reduction of duty on French wine following the 1860 Anglo-French Commercial Treaty and the Single Bottle Act of 1861 (which paved the way for the off-licence and thus a retail trade in alcoholic drinks) further fuelled demand for red bordeaux.

Following the fine vintages of 1864 and 1865, prices doubled. Two successive lean years then led to speculative buying of the hard and slow-maturing 1868 vintage, *sur souches*. Chx Lafite and Margaux offered their 1868 to the Bordeaux market, achieving record prices which were not to be surpassed for another 58 years. But this was already the beginning of the end of the first golden era of wine. The Bordeaux merchant Edouard Kressmann mirrored Hermann Cruse's earlier coup with his successful speculative purchase of the fine 1870 vintage harvested during the Franco-Prussian War. The 1875 vintage marked the end of this flamboyant period, however, as the imminent plagues of DOWNY MILDEW and PHYLLOXERA cast a blight over the vineyards of Bordeaux (see BORDEAUX, history).

History was to repeat itself nearly a century later. During the post-war period of economic regeneration, the turning point came in 1959, when, following two devaluations of the French franc, the Americans first decisively entered the market for fine Bordeaux wines. The 1959 vintage was hailed as the vintage of the century, a term which has subsequently come to be applied ad nauseam to almost any vintage of note (usually revealing more about the ability of the Bordelais to feed speculation than about the quality of the vintage at issue). The clamour increased for the small but spectacular vintage of 1961. Between 1958 and 1961, the prices of the FIRST GROWTHS, on which

most of the speculative activity was focused, more than quadrupled. By 1961, they had widened the gap between themselves and the other CLASSED GROWTHS to such an extent that their reputation as blue-chip investment wines became even more firmly established.

Towards the end of the decade, the devaluation of the French franc in 1969 and the rivalry between Chx LAFITE and MOUTON ROTHSCHILD contributed to a fresh climate of speculation that was to grip Bordeaux in the early 1970s. An opening-price battle between the first growths heralded the start of a boom, underpinned by a widespread feeling that demand would outstrip supply for the foreseeable future. A flood of foreign investment capital washed into Bordeaux to lap up the 1970 and 1971 vintages. Extortionate prices were asked—and paid—for the 1972 vintage, even though it turned out to be lean and mean.

A market develops

As inflation soared, red bordeaux became a wine investor's primary haven. The AUCTION houses Christie's and Sotheby's, whose new wine departments were established in, respectively, 1966 and 1970, provided the ideal forum for acquisitions and disposals. During the same period, numerous investment schemes were established to attract corporate finance, while wine merchants such as Justerini & Brooks set up their own schemes to cater for the speculative appetites of consumers.

Rising oil prices and the collapse of American financial hegemony already signalled impending disaster by the spring of 1973. Tastings of the 1972 vintage coincided with the prospect of a large 1973 vintage, which turned out to be unexceptional in quality. Circumstances were aggravated by a scandal in which the Bordeaux house of Cruse was charged with—and subsequently convicted of—fraud. By 1975 Chx Lafite and Mouton Rothschild had buried the hatchet and offered surplus stocks through Christie's.

Speculation fever was rekindled by the *annus mirabilis* of 1982, when an exceptional red Bordeaux vintage coincided with a relatively weak French franc and a strong American dollar. Opening prices of the first growths, FF170, were more than double those of the 1980s. The fashion for buying EN PRIMEUR, boosted by the superb 1982 vintage, created a new wave of populist investment fervour. The momentum for this new form of speculative buying was buoyed by a succession of fine vintages during the 1980s and by, for the first time, accessible press comment on the relative merits of individual, if embryonic, wine samples (see WINE WRITING). The 100-point SCORING system, introduced by the American critic Robert PARKER, brought fresh impetus to invest and an independent basis for assessing fine wine.

In the early to mid 1990s, despite particularly fine crops in 1985, 1986, 1989, and 1990, the market took a downward turn. The unfulfilled promise of increasing consumption was further aggravated by an embarrassing surplus of fine bordeaux. Following two

successive great vintages in 2009 and 2010, with an influx of interest from Asia and exorbitant prices to match, three consecutive vintages of average quality called into question the entire future of the en primeur market and the Place de Bordeaux as the principal incubators of the secondary market. Confidence was also dented by the proliferation of unscrupulous peddlars of wine investment schemes (some of whom owned very little wine and knew even less about it, but were adept at cold calling) and some widely publicized counterfeit wines. In the subsequent decade, prices of fine bordeaux failed to recover their 2011 peak. The en primeur campaign for the 2019 vintage—held when global pandemic restrictions precluded tastings in Bordeaux—created an opportunity to reset release prices downwards. That most 2019s came to market cheaper than any vintages physically available incited a resurgence in demand for the region's wines.

The electronic trading platform Liv-ex doubles as an independent monitor of market activity and prices. Its expanded indices show a growing spread of investment-grade wines from outside Bordeaux, in particular from Burgundy, Champagne, the Rhône, Italy, and the New World. Bordeaux's share of the secondary market decreased steadily from 2011, plummeting from 65% in 2011 to 30% in 2021 and conceding ground to Burgundy, in particular the DOMAINE DE LA ROMANÉE-CONTI, as an investment vehicle.

How to minimize the risks

The lessons of the recent past are that, in order to fulfil the promise of any investment, timing, knowledge, and skill (not to mention a measure of luck) are all essential preconditions for would-be investors, whether individuals or companies. Timing requires knowledge both of market conditions and of the potential of a wine for maturing. The finer the wine, generally speaking, the longer it takes to reach its peak and the longer it remains on a plateau of maturity. One of the best ways to acquire such knowledge is to keep abreast of the pronouncements of the most influential wine critics, but anyone buying for investment would be well-advised to read a range of expert opinions on any particular wine or vintage and keep track of price indices such as those published by winemarketjournal.com.

At the same time, investors need to be aware of less immediately obvious features of wine investment such as the importance of optimum storage conditions (see STORING WINE), the costs of storage, insurance, and reselling involved, disposal options, length of holding time, and ownership issues such as obtaining evidence, insofar as possible, to one's title to the goods. The better the guarantee of storage in ideal conditions, the higher the likely PROVENANCE. At the commercial auction houses, the vendor can expect to receive the current auction market price on disposal. At the same time, vendors should be aware of the requirement to pay a vendor's premium or, if a disposal is effected through a specialist wine BROKER or FINE WINE trader, commission on the disposal.

Investors need also to take full account of the buying options. If the conditions are right, the simplest and most attractive method of purchasing has been buying en primeur, or futures, but this no longer offers the returns it once did. Indeed, it may well have run its course.

Wine may also be bought at auction, in which case issues of provenance and storage conditions are paramount. For both reasons, any such purchase should be made at a commercial auction house holding regular, professionally run sales. And wine should ideally be

bought in complete, original CASES offered in BOND, to avoid the additional expenses of paying duty and tax. As demand has increased since the 1990s, prices have risen to encourage investors other than the traditional wine lover, and investment wine today is increasingly formalized through brokers and wine FUNDS.

Suitable wines for investment

The factors that make wine a worthwhile investment are numerous and complex. For one thing, political and economic auguries, specific market conditions, and likely future trends need all to be taken into account. Purchasing is usually best done in a buyer's market when conditions allow investors to take advantage of low prices such as during the glut at the end of the 1980s or those of the pandemic-affected 2019 en primeur campaign. The emergence of new secondary fine-wine markets such as those in ASIA can also promote capital growth in wine.

Wine purchased for investment must be available at a price attractive enough to give purchasers, after a reasonable period of holding on to stock, a return on their initial outlay that is at least comparable with other forms of investment. It follows that the type and format of wine chosen must be intrinsically capable of increasing sufficiently in value over a period of time. Generally speaking, investment wines should be capable of ageing for a good 20 years or longer so that investors are able to hold on to the wines and sell when the market is right (although the fine-wine market today seems to prefer young wines to old). Investment wines must either have an established reputation or, where the investor is in a position to evaluate likely trends, be lesser-known wines with the potential to gain in value. Investment-grade wines should come from a good, preferably great, vintage and should be capable of being easily traded. Account should be taken of the fact that magnums and LARGE FORMAT bottles may attract a premium on disposal.

Only a handful of wines fulfil these limited but strict criteria. Beyond wines with established reputations, the market for investment becomes too highly specialized for any but the best-informed insiders to dabble in with any degree of confidence or measure of success. When in doubt, *caveat emptor*, buyer beware, is always the best maxim.

Inzolia, sometimes spelt Insolia, white grape variety grown mainly on SICILY and to a much more limited extent in TUSCANY, where it is known as Ansonica. There were 4,563 ha/11,275 acres planted on Sicily in 2020. Its genetic roots seem to be in western Sicily, where it was valued as a relatively aromatic ingredient, with Grillo, in top-quality MARSALA. Today it is more often encountered as a VARIETAL, or blended with the much more common CATARRATTO, in dry white table wines. The best examples on Sicily show a certain nuttiness; the worst could do with more acid and more flavour. Tuscany's best Ansonica bottlings tend to be fuller bodied and more characterful.

ion exchange, chemical process used, for example, to soften water. Ion-exchange resins are available in two forms, cationic and anionic, making it a very versatile treatment that can be used for the removal of excess POTASSIUM from must or wine, reducing the possibility of TARTRATES and changing the ACIDITY. Using a cationic resin, the potassium (K+) in the wine is exchanged for sodium (Na+) from the resin, producing sodium bitartrate, which is more soluble than potassium bitartrate. This results in an undesirable increase in the sodium content of the wine. However, the resin can be charged with a mixture of hydrogen (H+), the source of acidity, and sodium, giving a useful result of tartrate stability combined with an increase in acidity. Alternatively, an anionic exchange resin could be used in its

hydroxyl (OH−) form, where the OH− ion is exchanged for the tartrate ion. Its use is permitted in most winemaking countries but is strictly regulated.

IPT, or indice de polyphénols totaux, common French measurement of total PHENOLICS, including TANNINS and ANTHOCYANINS.

IPW. See INTEGRATED PRODUCTION OF WINE.

Iran , large country in the Near East once known as PERSIA, under which heading details of Iran's important vinous history are to be found. Alcoholic drinks of all sorts are officially prohibited in modern Iran (see ISLAM), but HOME WINEMAKING is not unknown. According to OIV statistics, total vineyard area was 158,000 ha/390,430 acres in 2021. The country is an important producer of RAISINS.

Irancy, small Burgundy AOC near AUXERRE created in 1999 for structured reds from Pinot Noir with up to 10% of the local CÉSAR or Pinot Gris grapes. Nowadays SINGLE-VINEYARD WINES (Palotte, Mazelots, etc.) are featured.

Iraq , Middle Eastern country in which only 6,309 ha/15,590 acres of vines remained in 2020, grown chiefly for RAISINS and TABLE GRAPES, according to OIV statistics. In ancient times it was part of

MESOPOTAMIA, where there was a thriving trade in wine. See also BAGHDAD for evidence of early medieval viticulture, as well as ISLAM for an explanation of Iraq's modern relationship with wine.

Ireland may well have been a more faithful customer of GASCON wines than was England. Several Irishmen have played a part in the history of Bordeaux wine: the BARTONS provide one example, and the Lynch of PAUILLAC's Ch Lynch-Bages another.

There have been several attempts over the last 50 years at establishing commercial vineyards in the Republic of Ireland, but none has really succeeded. The climate, while mild, is just too wet and windy. In recent years, a few vineyards have been planted using new PiWi hybrids (see DISEASE-RESISTANT VARIETIES), which may prove more successful. S.S.

iron, an element essential for healthy vine growth in low concentrations, therefore known as a micronutrient (see VINE NUTRITION). Normally enough iron is taken up from the soil to meet a vine's needs, but iron deficiency is not uncommon. For example, lime-induced CHLOROSIS is a well-known disorder of vines growing on alkaline or CALCAREOUS soils. Leaves turn yellow, particularly between the veins, because iron is unavailable for the manufacture of chlorophyll. In alkaline and calcareous soils, iron occurs in insoluble compounds, which makes it unavailable to the vine roots. Soils can be analysed for their tendency to induce iron deficiency (see LIME, ACTIVE).

The problem cannot be solved simply by adding a fertilizer such as iron sulfate because the iron will be made unavailable by the SOIL ALKALINITY. However, iron sulfate can be applied as a foliar spray. Alternatively, iron may be added to the soil as a chelate, where iron is bound in an organic complex that prevents it from being precipitated in an insoluble form. UNGRAFTED VINES are reasonably lime-tolerant.

However, if tolerance of PHYLLOXERA or NEMATODES is required, then ROOTSTOCKS with a *Vitis berlandieri* parent are preferred. R.E.W.

AWRI, 'Trace elements' (2020). www.awri.com.au/wp-content/uploads/4_nutrition_trace_elements.pdf.

Irouléguy. AOC since 1970, this Basque vineyard at the foot of the Pyrenees in SOUTH WEST FRANCE owes much of its fame to being on one of the main routes for pilgrims crossing to St-Jacques. Its presence on the French side of the mountains is due to the work of the abbots of Roncevaux in Spain. The Treaty of the Pyrenees ceded all land on the French side to France, so the church moved the vineyard today called Irouléguy (a small local village) to France and gradually abandoned it to local farmers.

The Basque language is alive and well here and features on its bottles. The contents are largely red, based on TANNAT (not more than 50% allowed), the balance being either or both of the Cabernets. They are sturdy wines but not so powerful as the Tannat-based wines of MADIRAN. Rosé is becoming more important, and there are a few whites based on PETIT COURBU and both Gros and PETIT MANSENG. Wines which do not comply with the rules or are made outside the AOC boundaries may be marketed as IGP Pyrénées-Atlantiques.

The appellation's 200 ha/494 acres of vines are grown largely on steep terraces, notably those at Ispoure just behind the town of St-Jean-Pied-de-Port. Yields are therefore low. The soil is mostly SANDSTONE, with just a few hectares based on CLAY. The area is protected from the north winds and enjoys more sunshine than most others. There is an energetic CO-OPERATIVE and a dozen or so independent growers including the much-respected Michel Rieuspeyroux (Maison Arretxea). P.S.

irrigation, the application of water to growing plants such as vines, effectively a simulation of RAINFALL, which can be essential in drier regions. Few vineyard practices are more maligned, or misunderstood, than irrigation.

Opponents tend to think of irrigation as appropriate only for maximizing yield for TABLE GRAPES, RAISINS, and BULK WINES in hot, arid regions, using furrow or sprinkler distribution. That is some of the background for the view that only DRY-FARMED VINES can produce outstanding wines and that irrigation inevitably reduces quality or the expression of TERROIR.

Widespread adoption of DRIP IRRIGATION since the 1960s has blurred the distinction. Early trials were carried out in ISRAEL and AUSTRALIA. Since then it has replaced furrow and sprinkler irrigation in arid regions and is extensively used in MEDITERRANEAN CLIMATES, which are regularly dry during the summer growth and ripening periods, and also in climates with more uniform rainfall but which nevertheless periodically suffer from dry periods. The capacity to avoid severe WATER STRESS improves grape and wine quality, provided that irrigation does not excessively stimulate vine growth and yield. See also SOIL AND WINE QUALITY; SOIL WATER.

Irrigation is one of the oldest agricultural and viticultural techniques and was clearly practised, for example, in ancient EGYPT and in ancient ARMENIA too. The need for irrigation depends entirely on CLIMATE. Where EVAPORATION is high and rainfall low, vines invariably suffer water stress and may die. Many of the world's vineyards are in Mediterranean climates, where the rain falls mostly over the winter and the summers are dry and hot. The degree of water stress in the vineyard during the summer depends on winter rain storage in the soil. Soils such as sand and gravel hold only limited amounts of water, silts and clays much more. Vines with only shallow roots because of restricting soil conditions also experience water stress. On the other hand, some soils are able to store so much water from winter rainfall that vines can grow through the summer without significant water stress. Typically these are deep loamy or silt

soils and are commonly found on valley floors. Some of the deeper soils of California's Napa Valley are representative, and these may be found side by side with shallower soils where there is a need to irrigate.

While a modicum of water stress is desirable to encourage fruit RIPENING and enhance wine quality, excessive water stress has serious implications. In these circumstances, irrigation applied in a restricted fashion can actually improve quality (see PARTIAL ROOTZONE DRYING and REGULATED DEFICIT IRRIGATION).

It is easy to understand irrigation's notoriety, however. When vines have access to generous supplies of water, whether from rainfall, irrigation or soil-stored water, they grow rapidly, producing long shoots, large leaves, and much lateral growth with big berries; and where YIELD is increased, then ripening is delayed. Such vineyards typically have shaded CANOPIES. All of these are features of vineyards which produce poor-quality wine grapes. Yield is also greatly increased: depending on the severity of the water stress, irrigation may improve yield by 300% or more. In SPAIN, for example, increased use of irrigation in the late 1980s, often in association with the planting of higher-yielding CLONES, led to a marked increase in production despite significant EU-subsidized GRUBBING UP.

Irrigation is widely practised in the NEW WORLD but less frequently in the Old (although irrigation is commonplace in some of the oldest vineyards in the world in the Near East and central Asia). At one time it was in principle banned in much of the EU other than for young vines, but it is now much more widely permitted, sometimes, as in Austria, with the proviso that it is used to improve quality rather than to increase yields, although how or whether this is actually controlled is another matter. Restrictions do still apply in parts of France in the period just prior to harvest, with special derogations in times of DROUGHT, but such restrictions are typically applied locally rather than nationally. While some still believe that irrigation is intrinsically inimical to wine quality, and there are many examples of intentional over-irrigation, some of those who deliberately install irrigation

systems in southern Europe are motivated by the desire to make better wine. The modern view is that excessive water stress can be as damaging to quality as can excessive irrigation and that in drier regions carefully controlled irrigation can be a useful technique for maximizing yield and/or quality. Indeed, because of CLIMATE CHANGE, some famous Old World wine regions may need to turn to irrigation in the future.

The mechanics

Soils vary in their ability to store water. The field capacity is the maximum amount of water a thoroughly wetted soil will retain after normal drainage. The driest moisture content at which vines can extract water from the soil is called the permanent wilting point. Between these two limits is the soil's available water capacity. The ability to store water is highest for clay and silt soils and lowest for coarse sands and gravels. The latter soils are preferred for fine-wine production as there is less likelihood of excessive water supplies to the vine following rainfall.

The irrigation strategy employed by a vine-grower depends on his or her ambitions for quality and yield. Irrigation amount is measured as a depth of water applied: for unrestricted irrigation in a very hot climate, up to 800 mm/31 in of water can be applied during the growing season. Smaller quantities of water, say 200–300 mm/8–12 in, are more typically applied in cooler regions which are generally more humid, so there is less EVAPORATION.

There are several ways of deciding when to irrigate. In desert regions where the climate is relatively constant, such as much of Argentina, California, and inland Australia, irrigation is generally done by the calendar. The interval between irrigations can be longer in the early spring and late autumn, but the vineyards are irrigated most frequently in midsummer, when evaporation is highest. VINEYARD WEATHER STATIONS, either communal or located in the vineyards, are used to measure EVAPOTRANSPIRATION. In areas with more rainfall, and especially where it is irregular, irrigation has to be much more carefully timed according to measurements of either the soil moisture or, less frequently, the plant WATER STRESS.

Soil moisture can be measured in several ways. Instruments used to measure moisture at selected depths in the rootzone include tensiometers, gypsum blocks, and neutron moisture meters. More recently, capacitance probes and time domain reflectometry (TDR) have been employed. Data may be recorded in the field or transmitted by telemetry to the viticulturist's computer.

Plant stress can be assessed by the experienced viticulturist observing stress symptoms such as drooping shoot tips, tendrils, and leaves. Leaf temperature can also be measured, as can plant water potential, by using a so-called PRESSURE BOMB, which is common in California. However, values are much affected by sampling and time of day.

Methods of irrigation vary considerably. The ancient method, still used in some desert areas for bulk wine production, is flood irrigation. For this to work, the vineyard floor must be flat and the rows not too long. Furrow irrigation (see ARGENTINA) is very similar but allows greater control. More recent developments have been sprinkler irrigation, where sprinklers are typically about 20 m/65 ft apart and span several rows, and DRIP IRRIGATION. R.E.S.

Iland, P., et al., 'Water, soil and the vine', in *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

Irsai Olivér, aromatic Hungarian white vine CROSS of Pozsony Fehér × Csabagyöngye originally developed in the 1930s as a TABLE GRAPE. It is gaining ground in Hungary, with 2,376 ha/5,871 acres in 2021. It ripens extremely early and reliably (although it is prone to POWDERY MILDEW) and produces extremely light, intensely aromatic wines strongly reminiscent of MUSCAT. Also grown in Slovakia and Czechia.

Isabella, sometimes Isabel or Isabelle, widely distributed AMERICAN HYBRID of VITIS LABRUSCA × PETIT MESLIER. It is said to have been named after a southern belle, Isabella Gibbs, and to have been developed in South Carolina in 1816. It can withstand tropical and semi-tropical conditions and has been planted widely, notably in MOLDOVA, BRAZIL, where it is by a substantial margin the most common vine variety, and INDIA, where it is known as Bangalore Blue. In New York State, it was one of the first hybrids to be planted after PHYLLOXERA's late 19th century devastation, but it has largely been

replaced by CONCORD. New plantings were banned in France in 1934. The vine is high yielding, but the wines are very obviously FOXY.

Ischia, island and tourist destination in the Bay of Naples in the Italian region of CAMPANIA (see map under ITALY) which has managed to preserve a small part of the vineyards which once covered a significant part of the island. The DOC Ischia wine, produced from 103 ha/254 acres of vineyards in 2020, is most commonly a white blend based on 45–70% FORASTERA grapes, with BIANCOLELLA. Reds are typically a blend of GUARNACCIA and PIEDIROSSO (locally known as Per'e Palummo). The latter, on its own, may be either a dry red or a sweet DRIED-GRAPE WINE. While these red wine grapes are widespread in Campania, Forastera and Biancolella are almost exclusively grown on Ischia on steep, terraced vineyards, often accessible only by boat or monorail. W.S.

Isère, IGP in the Rhône-Alpes region of south-east France, on the border with Italy. White wines dominate in this cool, damp, and windy region, making up about 65% of production, particularly from Chardonnay, ALTESSE, and JACQUÈRE. The subappellation Grésivaudan applies to wines from the foothills of the Chartreuse, Belledonne, and Vercors mountain ranges; Balmes Dauphiné designates wines from a cooler area around 50 km/31 miles south-east of Lyons.

For the vine-training system, see TRAINING SYSTEMS.

isinglass, a particularly pure PROTEIN obtained from the bladders of sturgeon and other freshwater fish that has been used for FINING wine for centuries. As early as 1660, King Charles II of England regulated the use of isinglass by merchant VINTNERS.

Like GELATIN, isinglass reacts with the excess TANNINS in harsh young red wines. Although expensive and difficult to prepare, isinglass is also occasionally used in the CLARIFICATION of white wines.

However, there is a noticeable trend away from the use of animal-derived products for fining, mainly in the interests of VEGETARIANS AND VEGANS, and isinglass is now rarely used, especially on red wines. If used, it does not need to be declared on the label as it is not present in the final wine.

Islam, the Muslim religion founded by the Prophet Muhammad (spelt variously Mohammed, Mohamet, etc.) in the 7th century CE, has had, and continues to have, a most profound effect on the history of wine. The consumption of any alcoholic drink was prohibited by Muhammad, so wine is neither officially consumed nor enthusiastically produced in most of the Near and Middle East, some of North Africa, and parts of Asia. Wine is therefore no longer made in much of the land most closely associated with the ORIGINS OF VINICULTURE, and the rise of Islamic fundamentalism in the late 20th century represents a considerable constraint on the world's wine consumption.

Muhammad's prohibition

Wine (in Arabic *khamr*) was not prohibited from the outset of the Prophet Muhammad's preaching (between 610 and 632). Islam, both dogma and practice, emerged initially as the product of continuous revelation (the Qurʾān, often spelt Koran) during the Prophet's lifetime and his responses to the vicissitudes of the early Islamic community (these are recorded in the *hadīth* literature and constitute the second most substantive source of Islamic law). There are four verses in the Qurʾān which refer to wine; the first is quite positive (Sura 16, verse 69): 'We give you the fruit of the palm and the vine from which you derive intoxicants and wholesome food.' The following two verses are cautionary but are not considered by Muslim jurists to enjoin abstinence from alcohol (Sura 2, verse 216, and Sura 4, verse 46): 'They will ask you concerning wine and gambling. Answer, in both there is great sin and also some things of use unto men, but their sinfulness is greater than their use.' 'Believers do not approach your prayers when you are drunk, but wait till you can grasp the meaning of your words; nor when you are polluted—unless you are travelling the road—until you have washed yourself.'

There is consensus among medieval Muslim jurists, however, that the fourth verse, which came in response to disturbances in the community, was tantamount to an injunction (although it is not couched in the same language as the prohibition on other dietary items, such as pork) (Sura 5, verse 92): 'Believers, wine and games of chance, idols and divining arrows are abominations devised by Satan. Avoid them so that you may prosper. Satan seeks to stir up enmity and hatred among you by means of wine and gambling and to keep you from the Remembrance of Allah and from your prayers.'

Although this verse was understood universally to articulate prohibition, there was dissension when it came to establishing the precise nature of forbidden wine. *Khamr*, the word used in the Qurʾānic verses, is the Arabic generic term for wine. There were, however, many types of fermented beverages known to pre-Islamic and later Arabs. The second caliph, ʿUmar ibn al-Khattāb, is reported

in the *hadīth* literature to have settled the question: 'Wine has been prohibited by the Qurʾān; it comes from five kinds of fruits: from grapes, from dates, from honey, from wheat and from barley; wine is what obscures the intellect.' The issue remained whether beverages prepared in a way different from wine were prohibited. For example *tilāʾ* appears to have been allowed by ʿUmar; this was a kind of syrup made from grape juice which was cooked until two-thirds of it evaporated. However, the same source relates that ʿUmar punished a man who became drunk on this concoction.

Another tradition quotes the Prophet stipulating the kinds of vessels in which fruit juice beverages could be made or stored: '… I forbid four things: *dubbāʾ* [a gourd], *hantam* [glazed wine jars], *muzaffat* [a vessel smeared with pitch] and *naqīr*.' When asked about the nature of *naqīr* he answered: 'It is a palmtrunk which you hollow out; then you pour small dates into it and upon them water. When the process of fermentation has finished, you drink it with the effect that a man hits his cousin with the sword.' The community was, therefore, enjoined to store fruit beverages in leather skins that prevented fermentation.

Nabīdh, date wine, is the drink about which there has been the most controversy. Several traditions state that this beverage was among the drinks prepared by Muhammad's wives and drunk by him: ʿAisha said: 'We used to prepare *nabīdh*…in a skin; we took a handful of dates or a handful of raisins, cast it into the skin and poured water upon it. The *nabīdh* we prepared in this way in the morning was drunk by him in the evening; and when we prepared it in the evening he drank it the next morning.' Despite this, three of the four Sunni schools of law as well as the Shiah prohibit *nabīdh*. The Hanafi school allows it when used in moderation, although intoxication is still prohibited.

Most jurists now consider discussions about types of wine to be secondary casuistry. What is deemed crucial, on the basis of *hadīth*, is that any beverage which intoxicates should not be consumed.

Despite the Qurʾānic injunction, even those types of wine recognized to be *harām* continued to be imbibed in many periods of Islamic history; this is best reflected in the rich tradition of Bacchic

poetry which had its roots in pre-Islamic Arabia but flowered as a poetic genre in the early Abbasid period (see ARAB POETS). This canon of literature is largely mimetic and most certainly reflects the drinking habits of a significant sector of the Islamic community, notably—in some cases—the caliph and his entourage.

The wines consumed

Both Arabic poetry and other sources such as agricultural works tell us much about wine as a product. Although wine was produced in al-Tāʾif in the Hijaz (156 km/97 miles south-east of Mecca) from pre-Islamic times, it was imported mainly by Jewish and Christian merchants from SYRIA and MESOPOTAMIA. With the expansion of Islam, Arabs were introduced to finer wines grown mostly in the Christian monasteries of Iraq. ʿAna in upper Mesopotamia is only one of many areas that were known for viticulture. It was in the taverns around monasteries and in the monasteries themselves that most wine was consumed, as well as in some of the outlying towns of Baghdad, districts of Baghdad itself (especially al-Karkh), and not infrequently the caliphal court at the very heart of the Islamic community.

The most lauded of beverages were four types of wine—white, yellow, red, and black—made from both red and white grapes, from a variety of vine varieties whose names are preserved in medieval agricultural books (Heine gives details of 21 of them, including KIŠMIŠ). In poetry, the date wine *nabīdh* was despised (cf. above). Grape wine was always mixed with water before drinking (one-third wine to two-thirds water, about the same dilution as in ancient GREECE). The poets were fascinated by the bubbles which this mixing produced; although wine was celebrated as an ancient product (ʻIt has aged since the time of Adam'), it may be that it was often very young and thus still fermenting when consumed. There were three classes of age: young wine, which was less than a year old, low in alcohol, and had little bouquet; middle-aged, which was a year old; and old wine, which one source claims was usually sour. Kueny, K., *The Rhetoric of Sobriety: Wine in Early Islam* (2001).

Effect of Islam on wine history

In the Middle Ages, Muslim conquest by no means outlawed wine production, however. Muhammad's caliph successors were based in Damascus and, subsequently, in BAGHDAD, which had its own local wine industry. Wine production continued in Moorish Spain (the Alhambra built by the Moors in 14th-century Granada has its Puerta del Vino), Portugal, North Africa, Sicily, Sardinia, Corsica, Greece, Crete, and other eastern Mediterranean islands, usually under the heavily taxed auspices of Jews or Christians, even though they were ruled by Muslims. The Ottoman Turks made repeated raids on various eastern European wine regions in the Middle Ages and, if the TOKAJ legend is based on fact, could therefore be said to have been indirectly responsible for the discovery of BOTRYTIZED WINES. For some more details, see SPAIN, GREECE, and CYPRUS.

It is because of the dissemination of Muslim techniques associated with alchemy that the art of DISTILLATION is said to have spread through western Europe. Indeed the word ALCOHOL itself is of Arab origin.

isoamyl acetate is an ESTER present in all fermented beverages. At higher concentrations, it is sometimes associated with banana-like aromas, and it is often found in cool-fermented white wines and red wines that have undergone CARBONIC MACERATION. Some yeast strains are selected for their ability to produce high levels of esters, especially isoamyl acetate, during fermentation.

isoamyl alcohol. See ALCOHOLS.

isobutyl-methoxypyrazine, more properly, 2-isobutyl-3-methoxypyrazine, or IBMP, smells of green or bell peppers and grass and is found in all green matter. The perception threshold in red and white wines is 615 ng/l, and the concentration is higher in unripe

grapes and in fruit with low sun exposure because it is very sensitive to ULTRAVIOLET RADIATION. It is more often found in late-ripening varieties such as Cabernets Sauvignon and Franc and Carmenère. IBMP is very common in Sauvignon Blanc, where it is not generally considered a fault. Wines with high levels of IBMP may be described as HERBACEOUS.

Isonzo del Friuli, or Friuli Isonzo, relatively small DOC in the extreme north-east of Italy in the FRIULI region overlapping with the COLLIO zone. The Rive di Giare, the plain to the south of the Collio hills formed by the Isonzo river on its way to the Adriatic, is, from a geological point of view, split in two. The left bank of the Isonzo is like FRIULI GRAVE: a mixture of gravel and soil formed by fluvial and glacial deposits. The Rive Alte, the right bank, inland towards FRIULI COLLI ORIENTALI, is less fertile red gravel and said to produce Isonzo's best wines. The DOC's production rules allow each subzone to be mentioned on labels, but in reality they are rarely seen.

The zone included just over 681 ha/1,682 acres of DOC vineyard in 2020. As in the rest of Friuli, most wines are VARIETAL. The whites are generally fresh, simple, and fruity, while the reds are soft and forward, both colours often determined by the very high yields of 12–13 tonnes/ha allowed. Practically all white wine grapes may also be used to produce a late-harvest or a sweet DRIED-GRAPE WINE, while rosés may be varietal or a blend of white and red wine. All colours can come in SPUMANTE versions, too. While Isonzo's wines are generally clean and solid, the region lacks a clear identity because of the stress on INTERNATIONAL VARIETIES and a lack of an individual CONSORZIO since 2015. W.S.

isopropyl-methoxypyrazine (IPMP). See METHOXYPYRAZINES.

Israel , state on the eastern shore of the Mediterranean, bordering LEBANON to the north, SYRIA and JORDAN to the east, and EGYPT to the

south. Some of its 7,989 ha/19,741 acres of grapevines also extend into the disputed territory of the West Bank (see PALESTINE).

History

Historically the land of milk and honey (see CANAAN), this region has a long and illustrious relationship with wine. It was both necessary for religious ritual, particularly in Judaism and Christianity (see RELIGION AND WINE), and it was a mainstay of the economy. The region is rich in archaeological evidence of wine's importance in culture and trade, including a 3,800-year-old Canaanite palace at Tel Kabri in Galilee (the largest Canaanite wine cellar found to date) as well as a 1,500-year-old wine complex at the ancient port city of Yavne (the largest Byzantine winery), where annual production is estimated to have been 2 million litres. Over centuries, the Canaanites, Israelites, Greeks, Romans, Nabateans, Byzantines, and Crusaders all left their mark in winemaking in the Holy Land. (See also PALAEOETHNOBOTANY.)

The Ottoman period, *c.*14–early 20th centuries, decimated the region's commercial wine industry, but Jews and Christians always made wine, for their own use. There were also wineries mainly making sacramental wines in the Old City of Jerusalem from the mid 19th century; by the late 1800s, the Templars, and MONKS AND MONASTERIES such as Cremisan and Latroun, were also producing wine.

Beginning in 1882, Baron Edmond de ROTHSCHILD, owner of Ch Lafite in Bordeaux, began providing funds and French expertise for what would become the basis of the modern Israeli wine industry. He planted vineyards, built two large wineries with underground cellars, and founded the Société Coopérative des Grandes Caves in 1906, which traded as Carmel and dominated Israeli wine for over 100 years. In the 1980s, the Golan Heights Winery was founded, bringing expertise from California, cutting-edge technology, and an understanding of the importance of high-ELEVATION vineyards. Its success spurred a boom in small wineries, led by Domaine du Castel and Margalit Winery, that saw the number of wineries blossom from 12 in 1990 to more than 350 by 2022.

Geography and climate

Israel shows a wide diversity of soils and MESOCLIMATES, stretching 424 km/263 miles north to south along the eastern shore of the Mediterranean Sea. While Israel's Ministry of Agriculture recognizes five broad regions, the Israeli Professional Enology & Viticulture Organization (IPEVO) have produced a map (2019) with 15 regions defined by topography, climate, and soils. The most important of these are as follows:

Golan Heights, a volcanic plateau in the north-east which rises to 1,200 m/3,937 ft in elevation, with soils of TUFF and BASALT. Winter temperatures can dip to freezing, and rainfall can be as much as 1,100 mm/39 in annually.

Galilee, of which the Upper Galilee, bordering LEBANON, is the main vine-growing area. The soils are shallow TERRA ROSSA on LIMESTONE with some VOLCANIC soil, and the higher vineyards sit at 400m/1,312ft–800m/2,624 ft in elevation.

Coastal Plain, south of Haifa and south-east of Tel Aviv, including Zichron-Hanadiv Valley, with deeper RENDZINA soils and more Mediterranean influence.

Judea, in the centre of the country, including the Judean Foothills, rolling hills up to 400 m/1,312 ft of elevation with white chalky soils.

Judean Hills, rising towards Jerusalem, where old terraces are cut into very shallow terra rossa soils over limestone bedrock. Elevations range from 400 m/1,312 ft to 900 m/2,952 ft.

Shomron Hills, north of Jerusalem, a high-elevation (up to 800 m/2,624 ft) region with shallow soils on limestone bedrock.

Negev, in the south, including Mitzpe Ramon at 800 m/2,624 ft in elevation, a DESERT climate with LOESS soils and a broad DIURNAL TEMPERATURE RANGE.

The central mountainous region that runs down the spine of the country includes the West Bank, the territory in dispute since 1967

that is partially under the auspices of the Palestinian Authority. Both Israeli and Palestinian wineries operate there.

Viticulture

Historically, vineyards were concentrated in the warm, deep-soiled, low-elevation coastal regions. Over the years, winegrowers have been moving north and east in search of cooler, higher elevations. The main concentration of vineyards is now in the Galilee and Golan Heights in the north and the Judean Foothills and Judean Hills in the centre of the country. Average temperatures for July–August can range from 18 to 30 °C/65–86 °F. A major problem during flowering may be the *hamsin* (hot winds), when temperatures soar.

Most vineyards are spur-pruned on VSP training systems (see VERTICAL TRELLIS), although some new plantings of Grenache and Mourvèdre and some old-vine Carignan and Petite Sirah are BUSH VINES. DRIP IRRIGATION, pioneered by the Israelis in the 1960s, is widely used, although a growing number of vineyards on the valley floor are DRY-FARMED. CANOPY MANAGEMENT is used to maximize the phenolic ripeness at harvest. Sugar accumulation is not a problem, but there is a need to retain acidity and balance through deficit irrigation and ULTRAVIOLET RADIATION control. Nets are sometimes used to protect the fruit from SUNBURN.

The majority of the harvest is from August to October, but it can begin in late July with white grapes in the warmer regions.

Grape varieties

In the 1900s, the workhorse grape varieties were CARIGNAN, which predates Rothschild's arrival, and Alicante. Today, the dominant varieties for quality red wines are Cabernet Sauvignon, Merlot, Syrah, and PETIT VERDOT; whites are made from Sauvignon Blanc and Chardonnay. Increased attention is being paid to Mediterranean grape varieties such as Grenache, Mourvèdre, Roussanne, Marsanne, and Viognier, as well as 'adopted' varieties such as Carignan, PETITE SIRAH, and Colombard. Muscat of Alexandria is mainly used for lightly sweet, frizzante MOSCATO. Once most wines were marketed under VARIETAL names, but Rhône-style blends are increasingly popular.

Some crosses are grown, such as MARSELAN and Argaman, an Israeli cross of Carignan and SOUSÃO. There is also increased interest in Holy Land INDIGENOUS VARIETIES such as Dabouki, Marawi/Hamdani, Jandali (whites), and Bittuni (red), which were preserved through the Ottoman Empire period mainly by Palestinian growers in the Hebron region.

After decades of LEAFROLL VIRUS problems, new CLONAL SELECTIONS are being sought from South Africa, and the Golan Heights Winery has its own propagation block and nursery.

See also KOSHER (although by no means is all Israel's wine kosher).

ISVV, the Institut des Sciences de la Vigne et du Vin de Bordeaux, brings together under one roof in Villenave d'Ornon, a southern suburb of Bordeaux, the grape and wine research teams and students of several academic institutions, including BORDEAUX University, Bordeaux Sciences Agro, and INRAE Bordeaux. The first director, until his death in 2016, was Denis DUBOURDIEU. The current director is Philippe Darriet.

Italian Riesling, or Italian Rizling, sometimes Italianski Rizling, occasional synonyms for RIESLING ITALICO. See WELSCHRIESLING.

Italy , with FRANCE one of the world's two mammoth wine producers, sometimes producing as much as 47 million hl/1,033 million gal a year. Italy has more land under vine than any other country other than France and SPAIN, although, thanks to the European VINE-PULL SCHEME, the total has been reduced from close to 1.4 million ha/3.4 million acres in the early 1990s to 718,000 ha/1,774,217 acres by 2021. The country remains the second largest wine market in the EU and third worldwide (after the United States and France), with an estimated consumption of 24.2 million hl in 2021, and only Spain exports more wine. A significant but declining proportion of the wine exported from Italy has been inexpensive wine for BLENDING in and possible re-export from France and Germany, but a good 78% of exports are now in bottle, and Italy's top wines are sought after around the world, especially in the US and German-speaking markets.

Italy cultivates the vine virtually everywhere in the peninsula, from the Alps in the north to islands that are closer to the coast of North Africa than to the Italian mainland (see map). Viticulture traditionally impinged on the national consciousness, on the national imagination, and on daily life in a way that is hardly conceivable to those not accustomed to the Mediterranean way of life and its dietary trinity of bread, olive oil, and wine. It was unthinkable for Italians to sit down and eat without wine on the table until about the late 1980s, since when per capita wine consumption, as in France and Spain, has been plummeting.

To consider the history of wine in Italy is to consider the history of Italy itself, however; wine and Italian civilization are virtually synonymous. The ancient Greek name for much of Italy already acknowledged the importance of viticulture to the peninsula: OENOTRIA, or 'land of trained vines'.

Italy, Magna Graecia, and Roman Italy

The pastoral past of the tribes of Italy may be reflected in the use of milk in LIBATIONS rather than wine (see PLINY, *Natural History*, 14. 88), but viticulture and wine will have made an early impact as part of GREEK and ETRUSCAN culture (see ORIGINS OF VINICULTURE for more details). SICILY may have played a key role in the development of viticulture on the mainland. The Sicilian Murgentina grape, which flourished in volcanic soils, was successfully transplanted near POMPEII on the slopes of Vesuvius, where it was called locally the Pompeian grape. This in turn was introduced further north around Clusium (Chiusi) in Etruria, where it proved particularly prolific. Again, the Eugenia, the high-quality grape from Tauromenium (Taormina in Sicily), successfully found a home in the Colli ALBANI south of Rome but failed elsewhere.

Incidental mentions by historians suggest that by the time that Hannibal invaded Italy in the late 3rd century BCE, vines could be found throughout the peninsula, from beyond the Po Valley, down the Adriatic coast, and in CAMPANIA; but little wine was of particular note before the middle of the 2nd century BCE according to Pliny (*Natural History*, 14. 87). It was Pliny, too, who in a key passage (*Natural History*, 14. 94 ff.) made a particularly acute observation. He noted that OPIMIAN wine of the year when Opimius was consul (121 BCE) was accepted as one of the greatest vintages, but that this applied generally to wine in that year, not to any particular CRUS. An edict of the censors of 89 BCE imposing a price limit on costly wines refers only to wine made from the Aminnean grape (see ANCIENT VINE VARIETIES), not to any estates.

The creation of the grands crus of Roman Italy belongs to the 1st centuries BCE and CE. This fact is more or less confirmed by ARCHAEOLOGY. The expansion of villas connected with wine production and overseas trade, as evidenced by their AMPHORAE, may have begun in the late 3rd or 2nd centuries, but the real growth is later. Three

factors were involved in this development. First there was the exceptional growth of the city of ROME, which created a huge market for wine. Second, the opening up of trade routes to GAUL and SPAIN stimulated the growth of vineyards in the areas immediately behind ports; and finally there was the interest of the Roman aristocracy with an ever-increasing level of wealth to invest. So it is no accident that the areas in which the great wines of Roman Italy developed were LAZIO and Campania, regions within easy reach of the Roman market and where the Roman elites had their country homes. In the Colli Albani, the mainly sweet wines of Alba itself were highly prized, as were those of Velletri. The Emperor Augustus gave a boost to the wines of Setia (Sezze) by favouring them above all others. Beyond Terracina, CAECUBAN, produced in the marshes around the Lago di Fondi, was in the very front rank of wines. The wines from the slopes of Monte Massico, particularly the various types of FALERNIAN, long remained the most favoured. In northern and central Campania, the wines of Cales, along with Gauranum (from Monte Barbaro, overlooking the northern end of the bay of Naples) had reputations which were close to that of Falernian. Then on the bay of Naples itself were the noted vineyards of Pompeii and the Sorrento peninsula. The very light white wine of this region, SURRENTINUM, made from the Aminean Germana Minor grape, enjoyed very high status in the 1st century CE, although it did not win universal approval ('high-quality vinegar' was the view of the Emperor Tiberius).

Few wines outside Lazio and Campania ever approached the status of these wines, and none exceeded it. To the north and west, Etruria (TUSCANY) had a great variety of wines, but only those of Luni and Genoa in Liguria made much impact. In Magna Graecia (southern Italy), several areas produced wines of some note, including Tarentine (from Taranto). The Adriatic coast of Italy presents an interesting test case. It would be difficult to guess at the importance of the wines of this area simply from the rather limited literary evidence. But the evidence of amphorae shows that PUGLIA and ancient Calabria and, perhaps, areas further up the east coast exported wine to all the countries round the Adriatic and to the Greek

world from the 2nd century. Brindisi certainly was the focus for a flourishing export trade. Further north, Hadrianum, the wine of Atri, and the adjoining Praetuttian vineyards (roughly the northern area of Montepulciano d'ABRUZZO) achieved a high reputation in the 1st century CE. A significant development is to be associated with the time of the first Roman emperor, Augustus (31 BCE–14 CE); this was the increasing prominence of northern wines from the Po Valley and beyond. The distinctive type of amphora which carried the wines of this region was sometimes stamped with the names of those who rose to prominence in the entourage of Augustus and had estates in the region. These amphorae doubtless carried Praetuttian, the wines of Ancona, of Ravenna, and of the towns along the Via Aemilia. VIRGIL, Augustus' court poet, reflected the emperor's liking for the wines of Verona (see VENETO), made from the Rhaetic grape (although, because of its distance from the sea, it is unlikely this area's wines achieved more than a passing prominence). Augustus' wife Livia did her bit to promote the wines of the FRIULI region, by publicly ascribing her longevity to an exclusive diet of the wine of Pucinum, beyond Aquileia.

Archaeology has combined with history to give us this picture of viticulture in Roman Italy, which differs in significant ways from the current scene. It should always be remembered that, as now, there would be an enormous consumption of undistinguished, local wines which never travelled and are rarely to be identified in the historical record. J.J.P.

Pliny the Elder, *Natural History*, translated by H. Rackham (1945), Book 14.

Tchernia, A., *Le Vin de l'Italie romaine* (1986).

Medieval history

The fall of the Roman Empire did not put an end to viticulture in Italy, but barbarization and economic collapse meant the disappearance of the market for fine wines. With Goths, then Lombards, in Rome and most of the north, and the remains of the empire administered precariously from Ravenna, Falernian and Caecuban had become distant memories. Yet the Italian diet remained based on bread, olives, and wine, and so wine continued to be grown.

The Dark Ages were a period of economic stagnation; except for the importation of luxury goods from the Near East, trade was local. We know little about the wine that was grown until the 11th century, when population, production, and exchange increased, and Italy, particularly northern Italy, became politically and economically the most important part of Europe (see GENOA and VENICE). Between the 11th and the 14th centuries, the population of Italy grew from 7 to 9 million inhabitants. People of all social classes migrated to the towns, including members of the nobility. As a result, urban communes came to govern the countryside. South of Tuscany, however, the aristocracy lived near the land; the feudal system, with its lack of distinction between trade and agriculture, persisted.

One of the reasons for the strength of the Italian economy was that it had monopolized the trade in luxury items. These included the strong, sweet wines of Crete, Cyprus, and other parts of the Aegean (see MALMSEY) but also goods produced in Italy itself, such as high-quality wool and silk (from Lucca and Florence). When it became possible to transfer credit throughout the Mediterranean and western Europe (instead of having to carry and exchange actual coins), Florence became the banking capital of Europe. The Florentine house of ANTINORI is a good example of several of these developments. The Antinoris were, and still are, a noble Tuscan family that moved from the country to the city; having made their money in banking, they diversified into selling wine and also used their capital to buy up land to grow their own wine.

The rich merchants of the cities became a new market for fine wines. Good wine became a sign of affluence and a source of profit: it is no coincidence that the merchant dynasties of Bardi and FRESCOBALDI should have gone into winegrowing, buying up land for the purpose. All over Italy, the usual way to improve land was to deforest it and plant it with vines. When there was enough moisture, the vines were raised on trees, stakes, or trellises (see TENDONE), in the Roman way, to increase yields by exposing the grapes to the sun. Thus sown and planted crops could be raised in the same fields. In the drier regions, particularly in the south (with the exception of CAMPANIA), the vines were left to grow unsupported, as BUSH VINES, or left to trail on the ground in vineyards or at least in separate plots.

Vine-growing as well as winemaking in medieval Italy were much as they had been in the days of the classical AGRICULTURAL TREATISES, and in one crucial respect things were worse: since AMPHORAE and other impermeable earthenware vessels were no longer available, wine was kept in wooden BARRELS, which were hard to clean and not airtight. Unless a wine contained high proportions of two natural preservatives, sugar and alcohol, it would not last out the year.

The Roman VINE VARIETIES seem to have disappeared. In his treatise on agriculture (*c.*1304) PETRUS DE CRESCENTIIS, who had read the classical authorities and often repeats their advice, does not mention any of the famous Roman grape varieties. He lists some 37 contemporary Italian varieties, but he makes no attempt to relate those to the grapes encountered by his classical predecessors. The list he gives is mostly concerned with the northern half of Italy and, especially, his own city of Bologna. The list is not a great help to the modern scholar, because his descriptions are too brief for identification and many of the names are unrecognizable (although see below). None of Petrus' 17 red wine varieties has a familiar name, and Petrus does not devote much space to them. Like most medieval drinkers, he preferred white wines to red.

From the 13th century onwards, wine was medieval Italy's most profitable cash crop. Sharecropping was traditional throughout the country, with the landowner taking half the wine or more if

production was high. Sometimes a contract was drawn up for a longer period at a fixed rent. Smallholders survived in the highlands but in Tuscany and the northern plain they could not afford to stay on the better land. Peasants occasionally retailed their wine, but usually the landowners regulated sales to the towns. Consumption was high (the figure for Florence, *c.*1338, is a gallon a week for every man, woman, and child, but estimates for Milan and Venice are much higher); yet production more than met demand, particularly in Campania.

Italy is mountainous and has few navigable RIVERS, which made internal transport costly and difficult before the coming of the RAILWAYS. Also, because Italy was not a political unity, there were obstacles in the form of tolls, duties, and differences in coinage, weights, and measures. Transport by sea was cheap and export to other countries no more laborious than much internal trade, so merchants in northern Italy or near the sea readily turned to foreign markets. The northern districts sold wine in Switzerland and Germany, the Marche exported to the Levant via Venice, which enjoyed tax privileges in Constantinople, and Genoese ships took the wines of Liguria to Spain, Flanders, and England. Nevertheless, the volume of Italy's international wine trade was merely the surplus production of a fertile vine-growing country. The Italians could afford not to deprive themselves of any of the wine they wanted to drink and still make money out of what remained.

Modern history

That the revival of Europe's trade in the early Middle Ages began in the Mediterranean is by now universally accepted. It is therefore no surprise that specific references to what were to become some of Italy's most important grapes and wines can be found as early as the late 13th and early 14th centuries. The country's chronicles, both civic and monastic, of the 14th and 15th centuries abound with descriptions of the leading wines of their day—at times identified by grape variety, at times identified by their production zone. Many of them coincide, at least nominally, with the current wines of these same zones.

English records seem to indicate that wines such as Vernaccia, Trebbiano, and Greco were all known as such at this time. Sante Lancerio, cellarmaster to Pope Paul III, recounted the wines of his day in an account of papal travels in 1536, describing, criticizing, and praising the prominent products of his epoch, among which we find Aglianico, Aleatico, and Greco from the south, Vino Nobile di Montepulciano, Trebbiano di Romagna, Sangiovese di Romagna from the centre, and Cinqueterre from the north. And in Andrea Bacci's work we find a full-fledged treatise on Italy's wines, an attempt to deal with and describe the country's viticultural production in a national context, a surprising phenomenon inasmuch as Italy was far from being a nation in the modern sense in the late 16th century.

But it was precisely at this time—in the 17th and then the 18th centuries—that the development of Italian viticulture and wines began to diverge from that of its neighbours. This critical period, which saw the rise of wine in BOTTLES stoppered with CORK, left Italy virtually untouched. Old bottles from this period are non-existent. Although some of Tuscany's leading NÉGOCIANT houses trace their history back to the Middle Ages (see ANTINORI and FRESCOBALDI), they, and the few Piedmontese houses which have existed since the late 18th century, sold bulk rather than either bottled wine or estate wines until relatively recently.

Any overall evaluation of the quality of Italian wine in the 18th century is impossible, but signs of deterioration exist. The 'Florence' wines so greatly appreciated in the late 17th and early 18th centuries by Lady Sandwich, Swift, and Bolingbroke are described as 'disagreeably rough' by Sir Edward Barry in 1775, and there is good reason not to dismiss his words as a mere subjective reaction. Pietro Leopoldo, grand duke of Tuscany, during an inspection tour of his realm in 1773, reported a significant loss of viticultural commerce with England due to the lessened quality of the wines of Chianti. And many of Italy's wines, including many of its most famous ones, did not assume their current form until quite recently: Barolo and Barbaresco were allegedly sweet wines until the middle and end of the 19th century, respectively (although this may well have been simply because the wines did not routinely ferment to complete dryness); Chianti did not become a predominantly Sangiovese wine until the late 19th century; Brunello di Montalcino did not even exist as a wine until the end of the 19th century (see BIONDI-SANTI, who were bottling wine by then); Orvieto and Cinqueterre were predominantly sweet wines until the modern epoch; and the best-known wines of central Italy such as Orvieto, Verdicchio, Frascati, and the other white wines of the Castelli Romani were regularly SKIN-FERMENTED until the 1970s. The INTERNATIONAL VARIETIES which today play so important a role in the viticulture of Italy's north-east—Trentino-Alto Adige, Veneto, and Friuli—began to assume a significant role only after the replanting of the country's vineyards in the wake of PHYLLOXERA in the early 20th century. The crisp and refreshing white wines of Friuli are entirely a post–Second World War phenomenon; Sicily's first dry table wines were created only in 1824, by Duke Edoardo di Salaparuta.

The reasons for this period of stagnation, which in Italian historical literature is often called the period of Italy's *decadenza*, are not difficult to determine. The country experienced an extended domination by foreign powers, first by the Spanish Habsburgs both in the north and the south, then by Spanish Bourbons in the south and Austrian Habsburgs in the north. Meanwhile the increased influence—

both temporal and spiritual—of Counter-Reformation Catholicism effectively removed the country's destiny from its own hands. Even more significant was the general shift of trade and commerce from south to north, from the Mediterranean to the Atlantic, which transformed Italy's geographical position for the first time in two millennia from that of a central to that of a peripheral power. Italy was on the fringes of a Europe in which the most prosperous and progressive areas, the northern markets, were increasingly dominated by the fine wines of France and Germany.

The unification of Italy in 1861 and a slow but steady period of economic growth did much to reverse the decline of the previous two-and-a-half centuries. It was the economic boom after the Second World War which created a class of consumers with both an interest in wine and the means to purchase it, which gave Italian wine producers confidence in their own capacities and their own products. Although a keen importer of champagne, the Italian wine market has been understandably preoccupied by Italian wine and in the late 20th century came to be shaped by a handful of annual wine guides. While many encouraged INTERNATIONAL VARIETIES at the expense of Italy's rich heritage of INDIGENOUS VARIETIES and for many years encouraged the use of French BARRIQUES—not to mention favouring particular consultant OENOLOGISTS—this century has seen a return to a focus on Italy's unique grape varieties and TERROIRS.

Major developments in the recent history of Italian wine are described under DOC, DOCG, and IGT.

Geography and climate

Generalizations about a peninsula 1,200 km/750 miles long extending through about 10° LATITUDE are not easy. The dominant geographical feature of the 'boot' is the Apennines, which begin close to the border with France and then form the central ridge down the peninsula to the 'toe' in Calabria. In the far north are the Alps; in Sicily, the Madonie form yet another chain of central mountains, while Etna rises to 3,350 m/10,990 ft. Italian agriculture has traditionally been organized vertically, with the richer soils of the valley floors used for grain and vegetable cultivation and cattle grazing and with the hills reserved for vine and olive cultivation. Good-quality viticulture is almost entirely a HILLSIDE phenomenon in Italy; there are no Italian equivalents of the *vignoble* of Bordeaux, and the Friuli Grave and other flat viticultural areas of Friuli do not produce wine at the same quality level as the higher nearby districts of Collio and Colli Orientali.

A significant number of the country's most admired wines come from CALCAREOUS soils. Piemonte, Tuscany, the hillside zones of Friuli, and the Salento in Puglia all provide examples of this. The other dominant soil type is VOLCANIC, present in such zones as Soave and Colli Euganei in the Veneto, the Castelli Romani south-west of Rome, the coast of Naples (Campi Flegrei, Ischia), the interior of Campania and Basilicata, and Sicily.

ELEVATION, ASPECT, WIND, TOPOGRAPHY, SOIL composition, and proximity to the sea all affect climate. That Cabernet Sauvignon can be grown at latitude 46.30° N (north of Bordeaux) is due to the narrow, heat-trapping alpine valleys of Alto Adige. Umbria is generally cooler than Tuscany albeit further south; a wide span of central Italy —Umbria, the Marche, Lazio—is more renowned for white wines than for reds, while Piemonte, in the far north, is principally a producer of powerful red wines. Even Sicily confirms the rule that, in Italy, geography is not destiny: the island produces as much white wine as red.

While the climate of far northern Italy may be CONTINENTAL, that of central and southern Italy is MEDITERRANEAN. Italy's indigenous red grape varieties—with the exception of Dolcetto—are almost invariably later ripeners. Nebbiolo, Barbera, Refosco, Corvina, Sangiovese, Sagrantino, Aglianico, Negroamaro, Nerello Mascalese, and Nero d'Avola all require sustained heat throughout the summer and early autumn to ripen properly and lose their tannic and acidic asperity, and successful ripening is therefore far from automatic. Poor VINTAGES are by no means a strange phenomenon in Italy, although increased viticultural knowledge, strict grape selection, and CLIMATE CHANGE resulting in warmer growing seasons and notably earlier harvests have made completely disastrous vintages a thing of the past.

Viticulture

Two features distinguish Italian viticulture: first, the late development of vineyards as such and a significant presence until relatively recently of polyculture in grape-growing areas; second, the long-standing dominance of vine-TRAINING SYSTEMS created expressly for high YIELDS and easy MECHANIZATION, such as GUYOT.

Polyculture, a common phenomenon throughout Europe at one time, lasted into the modern epoch in Italy. Grain and vegetables such as potatoes were planted between rows of vines and central Italy was dominated by a type of mixed culture in which vines, planted amid olive groves and rows of grains, were trained up trees to prevent the grapes from being eaten by the animals allowed to roam freely in the fields (see ARBOREAL VITICULTURE). Modern vineyards, planted exclusively with vines in regular rows, did exist, particularly in Italy's north-west, but viticulture in general was merely part of a general system of agriculture, one cash crop among many. It is no surprise, therefore, that when Italy's vineyards were replanted in the 1960s and 1970s, frequently with the assistance of EU funds, vineyards were generally adapted to the new exigencies of mechanization and productivity. Whereas in France the practicalities of mechanization were adapted to the existing low-trained vines and high VINE DENSITY, Italian vineyards were redesigned when they were replanted to make them compatible with the TRACTORS and other machines which were then becoming generally available. The result was spacings of up to 3 m/10 ft between the rows and high training systems. This low-density viticulture, with an average of 2,500–3,300 vines per ha, coupled with the generous YIELDS due to high-yielding CLONES, had as their inevitable result the very high yields per vine, often as much as 5 kg/11 lb of grapes, and a reduction in vine longevity.

The higher training systems, especially PERGOLA, while offering improved protection against HAIL and FUNGAL DISEASES, were until recently thought to reduce the amounts of reradiated heat and result

in less ripe grapes with higher acidity, rougher tannins, and lower levels of EXTRACT. Recent research has shown that there is no marked difference in grape quality between Guyot and pergola-trained vines if yields are kept low; likewise, experiments with planting densities in central Italy have shown improved results at 7,500–10,000 vines per hectare and little if any improvement at higher densities, and so the 1980s fascination with ever-higher-density plantings is waning. Expansive vine-training systems such as TENDONE have found new favour, especially with old vines and ancient clones, and in ABRUZZO, for example, are producing some of the region's best wines. The ALBARELLO (bush vine) system once standard in the south may be LABOUR-intensive but tends to result in high-quality wine. More extreme horizontal systems such as Sylvoz, Casarsa, and other particularly productive CORDON systems are no longer popular. Meanwhile, in reaction to the environmental toll of vine moncultures, a new generation of BIODYNAMIC VITICULTURISTS have re-introduced polyculture in some places.

CLONAL SELECTION aimed at identifying and reproducing qualitatively superior clones of indigenous vine varieties and the most appropriate ROOTSTOCKS to graft them on to has been a relatively recent activity, although important research programmes were conducted specifically for Sangiovese, Nebbiolo, and some other indigenous varieties in the 1990s. The popularity of Kober 5 BB and other over-productive rootstocks, a feature of the planting period from 1965 to 1980, is unlikely to be repeated.

Winemaking

If Italian viticulture has tended to follow its own course, with little attention paid to the practices of other countries, the same cannot be said of its OENOLOGY and winemaking practices. Indeed, substantial investments in cellar equipment have made Italian winemaking facilities some of the most modern in Europe, and Italians make equipment such as BOTTLING lines that is some of the best, and most exported, in the world.

CHAPTALIZATION is forbidden, but ENRICHMENT with concentrated grape must is permitted in some areas and within certain limits.

Wooden FERMENTATION VESSELS, once vigorously abandoned in favour of STAINLESS STEEL, have been gradually making a comeback, especially tronconic ones, while CONCRETE vats and tanks are again widely used for both FERMENTATION and storage. TEMPERATURE CONTROL is widely accepted for the production of both red and white wines, and the PUNCHING DOWN of the cap of red wines has become as widespread as regular PUMPING OVER during fermentation, while there is a noticeable trend towards using the traditional *cappello sommerso* or SUBMERGED CAP technique, especially in Barolo and Barbaresco. The lengthy fermentations and MACERATIONS of the past, sometimes up to six weeks, were shortened, substantially so by most producers aiming for faster maturing and easier to sell wines, slightly less so by avant-garde producers seeking the highest quality. A new generation, however, combines both ancient and modern techniques in an ongoing investigation into what leads to original wines.

WHITE WINEMAKING techniques changed drastically in the 1970s and 1980s, with the introduction of cool fermentations, FILTRATION, and CENTRIFUGES. The most fundamental change of all was to end the practice of SKIN-FERMENTED white wines, once common in Friuli and throughout central Italy. Gains in lightness and freshness were obvious but were achieved at the price of a certain standardization. Producing white wines of more character without sacrificing the

newly achieved crispness and cleanliness is the current challenge for Italian white winemaking and there has been a return in some quarters to fermenting white wines on the skins.

Fermentation may have evolved considerably in the second half of the 20th century, but ÉLEVAGE underwent more profound modifications during the same period. Large casks, usually oval rather than upright, were long the preferred containers for CASK AGEING red wine in Italian cellars; long ageing periods, particularly for what were considered the grandest wines, were an almost unvarying rule; used barrels were generally preferred to new ones (although this may often have been for financial rather than qualitative reasons). Many of Italy's most renowned red wines have tannins which need a considerable time in cask to soften and round, and periods of two years in cask are by no means uncommon. In hot vintages many producers prefer to bottle their wines immediately after the mandatory oak ageing, to preserve freshness and halt premature ageing of their wines.

OAK has generally been the preferred wood for casks, much of it from Slavonia or elsewhere in central Europe. In the south of Italy, in areas such as Basilicata and Sicily, where chestnut forests abound and there are no local oak sources, the traditional chestnut cooperage has been gradually replaced by oak casks to achieve a more international style and to avoid the bitterness which old chestnut casks can impart, although many producers are experimenting with a return to chestnut.

The 1980s and 1990s saw Italian cellars invaded en masse by new French BARRIQUES, with Sangiovese and Barbera the first varieties to be widely aged in new small oak barrels. This century there is a marked return to larger, older casks (with considerations of HYGIENE paramount) in order to avoid dominating the flavours of Italy's indigenous grape varieties with those of oak. There is also a move towards eliminating any added wood flavour by using vessels such as AMPHORAE and QVEVRI, for fermentation as well as ageing.

Vine varieties

Italy boasts many hundreds of INDIGENOUS VARIETIES, and this is increasingly celebrated by a new wave of growers keen to rediscover local specialities. In 2020 the most planted variety was SANGIOVESE, with 55,100 ha/136,096 acres, down from 86,000 ha in 1990. The second most planted variety was GLERA, the variety responsible for Prosecco, with 34,154 ha, closely followed by Pinot Grigio (31,360 ha), CATARRATTO (29,575 ha), MONTEPULCIANO (27,000 ha), Merlot (27,000 ha), and Chardonnay (23,000 ha), its total presumably boosted by its popularity with producers of sparkling wines.

Large-scale plantings of INTERNATIONAL VARIETIES—principally French, although there is also some Riesling and Gewürztraminer—were initially confined to the country's north-east (which, in many cases, was under either direct Austrian rule or strong Austrian influence until 1919). They are planted in an arc stretching from Franciacorta in the eastern part of Lombardia through Trentino-Alto Adige, the northern part of the Veneto (the provinces of Vicenza and Treviso), and Friuli. Subsequent plantings of international varieties tended to follow international FASHION: various members of the Pinot family in the 1970s; Chardonnay, Sauvignon Blanc, and Cabernet in the 1980s; Syrah and Viognier in the 1990s. Central Italy, with only the late-ripening Sangiovese an important red grape, has seen considerable plantings of Cabernet, Merlot, and Syrah, especially on the Tuscan coast. But overall the fashion is waning, even if some producers and producer associations still seem to view the inclusion of some of them in official regulations as a passport to commercial success.

Organization of trade

Italy's wine trade resembles those of its European neighbours in terms of a division of labour between individual properties, commercial and NÉGOCIANT houses, and CO-OPERATIVE wineries. What distinguishes Italy is the overwhelming importance of the last two categories, a dominance which is the direct result of the extreme fractioning of vineyard property with individual holdings averaging just 1.8 ha/4.45 acres. Intermediaries for the marketing of the wines, be they négociants or co-operatives, are thus indispensable links in the distribution chain which connects growers to consumers. Private estates of a certain size are an important reality in Tuscany, Puglia, Sicily, and, to a lesser extent, in Friuli, while the development of a significant number of prestigious small 'domaines' in the finest zones of Piemonte might be considered a riposte to BURGUNDY.

Large commercial houses were a relatively late development in Italy, virtually all of them having been founded after the unification of the country in 1861 and thus being a century younger than comparable houses in France, Spain, and Portugal. This is because Italy was not a country prior to its unification, and the movement of merchandise across the borders of the many small states which existed in the peninsula was costly and cumbersome. REDDING cites 'a vexatious system of imposts' as a major cause of Italian viticultural backwardness in the 19th century. There was very little in the way of a national market and little knowledge of even the finest products outside their specific production zones. Even today, négociant houses are a major presence only in Piemonte, Tuscany, the Veneto, and Sicily, while co-operative wineries play a significant role in virtually all Italian regions.

Co-operatives, several founded as early as the end of the 19th century, became the dominant force in the production and distribution of Italian wine in the late 20th century, a logical development considering the political dominance of the Christian Democratic party in the country's various governments and the favour shown to co-operative movements in the social doctrine of the

Roman Catholic church. Income maintenance has been as significant a concern as the products themselves; this objective has entailed large volumes, which, thanks to ample subsidies, could be marketed at low prices. Quality has not always been the strong point of the resulting wines, although individual co-operatives, particularly in the north, have always been conscious of the need to create products that would please consumer palates. Italy enjoyed particular success in the 1970s and 1980s with its exports of the Riunite co-ops' LAMBRUSCO. This sweet foaming red has been joined by Pinot Grigio and Prosecco as the commercial ballast of Italy's wine exports.

As EU and national subsidies are reduced, Italian wines, like any other European wine, will have to respond more readily to free-market economics. While the total volume of wine produced has declined considerably, consumption within Italy has declined even faster, and Italy now exports around 70% of its wine, making full use of EU marketing incentives to help sell its wines in third markets.

There can be few doubts that Italy's new prosperity and the worldwide popularity of Italian food have changed prospects and possibilities for Italian wine. And there can be even fewer doubts that admirers and enthusiasts of Italian wine have never had such an embarrassment of riches as at the beginning of the third millennium CE.

For details of individual regions, see ABRUZZO, ALTO ADIGE, BASILICATA, CALABRIA, CAMPANIA, EMILIA-ROMAGNA, FRIULI, LAZIO, LIGURIA, LOMBARDIA, MARCHE, MOLISE, PIEMONTE, PUGLIA, SARDINIA, SICILY, TRENTINO, TUSCANY, UMBRIA, Valle d'AOSTA, and VENETO.

For details of terms to be found on Italian wine labels, see CLASSICO, DOC, DOCG, IGT, and RISERVA. A wine that fails to qualify as any of these is a WINE WITHOUT GEOGRAPHICAL INDICATION and is labelled simply VINO or Vino d'Italia. W.S.

Itata, subregion in southern CHILE rediscovered by De Martino winery in 2011, when it began to vinify wines from the region's old vines of Cinsault (see CINSAUT). Now the region is increasingly also known for old PAÍS and MUSCATEL, which grow on hills facing the sea in the Cordillera de la Costa. P.T.

IVDP, Instituto do Vinho do Douro e do Porto, which governs the production of both PORT and DOURO wine.

IWCA. Founded in 2019 by JACKSON FAMILY WINES and FAMILIA TORRES, International Wineries for Climate Action is a growing group of wine producers committed to continuing to reduce the wine industry's CARBON FOOTPRINT to zero by sharing knowledge and by regular audits.

J

Jackson Family Wines, growing international empire of high-quality, environmentally aware wine estates spun out of KENDALL-JACKSON of Sonoma, California.

In 1986, Jess Jackson and his second wife Barbara Banke acquired 1,000 acres/400 ha in SANTA BARBARA County based on the historic Tepusquet Vineyard and founded Cambria Winery and Vineyard, with Banke the listed owner. Stonestreet in ALEXANDER VALLEY followed three years later, and in 1991 a partnership was formed with a STAVE mill in the Vosges to assure OAK quality. Today this operation has grown into Merrain International.

By the mid 1990s, they were making wine in Chile and Italy and had bought what would be Hartford Family Winery in the Russian River Valley, Gauer Estate in the Alexander Valley, and another high vineyard on Howell Mountain. They continued to expand into mountain vineyards, especially those benefiting from Pacific influence.

In the early years of this century they acquired wine estates in Australia and St-Émilion.

Jess Jackson died in 2011 at age 81 after a long bout with cancer. Barbara Banke has since taken charge and has only increased the company's (including Kendall-Jackson's) commitment to SUSTAINABILITY, including the establishment of the Jess S. Jackson sustainable winery at DAVIS. With FAMILIA TORRES, the company founded International Wineries for Climate Action (IWCA), an attempt to decarbonize the wine sector, in 2019. Under Banke, and presumably with CLIMATE CHANGE in mind, the company has moved determinedly into Oregon and in early 2022 owned 40 wineries in California, Oregon, Australia, Chile, France, Italy, and South Africa,

each allowed an unusual degree of autonomy and totalling a landholding of 15,000 ha/37,000 acres, of which about one-third is planted to vines.

Jacquère is the most planted white grape variety in SAVOIE, where it produces high yields of lightly scented, essentially alpine dry white. It is one of the numerous natural progenies of GOUAIS BLANC. Plantings were a steady 920 ha/2,273 acres in 2019. Late ripening and relatively hardy, it has also been successfully grown for IGP blends in the northern Rhône.

Jacquez, also known as Black Spanish, dark-skinned American hybrid grown in TEXAS thanks to its resistance to PIERCE'S DISEASE and in Brazil for everyday wines and juice.

Jadot, Louis, merchant-grower based in BEAUNE, selling Burgundy and, from 2013, operating in OREGON, where they founded Résonance. They own 132 ha/326 acres of vineyards in the CÔTE D'OR, 75 ha/185 acres in BEAUJOLAIS, and 18 ha/44 acres in Fuissé in the MÂCONNAIS. The company has been owned by the Kopf family since 1985. Founded in 1859 by the eponymous Louis Jadot, the company was run from 1962 to 1992 by André Gagey, who joined the firm as an assistant in 1954. When Louis-Alain Jadot, last of the family line, died prematurely in 1968, Gagey was asked by the family to become general manager. He was succeeded by his son Pierre-Henry, whose son Thibault now works for the company. Jadot's success has been very much due to the combined talents of André Gagey and winemaker Jacques Lardière, who retired in 2013 to be succeeded by Frédéric Barnier. Both red and white NÉGOCIANT wines, made from bought-in fruit, are thoroughly reliable, but the firm's reputation is based on the high quality of its domaine wines. Jadot's holdings have continued to increase, not least in Beaujolais, notably Ch des Jacques in the 1990s and Domaine Ferret in 2008.

Jaen, Jaen Tinto, and Jaen du Dão, synonym for Galicia's MENCÍA red wine grape in Portugal's DÃO region, where it ripens early to produce deeply coloured wines that are notable for their modest acidity. Occasionally seen as a VARIETAL, it is normally stiffened with Touriga Nacional and Alfrocheiro. The vine was planted on a total of 3,249 ha/8,028 acres in northern Portugal in 2020. Jaén Blanco is a synonym for CAYETANA BLANCA.

Jahrgang, German for VINTAGE (as in the year rather than the HARVEST process, for which the word is *Ernte*).

Jakot, Slovenian name for the FRIULANO vine variety, the old name Tokaj spelt backwards.

Japan . More known for its sake and shochu, Japan also has a winemaking history of nearly 150 years, even though wine drinking has only recently become common. Though per capita consumption remains small compared with that of Europe and the United States, wine is produced in most prefectures, with 331 wineries and total production of 82,319 kl in 2020, and is forecast to grow further thanks to increased technical and financial support from both public and private sectors.

History

The exact origins of grape cultivation in Japan are unclear, obscured by several competing legends, but are believed to date as far back as the 8th century. It is thought that grapes had been cultivated only as TABLE GRAPES until the 15th century, when Portuguese MISSIONARIES brought red wine as gifts for the feudal lords of Kyushu in southern Japan in 1545. Others who followed continued the practice so that the locals acquired a taste for wine and began to import it regularly.

Until recently, it was believed that Japanese winemaking first began in the 19th century, when winemaking was encouraged by the Meiji government. However, newly discovered historical documents suggest a period of winemaking around 1627; the history is now being reconsidered.

In 1874, commercial winemaking began in Yamanashi Prefecture, and in 1877 the first privately owned winery was established in Katsunuma, in the centre of the prefecture. The winery sent two employees to France to study viticulture and oenology; their efforts convinced local authorities to permit the import of European VITIS VINIFERA and AMERICAN VINES as the basis for a new industry.

In 1893, Zenbei Kawakami, often credited as the 'father of Japanese wine', established a vineyard in Niigata and began developing HYBRID varieties suited to Japan's climate. Of the 22 varieties he developed, MUSCAT BAILEY A became one of the signature red wine grapes of Japan. Hybrids dominated the wine industry until the 1980s, when Japan's first 'wine boom' saw per capita consumption double during the 1980s, and an increased exposure to imported wine spurred a movement towards *vinifera* varieties.

Japanese wineries also focused on investment in modern winemaking equipment and on training their winemakers in the methods used in the major wine-producing nations (Suntory even went so far as to buy the ST-JULIEN classed growth Ch Lagrange, and the 1980s saw several substantial Japanese investments in the German, California, and Australian wine industries).

Since 2000, the growing demand for wines has spurred local authorities and regional wine associations to set voluntary standards in terms of varieties, viticulture, and winemaking, with an emphasis on Japan-grown wines. In recent years, the National Tax Agency Japan, the Ministry of Agriculture, Forestry and Fisheries (MAFF), and local municipal governments, among other official bodies, have been endeavouring to promote the wine sector.

Geography and climate

Japan is a long, narrow archipelago stretching from latitudes 26° to 44° N, with about 75% of the land surface covered by mountains. It is surrounded by the Pacific Ocean, the Sea of Okhotsk, and the East China Sea, sitting at the intersection of warm and cold currents. As the vineyards are widely spread out, the array of MESOCLIMATES is diverse, from subtropical to subarctic.

As of 2022 there were five GEOGRAPHICAL INDICATIONS (GIs) registered for wine: Yamanashi, Nagano, Yamagata, Hokkaido, and Osaka. The first three, all on the main island Honshu, account for almost 71% of the country's total production. Because of the subtropical, MARITIME CLIMATE and high level of precipitation, with the rainy season and typhoons complicating the growing season and prolonged rainfalls at harvest, an overhead PERGOLA trellising system known as *Tana-jitate* is traditionally used to allow ventilation as a defence against FUNGAL DISEASES.

Yamanashi Prefecture, west of Tokyo, boasts the largest area under vine, with 3,800 ha/9,390 acres (including TABLE GRAPES). The vineyards and wineries are concentrated around the Kofu basin centred on Katsunuma, surrounded by high mountains that provide protection from moist winds. The vineyards are mainly located on slopes at 300–550 m/984–1,805 ft in ELEVATION, with good DRAINAGE and fresh breezes. The high DIURNAL TEMPERATURE RANGE and long hours of sunshine during the growing season help the grapes to achieve PHYSIOLOGICAL RIPENESS. The region produces 96% of the country's Koshu grapes and 62% of Muscat Bailey A.

Nagano Prefecture, inland and west of Yamanashi, ranks second in production of Japanese wine. Surrounded by the Japanese Alps, more than 80% of its farmland is above 500 m/1,640 ft in elevation. Similar to Yamanashi, Nagano Prefecture has relatively low rainfall with a climate suited to fruit-growing. Nagano is the largest producer of Merlot, Concord, and Niagara grape varieties in Japan. Kikyogahara, the birthplace of winemaking in Nagano, is known for its Merlot.

Syrah grown in Ueda has attracted much attention in recent years. And Chardonnay from Chikuma River basin, produced in various styles according to elevation and soil, is also highly valued. This last area is particularly booming, boasting nearly half of the wineries in Nagano, thanks to local programmes offering training and support for new producers.

Hokkaido, Japan's northernmost island at latitudes 42–45° N, is rarely influenced by tropical cyclones and typhoons, but it is very cold, classified as Region I according to the Winkler Index (see CLIMATE CLASSIFICATION). Yet the region is drawing increased attention from winemakers looking for alternatives in the face of CLIMATE CHANGE. In addition to many new small-scale wineries, there are several large producers, and the region has attracted some prominent outside talent: Étienne de Montille from Burgundy has invested in Hakodate, and Italian consultant Riccardo Cotarella is working in Yoichi. A CUSTOM-CRUSH FACILITY in Iwamizawa also plays an important role in encouraging the local wine industry.

The centre of wine production in Hokkaido is the Shiribeshi district in the south-west and the Sorachi district in the centre. The Shiribeshi district—the larger of the two—rarely feels any influence from the cold currents of the Pacific Ocean, so there is little risk of frost damage or WINTER FREEZE and grape yield is stable. In Yoichi and Niki, government subsidies are used to support wine tourism projects as well as winery improvements.

Throughout the prefecture, grape varieties with high cold tolerance dominate, particularly white varieties KERNER and NIAGARA. In red grape varieties, Zweigeltrebe (ZWEIGELT) has the largest area under vine, and Pinot Noir is increasing. Less cold-hardy vines are pruned before snowfall and then buried under soil or snow for WINTER PROTECTION.

Japanese vineyard soils are in general very acid (see PH, SOILS).

Vine varieties

In Japan, the demand for table grapes is high, and so the majority of its 16,700 ha/41,267 acres of vineyard in 2020 is planted to Kyoho, Delaware, Pione, Shine Muscat, and other table grapes. Some table grapes are also used for wine.

The most significant Japanese variety is KOSHU. This is the descendant of the vines carried along the Silk Road to Japan 800 to 1,200 years ago and, in the public eye at least, is virtually synonymous with the industry of Katsunuma.

Koshu has survived as an important variety because it has adapted to the difficult growing conditions in Yamanashi Prefecture and because it is supported by long tradition. Also used as a table grape, it has high VIGOUR and a low rate of sugar accumulation. Koshu also contains a specific precursor which forms a THIOL compound, 3-mercaptohexanol, that gives an aroma of grapefruit, as found in Sauvignon Blanc. The grape lends itself to diverse wine styles, from still white wines to sparkling, dessert, and ORANGE wines. NIAGARA and DELAWARE are also popular for white wines, and ALBARIÑO cultivated along the coast of Niigata is attracting attention.

The major red grape varieties used for wine are Muscat Bailey A, CONCORD, and Merlot. Highly tolerant of wet, cool climates, Muscat Bailey A has a characteristic strawberry flavour and modest tannins that makes it amenable to a wide range of wine styles, from sparkling and rosé to reds in both early-drinking and ageable styles.

An indigenous variety, YAMABUDO, has also been gaining attention. This red variety belongs to *Vitis coignetiae*, an indigenous Asian vine species, and was registered for wine use with the OIV in 2020.

Industry organization

Until 2015, domestically produced wine or wines bottled from imported wines and/or fermented from concentrated must were permitted to be called 'domestic wine'. In 2015, Japan's National Tax Agency introduced new labelling standards, stipulating that only wine made 100% from grapes grown in Japan can be labelled as 'Japan wine'. These wines may also be labelled by GEOGRAPHICAL INDICATION, grape variety, and vintage. In 2020, the production of 'Japan wine' was about 20% of total wine production and forecast to increase.

However, the rapid rise in the number of wineries intent on producing wine from domestically grown grapes has led to a shortage of vine cuttings as well as grapes. In addition, as wine grapes trade at a lower price than table grapes in Japan, fewer growers produce wine grapes, and the number is dwindling. In response, the number of wineries who own their own vineyards is gradually increasing. Large wineries continue to dominate production, but 85% of Japan's wineries are small-scale, producing less than 100,000 l/26,417 gal.

K.O. & R.F.

Jasnières, white-wine appellation of just 75 ha/185 acres in 2020 dedicated to CHENIN BLANC and sheltered within the Coteaux du LOIR district in the northern Loire. Shared by the communes of Lhomme and Ruillé-sur-Loir, the vineyards cover a steep south-facing slope protected from the north winds by the Bercé forest (a favourite of coopers). Declared 'the best white wine in the world' three times by food critic Curnonsky, Jasnières failed to live up to its fame and almost disappeared in the 1950s, but growers such as Joël Gigou followed by outsiders such as Eric Nicolas have resurrected the appellation and its potential. Locals see Jasnières as 'the SAVENNIÈRES of Touraine' because of the austere profile of the dry wines in their youth but the region's complex geology of FLINT, CLAYS, and mica SCHIST over Turonian LIMESTONE allows for a broader expression of style resembling a steelier VOUVRAY. Rare, notable NOBLE ROT wines are also made. See also LOIRE, including map.

P. Le.

Jefferson, Thomas (1743–1826), third president of the United States, a wine lover whose interest in wine and hopes for American winegrowing typified the early Republic. As a VIRGINIA farmer, Jefferson grew grapes from all sources, native (see VITIS, AMERICAN VINE SPECIES) and VITIS VINIFERA, at his estate Monticello for 50 years with uniform lack of success: no Monticello wine ever materialized, but the hope never died. His vineyard at Monticello has been restored to the form it had in 1807.

As ambassador to France (1784–9), Jefferson made himself expert in wine, travelling to all the major French wine regions as well as to those of Germany and Italy. He tasted, discussed, and bought widely, and he acted also as agent and adviser for his friends in the selection and purchase of wines. The record of this activity contained in his papers is a small encyclopedia of pre-Revolutionary wine and wine production. As president (1801–9), Jefferson was celebrated for the variety and excellence of his cellar at the White House in Washington, which abounded in CHAMBERTIN, MARGAUX, HERMITAGE, YQUEM, and TOKAY.

At all times, Jefferson was eager to assist the many efforts to solve the riddle of successful winegrowing in America: he gave land next to his Virginia estate to support Philip Mazzei's Italian Vineyard Society, an ambitious effort to grow wine by importing Italian vines and vineyard workers; he encouraged such neighbours as James Madison and James Monroe in their viticultural experiments; and it was during his administration that land on the river Ohio in Indiana was granted to Swiss-born Jean Jacques Dufour for the enterprise that resulted in the first successful commercial wine production in the United States.

By such assistance, and by minimizing wine TAXATION, Jefferson hoped to make the US a wine-drinking country. He could be extravagant in his optimism: a wine from the native Alexander grape he called equal to Chambertin; a sweet SCUPPERNONG from North Carolina he thought would be 'distinguished on the best tables of Europe'. The US, he affirmed, could 'make as great a variety of wines as are made in Europe, not exactly of the same kind, but doubtless

as good', even though his own experience contradicted the proposition.

Jefferson's personal pleasure in wine was clear: 'Good wine is a daily necessity for me', he wrote. He also saw wine as an element in his vision of a nation of independent yeomen: 'no nation is drunken where wine is cheap', hence wine should be the nation's drink.

Bottles of late 18th century wines such as Ch LAFITE, T.P. supposedly ordered and even initialled by Jefferson, fetched record-breaking prices at AUCTION in the late 20th century but were subsequently shown to be COUNTERFEIT.

de Treville Lawrence, R. (ed.), *Jefferson and Wine* (2nd edn, 1989).

Gabler, J. M., *Passions: The Wines and Travels of Thomas Jefferson* (1995).

jerepigo, or jerepiko, unfermented dessert 'wines' in South Africa, the Cape's version of MISTELLE produced by adding alcohol to grape juice, generally from inland regions, before fermentation. Many are made from MUSCADEL, which name on the label may legally serve to indicate style as well as variety. Initially about 17% alcohol, many are now closer to a more recent lower limit of 15%, often with intense ripe fig and MUSCAT flavours. These traditional, warming wines, both red and white, once popular in South African winters but now sold in ever-declining volumes, probably derive their name from JEROPIGA.

Jerez, or Jerez de la Frontera, city in ANDALUCÍA, south-west Spain, that is the centre of the sherry industry. Jerez is also the name of the DOP which produces sherry. In Spain the wine is known as *vino de Jerez* (or simply *Jerez*), and 'sherry' is an English corruption of the Spanish word (while in France the town and drink are known respectively as Xérès and *xérès*). The town owes its full name to the fact that in the Middle Ages it was on the frontier between Christian and Moorish Spain. For more details on the wine, see SHERRY.

jeroboam. See BOTTLE SIZES.

jeropiga, Portuguese term for grape must prevented from fermenting by the addition of grape spirit. *Jeropiga* is often used to sweeten FORTIFIED WINES. (*Vinho abafado*, on the other hand, is partially fermented before spirit is added; see CARCAVELOS.)

jetting. See SPARKLING WINEMAKING.

Jewish heritage in German wine culture. By their Christian names, they could not be distinguished from their colleagues in Prussia or elsewhere in Germany. But by their family names, many of the late 19th century champions of the wine trade in Germany could be easily identified as Jewish: the sons of Hermann SICHEL, who spread from the old Rhenish wine capital Mainz throughout Europe and conquered the New World; Leo Levitta, who was raised in Rüdesheim on the Rhine; Julius Langenbach, a citizen of Worms, the town that centuries ago hosted one of the largest Jewish communities north of the Alps; and Sigmund Loeb, who had deserted the windy Hunsrück only to become one of the most renowned wine merchants of Trier and president of the Moselle Trade Association. In the last quarter of the 19th century, some excellent vintages, peace in notoriously war-torn Europe, and the free-trade spirit during the first wave of GLOBALIZATION helped propel Jews to the forefront of the German wine trade. Their centuries-old mercantile skills helped, as did the European aristocracy and nouveau-riche bourgeoisie's desire to acquire what were then regarded as the world's finest wines, as well as a thirst among emigrant communities throughout the Americas for wine from their German homeland.

Although Jews formed a significant part of the national and international German wine trade, there is no evidence that they endured particular scrutiny during the anti-semitic stirrings at the end of the 19th century. There was certainly some unease when Jewish brokers and merchants formed quasi-monopolistic structures, such as

those in Franken and the southern Pfalz. But according to the few sources available, there was neither stigma nor bias towards Jews by government officials in the prosecution of wine ADULTERATION AND FRAUD. And during the First World War, German Jews turned out to be as patriotic as everybody else. Sigmund Loeb's only son Otto Wolfgang was not the only one to fight in France.

When the war was over, the main export markets for German wine were off limits. The victorious UK despised the symbols of German prepotency, PROHIBITION had closed the US market, and Russia was torn apart by the Bolshevist revolution. In the 1920s, most parts of Western Europe stumbled from one political and economic crisis into another. The German wine market was close to collapsing and, as a result, so was the business of brokers and merchants. Once again, the Jews drew on their skills and their international networks. Alfred Fromm moved from Franken to Bingen across the Rhine from the Rheingau where he set up a new export business; the Sichels created the famous BLUE NUN—one of the first BRANDS in wine history. When Hitler was elected in 1933, some 60% of German wine was traded by Jewish agents and merchants, which was the main reason the Nazis held back from cracking down immediately on the Jewish wine community. The other reason: by exporting high-value wine, Jewish merchants delivered the precious foreign currency that the Nazis needed for the German war machine.

Only after the Olympic games in 1936 in Berlin, by which time non-Jewish wine marketing had consolidated, did the Nazis crack down on Jewish brokers, merchants, and retailers. Families such as the Levittas split up, with some members heading into exile; Sigmund Loeb's son, Otto Wolfgang, had already founded a subsidiary in London, O. W. Loeb, and managed to introduce opera lovers at the Glyndebourne Festival to Moselle wines; the Sichels eventually escaped to London and the US.

The 'Reichskristallnacht' in November 1938 marked the beginning of the final extinction of Jewish entrepreneurship in Germany. Those who had not left Germany were forced to sell their businesses or lost permission to do so. Although there are no detailed records, it seems

that quite a number of merchants survived the Holocaust, thanks to their international contacts. However, the brokers whose work was based on their local networks were murdered or gassed. Ludwig Levitta, one of the finest palates of his time, was deported with his wife and son to Theresienstadt and perished at Auschwitz in 1943.

Despite the Holocaust, most of the exiled Jews did not hesitate to engage in the German wine trade again and to restore the reputation of German wine in the UK and the US. Alfred Langenbach (d. 1964) published *The Wines of Germany*, the first comprehensive survey of German wines ever published in the English language (1951). Fritz Hallgarten (d. 1991) documented his experiences in his memoir *Rhineland-Wineland* (1951), and Otto W. Loeb (d. 1974) drew on his and his father's unique knowledge for his book *Moselle* (1971).

By that time, Loeb's efforts to initiate hundreds of members of Cambridge University Wine & Food Society into the mysteries of German Riesling and the wines of California had borne plenty of fruit —Hugh JOHNSON was one of the best and brightest of his adepts. Alfred Fromm (d. 1998) had joined Franz W. Sichel in influencing the reorientation of the California wine industry towards quality wine. Even with Peter Max F. Sichel (b. 1922) no longer active in the wine world from his base in New York and O. W. Loeb of London now under different ownership, the Jewish heritage of German wine cultural is still alive and, one hopes, will never be forgotten.

D.De.

João de Santarém, name used for the widely planted CASTELÃO red wine grape in parts of the TEJO region of Portugal.

Johannisberg, Valais name for SILVANER grapes in SWITZERLAND.

Johnson, Hugh (1939–), world's best-selling wine author. Johnson's passion for wine began when he was at Cambridge University, where he read English. One of the great stylists of the LITERATURE OF WINE, on graduation he was immediately taken on as a feature writer for Condé Nast magazines. As a result of his close

friendship with André SIMON, the founder of the International Wine & Food Society, he became general secretary of the society and succeeded the legendary gastronome as editor of its journal. At the same time he became wine correspondent of the *Sunday Times* and embarked on his first book *Wine*, whose publication in 1966 established him as one of the foremost English gastronomic writers of the time. More than 750,000 copies have been printed, in seven languages. He revised it in 1974.

His next book was even more successful, even though it allowed only limited scope for Johnson's matchless prose. *The World Atlas of Wine* represented the first serious attempt to map the world's wine regions and first appeared in 1971. More than 4.5 million copies in a total of 20 languages have been sold of this and subsequent editions in 1977, 1985, 1994, 2001, 2007, 2013, and 2019, the last four co-written with Jancis Robinson.

Pausing only to edit *Queen* magazine 1968–70, he then wrote a best-selling book on trees, *The International Book of Trees*, inspired by his acquisition of an Elizabethan house in Essex. In 1977 he went on to devise and write an annual wine guide, *The Pocket Wine Book*, which has sold more than 12 million copies in a dozen languages, between its first edition and 2023.

The more expansive *Hugh Johnson's Wine Companion* followed in 1983 and was revised in 1987, 1991, 1997, and 2003 with Stephen Brook. It sold widely in the US as *Hugh Johnson's Modern Encyclopedia of Wine*, in France, and in Germany as *Der Grosse Johnson*. This prolific output, encouraged by Johnson's publishers Mitchell Beazley, was supplemented in 1979 by *The Principles of Gardening*, another bestseller, and a succession of co-authored and less serious wine books (including even a 'pop-up' version).

Johnson's most distinctive work, however, did not appear until 1989. *The Story of Wine* is a *tour de force*, a sweep through the history of wine in which Johnson's literary skills and breadth of vision are headily combined. The book, updated and republished in 2020 as *The Story of Wine: From Noah to Now*, was written to coincide with an ambitiously international 13-part television series, *Vintage: A*

History of Wine, written and presented by Johnson. In 1992, he co-authored *The Art and Science of Wine* with Australian James Halliday. *A Life Uncorked* (2005), republished in 2022 as *The Life and Wines of Hugh Johnson*, is his most reflective and autobiographical work.

Between 1986 and 2000 Johnson sold the Hugh Johnson Collection, glassware and other wine accessories, with notable success in Japan, where he was a consultant to Jardines Wines and Spirits. He also served (1986–2001) on the administrative council of first growth Ch LATOUR and has been president of the *Sunday Times* Wine Club run by LAITHWAITE'S since its inception in 1973. In 1990, Johnson co-founded The Royal TOKAJI Wine Company, a reflection of his interest in wine history. Other activities include regular journalism on gardening. For 25 years from 1975 he was editorial director of the *Journal of the Royal Horticultural Society* and since 1975 has written a gardening column, now a blog, under the pseudonym Tradescant (SEE WEB LINKS www.tradsdiary.com), anthologized in 1992, 2009, and 2021. In 2005 and 2007 respectively, none too hastily one might argue, the French made him a Chevalier de l'Ordre National du Mérite and the British an OBE.

Johnson is one of the most vocal opponents of SCORING wine, and his writing has been characterized more by a sensual and historical enthusiasm for wine in all its variety than by the critical analysis of individual wines.

Johnson, H., *The Life and Wines of Hugh Johnson* (2022).

joint venture, common phenomenon in the late 20th century whereby two enterprises with very different strengths combine to produce a wine or wines. The modern prototype was that announced in 1979 between Baron Philippe de ROTHSCHILD of Bordeaux and Robert MONDAVI of California to produce Opus One, the luxuriously priced Napa Valley Cabernet Sauvignon, combining Mondavi's knowledge of and holdings in the Napa Valley with the prestige and winemaking expertise associated with Baron Philippe's first growth Pauillac Ch MOUTON ROTHSCHILD. Most joint ventures are designed to

justify a premium over the other wines made *in situ* by virtue of a much-heralded connection with a glamorous outsider, but they are also evidence of the GLOBALIZATION of wine. Joint ventures are particularly well suited to new wine regions such as those in CHINA and INDIA, for example, where the winemaking expertise of an established wine producer blends well with an enterprise which can offer local knowledge and contacts.

Jongieux, CRU in the upper Rhône Valley west of Aix-les-Bains whose name may be added to the French appellation SAVOIE. Vineyards produce a range of still varietal wines from MONDEUSE, PINOT NOIR, or GAMAY for reds and, more commonly, JACQUÈRE for whites. Above Jongieux village is a steep vineyard slope, reserved for the separate Marestel cru, which may append its name to ROUSSETTE de Savoie. W.L.

Jordan, Middle Eastern country on the eastern bank of the Jordan River with a viticultural tradition reaching back to at least 3500 BCE (see ORIGINS OF VINICULTURE). In 2021, however, of its 8,792 ha/21,726 acres of vineyard only 280 ha were dedicated to wine production, of which Zumot, an ORGANIC producer, owns nearly 200 ha. These are located in Jordan's north, in Sama as-Sirhan, at 630 m/2,133 ft in ELEVATION. Here the broad DIURNAL TEMPERATURE RANGE makes it possible to ripen grapes into October. While the climate is generally arid, humidity can reach 80% on summer mornings. Vine rows are oriented east–west to take advantage of the west wind, which keeps grape bunches aerated and reduces FUNGAL DISEASES. Vines depend on DRIP IRRIGATION, the water sourced from deep underground. A mixture of CLAY and LIMESTONE soils allows for moisture retention as well as good drainage; BASALT and GRANITE also appear. Of the 38 varieties Zumot has trialled since 2000, Cabernet Sauvignon excels; Syrah, Petite Sirah, Carmenère, Malbec, Viognier, Gewürztraminer, Sauvignon Blanc, Petit Manseng, and Chardonnay

are also promising. However, the prevailing culture and high alcohol taxes ensure that wine remains a niche market, mainly appreciated by tourists; Jordanians themselves generally prefer arak, their aniseed-flavoured spirit.

joven, Spanish for 'young', sometimes used to indicate wines destined for early consumption.

Juan García, crisp, lively, local dark-skinned vine speciality of the ARRIBES zone in Castilla y León, on the border with Portugal, where it is usually mixed in the vineyard with other, lesser vines. In 2020 there was a total of 626 ha/1,547 acres in Spain. On rocky hillside sites, it can produce highly perfumed, relatively light reds. A natural cross of CAYETANA BLANCA and ALFROCHEIRO, it is also known as Mouráton.

Juan Ibáñez, synonym for the MORISTEL red wine grape in northern Spain.

judging wine, an activity that most wine drinkers undertake every time they open a new bottle, but also a serious business on which the commercial future of some wine producers may to a certain extent depend. For details of domestic, amateur wine judging, see TASTING.

The judging process at a more professional level can vary from a gathering of a few friends, a few bottles, and much hot air to a COMPETITION in which wines have been carefully categorized by wine type, style, and possibly price and are tasted BLIND, in ideal conditions, without any consultation until a possible final discussion of controversial wines. Back-up bottles are always needed in case of CORKED bottles and to verify whether any other FAULT is confined to a single bottle. SCORING systems vary but typically involve awarding a specific allocation of points for various different aspects such as appearance, NOSE, PALATE, perhaps TYPICALITY, and overall quality.

MEDALS and trophies are often awarded as a result. Wine SHOWS are particularly important in Australia.

For the results of professional wine judging on an individual or small-group basis, see WINE WRITING.

Judgment of Paris, famous blind tasting comparing hand-picked California and French wines organized in Paris in 1976 by British wine writer, then Parisian caviste, Steven SPURRIER. Much to the fury and embarrassment of the renowned French tasters, California surprised everyone by winning hands down. The French claimed that this was simply because NEW WORLD wines mature faster, but a repeat tasting held 30 years later simultaneously in London and Napa had much the same result. The tasting made the reputations of producers such as Stag's Leap Wine Cellars and Mayacamas.

Taber, G., *Judgment of Paris: California vs. France and the Historic 1976 Paris Tasting that Revolutionized Wine* (2005).

jug wine, term used in the US for the most basic sort of wine, a counterpart to VIN ordinaire or PLONK. After PROHIBITION was repealed in 1933, most inexpensive California GENERIC table wine was bottled in half-gallon and gallon (1.9- and 3.9-l) glass jugs or flagons with SCREWCAPS to satisfy a demand largely made up of thirsty immigrant labourers from the Mediterranean and Eastern Europe. As this market segment has aged and died without direct replacement, jug wines have waned.

Juhfark, distinctive white grape variety once widely grown in Hungary whose total plantings had fallen to 160 ha/395 acres by 2021. After the PHYLLOXERA invasion it never regained its importance and is today found almost exclusively in the Somló region, where it produces tart wine which ages well. The vine, whose name means

'ewe's tail', is inconveniently sensitive to both frost and DOWNY MILDEW.

Juliénas, one of the ten BEAUJOLAIS crus, home to important LIEUX-DITS, including Les Mouilles and Les Capitans, which yield stoic and long-lived wines, particularly from higher elevations among its 564 ha/1,393 acres. J.F.B.

Julius-Kühn-Institut, viticultural research station at Siebeldingen in the Pfalz region of GERMANY known to insiders as Geilweilerhof and specializing in breeding vine varieties which combine resistance to FUNGAL DISEASES with superior wine quality. As early as 1926, Peter Morio and later Professor Husfeld were working on combining the desirable characteristics found in Asian and AMERICAN VINE SPECIES with the wine quality produced by VITIS VINIFERA varieties. Much of the focus of research is on improving VINE BREEDING efficiency, with particular reference to pest and disease resistance, frost and drought resistance, as well as important wine constituents (particularly aroma and PHENOLIC compounds), the genetic resources of *Vitis*, grape genomic research, biotechnology, and the development of sensor-based phenotyping technology. The most famous varieties from Geilweilerhof are MORIO-MUSKAT, BACCHUS, OPTIMA, and DOMINA. In the early 1990s, the successful breeding work of Professor Alleweldt led to the release of the first DISEASE-RESISTANT VARIETIES such as PHOENIX (1992) and REGENT (1994). By 2004, Regent was planted on more than 2,000 ha/5,000 acres in Germany, representing a breakthrough in the acceptance of NEW VARIETIES. Other new cultivars with both good disease resistance and potential wine quality were released later: Villaris, Felicia, Calardis Blanc, and Calardis Musqué (white); and Calandro and Reberger (black). Geilweilerhof provides three grapevine databases on its website, and the journal *Vitis* has been published since 1957. See also GEISENHEIM.

Since 2008 the station has also housed a plant protection department of the JKI, which focuses on the causal agents and control of diseases and pests of viticulture and fruit crops and advises the German government on these issues. M.C. & R.K.C.T.

www.julius-kuehn.de/en/ow

Jullien, André (1766–1832), seminal wine writer, Parisian wine merchant, and one of the first explorers of the *world* of wine, venturing even as far as 'Chinese Tartary' in order to discover and assess all international wine regions and their produce. His was an extraordinary outlook, and it must have been a demanding journey, in an era when his peers barely ventured beyond the threshold of their wine shops. He had clearly read the contemporary LITERATURE OF WINE, which, until that point, concerned itself almost entirely with the details of how to grow vines and how to make wine (see CHAPTAL, for example). His aim was to discover and categorize the characteristics of as many different CRUS as he could find, travelling throughout eastern Europe, along the Silk Road to Asia, as well as discovering the vineyards of Africa. There can be few WINE WRITERS today who are as well travelled. The result was the publication in Paris in 1816 of *Topographie de tous les vignobles connus*, a substantial volume full of useful detail which includes the most comprehensive wine CLASSIFICATION (into five classes according to quality) ever undertaken. Much of it was translated into English and published, in abridged form, as 'a manual and guide to all importers and purchasers in the choice of wines' in London in 1824. In effect, Jullien's work set the style for a high proportion of modern WINE WRITING.

For more details of Jullien's classification, see the LITERATURE OF WINE.

Jumilla, DOP in the north of Murcia in central, southern Spain (see map under SPAIN) producing mainly red wines. The climate is arid, with just 300 mm/11.7 in of RAINFALL in a year. The principal grape variety is the red MONASTRELL, which ripens in the summer temperatures of around 40 °C/104 °F to produce high-alcohol wines.

About half of the region's much-reduced total area of 21,620 ha/53,424 acres of vines lies in Castilla-La Mancha and the rest in the region of Murcia. For this reason, Jumilla is one of the three DOPs in Spain regulated by the Agriculture Ministry and not by regional authorities.

Much of the wine from Jumilla was traditionally produced by the DOBLE PASTA method and used for blending with lighter wines from other parts of Spain. The vast San Isidro CO-OPERATIVE dominates the region's production, although since the mid 1980s a number of smaller, private producers have been striving, with some success, to tame Monastrell. Jumilla's recognition on international markets, notably thanks to the wines of Casa Castillo and El Nido, is not matched in Spain so that most of the best wines are exported.

F.C.

Jura, small eastern French wine region between Burgundy and Switzerland that produces an extremely wide range of wines relative to its extent, including such unusual wine types as VIN JAUNE, VIN DE PAILLE, and MACVIN DU JURA, as well as a certain amount of MARC du Jura. Since the late 2000s the region has caught the imagination of sommeliers and wine amateurs worldwide.

Although this was once an important wine region, with nearly 20,000 ha/49,400 acres of vines in the early 19th century, in 2019 there were only about 2,072 ha of vineyards planted out of a possible 11,000 ha for the appellation. The climate here is even more CONTINENTAL than in Burgundy and winters can be very cold. There is

significantly higher rainfall too. Most vineyards are on west-facing slopes at ELEVATIONS of 250–450 m/820–1,476 ft on the foothills of the Jura Mountains east of the Bresse plain. The chief town is Lons-le-Saunier, although ARBOIS is deemed to be the wine region's capital. Although it has a certain symmetry with the CÔTE D'OR on the other side of the Saône, the geology is quite different with various colours of CLAY-rich MARL from the Triassic and Early Jurassic geological epochs. To eliminate use of chemical herbicides, today most vineyards are ploughed at least every other row with the other grassed down. Vines were often traditionally trained with bended canes but most today are in double GUYOT, relatively high off the ground. The ORGANIC and the NATURAL WINE movements are important in Jura: in 2020, it counted as the French wine region with the highest proportion of certified BIODYNAMIC area under vine at approximately 8%, while total certified organic vineyards account for close to 20% of the region.

Five grape varieties are of importance in modern Jura (although more than 40 played a role at the end of the 19th century). Chardonnay, which has been grown in the Jura since the Middle Ages, accounted for 43% of total plantings in 2019. Its consistent ripening and YIELD make it popular with growers who use it to make dry white wines of several distinct styles as well as for CRÉMANT du Jura and Macvin. Since better TERROIR selections and different winemaking techniques have been adopted, some Chardonnays now rival those from the Côte d'Or. More unusual are those made in an oxidative style with or without the influence of FLOR-like yeast called the *voile*, or veil. The most extensively planted red grape POULSARD, often called Ploussard, grown particularly in Arbois-Pupillin, makes very pale reds or occasionally deep-coloured rosés, sometimes with an orange tint. A variety prone to REDUCTION, since the 2010s it has been increasingly vinified and bottled with no added SULFUR DIOXIDE, sometimes using CARBONIC MACERATION, making it much sought-after internationally among lovers of natural wine. Poulsard is also used for *vin de paille*. Another local red wine grape variety, TROUSSEAU, needs the additional

warmth of gravelly soils to ripen and is grown chiefly near Arbois, where some producers are capable of fashioning it into deep-flavoured, long-lived reds. Pinot Noir may be used as a VARIETAL wine or in a red blend or CRÉMANT, as well as for rosé or red Macvin du Jura.

Jura's most distinctive grape variety, however, is the white SAVAGNIN, also called Naturé, genetically identical to TRAMINER and hence GEWÜRZTRAMINER. In the 21st century the versatile Savagnin has been used for an increasing range of white-wine styles including ORANGE (or macerated whites), although it is especially known as the sole permitted variety for the extraordinary, nutty, long-lived *vin jaune*, sold in the distinctive 62-cl *clavelin* squat bottle. (Other Jura wines may be sold in another specially shaped bottle with the word 'Jura' stamped on the shoulder.) See VIN JAUNE and CHÂTEAU-CHALON, which specializes in this unusual wine.

See also the more varied appellation ARBOIS, which makes red, pink, and white still wine along with *vin jaune* and *vin de paille*.

Côtes du Jura, the region's second most important appellation after Arbois, includes an extended but scattered vineyard area stretching around 80 km/50 miles from north to south. The area includes vineyards north of Arbois, near the historic salt-production and spa town of Salins-les-Bains; the densest plantings are south of Pupillin towards Lons-le-Saunier, especially around the Comté cheese-capital of Poligny, and villages including Passenans, Darbonnay, and Arlay (home to the historic vineyards of Ch d'Arlay that can trace Pinot Noir plantings back to the 13th century but today are best known for long-lived, peaty *vin jaune* and complex *vin de paille*). South of Lons-le-Saunier Chardonnay predominates in the area known as the Sud Revermont, long known for sparkling wines and oxidative styles. The grapes here often ripen a week earlier than further north, and the area is more prone to spring FROST DAMAGE. With land cheaper than around Arbois, several renowned organic producers, led by Domaine Ganevat, have given new life to villages such as Gevingey, Ste-Agnès, and Rotalier. In some areas, alongside marls, there are more limestone outcrops, and wines can be close in

style to top barrel-aged Mâconnais. Jura's largest producer and négociant, La Maison du Vigneron, part of Les Grands Chais de France, owns and buys mainly from Côtes du Jura vineyards; its winery is east of Lons-le-Saunier with a large facility for making Crémant du Jura and a vast *vin jaune* barrel cellar. This appellation is also used for wines from vineyards in L'Étoile and Château-Chalon that do not fit those appellations' criteria.

The appellation L'ÉTOILE is reserved for white wines only, including *vin jaune* and *vin de paille*. Crémant du Jura, sparkling wines which are generally white and occasionally rosé, and white, rosé or red Macvin may be produced anywhere in the region.

Winemaking techniques are generally traditional, with almost no use of new oak barrels but much use of older barrels, small and large, although many reds are matured only in tank. Both Chardonnay and Savagnin white wines are increasingly made conventionally, in which case they may be described as OUILLÉ (topped up); however, the tradition also continues of making them OXIDATIVELY, as in the case of *vin jaune*.

The wines are distinctive; whereas they were for many years drunk almost entirely within the greater Franche-Comté region which encompasses Jura, by 2020 exports reached 18% in some years. With marked acidity and mineral characteristics, they make particularly good candidates for FOOD-AND-WINE MATCHING. W.L.

Lorch, W., *Jura Wine* (2014).

Jurançon is the name, closely associated with SOUTH WEST FRANCE, of a distinguished white wine both dry (Jurançon Sec) and sweet (labelled simply Jurançon); of a relatively important, if undistinguished, dark-berried vine variety; and of an entirely unimportant light-berried vine.

The wine

This fashionable, tangy, distinctive white wine has been celebrated and fiercely protected since the Middle Ages, and Jurançon was one of France's earliest AOCs. In the 14th century, the princes of BÉARN and the parliament of NAVARRA introduced the concept of a CRU by identifying and valuing specific favoured vineyard sites. Locals claim this as France's first attempt at vineyard CLASSIFICATION, just as they claim the drop of Jurançon with which the infant Henri IV's lips were rubbed at his baptism in 1553 was responsible for most of his subsequent achievements. The Dutch were great enthusiasts for this wine, and there was also a flourishing export trade across the Atlantic until PHYLLOXERA almost destroyed the wine. Jurançon's reputation was further advanced in the early 20th century by the enthusiasm of the French writer Colette.

Historically Jurançon wines were exclusively sweet, but a dry style was introduced in the 1970s so that today there are two distinct AOCs: Jurançon Sec and Jurançon. Any wine bearing the name of Jurançon *tout court* is and has to be sweet.

In 2023 vines were grown on about 1,400 ha/3,460 acres of vineyards in this hilly, relatively cool corner of southern France near Pau at the relatively high average ELEVATION of 300 m/984 ft. Spring FROSTS are such a threat that many vines are ESPALIER-trained, but the Atlantic influence ensures sufficient RAINFALL. Although there are four distinct areas of production with widely different TERROIRS, a hint of honey is never far away in Jurançons of every style. The wines from the lower-lying Monein district are typically fuller in body than those from the higher-lying Chapelle de Rousse. The former is partly on CLAY, with pebbles (*galets*) on the higher ground. The latter is characterized by a mixture called 'poudingue', a cement-like crushed CHALK mixed with *galets*.

The principal grape varieties are PETIT MANSENG and GROS MANSENG, but the dry version may include up to 50% of local varieties PETIT COURBU, COURBU, Camaralet de Lasseube, and Lauzet.

Gros Manseng is chiefly responsible for Jurançon Sec, for which yields of 60 hl/ha (3.4 tons/acre) are allowed. Petit Manseng, with its small, thick-skinned berries, is ideal for the production of Jurançon's real speciality, long-living, sweet Jurançon made from grapes partially dried on the vine (see PASSERILLÉ) at a maximum yield of 40 hl/ha but often much less. If several TRIES are made through the vineyard (two are mandatory), the results may be bottled separately. These MOELLEUX wines, whose green tinge seems to deepen with age, serve well as APERITIFS and with a wide range of foods. There are also sweeter wines labelled VENDANGES TARDIVES, made only from Petit and Gros Manseng and harvested as late as December. OAK is used to increasing effect, particularly in the LATE HARVEST style.

There is a high-quality CO-OPERATIVE at Gan, where two-thirds of all Jurançon Sec is made, largely from members in the Monein region. There is also an increasing number (65 in 2023) of independent producers.

Red and rosé wines made in Jurançon must be sold as BÉARN.

The vine varieties

A red wine grape called Jurançon was once commonly grown all over south-west France, but today it is rather despised and rare. A white version is even rarer, confined to the making of armagnac. Neither has today anything to do with the wines of Jurançon. P.S.

Justino's, the largest single shipper of MADEIRA, bottling under a variety of names including Cruz, the largest single BRAND of Madeira (and PORT) in France. Established in Funchal in 1870 and taken in hand by a new owner in 1981, Justino's operates from modern industrial premises outside the city. The company was formerly known as Justino Henriques but was renamed to avoid confusion with Henriques & Henriques, which is also now controlled by the French import and distribution group La Martiniquaise. Quality has improved considerably, TINTA NEGRA is taken seriously, and a range of TABLE WINES is also made for the local market.

K

Kabinett, one of six so-called PRÄDIKATS applying to German wine that has not been CHAPTALIZED and reaches—depending on growing region and grape variety—MUST WEIGHTS of 70–82 °OECHSLE. As such, Kabinett designates the lightest end of the Prädikat spectrum, and Mosel Kabinetts that have RESIDUAL SUGAR are often as low as 7 or 8% alcohol. Widespread use of the term 'Kabinett', like the pegging of quality designations to minimum must weights itself, is a product of the 1971 German wine law. The name was chosen for its association with the English word CABINET, widely used in Germany prior to 1971 as a general term of approbation for wines in all styles. Kabinett still has resonance in the German marketplace even for wines from regions such as BADEN and the PFALZ, where dry Kabinetts may significantly exceed 13% alcohol and where among reputed producers most vintages since 1987 have involved no chaptalization. The VDP prohibits utilization of this and other Prädikat designations for legally dry (TROCKEN) wines.

Austrian wine law enshrines the term 'Kabinett' for unchaptalized, dry Qualitätswein of up to 13% alcohol and from grapes of at least 17 °KMW (84 °Oechsle), but the term is little used, particularly since the advent of DAC status for much of NIEDERÖSTERREICH, whereby 'Reserve' on labels of Riesling or Grüner Veltliner effectively replaces 'Spätlese trocken' and non-Reserve DAC bottlings are those that would formerly have been labelled 'Kabinett'. D.S.

Kadarka, Eastern European late-ripening red wine grape of uncertain origin but considered indigenous in Bulgaria (under the name Gamza), Romania (as Cadarča), and Albania (as Kallmet),

widely planted across the Carpathian Basin before the arrival of PHYLLOXERA. In Hungary, the variety grew on a total of just 274 ha/677 acres in 2021 and has been substantially replaced by the viticulturally sturdier KÉKFRANKOS, and by PORTUGIESER in Villány. Kadarka, ideally trained as BUSH VINES, can produce wines that are light ruby in colour, finely structured, and with a delicate aroma only if yields are curbed. The best examples are found mainly around Szekszárd, Eger, and Hajós and in southern Slovakia and Serbia. Bulgaria's 218 ha/539 acres of Gamza are planted mainly in the north, where it can produce wines of interest from long growing seasons if yields are restricted.

Kalecik Karası, vine variety that makes particularly fruity reds north-east of Ankara in TÜRKIYE where there are 7,044 ha/17,406 acres.

Kalterer or Kalterersee, German for the DOC in TRENTINO and ALTO ADIGE known in Italian as Caldaro or Lago di Caldaro, based on SCHIAVA grapes.

Kamptal, named for the river Kamp that traverses it, is an AUSTRIAN winegrowing region immediately north-east of the KREMSTAL. Centred on the town of Langenlois and incorporating the nearby villages of Gobelsburg, Kammern, Legenfeld, and Zöbing, its diminutive perimeter is deceptive since an extremely high density of vineyards comprising 3,582 ha/8,851 acres (in 2021) represent 8% of Austrian vine acreage, third in regional size after the WEINVIERTEL and NEUSIEDLERSEE. Like the nearby WACHAU (of which it was once loosely considered part), the Kamptal features a wide DIURNAL TEMPERATURE RANGE but slightly less rain and greater vulnerability to FROST. It shares the Wachau's prominence of soils derived from LOESS and GNEISS but boasts even greater geological diversity, as witness

the Permian SANDSTONE that defines its best-known vineyard landmark, the massive, terraced Heiligenstein, arguably among the top 20 sites for RIESLING worldwide. The nearby Gaisberg is this region's other renowned vineyard for Riesling, which by 2021 had grown to 10% of Kamptal acreage, while in between those two the gently sloping, loess-dominated Lamm is the region's most famous site for GRÜNER VELTLINER, which is planted on 55% of all Kamptal vineyard. Successful flirtations with other varieties are numerous, especially Chardonnay, Pinot Blanc (WEISSBURGUNDER), Sauvignon Blanc, Pinot Noir, ST-LAURENT, and ZWEIGELT. Known also for its density of ambitious, environmentally conscious growers, the Kamptal has benefited from winegrower Willi Bründlmayer's status as a long-standing unofficial ambassador for Austrian wine as well as from the chairmanship of Austria's TRADITIONSWEINGÜTER by Michael Moosbrugger, a Bründlmayer protegé who has had responsibility for the 850-year-old monastic estate of Schloss Gobelsburg since 1996.

Kamptal DAC is the official Austrian DAC appellation for Kamptal Grüner Veltliner and Riesling wines. A DAC Reserve category specifies higher minimum potential alcohol and later release. QUALITÄTSWEIN that does not qualify as Kamptal DAC must be labelled with its state of origin, NIEDERÖSTERREICH. This applies in particular to the 35% of Kamptal wines made from grapes other than Grüner Veltliner or Riesling. D.S.

Kangaroo Island, cool, maritime region 13 km/8 miles off the coast of SOUTH AUSTRALIA with just 144 ha/356 acres of vines in 2022. With 40% of the island subject to environmental conservation, the island is especially known for its concentration of endemic flora and fauna. R.J.T.

Kanzler, MÜLLER-THURGAU × SILVANER cross bred at Alzey in 1927 of which only 25 ha/62 acres remained in 2020 because it does not yield well.

Kazakhstan, independent central Asian, former Soviet republic. The largest land-locked country in the world, south of Russia and bordering China, it has an extreme CONTINENTAL climate, with summer temperatures exceeding 30 °C/86 °F and winter temperatures averaging −20 °C/−4 °F.

Evidence of grape culture in Kazakhstan dates back to the 7th century CE. The country's most ancient viticultural areas are around Turkestan in South Kazakhstan (where the grapevine was imported from the Samarkand and the Fergana regions of UZBEKISTAN) and the Panfilov area of the Almaty region (where grapevines are popularly believed to have come from CHINA's western Xinjiang province).

At the end of the 19th century, grapes were grown on a small scale by private farms. The development of commercial grape culture began in the 1930s, when the first fruit- and winegrowing state farms such as Issyk in the Almaty region, Uch-Bulak in the Zhambyl region, and Juvaly and Kaplanbek in South Kazakhstan were established. Viticulture developed rapidly after 1957, the land under vine expanding from 4,997 ha in 1958 to about 28,000 ha/69,190 acres prior to Mikhail GORBACHEV's anti-alcohol campaign in 1985. Most vineyards dedicated to wine production were subsequently pulled out and replaced with other crops or abandoned. More vineyards were lost after Kazakhstan declared independence from the Soviet Union in 1991 and vineyards belonging to the state farms were allocated among locals who often lacked the resources to care for the vines.

The 21st century has seen an increased investment from foreign and domestic sources in both vineyards and wineries. There has been a small but steady influx of viticultural and winemaking consultants from the UK, Australia, France, and Italy who have worked with local producers to improve quality. As with other parts of the former Soviet Union, there has been a move to produce fresher, more international styles and a move away from the sweet, heavy wines of the past. By 2021, the Kazakhstan's Bureau of National Statistics reported a total vineyard area of 13,240 ha/32,716 acres producing over 195,000 hl/5.5 million gals of wine.

As less than 4% of Kazakhstan offers favourable soil and climatic conditions for commercial grape culture, most vineyards are located in the warmer south and south-east of the country, principally in the Almaty, Zhambyl, South Kazakhstan, and Kyzylorda regions. Even here winters can be very cold, and most vineyards need WINTER PROTECTION. The exception is the Turkestan area, where mild winters allow vines to be GUYOT-trained with no winter protection.

The annual rainfall is 700–1,000 mm/27–39 in in the Trans-Ili and Talas Alatau but is as little as 100–150 mm/4–6 in in some areas of the Aktobe region in the west. IRRIGATION is the norm. PHYLLOXERA has never been detected, but most vines are GRAFTED for predictability in results and security of harvest volumes. Most vineyards are planted on flat areas, but some climb to 600–800 m/1,969–2,625 ft in ELEVATION in the foothills of Tian Shan mountain range.

There is currently no GEOGRAPHICAL INDICATION system in Kazakhstan and no official list of grape varieties permitted/recommended for winemaking. Popular wine varieties include Georgian ones such as RKATSITELI and SAPERAVI as well as local varieties Bayanshira, Kuljinski, and Maiski Cherny and CROSSES such as Rubinovy Magaracha. There is increasing interest in INTERNATIONAL VARIETIES, especially Cabernet Sauvignon, Merlot, Sauvignon Blanc, and Chardonnay but also Riesling, Pinot Noir, Aligoté, Aleatico, Cabernet Franc, and Gewürztraminer. X.V.

kegs, increasingly popular form of wine PACKAGING that keeps large volumes of wine fresh for six weeks or more after they have been broached and is therefore particularly well suited to wine-by-the-glass offerings. The reusable stainless-steel kegs similar to those used for beer are filled directly with wine. INERT GAS propels the wine out of a tap and fills the keg to prevent OXIDATION. The alternative is the single-use PET kegs with an alufoil bag inside, not unlike those used in wine BOXES. The wine is propelled by compressed air pumped

into the keg around the bag, thus preventing oxygen ingress. The former are much heavier to transport but can be reused or recycled. The latter are much lighter but not as straightforward to recycle. Both have a lower CARBON FOOTPRINT than glass bottles and take up less storage space. Kegs have been adopted with enthusiasm in America, initially in California and New York as part of a direct relationship between wineries and local bars and restaurants, and are increasingly popular in the UK, Ireland, Sweden, Denmark, Norway, and Australia. Some retailers particularly concerned with SUSTAINABILITY encourage their customers to fill their own containers from kegs.

Alko, 'Update of wine packaging LCA: final report Alko Oy' (2021). www.alko.fi/INTERSHOP/static/WFS/Alko-OnlineShop-Site/-/Alko-OnlineShop/fi_FI/Tavarantoimittajille/Muut/EN/Alko%20wine%20packaging%20LCA%20update_final%20report.pdf.

kék means 'blue' in Hungarian and, as such, can be a direct equivalent of BLAU in German or even NOIR in French.

Kékfrankos, Hungarian name for the increasingly fashionable red grape variety known in Austria as BLAUFRÄNKISCH (of which it is a direct translation) and grown on 7,542 ha/18,637 acres of Hungary in 2021, mainly around Szekszárd, Mátra, Eger, Villány, and, most successfully, in Sopron near the Austrian border, where it is responsible for some of Hungary's finest reds. It makes more straightforward wines and rosé in the Danube region. Many young producers have started to make concentrated, fruity bottlings, as well as NATURAL WINES.

Kéknyelű, revered but very rare white grape variety grown in Hungary, notably in Badacsony on the north shore of Lake Balaton, and named after its 'blue' stalk. Yields are very low; wines are crisp and perfumed. There were just 48 ha/119 acres planted in 2021.

Kékoportó, unofficial name for the PORTUGIESER grape in Hungary. Most of the 779 ha/1,925 acres planted in 2021 were in Villány, where it can occasionally produce concentrated wines, but it is also found in Eger, Kunság, and Szekszárd.

Keller is the German word for a cellar, even a small domestic cellar, while Kellerei refers to NÉGOCIANT facilities with a significant above-ground presence. A German wine specifying a Keller rather than a WEINGUT on the label is usually the produce of a merchant rather than an estate. In ALTO ADIGE, the Italian Tyrol, Kellereigenossenschaft is a common name for one of the many wine CO-OPERATIVES. Kellermeister is German for 'cellarmaster', similar to MAÎTRE DE CHAI in France.

Kendall-Jackson, original brand name of the winery and vineyard empire begun by attorney Jess Jackson in Lake County, California, in 1974. In many ways, Jess Jackson exemplifies the entrepreneurial nature of the CALIFORNIA wine industry as well as the go-go climate of the 1980s. He entered the wine industry almost accidentally when he purchased a small pear and walnut ranch as a weekend retreat. He planted grapes but had trouble selling them for a decent return, so he began to investigate converting them to wine.

Happily disregarding the California industry's movement towards vineyard designations, he concentrated instead on blending from various regions to achieve certain taste characteristics. To say this strategy worked would be a grave understatement, and K-J Vintner's Reserve Chardonnay is still America's most popular Chardonnay. Its hallmarks initially were refreshingly strong ACIDITY, creamy oak vanillins (see OAK FLAVOUR), exotic pineapple fruit flavour, and softness and immediate drinkability from just-perceptible RESIDUAL SUGAR. Classically inclined SHOW judges put up token resistance to the residual sugar, but consumers had no such reservations.

Speculation is that a dollop of Muscat-based SWEET RESERVE is the mystery ingredient driving this successful recipe. Verification is not available because Jackson went to court in 1992 to prevent his winemaker Jed Steele from revealing what he claimed were 'trade secrets', on his departure from K-J. Despite a noteworthy historical precedent in the California wine industry of shared information, Jackson prevailed.

Today the famous mass-market Chardonnay undergoes BARREL FERMENTATION with LEES stirred monthly. Kendall-Jackson sells a wide range of other California VARIETALS from a base in Sonoma that doubles as a tourist destination. See also JACKSON FAMILY WINES.

Kenya , African country virtually on the equator, with a very limited production of wines. VITIS VINIFERA came to the highlands of Maua with Italian missionaries in the early 1900s; BARBERA is still grown in home gardens around the area. Kenya's largest commercial wine producer, however, is in the Rift Valley north-west of Nairobi, where Rift Valley Winery began planting vines in 1992. Its Shiraz, Merlot, and Sauvignon Blanc, bottled under the Leleshwa brand, benefit from quick-draining VOLCANIC soils and ELEVATIONS over 1,900 m/6,235 ft, where the DIURNAL TEMPERATURE RANGE can be 6–32 °C/11–58 °F. Another vine-grower, Mukami Mwarania, has started a vineyard nearby with Barbera cuttings from Maua. The equatorial warmth allows for multiple harvests, though some producers revert to one growing season June–September (see TROPICAL VITICULTURE). In addition to climatic challenges, animals including giraffes and antelopes can wreak havoc in a vineyard.

Kerner, the most successful GERMAN CROSS, which, because of its Riesling-like wines, is still planted on 2,257 ha/5,577 acres of Germany, mainly in the Pfalz and Rheinhessen. It is also relatively popular in Württemberg, where it was bred from a red parent TROLLINGER (Schiava Grossa) × RIESLING. The large white berries

produce wines commendably close to Riesling in flavour except for their own leafy, sometimes candied and mawkish, aroma and slightly coarser texture. It is a cross which does not need to be subsumed in the blending vat but can produce respectable VARIETAL wines, up to quite high PRÄDIKAT levels, on its own account. Kerner is popular with growers as well as wine drinkers because of its late budding and therefore good FROST resistance. The 112 ha/277 acres of Kerner planted in Italy's Alto Adige in 2020 produce some of the region's most widely admired wines. It is also planted in Switzerland, England, Canada, and quite successfully in JAPAN.

Kevedinka. See KÖVIDINKA.

King Valley, Australian wine region in North East VICTORIA. ELEVATION of up to 800 m/2,625 ft is key to its versatility and COOL-CLIMATE credentials. Brown Brothers traces its roots back to the 1880s, but this former tobacco-farming area's big swing to wine came in the latter stages of the 20th century. Descendants of Italian migrants have championed SANGIOVESE, PINOT GRIGIO, GLERA (known in Australia as Prosecco and now by far King Valley's most prevalent variety), and others, while Chardonnay and Pinot Noir remain important.

kir, alternative name for a *vin blanc-cassis*, dry white wine and blackcurrant liqueur, named after a hero of the Burgundian resistance movement during the Second World War, Canon Kir, who was also mayor of Dijon. The typical base wine is the relatively acid Bourgogne ALIGOTÉ and to most palates a dash of crème de cassis is all that is needed. A kir royal is made with sparkling rather than still white wine.

Királyleánka, meaning 'princess', is identical to FETEASCĂ Regală in Romania, making lightly perfumed, crisp whites. Much of Hungary's 2021 total plantings of 949 ha/2,345 acres is in the north of the country, particularly in Balatonboglár. It may be an offspring of FETEASCĂ Albă, known as LEÁNYKA in Hungary.

Kisi, GEORGIAN vine variety making headily perfumed, well-structured whites planted on 317 ha/783 acres of vineyard in its Kakheti homeland in 2019.

Kis˛mis˛, Kišmiš, Kismis, Kishmish, Middle Eastern synonyms for the common SULTANA.

Klassik, when noted with an uppercase 'K' on an AUSTRIAN label (or price list), generally refers to unoaked, fruit-forward wines. The most established such category is Steierische Klassik, used for wines grown in the state of STEIERMARK and associated especially with the crisp, dry wines of SÜDSTEIERMARK that are intended for early drinking. The term 'Klassik' is also used—though generally without appearing on the relevant labels—for the lighter, non-Reserve of two categories of wine within many of Austria's DACS, and as of 2015 it designates a specific category of Austrian SEKT with a PDO. The name is also sometimes colloquially employed in Germany for the least expensive or simplest bottlings, as some French growers use the term *Tradition* to denote their basic bottling even though the word rarely appears on labels. Klassik is not to be confused with the specific category of German wine known as CLASSIC. D.S.

Klein Karoo, inland semi-desert ostrich- and sheep-farming region that is also an official wine region in SOUTH AFRICA also known as Little Karoo. The town of Calitzdorp is widely regarded as the PORT-style wine capital of South Africa.

Klevener de Heiligenstein is an ALSACE oddity, a vine speciality of the village of Heiligenstein in the Bas-Rhin planted in 1740 by its mayor Erhard Wantz. It is a locally adapted SAVAGNIN ROSE, occasionally known as Clevner de Heiligenstein, grown within five neighbouring communes of Heiligenstein to produce a dry wine, less scented than Gewurztraminer, with less alcohol and a little more acidity. In good vintages it can age well. In 2011 it was recognized as one of 14 DÉNOMINATIONS GÉOGRAPHIQUES COMPLÉMENTAIRES that may be specified within the Alsace appellation. See also GERMAN HISTORY.

Klevner, like CLEVNER, is, and more particularly was, used fairly indiscriminately in Alsace and other German-speaking wine regions for various vine varieties, notably but not exclusively for various forms of PINOT. References to Klevner in Alsace in the mid 16th century are common.

Kloster Eberbach, monastery in the RHEINGAU region of Germany with a tradition of viticulture; now seen as the cultural wine centre of the Rheingau. Kloster Eberbach was founded in 1135 by Bernard of Clairvaux. Throughout the Middle Ages, Cistercian monks produced wine at the monastery and made its name as one of the most important wine estates of its time. Through viticultural enterprise, the monastery became extremely powerful, owning a fleet of ships which sailed the Rhine. Kloster Eberbach nowadays lends its name to the vast Hessian State Domaine or Hessische Staatsweingüter, whose incomparable Cabinetkeller boasts abundant stocks of wines from the 19th century. Close to the adjacent MONOPOLE Steinberg vineyard is a lavishly appointed 21st-century production facility where SCREWCAPS were pioneered in Germany.

See also MONKS AND MONASTERIES. S.E.A. & D.S.

Klosterneuburg, small city on the right bank of the Danube just west of Vienna in AUSTRIA whose Augustinian monastery (*Stift*) has

been a major vineyard owner since the Middle Ages. Since 1860 it has housed Austria's centre for viticultural and oenological research (see ACADEME), also giving its name to Austria's standard measurement of MUST WEIGHT, commonly referred to by its abbreviation KMW. While the vineyard holdings of Stift Klosterneuburg include substantial tracts in the nearby growing regions of WIEN, THERMENREGION, and CARNUNTUM, its home vineyards long held the official status of a GROSSLAGE within the otherwise left bank region of WAGRAM. This status left neither party satisfied, but the Wagram DAC created in 2002 retains Klosterneuburg, while treating it as just one among 27 recognized communes. D.S.

KMW, or Klosterneuburger Mostwage, named for its origins at KLOSTERNEUBURG, is AUSTRIA's traditional unit of measurement for MUST WEIGHT, equivalent to approximately 5 °OECHSLE.

Knights Valley, inland California wine region and AVA between the northern end of Napa Valley and the southern end of Alexander Valley. See SONOMA.

Korea , rugged, mountainous peninsula on the Asian mainland, between China and Japan, encompassing the Korean Peninsula and more than 3,300 islands. Since 1945, the country has been split in two parts, North (the Democratic People's Republic of Korea) and South (the Republic of Korea).

While the country claims 13,294 ha/32,850 acres of vines in 2021, the vast majority are TABLE GRAPES. Grape wine gained a foothold only after Christian missionaries arriving in the late 1880s began to grow vines and make wine. The first commercial wine made from grapes grown in Korea was Sunry Port Wine, released in 1969. Produced by the Hankuk Suntory Co. in co-operation with Suntory Japan, it was made from mountain grapes grown in

Daejeon, in central South Korea. Wine did not take off, though, until Doosan Majuang, first released in 1977, gained the Vatican's approval as a SACRAMENTAL WINE. Wine consumption in Korea has since soared, but the market is still almost entirely reliant on imports as the climate makes grape-growing challenging, especially for VITIS VINIFERA. Summers are hot and humid, with temperatures often reaching 30 °C/86 °F in August, and average annual rainfall is 600–1,500 mm/24–59 in, with 40% of it falling in June–September. Winters are dry and windy, with temperatures below freezing. In addition, wine producers that plant *vinifera* do not benefit from the government support that is given when local grape varieties are used. Consequently, only small amounts of *vinifera* are cultivated, mostly Chardonnay, Muscat of Alexandria, and Riesling. More popular are VITIS LABRUSCA varieties such as Campbell Early, the most commonly cultivated variety, and VITIS AMURENSIS such as Sanmeoru. Many HYBRIDS are also grown, especially MUSCAT BAILEY A. Korean hybrids such Cheongsoo, Cheonghyang, and Cheongporang are gaining popularity, producing white wines with a refreshing character. Most wine grapes in South Korea are grown in Yeongcheon in the south-east, where the ALLUVIAL sandy soils, TEMPERATE climate, marked DIURNAL TEMPERATURE RANGE, and lower-than-average rainfall allows grapes to reach PHYSIOLOGICAL RIPENESS, attaining 24 °BRIX in some years. Yeongdong in west-central South Korea has also developed a small wine industry, its one corporate winery and 42 farm wineries attracted by the region's relatively low rainfall, abundant sunshine, and well-draining GRAVEL, SAND, and LIMESTONE soils. S.C.

Korinthiaki, dark-skinned variety from Greece mainly used for CURRANTS but also an important constituent (up to 49%) in MAVRODAPHNE of Patras. It takes its name from a corruption of the word 'Corinth'. Very occasionally used for winemaking in California and Australia.

kosher (meaning 'pure'). To the Jewish people, there is no communal, religious, or family event without wine. The vine was one of the seven fruits blessed in the Bible, and there is even a special blessing devoted to wine: 'Blessed are You, Lord our God…who creates the fruit of the vine.'

Adhering to the Jewish dietary laws (kashrut) is essential for all Orthodox Jews. Kosher wine laws were established in ancient times, so an observant Jew could avoid drinking *Yayin Nesech*, a wine used for idol worship, and *Stam Yeinam*, wine made by non-Jews.

For a wine to be considered kosher, only religious Jews may handle the product and touch the winemaking equipment from the time the grapes arrive at the winery. Only kosher substances may be used in the process. Examples of FINING agents not permitted include (animal-derived) gelatin, (dairy-derived) casein, and isinglass (because it comes from a non-kosher fish). Kosher wine is suitable for VEGETARIANS and, if egg whites are not used for fining, also for vegans.

There are also additional agricultural laws, which are observed only in Israel.

1. *Orlah*. For the first three years, fruit from the vine may not be used for winemaking.
2. *Kilai Ha'Kerem* (cross-breeding). Growing other fruits between the vines is prohibited.
3. *Shmittah*. Every seventh year, the fields should be left fallow. However, because of economic realities, often the land is symbolically sold to a non-Jew for the duration of this sabbatical year.
4. *Trumot and Ma'asarot*. Just over 1% of the production is poured away in remembrance of a tithe once paid in the time of the Holy Temple in Jerusalem.

Today, *Shmittah* and *Trumot and Ma'asarot* remain mainly symbolic.

'Kosher for Passover' means the wine and barrels have not come into contact with bread, grain, or products made with leavened dough. Most kosher wines are also 'Kosher for Passover'. The agricultural laws date back to the Bible and the laws of kashrut to Talmudic times.

Kosher regulations have no bearing on wine quality; standard winemaking procedures are followed in the HARVESTING, FERMENTATION, MATURATION, BLENDING, and BOTTLING. The kosher certification is irrelevant to quality.

Kosher wines were mainly sweet until Carmel in Israel began producing dry kosher wines, but the 1980s saw a major improvement in kosher wine quality led by the Golan Heights Winery in Israel, Hagafen and Herzog in California, and Royal Wine worldwide. In Israel especially, the change was pronounced as wineries began focusing on INTERNATIONAL VARIETIES in the vineyard, implementing cutting-edge technology in the winery, and employing internationally trained winemakers. (See ISRAEL for more detail.) The kosher winemaking industry was changed forever, being geared to quality.

There are, however, two categories of wine that damage the image of kosher wines. *Kiddush* wines are sacramental wines, usually red and sweet, made for use in religious rituals by traditionalists. Manischewitz and Palwin are two well-known examples.

Mevushal wines are kosher wines that have been PASTEURIZED to 80 °C/175 °F, using flash pasteurization or FLASH DÉTENTE. This is an extra requirement by some kosher caterers and kosher restaurants, particularly in the US. It is of interest mainly to the strictly religious as it permits the wine to remain kosher even if served by a non-observant waiter. Most kosher wines, and those of the finest quality, are not *mevushal*.

The largest market for kosher wine is Israel (though there are many non-kosher Israeli wineries), followed by the US and France. In Israel and California there are wineries devoted to making kosher

wines, and many well-known wineries make kosher cuvées, such as Ch Léoville-Poyferré and Ch Pontet-Canet in BORDEAUX and Mayacamas Vineyards in NAPA. Today, kosher wines are made in almost all wine-producing countries. A.S.M.

Rogov, D., *Rogov's Guide to Kosher Wines* (2011).

Koshu, best-known INDIGENOUS VARIETY in JAPAN. The pink-skinned grape is grown both for the table and for wine, and more wine is produced from this variety than from any other in Japan. Its thick skins withstand Japan's humid summers relatively well. Most Koshu is PERGOLA-trained with SPUR PRUNING, while ambitious producers such as Grace have started to train it low on double GUYOT, reducing yields and producing some of the most concentrated examples of Koshu. Koshu wine can rarely be accused of an excess of flavour, but it can be a fine accompaniment to sashimi. Still, sparkling, sweet, and oaked versions are made. DNA PROFILING by Goto-Yamamoto in 2015 suggested that Koshu is a natural HYBRID between an as-yet-unidentified variety of VITIS VINIFERA and an unknown variety, which is itself a hybrid between an individual of *Vitis davidii* and another unidentified variety of *vinifera*.

Goto-Yamamoto, N., et al., 'Genetic analysis of East Asian grape cultivars suggests hybridization with wild Vitis', *PLOS ONE*, 10/10 (2015).

Kosovo, or Kosova (spelling preferred by the majority ethnic ALBANIAN population), is a territory south of SERBIA. It declared its independence in 2008 and is recognized as a state by around 100 countries, crucially not including Serbia. This leaves its wine industry covered by two sets of legislation—its own and Serbia's. The climate

is mild CONTINENTAL, with Mediterranean influences, enjoying 276 sunny days per year on average and sufficient rainfall throughout the year to avoid IRRIGATION (Dukagjini averages 770 mm/30 in). Vineyards are typically at ELEVATIONS of 300–600 m/985–1,969 ft, surrounded by spectacular mountains.

As with the rest of the Balkans, wine history goes back at least 2,000 years. In the 1950s, the YUGOSLAV regime imposed high-volume wine production in the region via four large-scale state wineries. Most of the wine was blended with the exception of the light, medium-sweet red Amselfelder sold to Germany in volumes of 32 million litres/8.5 million gal in the 1980s. Kosovan vineyards then totalled about 9,000 ha/22,200 acres. Vineyard area fell to under 4,000 ha after the collapse of Yugoslavia and war in the late 1990s.

Today's industry is completely private and being modernized to align with EU standards, with new legislation on wine quality and zoning, as well as work going on to define PGIs and PDOs and to conserve local varieties. In 2021 there were 3,483 ha/8,607 acres on the vineyard register, while wine production was 92,979 hl/2,456,245 gal in 2020. Kosovo has designated two wine regions, Dukagjini and Kosovo Region. Dukagjini is further divided into north and south subregions. (Note that Serbian law recognizes two regions of North and South Metohija.) The south has five vineyard zones: Rahovec, Suhareka, Prizren, and the smaller Gjakova and Malisheva. The north has three small zones: Peja, Istog, and Klina. Kosovo grows more red wine grapes (1,653 ha) than white (872 ha) with the remainder as TABLE GRAPES. Local grapes are most important, led by Vranç/VRANAC (500 ha) and Prokupë/PROKUPAC (345 ha); Pinot Noir, Zhameta/ŽAMETOVKA, and Gamé/GAMAY are also grown. SMEDEREVKA (373 ha) dominates white plantings, followed by WELSCHRIESLING, Chardonnay, Riesling, and Prokup e Bardhë. The domestic market remains small, with annual consumption of just 2.5 litres per capita, so exports account for over 70% of production, largely to Croatia, Serbia, and Albania. C.G.

Kotsifali. Generous, spicy, if soft wines are produced from this red-grape speciality of the Greek island of CRETE, where it is the most common dark-skinned variety. It is best blended with something more tannic such as MANDILARIA. Total plantings in Greece were 1,246 ha/3,079 in 2021.

Kövérszőlő, one of the oldest and rarest grape varieties in TOKAJ and possibly the same as GRASĂ in Cotnari, Romania. There were 43 ha/106 acres in north-west Hungary in 2021.

Kövidinka, common pink-skinned Hungarian variety known as Ružica in Croatia and North Macedonia and as Kevedinka in Serbia.

krater. See CRATER.

Kratošija, relatively important grape in MONTENEGRO that is the same as ZINFANDEL.

Kreaca, white grape variety grown in SERBIA and, under the name Creață, in neighbouring parts of Romania. Its produce tends to be somewhat heavy. Also known as Banat Riesling or Banat Rizling.

Kremstal, wine region whose 2,256 ha/5,575 acres of vines in 2021 represent 5% of AUSTRIA's vineyards and characterized by considerable geological and mesoclimatic diversity. Long considered part of the WACHAU, the towering rocky terraced vineyards on the region's western edge—in particular those of the Krems-Stein suburb

—segue seamlessly into those of today's official Wachau. These include two of Austria's greatest RIESLING vineyards, the (Steiner) Hund and Pfaffenberg, as well as the estimable Kögl and Wachtberg that are closer to the city of Krems proper. The valley of the diminutive river Krems incorporates only 7 km/4.3 miles of vineyards that are dominated by LOESS close to Krems city limits, rising to magnificent rocky steepness upstream around Senftenberg, whose Ehrenfels, Hochäcker, and Pellingen vineyards are home to Riesling (10.8% of total Kremstal vineyard) and GRÜNER VELTLINER. The eastern and north-eastern fringes of Krems are dominated by mounds of loess, anticipating the soil and exposure of the neighbouring WAGRAM. Grüner Veltliner (59% of total Kremstal vineyard) overwhelmingly dominates in this sector, which includes wine villages Gedersdorf, Gneixendorf, Rohrendorf, and Stratzing. The Kremstal also incorporates extensive vineyards on the Danube's right bank, where SAND and GRAVEL from the Danube, which meandered around numerous islands until late 20th century dredging, vie with loess for vine roots' attention, and the varietal mix extends even to Cabernet Sauvignon and Merlot. Heading east from Mautern (in the Wachau), the villages of Furth, Palt, Oberfucha, and Tiefenfucha are dominated by the massive mountaintop Göttweig monastery—itself an important vineyard owner—while further downstream Hollenburg hugs the Danube's shoreline and shares its 'Hollenberg' conglomerate with the neighbouring TRAISENTAL.

Kremstal DAC is the appellation applying to this region's Grüner Veltliner and Riesling. Non-DAC QUALITÄTSWEIN grown here is labelled NIEDERÖSTERREICH. A February 2022 revision officially organizes Kremstal DAC wines into the categories of regional (Gebietswein), communal (Ortswein), and vineyard-designated (Riedenwein) while condensing potential communes of origin approved for labelling to just nine. D.S.

Krug, small but important Champagne house founded in Reims in 1843 by Johann-Joseph Krug, who was born in Mainz, Germany, in

1800 and had come to work in Champagne. From 1824 he was known as Joseph. By 1866 the firm occupied its current modest cellars, around whose courtyard the Krug family lived until 2014. Joseph Krug's vision was to craft the very best champagne he could every year, regardless of variations in climate, and so he created his Champagne n°1. Krug does not make an ordinary NON-VINTAGE champagne but specializes exclusively in PRESTIGE CUVÉES, of which the multi-vintage Grande Cuvée, modelled on Champagne n°1, is the flagship, having replaced the rather fuller-bodied Private Cuvée in 1979. Krug Grande Cuvée, sold at a similar price to Krug vintage-dated bottlings, was first made with a blend of 60–70 wines from five to six different years, but today the blend includes even more wines from even more years.

Krug is known for its plot-by-plot approach to champagne creation whereby each plot of vines is vinified and kept separately until the final blending decisions are made. Every year, the *chef de cave* tastes 400 wines—250 wines of the year and 150 reserve wines—each made from a single plot. In 1971 Krug acquired and replanted the CLOS du Mesnil, a walled vineyard of 1.84 ha/4.5 acres. Its Chardonnay grapes provide one of Champagne's few SINGLE-VINEYARD WINES, of which the 1979 vintage was the first. The 0.68 ha/1.7 acres of Clos d'Ambonnay planted exclusively with Pinot Noir is responsible for an even more expensive wine launched with the 1995 vintage. Small quantities of Krug vintage champagnes are aged on the LEES in the cellars for around 20 years and are then DISGORGED and presented as Krug Collection. In 2011, acknowledging the considerable variation between the Krug Grande Cuvées produced each year, Krug introduced the Krug iD, back-label codes identifying when each cuvée was disgorged and giving full details and composition of each bottle of Krug. Krug has been owned by LVMH since 1999, although sixth-generation Olivier Krug is director of the house, part of the tasting committee, and represents the house in Champagne and abroad.

Arlott, J., *Krug: House of Champagne* (1976).

Fountain, N., *Krug: A Journey Through History* (2011).

Krug, Charles (1825–92), German-born American wine producer, came to San Francisco in 1852 as a newspaper editor. After vineyard ventures in San Mateo and SONOMA, Krug settled in the NAPA Valley in 1860, founding a winery near St Helena in 1861. Krug was not the first Napa Valley winemaker, but he soon became the most eminent of his day and inevitably came to be called the 'father of Napa wine'. His success came in part because he understood public relations and because he developed his own sales organization. The winery he founded was acquired by the MONDAVI family in 1943 and is still notable among Napa Valley establishments, although Robert Mondavi left to set up on his own in 1965 after an acrimonious dispute with his brother Peter, whose family still run the enterprise.

KWV, the South African Co-operative Wine Growers' Association, or Ko-operatiewe Wijnbouwers Vereniging van Zuid-Afrika, was a statutory body established in 1918 after years of glut and grower bankruptcy, to fix production quotas and to minimize extreme swings between surplus and shortage. Over time, and as a result of the close ties between successive white governments and the influential grape-farming lobby, it became the dominant force in the South African wine industry. In 1998 it was relieved of its statutory authority and converted from CO-OPERATIVE to a company. It is now a moderate-sized player in the domestic and export market, producing increasingly impressive wines in its premium ranges, as well as aged brandies which enjoy international renown.

South African Wine Industry Directory (annually).

Kydonitsa, meaning 'little quince' and often marked by the aroma of that fruit, is a recently rescued and promising light-skinned vine variety from Lakonia in the southern Peloponnese that is increasingly appreciated in GREECE, with new plantings from Nemea to Macedonia.

Kyrgyzstan, mountainous central Asian republic on the border between KAZAKHSTAN and China that had a strong wine industry until Mikhail GORBACHEV's anti-alcohol campaign in 1985 resulted in widespread GRUBBING UP of vineyards. In 2020, the country had just 5,202 ha/12,854 acres of vineyard, according to OIV statistics, most of it in TABLE GRAPES and RAISINS.

L

labelling information. The amount of information required on wine LABELS seems to increase dramatically each year, encouraging some producers to use QR codes to provide consumers with a wealth of non-mandatory information. From 2022, the EU's new U label allows producers to provide the list of ingredients (see INGREDIENT LABELLING) and the nutritional declaration digitally or in print.

In the past, approaches to wine labelling differed significantly between countries, but the demands of international trade have led to a gradual convergence in the types of information required on a label (if not necessarily the underlying philosophies). The following basic items of information are now mandatory in virtually every country in some form or another.

Wine designation: usually this will be a self-explanatory term such as 'wine' or 'sparkling wine'. Wines made within the EU must, where applicable, indicate their status as a PDO or PGI and/or the name of the relevant PDO or PGI. In the US, the 'class and type' designation may be a generic term such as TABLE WINE (for wines between 7% and 14% alcohol) or a grape-variety name.

Country of origin: most wine-producing countries take this to refer to the origin of the grapes.

Name and address of importer, producer, or bottler: this is usually provided in a fairly straightforward fashion, although, within Europe, there are controls on the size of an address which happens to incorporate the name of a CONTROLLED APPELLATION on the label of a WINE WITHOUT GEOGRAPHICAL INDICATION, or even a PGI wine, so some sort of postal code is sometimes substituted.

Volume of wine: usually expressed in millilitres (ml or mL) or, in Europe, centilitres (cl or cL). See BOTTLE SIZES and BOXES.

Alcoholic strength: stated as a percentage of alcohol by volume (often abbreviated to 'alc. x% vol' or 'x% vol'). Tolerances can differ considerably, from the +/− 0.5% alcohol variance permitted in the EU and China to +/− 1.5% in the US, Australia, and New Zealand. However, for wines that are made to be exported to a range of countries, winemakers tend to stay within the strictest tolerances. See ALCOHOLIC STRENGTH. In some jurisdictions, STANDARD DRINKS information is also required.

Lot marking: packaged wine must be marked with a lot number unique to an individual batch or bottling so that it can be traced in the event of any complaint or recall. In Europe, the mark is an L followed by a coded date of packaging.

Allergen information: in most countries it is now obligatory to state on the label that a wine contains SULFITES if it contains more than 10 mg/l of SULFUR DIOXIDE. Sulfur dioxide is used to a certain extent in the making of virtually all wine and is a by-product of FERMENTATION, therefore virtually all wine contains this level of sulfites.

In most countries it is also now required to include a reference to the presence of egg or milk residues if the wine has been FINED with EGG WHITES, milk, or CASEIN and if these are present above detection limits (0.25 mg/l) in the finished wine, even though there is scant evidence of any health issues associated with the tiny concentrations found in wine as a result of such processing. See also VEGETARIAN AND VEGAN WINES.

Health-related information: health 'warnings' of various sorts are becoming more common on wine labels. Increasingly these are required by law, such as the US Surgeon General's warning and the mandatory pregnancy advisory messages and pictograms in France, South Africa, Australia, and New Zealand. In other countries such as the UK, these initiatives are voluntarily adopted by producers.

INGREDIENT LABELLING and energy labelling have recently been mandated by the EU and are under consideration in other countries as well.

The following items of information are generally optional but, if used, are subject to certain rules. Note that exporting producers must comply not only with the rules in their own country but also with those in the market to which they are exporting.

Geographical reference: typically, all but the most basic wines, or the most experimental, are distinguished by some form of geographical label reference that is more specific than the country of origin. In most cases this will be a GEOGRAPHICAL INDICATION (GI) of some sort, possibly accompanied by the name of a smaller area such as a vineyard name. The minimum permitted proportion of the blend that must be sourced from the named area often depends on the type of GI and ranges from 75% (US, Chile) to 80% (China), 85% (NZ, Australia, US AVAs, European PGIs), or 100% (Argentina, South Africa, European PDOs). In some jurisdictions, including the US and Australia, it is permitted to have more than one geographical indication on the label, but the regulations are varied and complex.

Vintage year: the year in which the grapes were harvested, although in rare cases (e.g. Canadian ICEWINE harvested in the new year) the vintage may in fact be the year in which most of the growing took place. The minimum content of wine sourced from the vintage ranges from 75% (Chile) to 80% (China), 85% (Australia, NZ, South Africa, US, European PGIs), or 95% (AVAs, Argentina, South Africa, European PDOs). See VINTAGE YEAR and NON-VINTAGE.

Varietal information: within many countries, including the EU, Argentina, Australia, New Zealand, Switzerland, South Africa, and Uruguay, if a single variety is specified on a label of wine then it must comprise at least 85% of the wine. For other countries, such as the US, China, Chile, and Brazil, the minimum content for a wine labelled as a single VARIETAL is 75%. If more than one variety is mentioned on the label, in many countries (e.g. the US, Europe, South Africa, and Chile) together they must comprise 100%. The varieties must typically be listed in descending order.

Bottling information: the relationship between the source of the grapes and the producer or bottler is indicated by exactly how this is expressed. See BOTTLING INFORMATION for more details.

On a CHAMPAGNE label, the code printed next to the registered number of the bottler tells you the type of business responsible for the wine.

Environmental labelling: labels indicating the status of a wine as ORGANIC, BIODYNAMIC, SUSTAINABLE, or similar are now common. Such claims are usually validated by accreditation to a particular programme or standard, some national, some international.

See also SWEETNESS and FIZZINESS. J.P.H.B.

labels, the principal means by which a wine producer or bottler can communicate with a potential customer and consumer (although see also BOTTLES, CASE, FOIL).

Wine labels are a relatively recent development, which awaited the widespread sale of bottled wine and use of glues strong enough to stick to glass, in about 1860. Before then wines were sold unlabelled and stacked in BINS, and served in decanters, so BIN LABELS and decanter labels are the precursors of today's wine-bottle label. For many years, wines were identified by branded CORKS rather than by paper labels, a habit that persisted longest for vintage PORT.

Every wine in commercial circulation has to have a main label, as its passport quite apart from its function as a sales aid. Many wines also have a neck label, typically carrying the VINTAGE year, so that the producer need not have new main labels printed for each new vintage, although labelling requirements can change so rapidly that in practice this sometimes seems necessary (see LABELLING INFORMATION). As wine consumers have become ever more sophisticated and curious, however, an increasing proportion of bottles carry a back label giving additional background information. This can vary from a genuinely useful outline of grape varieties used, vintage conditions, approximate SWEETNESS level, and serving advice to a collection of fine-sounding words involving the 'finest' grape varieties picked at 'perfect ripeness' in 'optimum conditions' and vinified according to the 'highest standards' but containing no genuine information whatsoever. Now that the amount of mandatory information required

on wine labels is so considerable, some design-conscious bottlers try to beat the system by conveying all of this detail on what is obviously meant to be the back label, while applying to a second label (which the retailer, but not the labelling inspector, is meant to treat as the main label) a dramatic design statement without all the clutter of the mandatory information.

Labels matter to lawyers and officials, and they matter enormously to the retail wine trade, in which they communicate far more effectively with many consumers than any recommendation or award, but they are relatively unimportant to wine sales from a website or catalogue or in the hotel and restaurant industry. The Italians have been as innovative in label design as in that of bottles, and some modern designs can be arresting, effective, innovative, and sometimes all three. ARTISTS' LABELS have a certain following. Producers of established wines have usually inherited a label and rarely do anything more than slightly modify it. The fact that the label of PETRUS would win no design award seems to do little to hinder sales. The label design of wine BRANDS, however, is an extremely important factor in their success.

Labels are usually, but not always, applied straight after BOTTLING as part of the same mechanized process. Some very small-scale producers still apply their labels by hand with pots of glue. Producers of champagne and other sparkling wines take particular care to use strong, water-resistant adhesive in applying their labels since their bottles are likely to spend their last hours in public circulation immersed in a bucket of water.

Wine labels have such a fascination of their own (and can help recollection of the circumstances of a wine's consumption) that wine-label collecting is a recognized activity. Some of those who practise it call themselves vintitulists.

labour. Viticulture, unlike winemaking, has long required a substantial input of labour. The Romans used slaves, while MONKS AND MONASTERIES played an important part in medieval vine-growing. A

peasant class was long necessary to maintain viticulture in Europe, and increasingly vineyard labour was paid for by leasing part of the vineyard to the labourer, sharecropping or, in French, MÉTAYAGE. Conscription or coercion of workers, for example Native Americans by Francisan missionaries or Chinese labourers in CALIFORNIA at the end of the 19th century, is rarely mentioned. The close association between vine-growing and people began to alter towards the end of the 20th century, however, mainly because of changes in technology.

There are three levels of labour input to viticulture: people alone, people plus draught animals, and people plus machines, including ROBOTS. In ancient vineyards, all work was done by people: WEED CONTROL, PRUNING, TRIMMING, DESUCKERING, LAYERING, and HARVESTING. The labour input was high, and vineyards on the plains required between 70 and 80 person-days per hectare per year. This means that any one person might tend about 3 ha/7 acres, with due allowance for using other labour at times of peak demand such as harvesting and pruning. The YIELD from such vineyards was not high compared with modern standards. A generous 33.5 hl/ha (2 tons/acre) meant that one person's labour might produce a maximum of about 15 tonnes of grapes. For HILLSIDE VINEYARDS, one person might tend only about 100 sq m of vineyard, although this was not necessarily full-time work, with a likely output of tens of kilograms of grapes per person per year. Such vineyards relying totally on manual labour are increasingly rare, as the price of labour has increased much more than the price of wine.

Intensive labour input continued for many vineyards up until the mid to late 19th century, when the invasion of POWDERY MILDEW, DOWNY MILDEW, and PHYLLOXERA led to the need for SPRAYING and the use of ROOTSTOCKS. Previously many vineyards had been planted haphazardly without rows and with high VINE DENSITY, almost like a field of wheat. Unhealthy vines were replaced by layering from adjacent vines. With the need to spray, and also for TILLING, draught animals became more common, not only horses but also mules, oxen, and even dairy cows. In France's Auvergne, for example, cows

provided meat, milk, and labour. Vines then needed to be planted in rows to make easy the passage of the animal, and there were typically many fewer plants per hectare because of the cost of GRAFTING plants on rootstocks. One horse was able to work 7 ha, and one person was needed for every 3 ha. A typical family farm consisted of about 7 ha of vines, one horse with two drivers, and one labourer.

After the Second World War, the pattern of viticulture changed in France and elsewhere with the widespread introduction of MECHANIZATION. This was no simple matter, as there were conflicts between generations of farmers about replacing horses with TRACTORS, as well as substantial changes in the support services in rural villages. Mechanics and fuel sellers replaced blacksmiths and fodder merchants. In the end, economic necessity determined the future; one person and a tractor was now able to tend 30 ha of vineyards, although with manual labour including pruning, trimming, and harvesting, 1 ha still required 43 days' work throughout the year. Growers outside Europe were generally quicker to switch to tractors.

In the 1960s, the mechanization revolution intensified. Under-vine tilling had been largely replaced by HERBICIDES, and then there was the introduction of MECHANICAL HARVESTING in the late 1960s, followed by that of MECHANICAL PRUNING in the 1980s. Some sprays were even applied from the air, using aeroplanes or HELICOPTERS (and, more recently, DRONES). There are some large corporate vineyards in south-eastern Australia where the total annual labour input is less than 50 person-hours per hectare: all operations are carried out mechanically including harvesting and pruning; spray units treat multiple rows at once; and weed control is by herbicides. On large estates with this degree of mechanization, one worker is required for each 30 ha, and the output can be more than 400 tonnes of wine grapes. This figure, compared with less than 15 tonnes per person about a century earlier, demonstrates how labour productivity has increased through mechanization. However, mechanization can compromise quality. For example, if simple mechanical pruning is not followed up by hand to

regulate the number of buds retained, the principles of BALANCED PRUNING may be violated.

Australian examples are relevant because of the acute rural labour shortage there and in New Zealand, although Asian and Pacific-island immigrants, as well as working students, were providing some solutions in the first decades of the 21st century. The wine industries of South America have never known a labour shortage. The same is true of South Africa, even after the abolition of the *dop* system, which continued long after it was outlawed. It encouraged workers to receive a portion of their wages in wine, thus keeping them in thrall to their employers. In California and elsewhere on the west coast of the US, Mexico has provided an exceptionally skilled viticultural labour force. At one time they were typically seasonal workers, but now they are more likely to be immigrants, sometimes the second or third generation of their family to be working in the vineyards (see CALIFORNIA).

Future developments are not obvious. With improved INFORMATION TECHNOLOGY, there is renewed interest in developing robots for mechanical pruning, for example, but the variability of vineyards, of terrain, and of the weather make the task of robot development and use more difficult than for the factory floor.

It seems likely, however, that an increasing proportion of vineyard tasks will be mechanized, even in countries where labour resources are not necessarily limiting or expensive, since mechanization is seen to offer benefits of timeliness as well as of economics. However, where the slopes are too steep for mechanized tilling, or where there is a wish to avoid SOIL COMPACTION, a small number of producers have returned to using ploughs pulled by draught animals such as horses.

Once the grapes have been delivered to the winery, winemaking requires relatively little labour. A WINEMAKER is required to make decisions and, increasingly, programme a computer which may control such operations as TEMPERATURE CONTROL and RACKING wine from one container to another (see INFORMATION TECHNOLOGY).

Only CAP MANAGEMENT, BARREL AGEING, and, particularly, LEES STIRRING require much manual labour (see CELLAR WORK). Otherwise, emptying vessels and cleaning are the chief manual operations.

R.E.S. & J.R.

labrusca. See VITIS LABRUSCA.

L'Acadie Blanc, winter-hardy grape variety speciality of NOVA SCOTIA, also planted in Quebec. Named after the French term for Nova Scotia, it is a cross of Cascade (a complex HYBRID created by SEIBEL) and SEYVE-VILLARD 14–287 made in 1953 at Vineland Research, Ontario (now part of Guelph University). It ripens early, has good disease resistance, and is particularly suitable for regions with very short growing seasons.

laccase, a powerful oxidative ENZYME particularly associated with BOTRYTIS BUNCH ROT which turns grape MUST brown.

La Clape used to be a subappellation within the LANGUEDOC in southern France but was awarded its own AOC in 2015. Once an island off the busy Roman port of Narbo (Narbonne), La Clape is today a quintessentially Mediterranean coastal mountain just south of Narbonne boasting one of France's highest average annual totals of sunshine. On the CLAY and LIMESTONE southern slopes of the rocky massif, the climate is heavily influenced by the sea. Vineyard ELEVATIONS can vary by as much as 200 m/980 ft, and the winds, particularly the tramontane, are ever present. La Clape is particularly well suited to growing BOURBOULENC, which must represent at least 40% of the grapes used in the production of La Clape's iodine-scented white wines; it must be blended with GRENACHE BLANC, and a host of other white grapes are allowed. However, most wine produced from the appellation's 807 ha/1,994 acres of vineyard in

2020 is full-blooded red, based on Grenache blended with Mourvèdre and/or Syrah and heavily scented by GARRIGUE. M.S.

Lacrima di Morro d'Alba, fast-maturing, wild-strawberry-scented red grape speciality of Morro d'Alba in the MARCHE. There were 252 ha/623 acres in Italy in 2015.

La Crosse, promising, cold-hardy, light-skinned complex American HYBRID released in 1983 and widely dispersed in the Midwest.

Lacryma Christi, is a blended white wine (CODA DI VOLPE with up to 20% FALANGHINA and/or GRECO) or red wine (PIEDIROSSO with maximum 20% AGLIANICO) from the Vesuvio DOC in CAMPANIA. Until recently the wines were considered mediocre, but the efforts of a new generation, often custodians of old-vine PERGOLA vineyards rooted in VOLCANIC black sand, have resulted in greater quality. W.S.

lactic acid, one of the milder ACIDS in wine, present in much lower concentrations than either MALIC ACID or TARTARIC ACID. Lactic acid, named after *lactis*, Latin for 'milk', is most frequently encountered as the principal acid in yoghurt, sour milk, and sauerkraut. Lactic acid is a common participant in both plant and animal metabolic processes. It is the end-product of intense muscular activity in animals (see ACIDS); a by-product of the alcoholic FERMENTATION process in wines and beers; and the end-product of the metabolic action of the many LACTIC ACID BACTERIA.

In wine, lactic acid can be produced by bacteria both from traces of sugar and from malic acid. The function of MALOLACTIC CONVERSION, which a high proportion of red wines and some white wines undergo, is to transform harsh malic acid into the much milder lactic acid.

A.D.W.

lactic acid bacteria, or LAB, an abbreviation of lactic-acid-producing bacteria, are some of the few BACTERIA that can survive in such an acidic solution as wine. They all produce LACTIC ACID. Those of importance to winemaking can be subdivided into the three genera: *Oenococcus* (of which the best-known species is *Oenococcus oeni*, formerly called *Leuconostoc oenos*), *Lactobacillus*, and *Pediococcus*.

Lactic acid bacteria are recognized for their ability to conduct MALOLACTIC CONVERSION, which converts harsher malic acid into milder lactic acid.

LAB naturally occur throughout the vinification process from grapes to wine. They can become so deeply embedded in the fibres of wooden VATS and BARRELS that they are not easily removed by conventional cleaning practices. Typically proliferating after the completion of FERMENTATION, they improve the sensory properties of wines with excess malic acid and contribute to their microbial stability. A winery may rely on spontaneous malolactic conversion or deliberately introduce lactic acid bacteria in order to have greater control over the process. *Oenococcus oeni* is the LAB species most tolerant to low PH (< 3.5) and ETHANOL and is generally preferred as it produces wines with favourable sensory properties.

Unfortunately, however, many strains of lactic acid bacteria, especially *Lactobacillus* and *Pediococcus* spp., can potentially cause wine spoilage (e.g. MOUSY off-flavours, over-production of DIACETYL, and turbidity). This is most likely to happen after the completion of malolactic conversion, when traces of sugar remain as nutrients in the wine, when wine pH is above the growth threshold for *Lactobacillus* and *Pediococcus* spp. (> pH 3.4–3.5), and when SULFUR DIOXIDE concentration is insufficient. Some species of LAB can also produce BIOGENIC AMINES, notably HISTAMINE, tyramine, and putrescine. These amines can range in concentration from 0 to 10 mg/l in white wine and 0–30 mg/l in red wine. Very few strains of *Oenococcus oeni*, for example, have been shown to produce histamine and putrescine, and those that do are not selected as malolactic starter cultures. A

range of other viticultural and winemaking factors can also affect the concentration of biogenic amines in wine.

See also ALLERGIES.

Fortunately, however, lactic acid bacteria are very sensitive to sulfur dioxide and are much easier to control than ACETOBACTER. Lactic acid bacteria grow best in very weakly acidic solutions and in the presence of ETHANOL in a temperature range of 15–30 °C/59–86 °F, although they are intolerant of high concentrations of ethanol. Bacteriologists regard them as 'fastidious' in that they require a wide range of micronutrients.

Their effect on new or young wine can therefore be limited by sulfur dioxide, low temperatures, and frequent RACKING so as to eliminate the possibility of providing micronutrients from the YEAST decomposition products in the LEES. P.J.C.

lactones. See OAK FLAVOUR.

Ladoix, the appellation from the village of Ladoix-Serrigny in the Côte de Beaune district of Burgundy's CÔTE D'OR, producing about 70% red wines from Pinot Noir grapes, sometimes sold as Côte de Beaune-Villages (see BEAUNE, CÔTE DE). White wines are growing in

popularity, especially those grown towards the top of the slope. Unusually in Burgundy, some of the PREMIERS CRUS are designated for red wine only (e.g. Les Joyeuses) or white wines only (e.g. Les Gréchons), while bizarrely a small number of premier cru vineyards located in Ladoix such as Les Moutottes are sold under the name Aloxe-Corton. Furthermore, 6 ha of Corton-Charlemagne and 22 ha (out of 160) of Le Corton, including part of Le Rognet and Les Vergennes, are actually sited in Ladoix (see ALOXE-CORTON for more details).

See also CÔTE D'OR, and map under BURGUNDY. J.T.C.M.

ladybirds. See LADYBUG TAINT.

ladybug taint, also known as lady beetle or ladybird taint, is an off-flavour found in both grape juice and wine that contributes undesirable peanut and green aromas and flavours, and possibly excessive bitterness. Two lady beetle species that migrate to vineyards during autumn—the seven-spot ladybird/ladybug (*Coccinella septempunctata*) from Europe and particularly the multicoloured Asian lady beetle (or harlequin ladybird, *Harmonia axyridis*)—are responsible. Both were originally introduced to North America to control aphids, but *Harmonia axyridis* is very invasive and is now also established in Europe, England, South America, South Africa, and New Zealand. It is unlikely that the beetles directly harm or taint the grapes. Instead, they cause contamination after they are inadvertently harvested with the fruit and are incorporated in the MUST. The compounds responsible are alkyl-methoxypyrazines—components of the insects' haemolymph—and are difficult to remove from affected juice and wine, although juice settling and must-heating prior to fermentation can help. While not always openly acknowledged, ladybug taint is a problem in some wines and vintages across many of the world's wine regions, including the US, France, Germany, and Canada. The first major widely reported incidence of ladybug taint in northern North America was in 2001,

while the 2004 and 2011 vintages in Burgundy were probably the first two to be widely discussed in this context. G.P.

Lafite, Château , subsequently Ch Lafite-Rothschild, FIRST GROWTH in the MÉDOC region of BORDEAUX. The vineyard, to the north of the small town of PAUILLAC and adjoining Ch MOUTON ROTHSCHILD, was probably planted in the first third of the 17th century. Inherited in 1716 by the SÉGURS, who also owned Ch LATOUR, it was sold in 1784 to Pierre de Pichard, an extremely rich president of the Bordeaux Parlement who perished on the scaffold. The estate was confiscated and sold as public property in 1797 to a Dutch consortium which in 1803 resold it to a Dutch grain merchant and supplier to Napoleon's armies, Ignace-Joseph Vanlerberghe. When he fell on hard times, he resold it to his former wife in order to avoid its falling into a creditor's hands. Perhaps for the same reason, or to avoid splitting it up under French inheritance laws, in 1821 she apparently sold it to a London banker, Sir Samuel Scott, for 1 million francs. He and then his son were the nominal owners for over 40 years. But when the real proprietor Aimé Vanlerberghe died without issue in 1866, the family decided to sell it and pay the fines owed because of the concealment. In 1868, after a stiff contest with a Bordeaux syndicate, it was knocked down to Baron James de ROTHSCHILD of the Paris bank, for 4.4 million francs, including part of the Carruades vineyard. Baron James died in the same year, and the château has remained in the

family ever since. Baron Eric de Rothschild took over direction of the property from his uncle Baron Élie in 1974, handing over to his daughter Saskia in 2018. In the famous 1855 CLASSIFICATION, Lafite was placed first of the PREMIERS CRUS, although there is controversy as to whether the order was alphabetical or by rank. Yet, as Christie's AUCTIONS in the 1960s and 1970s of 19th-century British country mansion cellars showed, in Britain Lafite was nearly always the favoured first growth.

The château itself is a 16th-century manor. The vineyard, one of the largest in the Haut-Médoc, had grown to 112 ha/276 acres by 2014: 72% Cabernet Sauvignon, 25% Merlot, 2% Cabernet Franc, and 1% Petit Verdot. Annual production varies, even more so since the estate was certified ORGANIC in 2021. About one-third of the crop goes into the GRAND VIN most years and the rest into the SECOND WINE, called Carruades de Lafite but not restricted to wine produced on the plateau in the vineyard known as Les Carruades, but this also varies. See ROTHSCHILDS AND WINE for other wine investments made by the owners of Ch Lafite. E.P.-R. & J.R.

de Rothschild, S., *Château Lafite: The Almanac* (2020).

Lafnetscha, rare Swiss Valais white grape often mistaken for COMPLETER. In fact, DNA PROFILING at DAVIS showed in 2004 that Lafnetscha is an offspring of HUMAGNE BLANCHE of the Valais and Completer of Graubünden. J.V.

Lafões, relatively undeveloped Portuguese DOC within the Vinho Regional Terras do DÃO and bordering VINHO VERDE. Sometimes referred to as *verdascos*, the light, dry white wines are not dissimilar to old-school Vinho Verde. Red wines—the mainstay of production—are light, acidic, and relatively rustic. S.A.

lagar, term used in PORTUGAL for a low-sided stone trough where grapes are trodden and fermented. Modern examples are made from stainless steel, but most have been replaced by conventional fermentation vats except in the DOURO Valley, where some of top ports continue to be foot-trodden in *lagares*. See PORT for more detail.

Lagoa, DOC in the ALGARVE in southern Portugal centred on the region's sole remaining CO-OPERATIVE winery.

La Gomera, rugged, mountainous CANARY ISLAND with its own small DO and 120 ha/300 acres of terraced vines planted at ELEVATIONS of 300–600 m/984–1,968 ft. White wines dominate here, mostly made from FORASTERA.

Lagorthi, name for VERDECA in Greece, where it is admired for its aromatic whites but is all too rare.

Lagos, westernmost DOC in Portugal's ALGARVE, exposed to northern winds and ocean on two sides, hence cooler and more humid than inland areas. S.A.

Lagrein, well-connected red INDIGENOUS VARIETY grown on 486 ha/1,200 acres in ALTO ADIGE in 2020 and on 215 ha in TRENTINO. Although often over-produced, it can produce Lagrein Scuro or Lagrein Dunkel, somewhat tannic reds of real character, as well as fragrant yet sturdy rosé called Lagrein Rosato or Lagrein Kretzer. Lagrein can be slightly bitter on the finish, and its presence, valued for both TANNINS and colour, can at times be detected in blends. DNA PROFILING has established that Lagrein is a natural CROSS between TEROLDEGO from Trentino and SCHIAVA Gentile from Alto Adige, a great-grandchild of Pinot, and a cousin of Syrah. J.V.

Lairén, very old minor southern Spanish white grape variety also known as Malvar and often mistaken for AIRÉN.

Laithwaite's, the world's biggest family-owned wine retailer and Britain's biggest wine company. It was founded as Bordeaux Direct in 1969 by Tony Laithwaite, a geography student who worked on a modest wine farm in CASTILLON, fell in love with wine, and began driving it back to the UK to sell from a railway arch in Windsor. His wife Barbara came on board the next year and steered the company with awesome efficiency until 1991. A key milestone was launching the Direct *Sunday Times* Wine Club in 1973, with Hugh JOHNSON as president. This feet-first introduction to the logistics of selling wine by mail order was enabled by Laithwaite's whimsical charm and lateral thinking; he has always prided himself on operating outside the wine-trade mainstream.

Never to be seen at the usual round of trade tastings, Laithwaite travelled the world instead and claims responsibility for introducing the British to the wines of Bulgaria, Romania, Moldova, Czechoslovakia, Australia, New Zealand, the Languedoc, Chile, Portugal ('the post-MATEUS new era'), and even England. Laithwaite's, Barbara Laithwaite, and one of their three sons now have, separately, their own English vineyards.

It was Tony Laithwaite who coined the expression FLYING WINEMAKER and in the 1980s made full use of putting southern-hemisphere winemakers to work in some of Europe's more primitive CO-OPERATIVE cellars. This fitted perfectly with the Laithwaite *modus operandi* of selling exclusive labels at high margins to customers who delighted in apparently buying them from their personal, compulsively literate friend Tony Laithwaite, a relationship which seemed to survive his short-term addition to the *Sunday Times* Rich List. By the 1990s the great majority of British direct wine sales, via whichever society or special offer, were fulfilled from Laithwaite's state-of-the art warehouse in the Berkshire countryside. They at last gained a major toehold in the traditional wine trade by acquiring the

historic Averys of Bristol between 2002 and 2006 and sell and store considerable quantities of FINE WINE as well their trademark quirkier offerings.

The Laithwaites had long before acquired and replanted the CASTILLON vineyard on which Tony Laithwaite did his apprenticeship, and in 2007 they opened their own substantial winery, the Chai au Quai, nearby. In 2003, to capitalize on the number of highly trained, under-funded, and, often, under-employed OENOLOGY graduates in South Australia, Laithwaite's opened the RedHeads Studio in McLaren Vale, a CELLAR RATS' playpen from which the company was able to buy the cream of the crop.

But the real game-changer came in 2006 when Laithwaite's acquired two businesses in the US, one in Connecticut and one in Illinois, which gave the firm a base from which to invade the growing American wine market. Today they operate the *Wall Street Journal*'s wine club as well as Laithwaite's in the US.

The next year they expanded into direct wine sales in Australia, where they operate the wine club of *The Australian* newspaper and Virgin Wines. In 2014 they franchised wine merchants in Taiwan and Hong Kong. By 2020 revenues were £360 million.

Laithwaite, T., *Direct: My Story* (2019).

Lake County, smallest viticultural district among CALIFORNIA's NORTH COAST counties. In this inland district east of MENDOCINO County and north of NAPA County, a vigorous but short-lived 19th-century industry died out with PROHIBITION, leaving scant historic guidance to the growers who restored vineyards to the region during the 1970s. The region boasts a unique climate: it is entirely high ELEVATION, with most vineyards planted above 457 m/1,500 ft, and this exposes the vines to more sunshine but also more ULTRAVIOLET RADIATION, which is thought to thicken the grape skins. Summers are hot but the winters can be cold and harsh, which is why much of the county's 3,845

ha/9,500 acres of vines are grown close to the moderating influence of Clear Lake, the largest lake entirely within California.

Of the seven sub-AVAs in 2022, two particularly stand out. Red Hills AVA rises above the lake's southern shores, its VOLCANIC and sometimes obsidian-laced soils adept at producing tannic, mineral-inflected Cabernet Sauvignon. Napa's Andy Beckstoffer is a vocal proponent of the region's potential and famously gave away several vintages of Cabernet fruit to top California producers in an attempt to spread the word.

High Valley AVA, north-east of Clear Lake, is a transverse valley with high, steep walls known for its wild weather and fast winds that cool down the grapevines and slow ripening. Sauvignon Blanc and Tempranillo are the early favourites, but Cabernet Sauvignon boasts significant plants as well. K.A.W.

lake effect, the year-round influence on vineyards from nearby large lakes, permits vine-growing in areas such as the north-east United States and Ontario in Canada despite their high LATITUDES, even if CLIMATE CHANGE has made this influence less predictable. In winter, the large lakes provide moisture to the prevailing westerly winds, which creates a deep snow cover, protecting vines from WINTER FREEZE even in very low temperatures, and the lake may eventually freeze, depending on its size. In early spring, the westerly winds blow across the very cold or frozen lake and become cooler, retarding BUDBREAK until the danger of FROST has passed. In summer the lake warms up. By autumn/fall, the westerly winds are warmed as they blow across the lake. The warm breezes on the vines lengthen the growing season by delaying the first frost. In other parts of the world, however, lakes and large inland seas also moderate climate through temperature effects alone. See MARITIME CLIMATE.
H.L.

Lalande-de-Pomerol, Bordeaux appellation very much in the shadow of POMEROL, the great red-wine district to its immediate north. It includes the communes of Lalande-de-Pomerol and Néac and

produces lush, Merlot-dominated wines which can offer a suggestion of the concentration available in a bottle of fine Pomerol but at a fraction of the price. Including about 1,100 ha/2,700 acres of vineyards, the Lalande-de-Pomerol appellation is much bigger than that of Pomerol, and its soils are composed of CLAY, SAND, and some well-drained GRAVELS in the south where it is divided from the Pomerol appellation only by the Barbanne river. At one time, the Barbanne separated that part of France which said *oc* for 'yes' (see LANGUEDOC) from that part which said *oil* and spoke the *langue d'oil*. J.R. & J.L.

La Livinière. This commune in the hilly far north of MINERVOIS in the LANGUEDOC successfully campaigned, hard and justifiably, for a special subappellation in 1999; in 2023 it was awaiting approval for standalone AOC status. Its 445 ha/1,100 acres extend over the rocky LIMESTONE plateau of Le Petit Causse, the vineyards climbing to 400 m/1,312 ft in ELEVATION, where the cool temperatures help to retain acidity and verve in the wines. Those wines are red, full-bodied, and structured blends of at least 40% SYRAH and/or MOURVÈDRE, with GRENACHE and LLEDONER PELUT, and smaller amounts of CARIGNAN, CINSAUT, PIQUEPOUL Noir, Rivairenc (ASPIRAN), and TERRET Noir allowed.

La Mancha. Europe's largest single demarcated wine region, in CASTILLA-LA MANCHA in the heart of Spain (see map under SPAIN). By 2012 the vineyards of the DOP La Mancha had shrunk to 160,000 ha/385,000 acres and have held steady since. Most of the area is arid table land stretching from the satellite towns south of Madrid to the hills beyond VALDEPEÑAS nearly 200 km/125 miles south. The Moors christened it Manxa, meaning 'parched earth', an apt description of the growing conditions. RAINFALL is unreliable, with annual totals averaging 300–400 mm/12–16 in. Summers are hot with temperatures rising over 40 °C/104 °F, while winters are bitterly cold with prolonged FROSTS. Looking on the bright side, FUNGAL DISEASES are almost unknown in La Mancha's dry growing season.

The doughty AIRÉN vine seems to be well suited to these extreme conditions and is therefore popular among La Mancha's 14,100 smallholders as of 2021. The variety covers about 200,000 ha/494,210 acres in the Castilla-La-Mancha autonomous region, nearly three-quarters of which is unirrigated BUSH VINES. It forms the basis of many of the region's fresh, inexpensive, if rather neutral dry white wines, sometimes blended with VERDEJO, SAUVIGNON BLANC, or CHARDONNAY.

Red wines rely mainly on Cencibel (TEMPRANILLO) grapes, alone or in blends with SYRAH, GARNACHA, CABERNET SAUVIGNON, MERLOT, and others. That said, the 2010s saw a rise in interest in local varieties such as Malvar (LAIRÉN), Tinto Velasco, Moravia Dulce (MARUFO), and Garnacha Tintorera (ALICANTE BOUSCHET). A large part of the annual harvest is also distilled into industrial alcohol or sent to JEREZ to make brandy de Jerez.

Most of the region's most interesting wines are not labelled DO La Mancha, as many producers prefer to use more generic IGPs such as Vino de la Tierra Castilla or even the simple Vino de España.

V. de la S. & F.C.

www.lamanchawines.com

Lambrusco, central Italian VARIETAL wine based on the eponymous red grape variety, or rather varieties, that was enormously popular with the mass market in the US and northern Europe in the 1980s. So successful was it that special white, pink, and 'light' versions were created, the colour and alcohol often being deliberately removed. Lambrusco's enormous commercial success has made it the most scorned and least understood of all Italian wine styles, although its industrial image is now challenged by a new generation of artisanal, dry versions.

Lambrusco also refers to a grape variety with several forms grown principally in the three central provinces of EMILIA—Modena, Parma, and Reggio nell'Emilia—although significant plantings can be found

across the river Po in the province of Mantova, and occasional plantings can be found as far afield as PIEMONTE, TRENTINO, and even BASILICATA.

The 2010 Italian vine-variety census distinguished between one Lambrusca and no fewer than 11 forms of Lambrusco, of which the most planted were Lambrusco Salamino (a national total of 5,003 ha/12,357 acres), Lambrusco Grasparossa (2,726 ha), Lambrusco Maestri (2,223 ha), Lambrusco di Sorbara (1,606 ha), and Lambrusco Marani (1,394 ha). (See also ENANTIO.) Lesser amounts of Lambrusco Viadanese, Lambrusca di Alessandria (known as Nebbiolo de Baja in MEXICO), Lambrusco Oliva, Lambrusco Montericco, Lambrusco Barghi, Lambrusco Benedetti, and Lambrusco del Pellegrino are also grown.

The total production of Lambrusco in 2020 was a staggering 160 million bottles, with only one-fourth produced under DOC rules, the majority labelled IGT Emilia. Efforts to increase the quality of Lambrusco have led to a change in production rules so that for IGT Emilia, the SECOND FERMENTATION for Lambrusco must be within Emilia. While most Lambrusco found on export markets is medium sweet or sweet, the traditional wine is dry and much favoured by Italians themselves, the pronounced ACIDITY and FIZZINESS being thought to help digest Emilia's hearty cuisine.

Most Lambrusco today is a fairly anonymous, standardized product made in industrial quantities by CO-OPERATIVES or large commercial wineries using the BULK METHOD together with heavy FILTRATION, STABILIZATION, and, frequently, PASTEURIZATION. This approach has tended to obscure the distinctive qualities of the different vine varieties and zones. However, five Lambrusco DOCs were created based on terroir and varietal differences, and an increasing number of artisan producers can be found in each. The first four are exclusive to the province of Modena.

DOC Modena encompasses the whole of Modena province, with some 9,000 ha/22,240 acres planted to any Lambrusco and 5,000 ha/12,355 acres registered as DOC. The two largest producers,

Chiarlo and Cavicchioli, produce 40 million bottles between them annually.

DOC Lambrusco Salamino di Santa Croce is the northernmost DOC on an extensive plain of ALLUVIAL sediment, SAND, and SILT. The high-yielding vines result in simple, violet-scented, fruity wines with medium tannins, although wines such as Luciano Saetti's SINGLE-VINEYARD Lambrusco proves that quality can be obtained here.

DOC Lambrusco di Sorbara overlaps with Lambrusco Salamino di Santa Croce and produces pale, rosé-like wines which tend to be dry and lively. Elegant wines come from potassium-rich sandy soils, while heavier wines come from clay-dominated soils.

DOC Lambrusco Grasparossa di Castelvetro is the furthest south. This early-budding, early-ripening, and least-vigorous Lambrusco is planted on undulating foothills around Castelvetro on sandy soils containing silt and marl. Considered the finest DOC of Lambrusco, its wines are rich in aroma, colour, extract, and tannin and may contain a little RESIDUAL SUGAR in compensation.

DOC Lambrusco Mantovano applies to the typically dry sparkling wines made in Lombardia.

Lambrusco is one of the suffixes of the DOC REGGIANO in EMILIA-ROMAGNA. Within this large area lies DOC Colli di Scandiano e Canossa, where Lambrusco Grasparossa is planted on HILLSIDES only, and yields are 16 tonnes/ha as opposed to the 18 tonnes/ha allowed in DOC Reggiano. T.D.C. & W.S.

Favaro, C., Everyone Calls It Lambrusco (2017).

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

La Méjanelle, small CRU (50 ha/124 acres) within the LANGUEDOC AOC in southern France, just east of MONTPELLIER. Unlike the rest of the AOC, this is a historic zone of individual estates, most notably Ch de Flaugergues. Syrah, Grenache, and Mourvèdre dominate in these

particularly MEDITERRANEAN vineyards, even as the city continues to expand.

Landot, or Landot 4511, cold-hardy FRENCH HYBRID making soft red wine in the north-eastern United States.

Landwein, PGI category of dry Austrian or German wine. In GERMANY, Landwein must have an ALCOHOLIC STRENGTH of at least 0.5% more than the minimum level for German WINE WITHOUT GEOGRAPHICAL INDICATION. Austria's much higher minimum is 14 °KMW (68 °OECHSLE), reflecting the warmer climate. Especially in Austria, this once rarely seen category has become the default for a number of experimental-minded and NATURAL WINE producers who do not aspire to, or whose wines fail to achieve approval as, QUALITÄTSWEIN. D.S.

Langhe, plural of Langa, name given to the hills to the north and south of the city of Alba in the province of Cuneo in PIEMONTE on the right bank of the river Tanaro. The soils, composed of clay MARLS, are the classic ones for the NEBBIOLO grape and produce the Langhe's most famous wines BAROLO and BARBARESCO, although they can also yield BARBERA, DOLCETTO, and MOSCATO of excellent quality. The hills gradually rise to the south of Monforte d'Alba, creating a climatic limit to the cultivation of Nebbiolo, and to the south of Dogliani up to 600 m/1,970 ft. The highest part of the area is increasingly important for the production of TRADITIONAL METHOD sparkling wines based on Chardonnay and Pinot Noir under the DOCG Alta Langa.

Langhe is also the name of a regional DOC, overlapping with the DOCG ROERO on the left bank of the Tanaro (and therefore not part of the Langhe geographically). Langhe DOC was originally created in 1994 to allow for the production of INTERNATIONAL VARIETIES, either as VARIETAL bottlings or blends often aged in BARRIQUES and commanding high prices but which could only be labelled as VINO DA TAVOLA. Today

Langhe DOC allows for 13 varieties, including non-traditional grape varieties such as Chardonnay, Sauvignon Blanc, and Riesling, as well as local ones such as ARNEIS and NAS'CETTA. (The latter obtained its own subzone, Novello, in 2010. It must comprise 100% of this variety rather than the 85% allowed under the Langhe DOC.)

Most Barolo and Barbaresco producers bottle a Nebbiolo for relatively early drinking and label it Langhe Nebbiolo because, perversely, the DOC Nebbiolo d'Alba is almost entirely confined to the left bank of the Tanaro, coinciding with Roero, and includes only tiny parts of the classic Barolo communes. This is also done because international demand for this wine, seen as an economically priced alternative to Barolo and Barbaresco, has inspired frantic plantings of Nebbiolo throughout the region, raising fears of future overproduction and devaluation. Its success is such that Nebbiolo threatens to replace Dolcetto, the main variety in the Dogliani DOCG, which lies within the Langhe. W.S.

Langhorne Creek, largely flat, productive wine region in SOUTH AUSTRALIA cooled by Lake Alexandrina and the nearby Southern Ocean. It has an unusual ability to produce large yields of medium-bodied red wines which achieve sensory ripeness in its TEMPERATE climate. There were 6,069 ha/14,997 acres of vineyards in 2022; Verdelho and Malbec are specialities.

language of wine. Wine-talk is a problem: 'When trying to talk about wine in depth, one rapidly comes up against the limitations of our means of expression … We need to be able to describe the indescribable. We tasters feel to some extent betrayed by language', comments Émile PEYNAUD.

Wine-talk is triply disadvantaged: first, people TASTE and smell wine differently from each other; second, a partially obscure conventional vocabulary has arisen: the wine flavour described as gooseberry, for example, does not taste very much like gooseberries (quite apart from the difficulties caused by the fact that gooseberries are known in only a limited number of cultures); third, the need to impress customers in a cut-throat market has led to ear-catching and sometimes bizarre descriptions: 'a fascinating old, old smell of unswept floorboards', 'old tarpaulin fringed with lace', 'Wham bam thankyou ma'am red, all rich, gooey, almost treacly fruit-dark plums and prunes awash with liquorice and chocolate and cream'.

In many ways, wine descriptions are in their linguistic infancy, parallel to the days when linguistic sounds could be described only by comparison to other sounds: in the 16th century, English *a* was described as like 'the balling of the sheepe when she feedeth', for example. Phonetics now has an International Phonetic Alphabet, with agreed parameters, but this is still far from true of wine terminology.

Descriptive terms should be distinguished from expressive or evaluative ones, it is sometimes argued. Yet even this proves to be difficult for wine: even the most straightforward descriptions are bizarre by the standards of 'normal' usage. An English speaker asked to describe the colours red and white is likely to mention blood versus snow, yet a red wine is typically reddish-purple and a white one pale straw, each with a range that goes beyond the usual boundaries for red and white. Other wine colour terms are equally odd: black, as in Greek MAVRODAPHNE 'black-daphne' or the old 'black wine' of CAHORS, refers simply to a hue darker than is usual for wines.

Yet colours illustrate one useful way in which wine terms can be partially analysed, by looking at the internal structure of the wine vocabulary. Red and white are opposites on a scale with rosé in the middle. Such antonyms are an anchor-point in descriptions. Possibly for this reason, the terms 'sweet' versus 'dry' are the first technical terms to be widely understood and are now regularly found in supermarket classifications, even though, outside a wine context, the average person would oppose sweet to sour, and dry to wet.

Technically, antonyms such as ‘sweet’ versus ‘dry’ are gradable, in that ‘sweet’ means ‘sweet in relation to a norm’, even though the norm is far from clear. Further opposites/scales have not generally caught on, though some recur in descriptions, as ‘young’ vs ‘mature’, ‘light’ vs ‘heavy’, ‘crisp’ (nicely acidic) vs ‘flabby’—though a basic problem is that a word such as ‘flabby’ tends to be used as a general derogatory term, so is also found in opposition to terms such as ‘hearty’, ‘sturdy’, ‘meaty’, which indicate a wine with BODY.

Synonyms are also useful in understanding vocabulary structure, and words for wines with ‘body’ abound—‘beefy’, ‘big’, ‘broad’, ‘chunky’, ‘powerful’, ‘robust’—though none has yet won out over others.

As the above examples show, most wine descriptions involve adjectives, though ones with a somewhat specialized interpretation. Adjectives depend for their meaning on the words to which they are attached: an old wine will be younger than an old house, but possibly older than an old friend, who may well not be aged. Many wine adjectives consist of a noun plus ending -y, as ‘buttery’, CHALKY, ‘chocolatey’, ‘earthy’, ‘FLINTY’, ‘flowery’, ‘fruity’, ‘grapey’, ‘herby’, ‘meaty’, ‘nutty’, ‘oaky’, ‘peppery’, ‘silky’, ‘spicy’, ‘sugary’, and ‘velvety’.

Readers of wine columns sometimes get the misleading impression that ‘anything goes’. Yet the majority of wine-flavour descriptions cover a fairly narrow range, mostly of other food words, as ‘appley’, ‘gamey’, ‘grapefruity’, ‘minty’, ‘peachy’, ‘plummy’—though these are often ‘code’ terms, in that a wine described as ‘grapefruity’ or ‘minty’ does not (to the uninitiated) taste very much like either. Terms that move outside these food flavours relate easily only to a small portion of wine qualities, as with the power terms listed above for wines with body. A further set relate perceived smoothness to fabrics, so wines may be ‘velvety’, ‘silky’, ‘satiny’—though even here, the range of fabrics is limited: a wine may be soft, though is not normally woolly. Shape and TEXTURE terms tend to be applied to wines with a high degree of ACIDITY, as ‘angular’, ‘austere’, ‘flinty’, ‘steely’. The AROMA (nose) is perhaps the aspect of wine that has caused the greatest controversy in recent years and seems to be hardest to convey: ‘cat’s

pee', 'pencil shavings', 'sweaty saddles', and 'tobacco' had relatively little attention paid to them, yet fury erupted when a serious critic referred to a wine as smelling of hamster cages. Any successful metaphor must achieve cultural resonance and avoid cognitive dissonance: it must fit in with existing traditions and preconceptions or risk being rejected.

Yet in many cases, wine descriptions are unclear only out of context or when single words are used. Humans often think about word meanings in terms of 'prototypes' or typical examples. Prototypes are bundles of characteristics: so a robin, a prototypical bird, has a red breast, is fairly small, has wings, slender legs, and so on. Similarly, a bunch of features characterize particular wines, some of them accurate, some evocative: a Sauvignon Blanc, for example, popularly referred to as 'cat's pee on a gooseberry bush', is spoken of as being 'acidic', 'clean', 'refreshing'. However, increasingly wines are acquiring shorthand labels for these bundles of characteristics: some Chardonnays, such as those produced in MEURSAULT, were once, before a more austere style predominated in the village, labelled 'buttery' for a fairly rich white wine—a description that was accepted even by those who love Meursault wines but dislike butter. A rioja is recognized and labelled 'oaky', even by those who have no idea why this tag is used.

All of this suggests that wine knowledge is becoming increasingly sophisticated. A future hope is that a more sophisticated classification system of the vocabulary of wine can match the knowledge of its drinkers.

Lehrer, A., *Wine and Conversation* (2nd edn, 2009).

Peynaud, É., *Le Goût du Vin* (1983), translated by M. Schuster as *The Taste of Wine* (2nd edn, 1996).

Languedoc, France's best-value, most fluid wine region, certainly its most important in terms of volume of wine produced and in terms

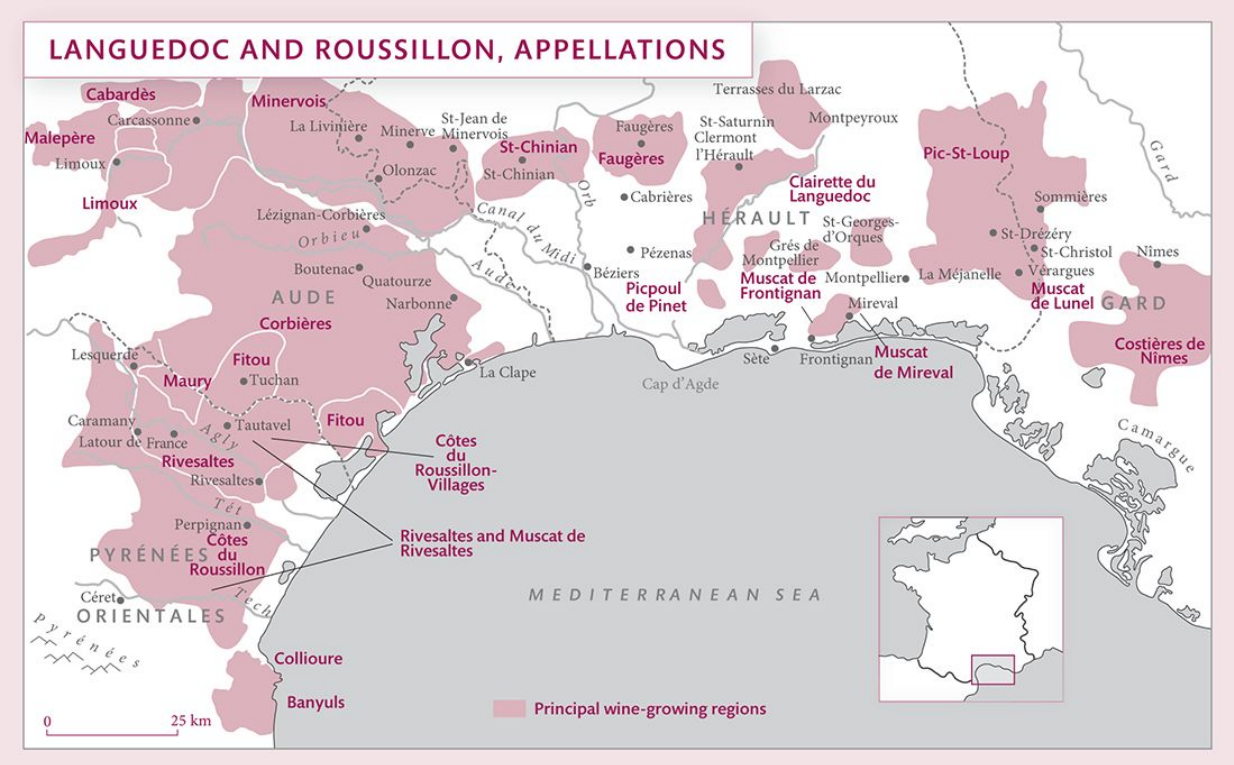
of the significance of viticulture to the region's economy. The Languedoc takes its name from a time when its inhabitants spoke Occitan, the language in which *oc* (rather than *oil*) is the word for 'yes', hence *langue d'oc*. It comprises the three central-southern *départements* of the Aude, Hérault, and Gard, a sea of little other than vines just inland from the beaches of the Mediterranean (see map and FRANCE).

For administrative purposes, the Languedoc is considered part of the Occitanie region, although prior to 2016 it was often bracketed with the region to its immediate south, as in Languedoc and Roussillon. Between them at the turn of the century a total of 31,541 vignerons cultivated 241,537 ha/596,596 acres of vineyard, one-quarter of all French vines. (It had represented one-third a decade earlier.) But strenuous EU-inspired VINE-PULL SCHEMES aimed at reducing Europe's wine SURPLUS were specifically targeted at France's deep south with considerable success. By 2018, Languedoc's vineyards covered 62,900 ha/155,429 acres of vines.

Despite its quantitative importance, Languedoc produces only about one-eighth of France's AOC wines. For many years, the Languedoc's only appellation was Fitou, but in 1985 Corbières, Minervois, and the catch-all appellation Coteaux du Languedoc (now LANGUEDOC) were elevated from VDQS to AOC status; by 2021, there were 23 AOCs and 20 IGPs.

A high proportion of the vast area included in these AOC zones is dedicated to non-appellation wine, however, either because the ENCÉPAGEMENT is outside the appellation specifications or because the vigneron continues to be more interested in quantity than quality. In addition, some important producers, dissatisfied with the detail of the appellation laws, routinely ignore the AOC system and put their effort into making high-quality IGP wines instead. The Languedoc remains by far the principal producer of VSIG and produces nearly 60% of France's intermediate IGP, much of it labelled regionally and, typically, VARIETALLY, as Pays d'Oc.

About 18% of the Languedoc's AOC wine output was white in 2018. The best Languedoc whites, after a decidedly OAK-dominated phase, have become increasingly fine and interesting. Almost as much rosé wine is made, and it, too, has been taken more seriously in the last decade, much of it being made in a lighter PROVENCE style. A substantial quantity of VIN DOUX NATUREL is made (see MUSCAT), and LIMOUX is the Languedoc's centre of SPARKLING WINEMAKING. The Languedoc is still principally a source of red wine, however, a typical representative being no longer a thin, pale remnant of the region's past as a BULK WINE supplier but a dense, exciting, increasingly supple ambassador of some of France's wildest countryside.



History

Vines were planted as early as 125 BCE on the hills near the Roman colony of Narbo, modern Narbonne, which today produce Corbières, Minervois, and Languedoc AOC. Narbonne was then an important Roman port, protected by what was then the island of LA CLAPE. Cargoes would be taken upriver as far as Carcassonne and then transported overland to join the GARONNE and thence to the Roman legions in Aquitaine. The hinterland of Narbonne and Béziers came to produce so much wine that it was exported to ancient ROME, although the edict of DOMITIAN was designed to put a stop to this.

It was not until the Middle Ages, under the auspices of the Languedoc's MONKS AND MONASTERIES, that viticulture once again thrived (although today only the Abbaye de Valmagne and Abbaye de Fontfroide retain their wine-producing roles). Already the University of MONTPELLIER was established, and ARNALDUS DE VILLANOVA oversaw several important developments for wine and spirit production there. The development of greatest potential significance for the Languedoc and its wines was the late 17th century construction of the Canal du Midi, which connected the Mediterranean with the Atlantic. The Bordelais were by now so experienced at protectionism, however (see HAUT-PAYS, for example), that the wine producers of the Languedoc failed to benefit substantially from this new distribution network until the end of the 18th century.

Much more profitable were the efforts of the DUTCH WINE TRADE in the late 17th century to develop northern European markets for *picardan*, a sweet white wine made from CLAIRETTE and PICQUEPOUL grapes that was well known in Holland by 1680, and subsequently for eaux-de-vie. The port of Sète was established in 1666 and became particularly important for exports to ENGLAND and the NETHERLANDS, Narbonne having long since silted up. Sweet wines were also produced, notably a DRIED-GRAPE WINE made from Muscat grown at FRONTIGNAN, whose inhabitants insist that it was as a result of a visit by a Marquis de Lur-Saluces to Frontignan after the great frost of

1709 that Ch d'YQUEM became a sweet wine property, and that their straight-sided bottle was adopted for bordeaux.

By the mid 19th century, the vineyards of the Languedoc could be divided into the HILLSIDE VINEYARDS, vines planted on GRAVELLY terraces at mid ELEVATION (roughly approximating to the majority of modern Languedoc appellations), and vines, mainly ARAMON and TERRET grapes, planted on the plains for DISTILLATION into brandy.

In 1855, the Languedoc's fortunes were to change forever as a result of its first RAILWAY connection, via Lyons, with the important centres of population in the north. A link via Bordeaux was opened the next year. From 1850 to 1869, average annual wine production nearly quadrupled in the Hérault *département*. The arrival of PHYLLOXERA could hardly have been worse timed, but, thanks to feverish experimentation and the eventual adoption of GRAFTING, as well as HYBRIDS and some of the new BOUSCHET crosses, the Languedoc vineyard was the first to be reconstituted after the devastations of this American pest. By the end of the 19th century, the Languedoc became France's principal wine supplier, producing 44% of France's entire wine production, from 23% of the country's total *vignoble*.

This superficial success was at some cost, however. Dr GUYOT had in 1867 warned against the over-industrialization of the Languedoc wine trade and the increasing influence of VINE VARIETIES and practices designed to produce quantity rather than quality. By the turn of the century, the plains of the Languedoc, the Hérault particularly, were being milked of thin, light, pale red that needed blending with the much more robust produce of new colonial vineyards in ALGERIA to yield a commercially acceptable drink. France had sown the seeds of its (continued) dependence on wine imports. Such was the extent of commercial interference in the French table-wine market, including widespread ADULTERATION AND FRAUD, that prices plummeted, and France's social crisis of 1907 provoked what were merely the first in a long series of wine-related riots.

Since then the vignerons of the Languedoc, typically but by no means always members of one of the region's hundreds of CO-OPERATIVES, many of them formed in the 1930s and most now part of a larger group, have been some of the world's most politicized. Their sheer number has given them political power, but the fall in demand for basic VIN DE TABLE and difficulty in selling even the keenly priced VIN DE PAYS, which took its place as the Languedoc's principal product, led to increasing frustration among growers.

Land here is relatively inexpensive, which has drawn a wide range of investors, both producers with an established record in a more famous wine region and complete outsiders.

Geography and climate

The great majority of the Languedoc's vines are or were planted on the flat, low-lying plain, particularly in the southern Hérault and Gard. In the northern Hérault and western Aude, however, vines may be planted several hundred metres above sea level, in the foothills of the Cévennes and the Corbières Pyrenean foothills, sometimes at quite an angle. Soils are very varied and can include GRAVELS, LIMESTONE, SCHIST, and VOLCANIC stones.

The climate in all but the far western limits of the Languedoc (where Atlantic influence is apparent) is definitively MEDITERRANEAN, and one of the major viticultural hazards is DROUGHT. Annual rainfall is often as little as 400 mm/15.6 in by the coast. July and August temperatures often exceed 30 °C/86 °F; such rain as does fall tends to arrive in the form of localized deluges. WIND is common throughout the growing season, with the tramontane bringing cool air from the mountains.

Viticulture

The Languedoc is a mosaic of predominantly privately owned vineyards. The size of the average holding is small and usually much divided between parcels inherited from various different branches of the family. BUSH VINES still predominate, although an increasing proportion of vines, especially the newer INTERNATIONAL VARIETIES, are being trained on WIRES. IRRIGATION is theoretically permitted only within strictly specified limits, and in practice only the best and the worst producers tend to have any form of available irrigation system. The flatter, larger vineyards lend themselves to MECHANICAL HARVESTING, but their parcellation, and ripping out, has slowed the inevitable invasion. The region is by no means free of FUNGAL DISEASES, and some sprayings are usually necessary.

Vine varieties

The dominant late 20th century vine variety CARIGNAN has been definitively routed by the VINE-PULL SCHEME of the EU, and in 2015 was only the third most planted variety in the Languedoc after Syrah and then Grenache Noir. Merlot, grown mainly for IGP wines, covers almost as much ground as Carignan, with Cabernet Sauvignon some way behind. Most red-wine appellations in the Languedoc specify various combinations of Syrah, Grenache, and Mourvèdre, with declining proportions of Carignan and most often, usually as minor blending ingredients, CINSAUT (especially good for rosés and fruity reds) and the Grenache relative LLEDONER PELUT.

By far the most planted white wine grape, though even less common than Cabernet Sauvignon, is Chardonnay, used for both varietal IGP wines and the still and sparkling wines of LIMOUX. Sauvignon Blanc is the next most planted and Viognier the fourth most popular white wine grape, further signs of how important INTERNATIONAL VARIETIES are to white-wine production here. Each white-wine appellation has a different cocktail of preferred ingredients from a palette of traditional pale-skinned Languedoc varieties, including BOURBOULENC, CLAIRETTE, GRENACHE BLANC, MACABEO, PIQUEPOUL, and VERMENTINO, although ROUSSANNE and MARSANNE are also specified occasionally.

Winemaking

While many traditional producers still work with modest materials and means and CO-OPERATIVES still dominate production, winery techniques and equipment have improved significantly in the last decade in the Languedoc. As many new incumbents have taken over family domaines and outside investors have arrived in the region, so the move to adopt new materials and techniques has gathered pace. STAINLESS STEEL has gained a significant foothold in the winery; likewise CONCRETE *cuves*, which fell out of favour in the 1990s, have been refurbished or newly installed as the enthusiasm for this medium has returned. It is now also common to see oak BARRELS, often new, of various sizes from BARRIQUES to demi-muids (see BARREL TYPES) in cellars as producers experiment with BARREL AGEING. CARBONIC MACERATION is still common for Carignan, but Syrah, Grenache, and Mourvèdre are vinified in everything from concrete egg to clay AMPHORA. The increased interest in white and rosé production has also led to more sophisticated TEMPERATURE CONTROL from reception to maturation. BARREL FERMENTATION and BARREL AGEING for these styles is now also more commonplace.

For more specific information, see the individual appellations CABARDÈS, CLAIRETTE DU LANGUEDOC, CORBIÈRES, FAUGÈRES, FITOU, LANGUEDOC AOC, LIMOUX, MALEPÈRE, MINERVOIS, PICPOUL DE PINET, and ST-CHINIAN, and also the vin de liqueur CARTAGÈNE, and various MUSCAT vins doux naturels. M.S.

www.languedoc-wines.com

Languedoc AOC was established in 2007 to create a generic appellation for the whole of this region in southern France. It replaced the former Coteaux du Languedoc, which covered several areas from Nîmes to Narbonne. Languedoc AOC, somewhat confusingly, extends across the whole of both Languedoc and Roussillon, covering all four *départements* of the Gard, Hérault, Aude, and Pyrénées-Orientales. It can be used for red, white, and rosé wines and allows producers to blend across regions under an appellation designation. It provides an alternative to the other cross-regional option of IGP Pays d'Oc but stipulates lower yields (max 50 hl/ha) and that the wines must be a blend of at least two varieties.

Although much of the zone qualifies for the basic Languedoc appellation, a number of subappellations, CRUS, or specific 'named terroirs' (see DÉNOMINATION GÉOGRAPHIQUE COMPLÉMENTAIRE) are allowed to append their own name to that of the appellation on labels. These include CABRIÈRES, GRÉS DE MONTPELLIER, LA MÉJANELLE, MONTPEYROUX, PÉZENAS, QUATOURZE, ST-CHRISTOL, ST-DRÉZÉRY, ST-GEORGES-D'ORQUES, ST-SATURNIN, and SOMMIÈRES. M.S.

www.languedoc-wines.com

Lanzarote Spanish DOP including the whole of this relatively flat island in the CANARY ISLANDS. There were still 1,837 ha/4,539 acres of vineyards in 2020, clearly dominated by the white MALVASIA Volcánica grape variety, as on LA PALMA. In reds, LISTÁN NEGRO dominates. Lanzarote's vines are often planted in individual shallow indentations in the black VOLCANIC soil and protected from the strong Atlantic winds by stone walls. The El Grifo winery, founded in 1775, has been a pioneer in the development of modern dry Malvasía, and the overall quality of the other producers, led by Los Bermejos and Mozaga, has advanced significantly. V. de la S. & F.C.

La Palma, Spanish DOP that includes the entire eponymous island in the CANARY ISLANDS. The vineyard surface of the VOLCANIC island had by 2019 dropped to 537 ha/1,327 acres, planted at 200–1,400 m/656–4,600 ft in ELEVATION. A large range of grape varieties are cultivated, dominated by NEGRAMOLL and LISTÁN blanco, but La Palma's most distinguished wine is traditional sweet MALVASIA, almost forgotten in recent years but whose reputation, as Canary SACK, goes back to Elizabethan England. Its most traditional wine is *vino de tea*, a spicy, resinous wine aged up to six months in barrels made from the Canary pine (*Pinus canariensis*). V. de la S. & F.C.

large format, BOTTLE SIZE larger than the standard 75-cl size and of particular interest to collectors and investors (provided it is filled with FINE WINE).

La Rochelle, port on the Atlantic coast about 160 km/100 miles north of BORDEAUX in the *département* of Charente-Maritime. In the Middle Ages, La Rochelle was a New Town, having been founded in 1130, in an age of economic expansion. The climate at La Rochelle is hot and dry enough for the winning of sea salt, and salt was initially the basis of La Rochelle's economy. Merchants came from the north to buy salt, but they also wanted wine, and it was in response to that demand that the people of La Rochelle turned to viticulture. Because of its favourable climate, Poitou was a more reliable producer than the Seine basin (see PARIS), Reims (see CHAMPAGNE), BURGUNDY, or the RHINE. Hence the English and the Flemish turned more readily to the wines of Poitou, all the more so because these wines were less acidic than those of Reims and Paris. La Rochelle also exported its wines to Normandy, Scotland, Ireland, and even Denmark and Norway. In 1199, Poitou was the wine the royal household bought most of, with the wines of ANJOU and the Île-de-France coming second and third. But in 1224, when La Rochelle fell to the French, it had to cede its position as leading wine supplier to Bordeaux, although the wines of

La Rochelle remained popular with the English in the 14th and 15th centuries.

The grape varieties were probably those of Burgundy and the Paris region: MORILLON, which was an early form of PINOT NOIR; and Fromenteau, thought to be the ancestor of PINOT GRIS. In documents of the 13th and 14th centuries, a third variety appears: called Chemère, Chemière, Chenère, or Chenère Blanche, it is likely to have been the parent of CHENIN BLANC. In accordance with medieval preference, most of the wines that Poitou made were white.

See also DUTCH WINE TRADE and HAUT-POITOU. H.M.W.

Dion, R., *Histoire de la vigne et du vin en France* (1959).

Laški Rizling, the name current in SLOVENIA, SERBIA, and some other parts of the former Yugoslavia for the white grape variety known in Austria as WELSCHRIESLING (under which name more details and more of its many synonyms appear). It is the most widely planted variety in Slovenia, cultivated most successfully in the country's higher vineyards (just over the border from the spirited Welschrieslings of STYRIA) and in Serbia's Fruška Gora, where it can produce equally crisp and delicately aromatic wines, often under the historical name Grašac. Few of these superior examples have been exported, however, whereas for decades in the second half of the 20th century a Slovenian BRAND, Lutomer Riesling (renamed Lutomer Laški Rizling after German lobbying), was the best-selling white wine in the UK, its heavily sweetened style conveying little of the intrinsic character of the variety.

La Tâche, great red GRAND CRU in Burgundy's CÔTE D'OR. For more details, see VOSNE-ROMANÉE and DOMAINE DE LA ROMANÉE-CONTI.

late harvest, a general term used to describe grapes that have been harvested later than is normal for dry wines in order to make a

SWEET WINE, generally without the aid of NOBLE ROT. They are usually left on the vine so that the berries are rich in sugar (see MUST WEIGHT) or, even longer, so that the fruit starts to desiccate, resulting in DRIED-GRAPE WINES. See VENDANGES TARDIVES for a highly regulated French example of a late-harvest wine.

lateral shoot, sometimes called simply a lateral, secondary shoot that grows from the axil of a leaf on the main shoot. Its origin on grapevines is linked with the complex development of the BUD. At most nodes, especially on weak vines, the lateral shoot is short (less than 20 mm/0.8 in), fails to become woody, and drops off in autumn leaving a prominent scar at the side of the bud. But on more vigorous shoots, especially at the middle nodes or at the end where vigorous shoots have been topped or trimmed, the lateral shoot grows in the same way as a primary shoot, producing hardened permanent wood. Sometimes, lateral shoots are fruitful (see SECOND CROP). Laterals that develop on secondary shoots are called tertiaries; quaternaries have even been seen on extremely vigorous vines. B.G.C.

Latin America. See SOUTH AMERICA and MEXICO.

latitude, angular distance north or south of the equator, measured in degrees (°) and minutes (′). The main northern-hemisphere viticultural regions extend between 32° and 51° N, and most of those in the southern hemisphere between 28° and 42° S. Those closer to the poles are cooler, and near the equator warmer. Viticulture is spreading polewards and is likely to continue to do so due to CLIMATE CHANGE. Whereas ten years ago 52° N in ENGLAND (and Ireland) was around the northern limit, vines are now planted in NORWAY and SWEDEN, up to 61° N. The extension in the southern hemisphere is limited by the general size of landmasses, with Chiloé Island, CHILE, at 43° S; Sarmiento, ARGENTINA, just under 46°; and vineyards in Central Otago, NEW ZEALAND, at just over 46°. Some vines are also cultivated

for wine production in tropical lowlands and highlands or irrigated desert conditions as close to the equator as 8–9º (e.g. lowlands such as the Pernambuco region in north-east BRAZIL). See TROPICAL VITICULTURE.

Comparisons between hemispheres based purely on latitude are misleading. Northern-hemisphere vineyards are on average warmer during the growing season at given latitudes, a fact largely related to their greater CONTINENTALITY. But even over the whole year, the northern hemisphere is on average warmer than the southern hemisphere at similar latitudes, partly because of the greater land mass and its disposition around the North Pole and partly (in the case of western Europe) because of warming by the Gulf Stream.

Slinde Vineyard on the northern side of the Sognefjord in western NORWAY is one of Europe's most northerly, at a LATITUDE of 61.2° N. Planted by Bjørn and Halldis Bergum in 2014, these south-facing SOLARIS vines benefit from the mild winters and high SUNLIGHT intensity of the country's deepest and longest fjord. © Bjørn Bergum

Comparisons between vineyard regions based on latitude can also be misleading, since TEMPERATURE, which is influenced more by

distance from the sea and ELEVATION than by latitude, has a greater impact than latitude on VINE PHYSIOLOGY, PHENOLOGY, and wine style. See CLIMATE AND WINE QUALITY, HUMIDITY, TEMPERATURE VARIABILITY, DIURNAL TEMPERATURE RANGE, and map under WORLD PRODUCTION.

Jones, G. V., et al., 'Climate, grapes, and wine: structure and suitability in a variable and changing climate', in P. Dougherty (ed.), *The Geography of Wine: Regions, Terroir, and Techniques* (2012), 109–33.

Latium, Anglicized version of the Italian wine region LAZIO.

Latour, Château, famously long-lived FIRST GROWTH in the MÉDOC region of BORDEAUX. The originally square tower from which the château takes its name was one of a defensive line against ocean-going pirates. Vines were already planted here in the late 14th century, and at least one-quarter of the land was vineyard by 1600. At the end of the 17th century, a number of smallholdings were accumulated into one ownership under the de Mullet family. The New French Clarets they produced made their first publicized appearances in AUCTIONS in London coffee houses early in the 18th century. Owned from 1677 by the Clauzel family, it passed by marriage to the powerful SÉGURS, who also owned LAFITE, MOUTON, and Calon-Ségur. On the death in 1755 of the Marquis Nicolas-Alexandre de Ségur, 'Le Prince des Vignes', his properties passed to his four daughters, three of whom in 1760 acquired Latour. Their male descendants owned the château, which in 1842 became a private company, until its purchase by the British Pearson family in 1963, with 25% acquired by Harveys of Bristol and a diminishing minority remaining in the hands of the French families. The property was greatly improved, with STAINLESS STEEL tanks controversially installed as FERMENTATION VESSELS in time for the 1964 vintage, partly on the advice of director Harry WAUGH. In 1989, the estate was sold to multinational corporation Allied-Lyons, already owners of Harveys, for the equivalent of £110 million. In

1993, Allied-Lyons sold their 94% share of the property to French businessman François Pinault (who acquired the London AUCTION house of Christie's in 1998), when Latour was valued at £86 million. See ARTÉMIS DOMAINES.

Thanks to 21st-century expansion, the estate comprised 96.5 ha/238 acres of vineyard by 2022 with 75% Cabernet Sauvignon vines, 24% Merlot (increased from 15% in the 1980s), and a very small amount of Cabernet Franc and Petit Verdot, with an average annual production of about 25,000 cases (less than it once was) of the three wines made there. In 1966 a SECOND WINE, Les Forts de Latour, made from the produce of young vines and from three plots on the other side of the St-Julien–Pauillac road, was introduced as a permanent fixture. A third wine is also bottled and sold as Pauillac. Latour's wines generally require much longer to develop than those of the other first growths, and they often have greater longevity. Latour is also known for its ability to produce good wines in lesser vintages.

It also possesses better archives, back to the 14th century, than any other wine estate in Bordeaux and so has spawned an unusual and useful array of monographs.

Since 2008, HORSES have worked the vineyards, and the estate was certified ORGANIC in 2018 with L'Enclos, a key walled vineyard, farmed BIODYNAMICALLY. In 2012 Latour's director Frédéric Engerer decided to withdraw from the annual Bordeaux EN PRIMEUR market, the first major Bordeaux château to do so, with a view to releasing wines only as they are ready to drink.

Latour, Louis, one of Burgundy's most commercially astute, and oldest, merchants. Jean Latour first planted vines in Aloxe-Corton, then called simply Aloxe, in 1768; his family had grown vines on the plain to the east of Beaune since the 16th century. Jean's son was the first in a long line of Louis Latours and enlarged the domaine considerably. It was not until the late 19th century that the family added wine brokering to their vine-growing activities.

With an eye to the developing export markets, the third Louis Latour bought the Lamarosse family's NÉGOCIANT business in Beaune's historic Rue des Tonneliers in 1867; this was so successful that in 1891 he was able to buy Ch Corton-Grancey in Aloxe-Corton, one of the earliest purpose-built GRAVITY-FED wineries in the world. With this acquisition came one of the most handsome, and most photographed, houses in the Côte d'Or and some notable vineyards around the hill of Corton to add to the Latour family holdings, which already included some Chambertin, Romanée-St-Vivant, Les Quatre Journaux; and Chevalier-Montrachet, Les Demoiselles. (Today Domaine Louis Latour enjoys the largest single holding of GRAND CRU vineyards on the CÔTE D'OR.) It was the third Louis Latour who is reputed to have realized the hill of Corton's potential for great white wine when he replanted some of the hill now designated Corton-Charlemagne with Chardonnay vines after PHYLLOXERA had laid waste to vineyards originally planted with Pinot Noir and Aligoté.

Innovations of succeeding Louis Latours include a succession of 'new' and increasingly daring white wines. What was then known as Grand Pouilly (and subsequently became known as Pouilly-Fuissé) was introduced to the United States in the 1930s, immediately after the Repeal of PROHIBITION. A wine known as MÂCON-Lugny was introduced as a respectable alternative to Côte d'Or white wines in close co-operation with the Lugny CO-OPERATIVE. Louis Latour also pioneered the planting of Chardonnay vines in the relatively unknown ARDÈCHE in the early 1980s. The firm has 350 ha/965 acres of vines under contract to local growers, whose produce is vinified at Latour's winery in Alba. In the late 1980s, Louis Latour bought land in the Var

département in PROVENCE, planting the Beurot selection of Pinot Noir to produce gentle red wines sold as Pinot Noir, Domaine de Valmoissine. Louis Latour acquired Chablis producer Simonnet-Febvre in 2003 and Beaujolais producer Henry Fessy in 2008. Continuing their development of Pinot Noir and Chardonnay grown in fringe areas, they more recently acquired land in the Terres Dorées in BEAUJOLAIS and in Auxois midway between Chablis and Dijon.

The house enjoys a solid reputation for its white wines but has in the past incited controversy over its endorsement of PASTEURIZATION of even its finest red wines. They use and sell barrels from their own cooperage.

Latour-de-France, small village on brown SCHIST that once guarded the border between France and Spain, and whose name may be a suffix to the appellation Côtes du ROUSSILLON-Villages. It covers Cassagnes, Montner, Estagel, and Planèzes as well as Latour-de-France itself. Wines must be a blend of at least two varieties, with Syrah and Mourvèdre accounting for at least 30% (together or separately) and Grenache Noir, Carignan Noir, and Lladoner Pelut allowed. The main variety should not be more than 70% of the blend. The village is also known for an energetic band of producers of NATURAL WINES.

Latvia, former Soviet republic on the Baltic Sea bordered by LITHUANIA to the south, ESTONIA to the north, and RUSSIA and Belarus to the east. Winegrowing in this far northern country dates to the 14th century, when German crusaders planted vines on a hill in Sabile, a town in what was then Livonia, but died out with the Livonian War in the late 1500s. Several more starts were made, including in the early 1930s, when growing wine grapes in greenhouses became a trend, but the country's modern industry started only in the 21st century, with the restoration of the Sabile vineyard and the start of a GARAGE winemaking movement led by the country's most prominent winegrower Martins Barkans at Abavas.

While Latvia has a rich tradition of fruit wines, VITIS VINIFERA is challenging to grow in the climate, with its cold winters, short summers, and wet autumns. Therefore the majority of the estimated 30 ha/74 acres of vines in 2022 are cold-hardy HYBRIDS such as Zilga, a Latvian CROSS, as well as ZWEIGELT, BACCHUS, and RONDO for red wines and SOLARIS and Muscaris (Solaris × Muscat) for whites. Stylistically most wines are semi-sweet, as they were in Soviet times, but the taste for dry wines is growing, as is interest in NATURAL WINE.

R.T.

law is of fundamental importance to the wine sector. It is what requires wine to be made from fresh grapes without the addition of colouring or flavouring. It is what turns a distinctive TERROIR into a CONTROLLED APPELLATIONS. It dictates who can grow, produce, and sell what, where, and how—and of course how much tax they must pay (see TAXATION). It controls what can and cannot be said on labels and in advertising. It is the forum where every major crisis, issue or contest of ideas in wine is eventually played out, from PHYLLOXERA to PROHIBITION to pregnancy warning labels (see LABELLING INFORMATION).

Different countries approach the regulation of wine in different ways according to their histories, legal systems, and the relative importance of wine in their economies. The 27 EU countries share an overarching wine regulation strongly influenced by France's wine laws. It is comparatively prescriptive in approach but also provides the basis for systematic financial support that is not enjoyed by most other wine countries. Elsewhere, wine laws vary considerably but are typically more flexible than those of the EU.

The oldest known set of wine laws are part of the code of Babylonian king HAMMURABI (d. 1750 BCE). Two perennial wine-law questions—ADULTERATION AND FRAUD and public order—are addressed, although the punishments are somewhat stricter than for equivalent infractions today. Law 109, for example, states: 'If a wine merchant has collected a riotous assembly in her house and has not seized those rioters and driven them to the palace, that wine merchant shall be put to death.' Throughout subsequent millennia, where there has

been trade in wine there have been laws regulating production, preventing adulteration, controlling consumption, and levying taxes according to the mores of the times.

The modern wine sector has evolved in lockstep with modern wine law. The phylloxera crisis of the mid 19th century precipitated the development of national wine laws within Europe. To address the problem of COUNTERFEIT WINES in the wake of grape shortages, France created a formal legal definition for wine in 1889. It prohibited any product from presenting itself as wine unless it was 'the exclusive product of the fermentation of fresh grapes or the juice of fresh grapes'. Without this protection, wine could have followed another path to become a largely manufactured product.

While there are many older precedents, the legal notion of a nationally regulated system of geographical DELIMITATION for wine is also comparatively modern. France's AOC system was fully formed only in 1935. It established a link we now take for granted between the government, winegrowers, and the place of production. The idea of geographical distinctiveness, of TERROIR, is now virtually inseparable from the system of laws that define and control the places where wine is grown, even if these laws and the ideas they embody differ quite significantly around the world.

Many other factors have influenced the laws governing wine and thus the direction of the wine sector—perhaps none more so than PROHIBITION in the US. The current laws governing the US wine sector are a direct legacy of Prohibition, and some of the country's most successful wine producers today emerged in its aftermath.

Today, law remains a major factor in the development of the wine sector. Concerns about harmful consumption of alcohol have given rise to laws requiring minimum pricing, tax increases, and warning labels in many countries. Lawmakers wrestle with questions thrown up by winemaking techniques never contemplated in past centuries. Debate surrounds the issue of whether or not NATURAL WINE should be legally defined. Governments grapple with the implications of new technological tools such as BLOCKCHAIN that have the potential to transform legal compliance and traceability. There is no doubt that

the law will continue to play a major role in mediating the technological and social forces that shape wine in the future.

J.P.H.B.

layering, known as *marcottage* in French, is an ancient method of vine PROPAGATION which involves taking a long CANE from one vine and training it down to the soil, then burying a section to normal planting depth but with the end bent up and emerging in a desired position. This is a useful method of filling empty spaces in established vineyards but only if resistant ROOTSTOCKS are not required. Thus layering may be used only in areas without PHYLLOXERA, NEMATODES, and other soil-borne pathogens (such as BOLLINGER's Vieilles Vignes vineyard, the Greek island of SANTORINI, COLARES in Portugal, and much of Australia and Chile). The foster vine may be left connected to the parent or may be separated after it has reached normal size.

B.G.C.

laying down wine is an English expression for holding wine as it undergoes AGEING. Thus most people lay down wine in their (however notional) CELLARS. Considerable quantities of red bordeaux are laid down by collectors all over the globe, for example.

Layon, Coteaux du, 1,400 ha/3,400 acres of CHENIN BLANC making generally medium-sweet white (much richer from the best independent vignerons) in the ANJOU district of the LOIRE. TERROIR means everything here, for Coteaux du Layon should be an intense wine made ideally from several *tries* (see TRI) through the vineyard, selecting BOTRYTIZED grapes or, more frequently with CLIMATE CHANGE, those that have begun to raisin on the vine. Yields vary enormously according to the conditions of the vintage but are officially limited to 35 hl/ha for the generic appellation and 30 hl/ha for wines labelled Coteaux du Layon plus the name of one of the villages Beaulieu (-sur-Layon), Faye (d'Anjou), Rablay (-sur-Layon), Rochefort (-sur-Loire), St-Aubin (de Luigné), and St-Lambert (du Lattay), and 25 hl/ha for CHAUME. The stretch that includes the seven village CRUS is

spread along both sides of the Layon river for about 20 km/12 miles with most of the best vineyards located on the south-west-facing slopes of the right bank in an extremely narrow strip of sometimes terraced vineyards. Two small areas within this zone produce wines of such quality that they have earned their own appellations, BONNEZEAUX and QUARTS DE CHAUME. On the left bank, flatter, sandier hills also enjoy the botrytis-inducing MESOCLIMATE yet produce lighter expressions. Producers such as Claude Papin of Ch Pierre Bise vinify grapes grown on SLATE, SCHIST, CLAY, and SANDSTONE separately to demonstrate the variation in style and potential longevity. Wines may be sold as DEMI-SEC, MOELLEUX, and, sweetest of all, LIQUOREUX.

After a period in the late 1990s when maximum possible sugar levels were sought at all costs, top growers today such as Philippe Delesvaux, Dom de Juchepie, Emmanuel Ogereau, or Patrick Baudouin tend to pick at 18–23% POTENTIAL ALCOHOL, producing wines with RESIDUAL SUGAR of around 100 g/l, perhaps up to 200 g/l from the finest *tries*, which are sweet but balanced by the naturally high acidity of Chenin Blanc. In favourable vintages, some superb, long-lived wine is produced in this appellation, with the most concentrated, NOBLE ROT-affected wines designated SÉLECTION DE GRAINS NOBLES. Yet a substantial quantity of ordinary just-sweet wine is sold under the name Coteaux du Layon.

See also LOIRE, including map. P. Le.

Lazio, known as Latium in English, is the ancient homeland of the Latins (see ITALY, history), the seat of Italy's government and administration in the capital, Rome (see map under ITALY), and the IGT Lazio covering the entire region. After a decade of decline, Lazio's total vineyard area was 18,323 ha/42,000 acres in 2020 but is now showing signs of recovery. With only 3% of its wine exported and average vineyard holdings of 1.4 ha/3.5 acres, Lazio remains largely a supplier to an undiscerning local market.

Most of Lazio's 27 DOCs are dedicated to the production of white wines, with a provision for reds based on Sangiovese, Montepulciano, and Merlot. These undistinguished DOCs, in combination with a notable absence of viticultural and oenological research centres and a general lack of interest in INDIGENOUS VARIETIES, make for a lacklustre picture. This overshadows the fact that a large part of Lazio's vineyards are on VOLCANIC soils, with the potential to produce high-quality wines.

But there are signs of a renaissance, especially in the triangle of Piglio, Affile, and Olevano Romano, the epicentre of the red CESANESE, which can produce characterful, structured reds. Before PHYLLOXERA struck, this variety was once at least as important in the CASTELLI ROMANI as its whites, while nowadays the historic FRASCATI is shockingly underperforming in this DOC. The same can be said of Est!Est!!Est!!!, which in spite of its name is an insipid drink.

The Cori DOC is one of very few to remain faithful to the local varieties, the white Bellone and the red Nero Buono di Cori grape, while the DOC Aleatico di Gradoli, a sweet DRIED-GRAPE WINE, is on the brink of extinction.

The IGT Lazio has long been the resort for wines made of INTERNATIONAL VARIETIES but did little to increase Lazio's visibility and identity. In a twist of fate, this IGT now offers refuge to a new generation making original wines from indigenous varieties but, perversely, refused under the DOC system as 'atypical'. W.S.

Le. For anything prefixed 'Le', see under the next letter of the name.

lead, one of the familiar and widely dispersed heavy metals, which occurs naturally in trace amounts in all plants, therefore in grapes and, usually in microgram per litre quantities only, in wines. This

ubiquitous element, which has no known biological function in plants or animals, is now known to be a neural toxin of particular danger to children. This has resulted in the reformulation of many products, particularly petroleum products, so as to exclude lead.

History

Lead has been associated with wine since the time of ancient ROME. The Romans recognized that lead not only prevented wines from turning sour (and rescued those that already had) but also made them taste sweeter (see PLINY). What they did not know, however, is that, even when taken in only very small quantities over a long period, lead is a poison.

Its dangers were understood from the end of the 17th century when a German doctor, Eberhard Gockel of Ulm in Württemberg, noticed that the symptoms suffered by some of his wine-drinking patients matched those observed in lead miners. Gradually legislation was passed in Europe banning the use of lead in wine, but the practice continued. At last, in 1820, the campaigner Frederick Accum complained that 'the merchant or dealer who practises this dangerous sophistication, adds the crime of murder to that of fraud'.

Poisoning could result not only from the wilful addition of lead to wine. The Romans heated grape juice in lead vessels in order to produce *sapa*, a sweet concentrate used as a wine additive and in cooking, and even in the 19th century wine BOTTLES were cleaned with lead shot, thereby contaminating the wine. H.B.

Viticultural aspects

Grapes containing lead may produce wine containing lead. However, two principal sources of lead in grapes are now prohibited: leaded fuels that resulted in exhaust particles settling on both grapes and soil in roadside vineyards; and the insecticide lead arsenate, which had previously contaminated many vineyard soils, especially those with high SOIL ACIDITY. R.E.S.

Lead in modern wine

Most of the traces of lead from grapes are precipitated out with the LEES during winemaking. However, as analytical methods have improved, microgram quantities per litre are likely to be found in most wines.

The equipment used in modern wineries should not result in any lead contamination. The few wines which contained lead in milligram per litre concentrations derived it principally from capsules or FOILS which contained lead, or from lead-crystal DECANTERS. Modern bottles are made of lead-free glass, and lead foils were banned in the US in 1996 and were no longer in use elsewhere by the end of the 20th century. On older wines made before the ban, seepage of wine around the cork can corrode the foil; if the lip of the bottle is not thoroughly cleaned before pouring, the wine may be contaminated by some of the lead salt.

Lengthy storage of wines in lead-crystal decanters provides time for the wine acids to leach some lead from the glass, but keeping a wine in a lead-crystal glass or decanter for the usual period of no more than a few hours is too short for dangerous amounts of lead contamination. One study found a lead concentration of around 5 mg/l in PORT left in a lead-crystal decanter for four months, so that 10 l of it would have to be consumed in a short time for a potentially toxic human intake of lead.

Analyses of thousands of representative samples of wine suggest that the lead content of wines is decreasing in general but in the early 1990s ranged from 0 to 1.26 mg/l, with the average lead content being 0.13 mg/l, values well below any legal maximum. An Australian study found that there was minimal uptake of lead from wine when it was consumed with food. H.B., R.E.S. & J.E.H.

leaf (*feuille* in French, *Blatt* in German, *foglia* in Italian, *hoja* in Spanish). Vine leaves range in size up to that of a dinner plate but are normally the area of a human hand (100–200 cm2). Their individual area correlates with shoot VIGOUR and also varies with vine variety (Merlot has large leaves, for example, while Gewürztraminer has small leaves). The vine is a leafy plant with sometimes many hectares of total leaf area per hectare of vineyard. A proportion of these leaves will be shaded and therefore not PHOTOSYNTHETIC. The total leaf and shoot system of a vine is known as the CANOPY.

The green, flat zone of the leaf connected to the stem by the PETIOLE is known as the leaf blade, or lamina. The lamina of a grape leaf expands to nearly its full area in six or more weeks, growing to a shape and form characteristic for each VINE VARIETY. The arrangement of the five lobes, the shape of the 'teeth' at the edge of the leaf, the size and shape of the sinuses, and especially the angle and lengths of the main veins are features that are measured (ampelometry) for vine variety identification by AMPELOGRAPHERS.

Leaf colour is responsive to VINE NUTRITION, becoming yellow all over with deficiencies of nitrogen and SULFUR, or patterned with yellow or red and/or dead zones with most other deficiencies. Similarly, yellow and dead areas on leaves occur with some virus infections and as a result of HERBICIDE contamination, although usually in different patterns. With the onset of autumn, leaf colour changes naturally from green to yellow or red, depending on the vine species and the presence of certain VIRUS DISEASES. See LEAFROLL VIRUS, for example. B.G.C.

leaf aldehydes make wines taste HERBACEOUS.

leaf fall, the process which occurs naturally in autumn, often after the first FROST, which marks the end of the VINE GROWTH CYCLE. Ideally this is some time after HARVEST, so that the vine has been able to build up its reserves of the CARBOHYDRATES important for growth the following spring. See also DEFOLIATION. R.E.S.

leafhoppers, members of the insect family Cicadellidae which can cause both direct and sometimes serious indirect damage to vineyards. In California, both the grape leafhopper, *Erythroneura elegantula*, and the closely related and biologically similar variegated grape leafhopper, *Erythroneura variabilis*, cause damage to grapes. They begin to feed on grapevine foliage as soon as it appears in spring, by sucking out the contents of leaf cells. As injury progresses, heavily damaged leaves lose their green colour and PHOTOSYNTHESIS is much reduced. TABLE GRAPES are spoilt by spots of leafhopper excrement. The damage caused is in direct proportion to the numbers, so when there are 20 or fewer leafhopper nymphs per leaf, no control is required. If there are more, insecticides are used, but leafhoppers also have a number of natural enemies, the most important being a tiny wasp, *Anagrus epos*.

Some other leafhopper pests do not cause direct damage but spread important grape diseases. PIERCE'S DISEASE of the Americas is spread by so-called sharpshooter leafhoppers (subfamily Cicadellinae). The bacteria that cause Pierce's disease inhabit the XYLEM of the plants, and xylem sap-feeders can transmit the bacteria from plant to plant. FLAVESCENCE DORÉE is caused by a PHYTOPLASMA that inhabits the PHLOEM and appears to be transmitted exclusively by the leafhopper *Scaphoideus littoralis*. A.H.P. & R.E.S.

Bettiga, L. J. (ed.), *Grape Pest Management* (3rd edn, 2013).

leaf removal, vineyard practice aimed at helping to control BOTRYTIS BUNCH ROT and other BUNCH ROTS and at improving GRAPE COMPOSITION and therefore wine quality. Typically the leaves are removed around the bunches to increase exposure to the sun and wind. The bunches dry out more quickly after dew and rain so that moulds are less likely to develop. Further, increased exposure to SUNLIGHT, especially to ULTRAVIOLET RADIATION, helps the berries produce more of the PHENOLICS and FLAVOUR COMPOUNDS important in wine quality. The optimal time is when berries are pea-sized, according to studies by Deloire. Grape SUGARS are also increased and MALIC ACID and METHOXYPYRAZINES are reduced, all of which contribute to improved wine quality. Leaf removal is also used to improve the colour of black and red TABLE GRAPES.

In Europe it is common to remove leaves nearer to the time of harvest, primarily to reduce the risk of botrytis bunch rot. Studies by Poni in Italy have shown that removal of lower, mature leaves on the shoot by the time of flowering reduces fruit set or berries per bunch. As a result, the bunches are looser, with less berry-to-berry contact, and are therefore less prone to botrytis bunch rot. Sugar and ANTHOCYANIN levels were also found to be higher. The leaves adjacent to the bunches are important suppliers of CARBOHYDRATES by photosynthesis, so removal may have negative effects on bunch development and RIPENING.

Excessive leaf removal in warm to hot climates can have negative effects on fruit composition (see SUNBURN) because the bunches are heated by the sun to temperatures up to 15 ºC/27 ºF above air temperature, and consideration must also be given to the increasing incidence of HEATWAVES. The alternative is to do less removal on the western side of the canopy to avoid exposure when daily temperatures are at their highest in the afternoon.

Traditionally leaf removal has been done by hand, requiring about 50 hours of LABOUR per hectare (2.5 acres), but machines which take less than five hours per hectare to remove leaves by suction and/or

cutting have been developed, and manual leaf removal can often be excessive unless labour is well supervised.

Decreasing dependence on AGROCHEMICALS in the vineyard has led to renewed interest in leaf removal. As well as making the fruit less prone to FUNGAL DISEASES by improving aeration, leaf removal can also increase the effectiveness of such chemicals as may be applied to protect the fruit. R.E.S.

leafrollers. See MOTHS.

leafroll virus, virus disease that is widespread in all countries where grapes are grown. The disease is now thought to be due to a complex of ten different filamentous viruses referred to as grapevine leafroll associated viruses (GLRaVs). Of all the VIRUS DISEASES of vines, it can have the most serious effects on wine quality. These dramatic effects are not understood by the many appreciative TOURISTS in wine regions who marvel at the attractive autumnal red colours of vineyards. Few realize that these colours often indicate the presence of a serious disease, although other factors may also contribute to autumnal colours. Leafroll virus causes YIELD to be reduced by as much as 50%. Wine quality is also affected because of delayed RIPENING. Thus wines from infected vines are lower in alcohol, colour, flavour, and body. The disease does not kill vines, so they are infrequently removed, yet removal is the only known treatment.

Characteristic symptoms are downwards and backwards rolling of the leaf blade in autumn. The area between the leaf veins turns red for black-fruited varieties and, less obviously, yellow for white-fruited varieties. Some varieties such as Cabernet Franc and Chardonnay show the classic symptoms; others such as Riesling and most ROOTSTOCKS show no symptoms at all. Infected vines may be stunted, but this is hardly sufficient for diagnosis.

Leafroll probably originated in the Near East along with VITIS VINIFERA and was carried along with grape CUTTINGS. The disease is spread chiefly by humans, using cuttings or buds from infected vines. Cuttings for BUDWOOD are taken when the vines are dormant and no leaves are present to show symptoms, making it impossible to distinguish healthy from infected plants. Once infected planting material is used, then the new vineyard is immediately infected and will perform at below its potential for its lifetime.

As GRAFTING on to PHYLLOXERA-resistant rootstocks has become more commonplace, this virus disease, like many others, has become more widespread because grafting increases the chances of using infected material. Thus, many OLD WORLD vineyards planted early in the 1900s show the virus. Some tasters believed that grafting to phylloxera-resistant rootstocks from the 1880s onwards led directly to a decline in wine quality. In fact this supposed drop in quality may have been an effect of the increased spread of leafroll virus due to grafting.

Of recent concern are reports of the natural spread of GLRaV, especially strain 3, beginning in South Africa in 1985 and subsequently to Spain, Italy, Australia, California, and New Zealand. This strain can have significant effects on YIELD and GRAPE composition. MEALYBUGS and soft scale have been shown to be vectors. Successful management programmes have been introduced in South Africa, New Zealand, and California involving removing affected vines, control of vectors, and replanting with disease-free vines. Since disease symptoms are harder to detect on white wine grape varieties, CHIP BUDDING a dark-skinned grape variety (preferably Cabernet Franc) on the trunk of the white vine can reveal the virus.

Because there is no control for this disease, growers should ensure that they plant only material that is tested free of the virus. The University of California at DAVIS led the world in developing a 'clean stock' programme, now known as FOUNDATION PLANT SERVICES, with the result that vineyards planted in California since the early 1960s are generally virus free. In addition, this virus-tested planting stock has been exported; for example, many of the vineyards of Australia and New Zealand are planted with such material. The virus is detected by INDEXING, or by using faster and more reliable methods such as immunoassays (see ELISA) or nucleic acid-based RT-PCR. Healthy planting material is produced by eliminating viruses using THERMOTHERAPY or heat treatment or, more reliably, by TISSUE CULTURE. Propagation is recommended from these 'clean' mother plants.

leaf to fruit ratio, viticultural measurement which indicates the capacity of a vine to ripen grapes. The ratio of vine leaf area to fruit (grape) weight determines just how well a vine can mature grapes and how suitable they will be for winemaking. Although it is less understood and discussed, it can have an even more important effect on wine quality than YIELD, although it is the latter that is highly regulated in most European CONTROLLED APPELLATIONS and frequently discussed by OENOLOGISTS and WINE WRITERS.

This ratio indicates the vine's ability to manufacture compounds important for grape RIPENING. If most leaves are exposed to the sun,

then the leaf area is generally proportional to the ability of the vine to make SUGARS by PHOTOSYNTHESIS. Against this should be set the weight of grapes to be ripened.

A low value of leaf to fruit ratio, for example 5 sq cm per g grape weight, indicates that the fruit will ripen sluggishly, and so levels of SUGAR IN GRAPES will increase slowly along with PHENOLICS and FLAVOUR, but PH will be relatively high for the corresponding sugar level. The other extreme of, say, 30 sq cm per g grape weight suggests a very leafy vine with a small crop of grapes, but one which will ripen quickly and completely and so produce better wine quality than for the low leaf to fruit ratio. Such low yields, however, may be uneconomic, and so most vine-growers would aim to manage their vineyards with a sufficient but not excessive leaf to fruit ratio (see vine BALANCE). A value of between 10 and 15 sq cm per g grape weight is considered adequate for ripening of most vine varieties, although higher values are considered necessary by some for PINOT NOIR and perhaps MERLOT. Also, high leaf to fruit ratios must be carefully managed in the vineyard in order to avoid any negative effects on wine quality due to canopy SHADE. R.E.S.

leafy, tasting term usually used synonymously with HERBACEOUS.

Leánka, meaning 'maiden', widely planted Hungarian white wine grape identified by DNA PROFILING as Romania's FETEASCĂ Albă. Varietal Leánka has long been produced in EGER and neighbouring Bükk and Mátra. Total plantings were a declining 604 ha/1,493 acres in 2020. It

may be a parent of KIRÁLYLEÁNYKA (see FETEASCĂ Regală). For more details, see HUNGARY.

Lebanon, one of the oldest sites of wine production, incorporating some of the ancient eastern Mediterranean land of CANAAN and, subsequently, most of PHOENICIA, whose people were arguably the first to treat wine as a tradable commodity (see ORIGINS OF VINICULTURE). In Baalbek—the ancient Greek, and then Roman, city in the Bekaa Valley which is the vine-growing centre of Lebanon—is the temple of BACCHUS, built in the middle of the 2nd century.

In the Middle Ages, the rich wines of Tyre and Sidon were particularly treasured in Europe and were traded by the merchants of VENICE, to whom these ports belonged for much of the 13th century. In 1517, what is now Lebanon was absorbed into the Ottoman Empire and winemaking was forbidden, except for religious purposes, allowing Lebanon's Christians, mainly Maronites and Greek and Armenian Orthodox, to perpetuate a tradition of viniculture. In 1857, the Jesuit missionaries of Ksara introduced new vine varieties—mainly CINSAUT and CARIGNAN with some Grenache and Ugni Blanc—and production methods from French-governed Algeria, laying the foundations of the modern Lebanese wine industry.

The French administration that governed Lebanon between the wars created unprecedented demand for wine, while Lebanon's post-independence role as a cosmopolitan financial hub allowed the new wine culture to take hold. It lasted until 1975 when the country descended into a 15-year civil war. Although just two harvests were lost to the fighting, only Ch Musar, which recognized the need to penetrate new markets if it was to survive, genuinely thrived during this turbulent period, establishing an enduring fan base in the UK.

With peace came growth. The success of Ch Kefraya, which began producing wine in 1978 after decades of supplying grapes to other producers, and the popularity of NEW WORLD wines galvanized Lebanon's few established wineries and inspired a new generation, many of whom were producers of arak, the aniseed-flavoured eau-

de-vie that is the country's national drink, to exploit the potential of the Bekaa Valley's formidable TERROIR.

In the quarter-century since the mid 1990s, the number of wineries has increased from five to nearly 50. In 2020, total production was estimated to be 9 million bottles from 2,000 ha/5,000 acres of vines dedicated to wine production. In 2013, a National Wine Institute, a public/private body, was officially established with a view, inter alia, to creating a system inspired by France's AOC. In its first eight years it achieved next to nothing, but the election of a new board at the end of 2021 offered some hope that the institute might be given the funding and the latitude to execute its mandate. Meanwhile, the Union Vinicole du Liban (UVL), a loose association of leading producers, remains a credible and effective organization.

The Bekaa Valley is the epicentre of the wine industry. The majority of the vineyards are in the Western Bekaa, Zahlé, and more recently the drier regions of Baalbek and Hermel. More a plateau than a valley, and sitting at an ELEVATION of around 1,000 m/3,280 ft between the Lebanon and Anti-Lebanon mountain ranges, the Bekaa enjoys dry summers, cool nights, and consistent rainfall so that the grapes rarely ripen before the middle of September. Minimal vineyard treatments are needed, and almost half of all vines for wine production are trained on WIRES, although the sprawling and vigorous GOBELET form is still widely used, offering SHADE in a region with little risk of POWDERY MILDEW. Average yields are around 5 tonnes/ha.

Other regions are emerging. Home to eight producers, the northern district of Batroun has a MESOCLIMATE that allows it to produce wines at an elevation which would be otherwise too low in a hot country like Lebanon: its hills and valleys create a wind corridor, funnelling cooling clouds from the Mediterranean on an almost daily basis in summer. The vineyards of the west, sea-facing Mount Lebanon, the Chouf, and Jezzine in south Lebanon have different TERROIRS and have contributed to expanding Lebanon's variety of styles, often by planting varieties such as ALBARIÑO, TOURIGA NACIONAL, and SAPERAVI, not found in the Bekaa.

French influence on the country is still apparent in the grape varieties most commonly planted and the wines made. Ch Musar remains Lebanon's most celebrated producer, its top wine a gamey blend of Cabernet Sauvignon, Carignan, and Cinsaut. It has been both fêted as a work of genius and dismissed as an anachronism, flawed with excessive VOLATILE ACIDITY and hype, but its fans are legion. Influenced by a close relationship with the BARTONS of Bordeaux in the early 1960s, the Hochars introduced DESTEMMING and BARREL AGEING in new French OAK.

But styles are changing. Faouzi Issa at Domaine des Tourelles has led a movement to champion Lebanon's so-called heritage varieties, Cinsault and Carignan, as well as OBEIDEH and MERWAH. At Ch Kefraya, whose Cabernet–Syrah blend Comte de M 1996 convinced the outside world that there was more to Lebanese wine than Ch Musar, there is now Saperavi made in AMPHORA, as well as a blend of Assouad Karech and Asmi Assouad, two local varieties 'rediscovered' by Kefraya's winemaker Fabrice Guiberteau.

Even Ch Ksara, Lebanon's biggest producer, responsible for more than one-third of all the wine sold in Lebanon, has been gradually shedding its reputation for classic French blends such as its 'Chateau' wine, a MÉDOC tribute act that debuted in 1921, introducing VARIETAL bottlings of Merwah and OLD VINE Carignan.

In total, around 40 varieties are grown in Lebanon, including a parcel of the little-known French variety ARINARNOA and the local white-wine variety Meksassi.

High-elevation Lebanese whites, once an afterthought, are now being taken seriously. In addition to Chardonnay, Sauvignon Blanc, and to a lesser extent Viognier, the increasingly popular INDIGENOUS VARIETIES Obeideh and Merwah (or Merweh) are demanding long-overdue respect in both varietal wines and blends.

Both Sept, a microwinery from the tiny village of Nehla in the Batroun region, and the equally bijou Vertical 33, perched on an east-facing mountain overlooking the Bekaa Valley, have championed indigenous and 'heritage' grape varieties, while Sept's owner, Maher

Harb, made an even more avant-garde statement with Lebanon's first SKIN-FERMENTED Obeideh. M.R.K.

www.winesoflebanon.co.uk

Lébrija, a VINO DE CALIDAD in Andalucía in southern Spain promoted by the González Palacio family. While their vineyard is in the JEREZ cultivation area, it does not fall within the ageing area, so they cannot use terms such as MANZANILLA even though the wines are made in the image of SHERRY. F.C.

lees, old English word for the dregs or sediment that settles at the bottom of a container such as a FERMENTATION VESSEL. Wine lees are made up of dead YEAST cells, the cell membranes of pulp, stem and skin fragments, and insoluble salts and macromolecules that are deposited during the making and ageing of wine. A distinction is sometimes made between fine lees and gross lees, the latter comprising mainly the yeast cells, both dead and viable, plus cellular matter from the grape.

In the production of everyday wines, clear wine is separated from the lees as soon as possible after FERMENTATION and quickly clarified and stabilized (see CLARIFICATION and STABILIZATION). Some wines, especially white, may be deliberately left on their lees for some months in order to benefit from lees AUTOLYSIS. This is called LEES CONTACT.

Fine wines left on lees for a considerable time usually require much less drastic processing than more ordinary wines that were

separated early from the lees, because autolysis releases MANNOPROTEINS from the lees, and these naturally stabilize wines by inhibiting the crystallization of TARTRATES and encouraging the precipitation of PROTEINS.

Deposits of FINING agents used in clarification such as BENTONITE and CASEIN are also referred to as lees. They are usually simply settled to permit the recovery of as much wine as possible but in some large wineries are processed by ROTARY DRUM VACUUM FILTRATION to salvage a bit more wine with a strong lees flavour.

Once the maximum amount of good wine has been recovered, usually by RACKING after prolonged SETTLING, the lees may be used to remove any unwanted colour from wines such as champagne. The lees are also valuable for their potassium acid tartrate (cream of tartar) and small amounts of alcohol. Other methods of lees disposal need to ensure they minimize the environmental impact of organic WINERY WASTE. V.L.

lees contact, increasingly popular and currently fashionable winemaking practice known to the ancient Romans (see CATO) whereby newly fermented wine is deliberately left in contact with the LEES. This period of lees contact may take place in any container, from a bottle (as in the making of any BOTTLE FERMENTED sparkling wine where yeast AUTOLYSIS produces desirable flavour compounds) to a large tank or vat—although a small oak BARREL is the most common location for lees contact. It may take place for anything between a few weeks and, in the special case of some sparkling wines, several years (see SPARKLING WINEMAKING). Most commonly, however, lees contact is prolonged for less than a year after the completion of FERMENTATION.

Lees contact encourages MALOLACTIC CONVERSION because the LACTIC ACID BACTERIA necessary for malolactic conversion feed on micronutrients in the lees. This has the effect of adding complexity to the resultant wine's flavour. Many producers, particularly those of

white BURGUNDY and other wines based on CHARDONNAY grapes, try to increase the influence of the lees on flavour by LEES STIRRING. Both lees contact and lees stirring also enhance the structure and MOUTHFEEL of a wine since some molecules released from the dead yeast cells by autolysis can significantly reduce astringency and increase body.

The results of lees ageing on Chardonnay in barrel have been summarized by Gambetta et al.: yeast lees contribute to floral and fruity aromas, but overall they reduce the ESTER content of the wine and release polysaccharides (mainly MANNOPROTEINS) into the wine; the lees adsorb both positive ester-derived aromas but also negative off-odours (MERCAPTANS); they attenuate the impact of wood from the barrel; and they create an overall REDUCTIVE environment that protects the wine from OXIDATION. Lees contact also naturally improves the PROTEIN and TARTRATE stability of wines.

White wines made with deliberate lees contact are sometimes described as SUR LIE, a description commonly used to differentiate one type of MUSCADET from another, although in this case small barrels rarely play a part in the process. Lees contact even in BULK STORAGE is increasingly used as a way of increasing and stabilizing flavour in everyday white wines.

Red wines, with their more robust flavours, gain less obvious benefit from lees contact not least because the lees include much more vegetal matter and fewer yeast cells. Neverthless, there is a growing trend to leave red wine on the lees even though it increases the risk of BRETTANOMYCES. Ageing red wines on lees has been shown to reduce BITTERNESS and ASTRINGENCY and give roundness and more BODY to red wines (Del Barrio-Galán et al., 2011)—more so than ageing in barrel alone (Fernández et al., 2011). This is due at least in part to the adsorption of condensed TANNINS to yeast lees (Mazauric and Salmon, 2006) or to yeast POLYSACCHARIDES. Ageing on lees has also been shown to improve the colour stability of red wines (Escot et al., 2001).

Wines left in contact with lees in large stainless-steel tanks after fermentation are very likely to develop HYDROGEN SULFIDE, disulfide, or mercaptan odours. This is why it is important to rack new wine from its gross lees (see LEES), so that the lees level does not become too thick, or to keep the wine separate from the lees for a month, during which time they lose their ability to generate VOLATILE SULFUR COMPOUNDS. V.L.

lees stirring, *bâtonnage* in French, is the winemaking operation of mixing up the LEES in a barrel, cask, tank, or vat with the wine resting on them. It is an optional addition to the process of LEES CONTACT and is often employed, particularly for whites which have undergone BARREL FERMENTATION. As the French name suggests, such stirring is usually done with a stick, although some racking systems allow the barrel itself to be rotated *in situ*.

Lees stirring is done partly to avoid the development of malodorous sulfur compounds by homogenizing the REDOX POTENTIAL in the upper and lower parts of the barrel. This prevents the formation of HYDROGEN SULFIDE in the lees (see LEES CONTACT).

Stirring up the lees in the barrel also affects OAK FLAVOUR, however. If the lees are stirred, they act as a buffer between the wine and the wood because their cell walls adsorb compounds extracted from the wood such as TANNINS and PIGMENTS. Wines subjected to lees stirring therefore tend to be much paler and less tannic than those whose lees are not stirred.

Regular lees stirring also stimulates the release of MANNOPROTEINS, thereby improving the stability of the wine. Some producers believe that the technique makes the wine heavier and that over-zealous stirring may increase the risk of PREMATURE OXIDATION, but stirring actually helps the lees consume any dissolved oxygen in the wine, reducing the risk of oxidation. V.L.

left bank, an expression for the BORDEAUX wine regions that are on the left bank of the rivers GARONNE and GIRONDE. It includes all the MÉDOC appellations, including MARGAUX, PAUILLAC, ST-ESTEPHE, and ST-JULIEN, as well as GRAVES, CÉRONS, SAUTERNES, BARSAC, and PESSAC-LÉOGNAN. The most obvious characteristic shared by the red wines of these appellations, as distinct from RIGHT BANK appellations, is that the dominant grape variety is Cabernet Sauvignon rather than Merlot and Cabernet Franc.

leftover wine in an opened container such as a half-empty bottle is prey to OXIDATION, and steps must be taken in order to prevent it turning to VINEGAR—which could happen within hours or even minutes for a very old wine, within two or three days for most young table wines and most bottle-matured PORT, within a few weeks for a robust wood-matured port such as a tawny, or OLOROSO sherry, or within months, possibly years, for most MADEIRA.

Because OXYGEN is the villain in this piece, the easiest way to avoid spoilage of leftover wine is to decant it into a smaller container, perhaps a half-bottle, which approximates as closely as possible to the volume of wine left. There are also patent devices for filling the ULLAGE in a bottle or decanter with INERT GAS, by pumping or spraying, or an attempt can be made to create a vacuum with a pump device. Some drop small, inert objects such as spheres of glass into an opened bottle to restore the fill level to the bottleneck. Leftover wine, no matter what the container or colour, is best stored cool to slow the reactions involved in its deterioration.

The most satisfactory way of disposing of wine leftovers is surely to drink them, and the leftovers of some wines, particularly concentrated young red wines, can taste better, and certainly softer, after a day or even two on ullage (see AERATION and DECANTING).

Leftover wine can also be used quite satisfactorily as COOKING wine or to make vinegar.

legno riccio, Italian name for the RUGOSE WOOD complex of vine VIRUS DISEASES.

legs, outmoded tasting term and alternative name for the TEARS left on the inside of a glass by some wines.

legumes, a common component of vineyard COVER CROPS due to their ability to fix atmospheric NITROGEN into the soil. Legumes are

members of the Leguminosae family and include clovers, trefoils, lucerne, lupins, and medics. R.E.S.

Leithaberg, wine region in AUSTRIA covering 2,878 ha/7,112 acres in 2021. It is named for the predominantly LIMESTONE and SCHIST Leitha Hills (the Leithagebirge) that, prior to the creation of BURGENLAND, formed the Austro-Hungarian border and that extend to the western and northern fringes of the NEUSIEDLERSEE. The Leithaberg DAC applies to wines from what was formerly known as the Neusiedlersee-Hügelland growing region, including red and dry whites grown in Rust (which has its own DAC, RUSTER AUSBRUCH, for sweet wine). Leithaberg DAC reds must be at least 85% BLAUFRÄNKISCH—a grape variety that represented 21% of the region's vineyard surface area in 2021—together with any combination of Pinot Noir, ST-LAURENT, and/or ZWEIGELT. They must be OAK-AGED and not released before September of the second year following harvest. Whites may comprise any combination of Pinot Blanc, Chardonnay, GRÜNER VELTLINER, and/or NEUBURGER. The region's non-DAC wines are labelled for their state of origin, Burgenland.

Burgenland's state capital, Eisenstadt, and several of its hillside suburbs—Müllendorf, Grosshöflein, and St Georgen in particular—are home to outstanding reds and whites which benefit from CALCAREOUS soils and prevailing breezes. East of Eisenstadt, Schützen-am-Gebirge reflects a transition to soils based on weathered GNEISS and mica SCHIST, outstanding for Blaufränkisch but also supportive of white varieties, which dominate the next village north, Donnerskirchen, where even RIESLING flourishes on an especially high stretch of hills. Closer to the Neusiedlersee and running north–south, Breitenbrunn, Purbach, and Oggau also distinguish themselves. Although Rust is famous for sweet whites, it is also where modern appreciation of VARIETAL Blaufränkisch arguably began, with Ernst 'ET' Triebaumer's 1986 Mariental bottling. Möbisch, on Lake Neusiedl immediately south of Rust, St Margarethen, Siegendorf, and Zagersdorf—more or less midway between the lake and the Leitha range—are worth noting for

reds from Blaufränkisch and St-Laurent as well as for both dry and sweet whites. D.S.

Lemberger, also known as Blauer Lemberger and occasionally Limberger, is the German name for the black grape variety much more widely grown in Austria as BLAUFRÄNKISCH and in Hungary as KÉKFRANKOS. Germany has very much less of the variety planted, but like all red varieties it has steadily become more popular so that by 2020 there were 11,940 ha/4,794 acres in all, mostly in Württemberg, where it is so successful that it may carry the GROSSES GEWÄCHS designation.

Lemberger once had a limited following in WASHINGTON State, but plantings had fallen to 22 ha/54 acres in 2017.

Len de l'El, also spelled Len de l'Elh, a primary but not necessarily major ingredient in the white wines, especially the sweet ones, of GAILLAC. Its name is local dialect for *loin de l'œil*, or 'far from sight'. This vigorous vine needs a well-ventilated, well-drained site if it is to escape ROT in lesser years. All but three of France's 626 ha/1,547 acres in 2019 were in Gaillac country.

length or persistence of flavour is an important indicator of wine quality. See the tasting term LONG.

Lenz Moser, a TRAINING SYSTEM developed in Austria in the 1920s by Dr Lenz Moser III. It employs wider rows (about 3.5 m/11.5 ft) and higher trunks (1.3 m) than had previously been the norm, thereby reducing VINE DENSITY. Lenz Moser's ideas influenced Professor Nelson SHAULIS, who developed the GENEVA DOUBLE CURTAIN.

The Lenz Moser system found favour in parts of Europe in the mid 20th century because it decreases LABOUR and therefore production costs, without any need for special machinery. French and German

studies found reductions in fruit quality, however, probably because of SHADE in the fruit zone, and it is now less common even in Austria. It is also known as high culture, or *Hochkultur* in German. The name is probably more familiar as that of one of the biggest wine producers in Austria, with operations as far afield as China. R.E.S.

León, promising DOP created in 2008, encompassing some 1,465 ha/3,515 acres of vineyards south of the BIERZO appellation in north-west SPAIN on well-drained, LIMESTONE-based ALLUVIAL terraces. This is the birthplace of the red PRIETO PICUDO grape and shares with Asturias the white Albarín, so that its wines are quite different from those of its neighbours that are dominated by Tempranillo and Mencía.
V. de la S. & F.C.

Léon Millot, minor French HYBRID producing small quantities of dark-red wine in northern Europe and North America, where its early ripening is valued.

Le Pin. This micro-estate in POMEROL originally consisted of just one hectare of vines on a gentle, south-facing slope of GRAVEL and SAND, with deep CLAY subsoils. It was bought for a million French francs in 1979 by three members of the Thienpont family, Belgian NÉGOCIANTS who also own nearby Vieux Château Certan in Pomerol and properties in the FRANCS Côte de Bordeaux. The vineyard had previously been farmed by a grower in Lalande-de-Pomerol *en* MÉTAYAGE, and its produce had for years been vinified there and sold as Le Pin, but not as a CHÂTEAU BOTTLED wine. When the Thienponts bought it, one-third of the vines were only a year old. The first commercial vintage was 1979, and until the mid 1980s the wine was quite a hard sell. Jacques Thienpont, who commuted between Belgium and Bordeaux, managed to buy out his two co-investors in 1988 and, by adding a further 1.5 ha in three contiguous plots, now owns and manages the grand total of about 2.5 ha/6 acres, all Merlot. The wine was always distinctive, deep, and luscious with an

almost Burgundian richness, absolutely in tune with the FASHION for early-maturing, sensual wines. Le Pin was the first red bordeaux to have its MALOLACTIC CONVERSION completed in 100% new oak barrels (no great investment when the total production of the property averaged 600 cases). Demand for this rarity escalated towards the end of the 1980s, and the price of the fashionable 1982 vintage reached a peak of £2,500 a bottle in 1997, just before the ASIAN boom began to falter. Le Pin's success inspired the rash of new, small, luxury RIGHT BANK estates (see GARAGE WINES). In 2011 a new winery designed by Belgian architects Robbrecht en Daem was inaugurated. In 2010 Jacques Thienpont bought 8 ha/20 acres of ST-ÉMILION grand cru vineyard, the former Ch Haut-Plantey, renamed L'If (the French word for a yew tree, another conifer). The cellars are located next door to Ch Troplong Mondot (incidentally also owned by the Thienpont family between 1921 and 1933). A third estate, L'Hêtre (French for 'beech tree') in CASTILLON, was added to the portfolio in 2016.

Leroy, famous name in French wine, not just because Baron le Roy of CHÂTEAUNEUF-DU-PAPE was instrumental in the development of the AOC system, but also in the CÔTE D'OR. The NÉGOCIANT house Maison Leroy was founded in the small village of Auxey-Duresses in 1868, and its extensive warehouses there still house substantial stocks of fine, mature burgundy. Henri Leroy joined the family firm in 1919 and made his fortune exporting fortified wine from the Charentes to Germany between the two World Wars. This enabled him to buy a half-share in the world-famous DOMAINE DE LA ROMANÉE-CONTI (DRC), a holding inherited equally by his two daughters Pauline Roch-Leroy and Lalou Bize-Leroy on his death in 1980.

Lalou, a prodigious taster, avid rock climber, and glamorous dresser, had been co-director of the Domaine since 1974 and contributed considerably to its winemaking policy of quality above all. She also ran Maison Leroy, but Burgundy's steady move towards DOMAINE BOTTLING made her job of buying the finest raw materials for

her négociant skills of ÉLEVAGE increasingly difficult. In 1988, helped by an £8 million investment from her Japanese importers Takashimaya, she succeeded in buying the Domaine Noëllat of VOSNE-ROMANÉE, an already fine canvas on which to paint her vision of the perfect domaine, soon renamed Domaine Leroy. This domaine now comprises 22 ha/54 acres of some of the Côte d'Or's finest vineyards, including a total of nearly 7 ha in nine different GRANDS CRUS.

This effectively entailed setting up in competition with DRC, since the Domaine Leroy is based in the same village and, like DRC, has holdings in the grand crus ROMANÉE-ST-VIVANT and RICHEBOURG. Unfettered by the commercial considerations of the dozen or so shareholders in DRC, Lalou was able to institute fully BIODYNAMIC VITICULTURE, almost uneconomically low YIELDS, and every possible winemaking luxury. The wines, which come from a much broader range of (mainly red-wine) appellations than those of DRC, are extremely concentrated, expressing as definitively as possible their exact geographical provenance.

Lalou also owns the Domaine d'Auvenay, another biodynamically farmed enterprise founded in 1988, with total holdings of around 4 ha in 80 PARCELS, including small plots in five different grands crus.

A sales company, Société Leroy, enjoyed the exclusive distribution rights to DRC wines, some of the most highly priced in the world, in all markets except the US and UK until a bitter dispute in 1992 which ousted Lalou from co-directorship of DRC. Today, only Domaine Leroy prices rival those of DRC.

Lalou's daughter Perrine Fenal is now co-director of the Domaine de la Romanée-Conti.

Les Aspres became part of Côtes du ROUSSILLON-Villages in 2017. Covering 19 villages in the Eastern Pyrenees, the AOC is devoted exclusively to red wines blended from at least three of the four allowed grape varieties (Syrah, Mourvèdre, Grenache, Carignan) and aged at least 12 months. R.E.G.

Les Baux de Provence . A spectacular and famous small hilltop settlement in the far west of PROVENCE dominated by Michelin-starred restaurants and their customers' cars gives its name to a local AOC created in 1995 and substantially amended since. The AOC's 232 ha/573 acres sit mainly on LIMESTONE rubble from the craggy Alpilles chain, and it is slightly warmer and wetter than much of the Coteaux d' AIX-EN-PROVENCE AOC, from which it was ceded. Red wines are made from Grenache, Syrah, and Mourvèdre, which must together make up at least 60% of the blend, together with Cinsaut, Counoise, Carignan, and Cabernet Sauvignon (the last of which must represent no more than 20% of the total, thus forcing the respected Domaine de Trévallon to use the IGP denomination ALPILLES). Cinsaut takes the place of Mourvèdre in the rosés, which make up about two-fifths of the appellation. Clairette, Grenache Blanc, and Vermentino are the principal grapes for the white version although Marsanne, Roussanne, Bourboulenc, and Ugni Blanc may be included in the blend. The region prides itself on its high percentage of winegrowers practising ORGANIC and BIODYNAMIC VITICULTURE, even having (unsuccessfully) petitioned the INAO to require organic viticulture in the appellation regulations. The mistral wind helps to keep the vines healthy. E.A.G.

Lesotho. One hectare (2.5 acres) of mainly Chenin Blanc with some Pinotage was planted in 2008 in this land-locked country surrounded by SOUTH AFRICA at an ELEVATION of 1,791 m/5,876 ft some 25 km/15.5 miles east of Maseru, with guidance from the South African winery Groot Parys 1,100 km/685 miles to the south. Challenges include spring HAIL, summer rain, and scarcity of electricity and water, but by 2022 the Thamea family had doubled the size of the vineyard and was distributing wines under the Sani Wines label. Other Lesotho wineries import South African fruit for their wines.

Lesquerde, far western communal appellation of Côtes du ROUSSILLON-Villages in a mountain enclave dominated by GRANITE. Carignan, Grenache, and Syrah provide the backbone of these concentrated reds. R.E.G.

Lessona, tiny historical and increasingly important red wine DOC in the Vercelli Hills in the subalpine north of the PIEMONTE region of north-west Italy. On just 17 ha/42 acres a growing number of producers make a wine from NEBBIOLO grapes (here called SPANNA), optionally softened with some UVA RARA or VESPOLINA from vineyards on yellow SANDS of marine origin. The Sella estate was established way back in 1671. In 1999 Paolo De Marchi, former owner of Isole e Olena in Chianti Classico, revitalized his family estate, Villa Sperino, inspiring others to follow, including a new generation of winegrowers who have started buying land here. W.S.

L'Étoile, small appellation in the JURA region of eastern France which specializes in traditional, OXIDATIVE white wines aged in non-topped-up barrels. These are often pure Chardonnay but may be Chardonnay blended with the local SAVAGNIN grape. From the 2010s there has been an increasing number of *ouillé* (topped-up) Chardonnays from these fossil-laden MARL soils. It also produces VIN DE PAILLE, CRÉMANT du Jura, and the extraordinarily nutty VIN JAUNE. W.L.

Leyda, subvalley of San Antonio Valley in CHILE that began to be planted in the late 1990s and is now a reliable source of Sauvignon Blanc, Pinot Noir, and Chardonnay grown under the influence of cool Pacific Ocean breezes. P.T.

Liatiko, ancient Cretan vine that is this Greek island's third most planted, producing relatively soft, light red, usually blended with the stronger MANDILARIA and KOTSIFALI to make sweet wines (exported in

great quantity by Venetian merchants in medieval times), and dry reds, sometimes blended with SYRAH. VARIETAL wines are typically pale and quickly lose their colour intensity with age. There were around 400 ha/988 acres on the island in 2021.

libation, the pouring out of wine (and occasionally other liquids: water, oil, milk, honey) as a religious act is found widely in human societies. The practice of offering a libation to a god was universal in the Greek and Roman world and was an essential element in animal sacrifice. Whenever wine was drunk in formal gatherings, such as SYMPOSIA, a libation was poured while a prayer was said to invoke a chosen god. Libations also regularly accompanied prayers and sacrifices on all sorts of occasions. The origins of the practice are to be found in the offering of the first fruits to gods; but libation should also be seen in the context of the way in which social intercourse between humans (and by analogy between humans and gods) was maintained by the mutual exchange of gifts. Libations poured on the ground were also specifically seen as a gift for the dead. 'The souls are nourished by libations', as Lucian says. J.J.P.

Burkert, W., *Greek Religion* (1985).

Libourne, small port on the RIGHT BANK of the Dordogne in the Bordeaux region. It is now the commercial centre for the right-bank appellations, although it was established in the 13th century, much later than ST-ÉMILION's port Pierrefitte, and was at the time considered a parvenu in comparison with FRONSAC. In modern history, its wine trade is much more recent than the Chartronnais of the BORDEAUX TRADE in the great city across the Garonne, and its more modest traders concentrated initially on selling in northern mainland Europe rather than in the British Isles. Of merchants based here on the banks of the river Dordogne, J. P. MOUEIX is the most important. For more details, see POMEROL, the wine region on the eastern outskirts of the town.

The wines from St-Émilion, Pomerol, and especially Fronsac are sometimes referred to collectively as Libournais.

Lichine, Alexis (1913–89), was born in Russia but, unlike André TCHELISTCHEFF, another Russian who was to shape the American wine industry, he and his family left before the Revolution, and he was educated in France.

After the Repeal of PROHIBITION, Lichine sold wines, first in a shop in New York and subsequently for the gifted American wine importer Frank SCHOONMAKER. After the Second World War, in which he served with distinction, he returned to finding French and German wines from individual estates and selling them in an America where wine was all but unknown.

His success in doing this was considerable and came from a flair for seeing and recounting the romantic side of wine and winemaking, as well as appreciating the pleasures wine can bring.

During the 1950s, he became a major figure in the French wine world, setting up his own company, Alexis Lichine & Co., to sell only CHÂTEAU BOTTLED and DOMAINE BOTTLED wines, for the most part from major properties. He sold this company to British brewers Bass-Charrington in 1964 and gradually left the commercial world to make wine and write books. For more detail, see the LITERATURE OF WINE.

Lichine assembled a group of investors to buy and renovate the MARGAUX second-growth Ch Lascombes in 1952 and ran the property with great success before selling it, again to Bass-Charrington, in 1971. He also bought in 1951 the fourth-growth Ch Prieuré at Cantenac just outside Margaux. He officially renamed this property, based on an old Benedictine priory, Ch Prieuré-Lichine in 1953, and it was at this property, typically one of the first to welcome passing visitors, that he died in 1989. His son Sacha ran the property until its sale in 1999 and then created the hugely successful brand WHISPERING ANGEL, a ground-breaking Provençal rosé. W.B. & J.R.

licoroso, Portuguese sweet FORTIFIED WINE (as opposed to a GENEROSO, which may be dry).

lie or lies, French for LEES.

Liebfraumilch, quintessentially mild, slightly sweet white wine from GERMANY's RHEINHESSEN, PFALZ, NAHE, or (rarely) RHEINGAU regions known almost exclusively in export markets where it weaned many a potential wine drinker off soft drinks. In its heyday in the 1980s, it accounted for an extraordinary, some would say horrifying, 60% of all German wine exported. These wines were generally dominated by SILVANER, MÜLLER-THURGAU, or KERNER grapes, but the Liebfrauenstift-Kirchstück (Our Lady's Cloister) in Worms from which the name Liebfraumilch was derived continues to be a source of good RIESLING.

lieblich appears (albeit usually in small print) on labels of Austrian wines with 19–45 g/l RESIDUAL SUGAR. In Germany, the term is seldom seen on labels, but it often used informally to describe German wines sweeter than those labelled TROCKEN, HALBTROCKEN, or FEINHERB.

Liechtenstein, principality between SWITZERLAND and AUSTRIA with about 20 ha/49 acres of vines in 2021. The majority of its vineyards are concentrated on the capital Vaduz, above and at some distance from the river RHINE, where the climate is strongly influenced by warming föhn winds. There are about a hundred vine-growers and just four commercial wine producers, of which the biggest is Hofkellerei des Fürsten von Liechtenstein, run in tandem with the Hofkellerei Wilfersdorf in Austria's WEINVIERTEL. Viticulture is mainly focused on white wines from Chardonnay, Pinot Blanc, and Riesling, with some reds from Merlot, Pinot Noir, and ZWEIGELT.

Ospelt, M. and Müller, W., *Weintradition Liechtenstein* (2004).

lieu-dit (plural lieux-dits), French term used quite generally to refer to the local, traditional name of a small area of land, usually defined by TOPOGRAPHY or history. Such locally given names are also used more specifically, especially in ALSACE, Burgundy, and the RHÔNE, to refer to a plot of land or vineyard within a larger appellation. In Burgundy, these names are used on labels for vineyards below PREMIER CRU in rank, for example Les Tillets in the commune of Meursault.

lifted, tasting term for a wine with a high but not excessive level of VOLATILE ACIDITY. Such a wine may also be said have lift conferred on it.

light. A wine is described by wine tasters as light, or light-bodied, if it is low in ALCOHOL and VISCOSITY. See BODY for more details. Wines are sometimes also described as light as opposed to FORTIFIED.

light brown apple moth. See MOTHS.

lightning, a climatic phenomenon, an electric discharge from the atmosphere under storm conditions, which may strike a vineyard and, by travelling along a wire, damage vines around the point of contact. Most vines recover after a lightning strike, however.

lightstrike, known as *goût de lumière* in French, is the damaging effect that light at short wavelengths in the ultraviolet and blue end of the spectrum can have on wine, as well as products such as beer and milk. The light provokes a chemical reaction with riboflavin and AMINO ACIDS in the wine, resulting in malodorous sulfur-related compounds such as dimethyl disulfide (DMDS) and methanethiol (see MERCAPTANS), which smell variously of cardboard, garlic, and cooked cabbage. White wines in clear bottles exposed to artificial light,

particularly fluorescent light, even for a relatively short period of time, are the most likely to be affected, although bright daylight is equally damaging. Sodium lighting is often used in cellars in Champagne for this reason. Green glass is better than clear but not as good as amber, and red wines are less likely to be affected because PHENOLICS, especially TANNINS, help to protect the wine. Coating or sleeving the bottle is another solution but again adds to the production costs. Some champagne producers such as Roederer protect their best bottles by wrapping them in amber-coloured cellophane. Reducing the intensity and changing the direction of shop lighting would be a cheaper solution but harder to control. Research by the CIVC has concluded that amber-coloured LED lights exclude those wavelengths that cause lightstrike.

lignification, botanical term for the process in which SHOOTS or STEMS become woody. See also CANE RIPENING.

Liguria. The crescent-shaped strip that runs along Italy's Mediterranean coast from the French border to the edge of Tuscany is Italy's third-smallest wine-producing region after the Valle d'Aosta and Molise. See map under ITALY, and see GENOA, VERNACCIA, and ITALY for some historical detail. The extremely rugged terrain—the Apennines descend virtually all the way to the sea—combined with

the minute size of individual properties makes agriculture in general and viticulture in particular a marginal activity, and the greater economic possibilities offered by the thriving tourist industry and commercial flower-, vegetable-, and olive-growing have steadily depleted the workforce from the region's vineyards ever since the Second World War. However, Liguria's total vineyard area, 1,615 ha/3,990 acres, has been stable in recent years, with more than half of it dedicated to the production of DOC wine.

A crossroads of trade and traffic between Italy, France, and Spain, Liguria has long cultivated myriad vine varieties, and a census of the province of Imperia in 1970 revealed no fewer than 123. Many of these have since been abandoned, although renewed interest in INDIGENOUS VARIETIES has saved several from extinction, notably the white Scimiscià, which in 2003 was officially included in the national register. The region is concentrating its efforts on the white wine grapes VERMENTINO (PIGATO) and BOSCO and the red varieties ROSSESE, SANGIOVESE, and DOLCETTO (the last of these called Ormeasco in Liguria). Ormeasco, Pigato, Rossese, and Vermentino each have their own overarching DOC within the Riviera Ligure di Ponente zone, a wide stretch of territory between Genoa and the French border, which has been divided in five subzones: Albenga, Finale, Quiliano, Riviera dei Fiori, and Taggia.

Liguria's most renowned wine, the white Cinqueterre, is perhaps most famous for its vertigo-inducing vineyards perched on TERRACES sculpted into cliffsides high above the Ligurian Sea. The wine itself, made from Vermentino plus Albarola and/or Bosco, occasionally rises above thirst-quenching level. The rare Sciacchetrà, a sweet Cinqueterre made from PASSITO grapes, is enjoying a modest comeback.

Production of Vermentino is concentrated in Castelnuovo Magra, to the south of La Spezia in the Colli di Luni DOC zone, and in Diano Castello and Imperia in the province of Imperia. The name Pigato is traditional in Ranzo and Pieve di Teco, north of the city of Imperia. Ormeasco (DOLCETTO) is produced almost exclusively in Pornassio and Pieve di Teco. The Rossese grape, sometimes called 'Italy's Pinot

Noir', has its own DOC near Ventimiglia, Rossese di Dolceacqua or simply Dolceacqua. The wine, combining aromas of blackcurrants and roses with power and delicacy, is produced on steep vineyards clinging to the coast, fighting a losing battle against greenhouses for vegetables. This admired but tiny DOC is divided among 14 villages, each with their own CRU vineyards at 400 m/1,312 ft ELEVATION, sometimes higher. A new generation, determined to save the steep vineyards from being abandoned, is focusing on the production of high-quality wines which seem ripe for elevation to DOCG status.

W.S.

Liliorila, a 1956 BAROQUE × CHARDONNAY cross recently authorized in Bordeaux, within certain limits (see VIFA), because of its potential resilience to CLIMATE CHANGE.

Lima, large DOC subregion of VINHO VERDE in north-west Portugal on the Lima River, best known for particularly floral VARIETAL wines made from the LOUREIRO grape. Single-estate examples, typically from inland areas, are among Vinho Verde's best. S.A.

Limarí, valley in the northern region of Coquimbo in CHILE increasingly known for Chardonnay and Pinot Noir.

lime, in the forms of slaked lime (calcium hydroxide) or ground limestone (calcium carbonate), can be added to soils to neutralize SOIL ACIDITY. Because limestone is very insoluble, it should be thoroughly incorporated through TILLAGE to be fully effective. Liming is therefore most appropriately used, if needed, before vine PLANTING. It is relatively easy to change the topsoil PH but very difficult in effect to change it in the subsoil (below 50cm/20 in). The CALCIUM in lime or LIMESTONE also helps to give the soil a stable and friable structure (see SOIL STRUCTURE). Gypsum (calcium sulfate), which is more soluble than lime, can be used to supply calcium in soils where acidity does

not need to be corrected. One common problem of over-liming is lime-induced CHLOROSIS (IRON is involved in photosynthesis and deficiency results in yellowing of leaves). R.E.W.

lime, active, refers to calcium carbonate that is more available to the vine than LIMESTONE rock because it is finely divided (less than 0.02 mm diameter) and therefore more soluble. Its presence in the soil is not necessarily due to underlying limestone, which is generally hard and insoluble, and may be the result of soil-forming processes in a low-rainfall environment. There is no direct relationship between the amount of active lime in the soil and wine quality. However, active lime raises a soil's PH above 7 and may enhance the vine's root development. Too much may lead to lime-induced CHLOROSIS. See also LIME and SOIL ALKALINITY. J.E.H. & R.E.W.

Baize, D., 'Total and "active" calcium carbonate', *Soil Science Analyses. A Guide to Current Use* (1993).

White, R. E., *Soils for Fine Wines* (2003).

limestone, constituted principally of the MINERAL calcite (calcium carbonate), is the most common CALCAREOUS rock. Increasing proportions of CLAY give argillaceous limestone (see ARGILO-CALCAIRE) and MARL; dolomitic limestone or dolomite is calcium-magnesium carbonate. CHALK is a special subvariety of limestone. Most limestones formed in warm, sunlit shallow seas (resembling the Bahamas today) and can be rich in fossils (see GEOLOGY), the accumulated debris of calcareous organisms such as plankton, corals and clams. Pedogenic limestone, however, forms *in situ* in relatively arid areas such as Central Otago and Mendoza when carbon dioxide dissolved in soil water encounters calcium released by weathering of parent rocks.

Common limestones differ from chalk in being hard and not readily penetrated by plant roots, except through cracks. Unless mineral material is brought in by wind or water, the depth of soil formed on

limestone depends on the impurities (clay, SILT, and SAND) in the limestone because the dissolution of calcite produces only calcium and bicarbonate ions. Limestones tend to yield stony soils with a PH around neutral, invariably well drained but also with good water storage. Depending on impurities, the colour ranges from almost white to darker greys and other colours. Some limestone soils, such as the Mediterranean TERRA ROSSA, are red-brown in colour; these are moderately alkaline and have a good clay-loam texture and structure.

Some limestone soils overlie substantial reserves of ground water, generally of high quality for IRRIGATION. The longer roots of well-established vines may reach this water, if it is not too deep. Deep RIPPING to shatter the hard limestone may be carried out before PLANTING, typically to 1 m/3 ft depth, but any slabs of limestone brought to the surface may need to be removed. Limestone-derived soils are in general valued most highly in COOL-CLIMATE viticultural regions. The great wines of BURGUNDY come from vines grown on the slopes of the CÔTE D'OR escarpment, where various Jurassic limestones predominate.

The red limestone-derived terra rossa of Coonawarra in SOUTH AUSTRALIA similarly produces some of Australia's best red wines from Cabernet Sauvignon and Shiraz, both vine varieties being close to the cool limit for their reliable ripening.

In warm climates, however, such as in the south of France and the Riverland of South Australia, limestone soils are not regarded as superior or even necessarily as suitable for viticulture (see SOIL AND WINE QUALITY). The high pH of purer limestones can prompt nutritional difficulties, root growth can be restricted, and most of the North American ROOTSTOCKS on to which vines are grafted in order to combat phylloxera perform poorly on limestone. R.E.W. & A.J.M.

Limestone Coast Zone, moderately cool, high-quality wine area in SOUTH AUSTRALIA encompassing the traditional lands of the Buandig, Bindjali, and Ngarrindjeri people. The zone includes the Coonawarra,

Mount Benson, Mount Gambier, Padthaway, Robe, and Wrattonbully wine regions. The districts of Bordertown and Penola in the upper south-east of the region are candidates for official recognition, too. Bordertown, the furthest north, is the warmest area, producing robust Shiraz and Cabernet Sauvignon, for example. Mount Gambier, to the extreme south, is the coolest, best suited to Pinot Noir and Chardonnay.

Limnio, dark grape variety native to the island of Límnos in GREECE, where it can still be found. It has also transferred successfully to Halkidikí in north-east Greece, where, sometimes blended with Cabernet, it produces a full-bodied wine with a good level of ACIDITY and some herbal aromas. Limniona, a promising dark-skinned variety recently resurrected on mainland Greece, is unrelated, according to DNA PROFILING.

Limousin, old French province centred on the town of Limoges, and a term encountered most frequently in the wine world as a name for the region's OAK.

Limoux , small town and appellation in the eastern Pyrenean foothills in southern France. For centuries it has been devoted to the production of white wines that would sparkle naturally after a second fermentation during the spring. They became known as Blanquette de Limoux, *blanquette* meaning simply 'white' in Occitan. Locals claim that fermentation in bottle was developed here long before it was consciously practised in CHAMPAGNE, dating the production of cork-stoppered sparkling wines at the Abbey of St-Hilaire from 1531 (Limoux is just north of CATALUÑA, a natural home of the CORK oak), although Stevenson casts doubt on both the date and claims that the wine was sparkling.

The region's vineyards are so much higher, cooler, and further from Mediterranean influence than any other Languedoc appellation

(even MALEPÈRE to its immediate north) that many are Atlantic-influenced even though they are just inland from the CORBIÈRES hills. Within the region there are several distinct zones differing in ELEVATION, soil types, and the influence of the Atlantic or Mediterranean.

The grape used traditionally was MAUZAC, called locally Blanquette, but increasing amounts of CHARDONNAY and, to a lesser extent, CHENIN BLANC have been planted so that in the 1980s the Limoux vineyards were much valued as one of southern France's very few sources of Chardonnay grapes from mature vines. Still wines made from them were then in great demand, especially for export markets. This international success was cleverly capitalized upon by Toques et Clochers, an annual charity AUCTION of Chardonnay barrel samples, inspired by the famous HOSPICES DE BEAUNE auction but embellished by the involvement of some of France's most famous chefs. These often lean, oak-aged Chardonnays regularly fetched prices far in excess of their then classification as VINS DE PAYS so the Limoux appellation was thoroughly overhauled in 1993. It now encompasses still whites made mainly from Chardonnay (although Chenin Blanc and Mauzac may be included, or may be the main or sole variety), with, unusually, compulsory BARREL FERMENTATION and BARREL AGEING.

In 2004, a red wine Limoux appellation was added, with Merlot compulsorily making up at least 50% of the blend and Côt (MALBEC), Syrah, and Grenache constituting at least 30%. Cabernet Sauvignon and Cabernet Franc may play a part—truly an Atlantic and Mediterranean blend. Such (relatively light) wines used to be sold as the IGP Haute Vallée de l'Aude, a name now more commonly encountered on the region's most promising red wine grape, Pinot Noir.

But Limoux is essentially a sparkling wine town. Blanquette de Limoux is the region's most famous product, a fruity sparkling wine made up of at least 90% Mauzac, although Chardonnay and/or Chenin Blanc may play a minor part. The Crémant de Limoux appellation was devised in 1990 for more complex TRADITIONAL

METHOD sparkling wines. In 2006, a rosé style was permitted using up to 15% Pinot Noir in the blend. See CRÉMANT for more details.

Limoux's distinctly marginal speciality is Blanquette Méthode Ancestrale (see SPARKLING WINEMAKING), a sweeter, often slightly cloudy, less fizzy sparkling wine made exclusively from Mauzac grown on 65 ha/160 acres in 2012 and left to ferment a second time in bottle without subsequent disgorgement of the resultant sediment. Like the GAILLAC Mousseux made from Mauzac by the *méthode gaillacoise* with similar regard for tradition, these hand-crafted wines are low in alcohol, are high in Mauzac's old-apple-peel flavours, and can taste remarkably like a superior sweet cider.

Limoux's sparkling wine business is dominated by the dynamic local CO-OPERATIVE, which sells a range of bottlings under such names as Aimery and Sieur d'Arques, but there are also some fine individual estates in the pretty hills here.

Stevenson, T., *How The English Invented Champagne* (2014).

Lincoln University New Zealand's specialist land-based university with research and teaching focused on agricultural science. The VITICULTURE and OENOLOGY programme, established in 1989, offers undergraduate and post-graduate studies. Teaching programmes emphasize the integration of grape-growing and winemaking from vine to glass. The university has its own vineyard and is home to the Centre for Viticulture and Oenology, a research hub that brings together scholars and scholarship related to viticulture and wine production. COOL-CLIMATE grape varieties important to New Zealand's wine industry, namely Sauvignon Blanc and Pinot Noir, receive particular attention. Current research areas include: grapevine physiology and berry composition; SUSTAINABLE grape production; oenology, including FERMENTATION processes and wine chemistry and composition; sensory science related to how wines are perceived, appreciated, and consumed; and wine marketing and TOURISM.

www.lincoln.ac.nz

lipids, a group of chemicals that includes oils, fats, and waxes. Lipids are distinctive in plants because, despite the plant's watery environment, they are not soluble in water, and this is the basis of their important roles. They make up the membranes of plant CELLS which keep apart entirely different zones of metabolic activity, often with large differences in ACIDITY on either side of the membrane. They make energy-rich reserves of food as in seeds, grapeseed oil being a good example. Also they coat the surface of the plant with a water-impermeable layer of waxy cutin which stops desiccation. A host of other compounds have lipid-like structures, including important plant pigments such as chlorophyll and CAROTENOIDS. The sediment in MUST contains a significant amount of lipids that play an important role in FERMENTATION. If CLARIFICATION of the must is too severe (so that the turbidity is less than 150 NTU), the risk of sluggish fermentation is higher than in more turbid juices with higher levels of solids. B.G.C. & D.D.

Liqueur Muscat, old name for the very special sort of STICKIE made in AUSTRALIA from Brown MUSCAT grapes. For more, see TOPAQUE.

liqueur wine is the official EU term for FORTIFIED WINES that have an ALCOHOLIC STRENGTH of not less than 15% and not more than 22%. See also VIN DE LIQUEUR.

liquoreux, French term meaning 'syrupy sweet', used for very rich, often BOTRYTIZED, wines that are markedly sweeter than MOELLEUX wines.

liquoroso, Italian for a strong, usually sweet, FORTIFIED WINE.

Lirac, large appellation on the west bank of the Southern RHÔNE producing wine from 818 ha/2,021 acres of vineyards in 2020. It includes three communes other than Lirac, of which Roquemaure was an important 16th-century port from which wines would be shipped as far north as England and Holland (see RIVERS). In the 18th century, Roquemaure was a much more important wine centre than CHÂTEAUNEUF-DU-PAPE. Lirac is now the only southern Rhône AOC apart from VACQUEYRAS to make wine in all three colours. For reds and rosés, the majority of the blend must be composed of Grenache, Syrah, Mourvèdre, and/or Cinsaut, with a long list of secondary varieties that can also be included. For whites (10% of production), the majority of the blend must comprise Bourboulenc, Clairette, Grenache Blanc, and/or Roussanne. In all three colours, the wines are unmistakably southern Rhône but often have a distinct finesse to their shape and texture. The terrain is a patchwork of soils, with vines grown on SAND, CLAY, GALETS, and LIMESTONE.

See map under RHÔNE. M.C.W.

Lisboa, VINHO REGIONAL in western Portugal sometimes known colloquially as Oeste (West) and known until 2009 as Estremadura. Although it incorporates no fewer than nine DOCs—ALENQUER, ARRUDA, BUCELAS, CARCAVELOS, COLARES, ENCOSTAS D'AIRE, Lourinhã (exclusively for brandy or aguardente), ÓBIDOS, and Torres Vedras—as of 2021 all but 3% of wine from this sizeable coastal strip is classified as Vinho Regional (VR). A growth spurt of certified wine (as opposed to VINHO or the returnable 5 l/1.3 gal flagons known as *garrafoes*, once the mainstay of taverns and restaurants all over the Portuguese-speaking world) has shifted the emphasis from quantity to quality. The region's ten remaining CO-OPERATIVES now represent only around one-fifth of VR sales following a rising tide of privately owned producers. Exposure to Atlantic westerlies can be challenging for volume red

winemaking, sometimes resulting in thin reds with clumsy RESIDUAL SUGAR levels. However, fast-improving contemporary commodity wines have leveraged the capital's popularity as a TOURISM destination to great effect. While Bucelas, Carcavelos, and Colares, historically the most distinguished wine regions, are now too small to be qualitatively significant, all are experiencing a revival of interest from producers and consumers alike. Exciting Atlantic VR wines from Sintra are in growth, some even made from Colares's rare signature grapes, RAMISCO and MALVASIA de Colares. Elsewhere across this extensive VR, hitherto uncelebrated pockets of excellence are steadily emerging, typically defined by Lisboa's propitious CLAY and LIMESTONE soils, ELEVATION (up to 500 m/1,640 ft), or coastal locations. Recently introduced promising varieties include TOURIGA NACIONAL and TINTA RORIZ (Tempranillo), together with such INTERNATIONAL VARIETIES as Syrah, Cabernet Sauvignon, Grenache, Pinot Noir, Sauvignon Blanc, Riesling, and Viognier. Local grapes such as ARINTO, FERNÃO PIRES, VITAL, MOSCATEL, Jampal, CASTELÃO, and TINTA MIÚDA are being re-explored, too, and, in the right hands and right places, are producing exciting wines. S.A.

Mayson, R. J., *The Wines of Portugal* (2020).

Woolf, S. J., and Opaz, R., *Foot Trodden: Portugal and the Wines That Time Forgot* (2021).

Lison-Pramaggiore, DOC mainly in the VENETO region of north-east Italy created in 1986 by the fusion of two previous DOCs, the Cabernet di Pramaggiore and Tocai di Lison. The DOC Lison was created in 1971 for the production of Tocai Bianco and Tocai Rosso, now officially known as Tai Bianco (identical to FRIULANO) and Tai Rosso (the same as GRENACHE) after Hungary successfully claimed ownership of the Tocai name. It was joined in 1972 by Pramaggiore to accommodate Merlot. With the unification of the two DOCs in 1985 a raft of new varieties such as Pinot Bianco, Chardonnay, Pinot Grigio, Sauvignon Blanc, and Friuli's Refosco was allowed, with Malbec added

in 2000. As a result of the EU viticultural reforms of the late 2000s, the entire Lison part of the DOC was, questionably, elevated to DOCG status, allowing Tai Bianco and Tai Rosso only. The Lison Classico DOCG denotes wines from the original heartland of the zone.

The vineyards themselves are in the wide plain created by the Piave River as it descends from the hills of Conegliano and Montello towards the Adriatic and, as such, can be considered an eastward continuation of the PIAVE DOC zone, extending into the Pordenone province of FRIULI. Total vineyard surface in 2020 was 172 ha/425 acres. The wines are fresh and pleasurable, if not memorable, with Cabernet (predominantly Franc) regularly giving the most interesting results. Cooler vintages, together with the high percentage of Cabernet Franc and high yields in the vineyards (90 hl/ha), tend to bring out a HERBACEOUSNESS which may be more appealing to local markets than to international ones. W.S.

www.lison-pramaggiore.it

Listán, synonym for PALOMINO FINO, the white grape variety that can produce superb SHERRY around JEREZ. As Listán, or Listán Blanco, some of its most interesting wines are those grown on the VOLCANIC soils of the CANARY ISLANDS, where it can produce unfortified wines of much greater tension, individuality, and distinction than most of those on the Spanish mainland. The rebirth of Canary wines in the 1990s thus gave this much-maligned variety a new lease on life. The Spanish vine census of 2020 cites the total area of 'Listán Blanco de Canarias' as 1,580 ha/3,904 acres. Listán de Huelva is a distinct but minor Andalucian pale-skinned variety while the dark-skinned, well-travelled PAÍS of Chile is known in Spain as Listán Prieto.

Listán Negro, recently appreciated INDIGENOUS VARIETY, also known as Almuñeco, which dominates wine production on the island of

Tenerife in the CANARY ISLANDS, planted on 1,511 ha/3,734 acres in 2020. CARBONIC MACERATION has managed to coax exceptional aromas out of this medium-bodied wine.

Listrac, or Listrac-Médoc, one of the six communal appellations of the Haut-Médoc district of BORDEAUX. In relation to the other five (MARGAUX, ST-JULIEN, PAUILLAC, ST-ESTÈPHE, and even MOULIS, with which it is often compared), Listrac seems the least well favoured. It is, just, the furthest of them all from the Gironde estuary, and the vineyards (354 ha/874 acres declared in 2020) are planted on mainly clay-limestone on a gentle rise which, at an ELEVATION of about 40 m/131 ft, constitutes some of the highest land in the MÉDOC. Although the Merlot grape is increasingly planted, the wines can be relatively austere in youth. The most cosseted property is probably the late Baron Edmond de ROTHSCHILD's Ch Clarke, and the trio Fourcas-Borie, Fourcas-Dupré, and Fourcas-Hosten (also well-pampered) are generally reliable. J.R. & J.L.

literature of wine. The literature that concerns wine specifically, as opposed to references to wine in more general writing (for which see ENGLISH LITERATURE), is a complicated tapestry of texts and books that has been woven from a broad variety of strands from classical times to the present day. Most writers concern themselves with how and where grapes are grown, how and where wine is made, and how individual wines taste, but their methods vary considerably, and there are works on wine which are also works on travel, history, medicine, agricultural matters, and gastronomy.

Early works and agriculture

Many early works are richer in references to the effects of drinking wine (see DRUNKENNESS) than to the wine itself. CLASSICAL TEXTS constitute the earliest known literature of wine (although see also ancient MESOPOTAMIA). While Mago of CARTHAGE clearly inspired many subsequent writers, his text does not survive, and the first known classical writers to concentrate on wine and winemaking were probably CATO (234–149 BCE) and VARRO (116–27 BCE). Cato, particularly, was keen on the profit motive in winemaking, and his instructions appear mainly to have been aimed at quantity rather than quality, even suggesting, at one point, how Coan wine (from Kós, one of the AEGEAN ISLANDS) could be faked from Italian grapes.

Much more modern in his outlook towards the production of wine was COLUMELLA (2 BCE–65 CE), whose family, based near Cádiz in southern Spain, may well have owned vineyards. His *De re rustica* gives detailed advice on such matters as CLONAL SELECTION, the planting of vineyards, and the need for wines to be as NATURAL as possible: 'The wine is clearly the best which can solely give pleasure by its own nature.' PLINY the Elder (23–79 CE) was the last great classical writer on wine and winemaking, although he was clearly influenced by Varro. The works of all these three, and the more derivative PALLADIUS in particular, were translated and used as textbooks throughout Europe until the end of the 16th century.

In these books, viticulture was treated merely as a part—albeit a major part—of the broader subject of agriculture. This tradition was continued by such writers as PETRUS DE CRESCENTIIS (1230–1310), an Italian lawyer who was forced to leave his own country and spent 30 years in exile in Spain and France. One volume of his monumental *Liber ruralium commodorum* dealt specifically with winegrowing and winemaking. The work was translated into French on the instructions of Charles V.

The first French writer to attempt to classify wines in any way was Charles Étienne (1504–64). His *Vinetum…*first appeared in Lyons in

1536. This was subsequently translated into French and incorporated in *L'Agriculture et maison rustique des maistres Charles Étienne et Jean Liebault* (1564) (Liebault was Étienne's son-in-law). This was a bestseller and was translated into English by Richard Surflet in 1606. It was followed in due course by the *Nouvelle Maison rustique* by Louis Liger of AUXERRE, which appeared in many editions throughout the 18th and early 19th centuries. While this book deals with a broad selection of rural topics, the section on wine is particularly fascinating with its details of the then-popular wines of Orléans, Burgundy, and Champagne. The characteristics are also given of 50 different VINE VARIETIES grown in France both for table grapes and for winemaking, of which 'morillon noir' is today's PINOT NOIR and 'gamet' is today's GAMAY. More than 15 varieties of MUSCAT are mentioned, but CABERNET SAUVIGNON is notably absent (in the late 1990s DNA PROFILING explained why).

In some ways, an English equivalent was Philip Miller's *Gardeners' Dictionary*, which first appeared in 1731. Here, under the headings 'Vitis' and 'Wine', are detailed articles on such subjects as grape varieties, Burgundy, Champagne, and English vineyards, although he says of these last, 'There have of late years been but very few vineyards in England, tho' they were formerly very common.'

As wine was the everyday drink throughout much of Europe, in parallel with the books on the agricultural aspects of wine there were others devoted, perhaps only in part, to its keeping and serving. In England the anonymously written *Mystery of Vintners* appeared in 1692, and *L'Art d'améliorer et de conserver les vins* (1781) was first published in Paris, under the title *Dissertation sur les vins*, in 1772. Further editions came out in Liège and Turin soon afterwards. The information they gave was often plagiarized and adapted to appear in such general books as *The Laboratory, or School of Arts* (1799).

Wine as medicine

The role of wine in the world of MEDICINE had been important from the earliest of times. It was used widely as a medium for the infusion of medicinal herbs, and many wine-based remedies were given in such books as *The Secrets of Alexis of Piedmont*, which appeared in a number of languages from 1555 onwards.

Indeed the first book specifically on wines in English, *A New Book of Wines* (1568), was written by William Turner, who studied medicine at Cambridge. He warned of the danger of drinking the sweet, heavy wines of the Mediterranean as opposed to the healthy, light wines of the Rhine.

This medicinal tradition was adapted by the wine merchant Duncan McBride in his *Choice of Wines…*(1793), which included general discussion about the wines that were available at the time and their potential application for various medical conditions.

A much later sequel is *Wine is the Best Medicine* (1974, updated 1992) by the Frenchman Dr E. A. Maury. This had a more rational approach to the subject, with a variety of individual French wines being recommended for everything from flatulence to cystitis.

DOCTORS have always had a major role to play in English wine literature. Sir Edward Barry was a Bath physician whose *History of Classical Wines* appeared in 1775. He was criticized for relying too closely on the work of the 16th-century papal medical adviser Barrius, but he also includes an appendix on modern wines and viticulture in England.

Doctors were also responsible for the first two 'modern' books to deal with wine in depth. While the title of *A Practical Treatise on Brewing, Distilling and Rectification*, by R. Shannon MD (1805), might put off the oenophile, there is 'A Copious Appendix on…Foreign Wines, Brandies and Vinegars'.

Dr Alexander HENDERSON's *The History of Ancient and Modern Wines* (1824) is perhaps the first book in English to attempt to give descriptions of a broad range of wines, based upon his own travels to

France, Germany, and Italy. It is also the first book to try to analyse the science of TASTING.

The golden age

In the number of wines it talks about, Henderson's book is overwhelmed by what must be the most remarkable book on wine ever published, the *Topographie de tous les vignobles connus* (1816) by André JULLIEN, a Parisian wine merchant who was born in Burgundy. In this are rated all the wines, not just of France but of all known wine regions of the time, including California, South America, South Africa's Cape, and 'Chinese Tartary'! He forecasts (or perhaps helps to shape) the 1855 CLASSIFICATION in Bordeaux by rating as first-class wines Lafitte (*sic*), Latour, Ch-Margaux, and Haut-Brion.

Outside Europe, his favourites all seem to be dessert wines, including TOKAJI, CONSTANTIA, COMMANDARIA, and COTNARI. Both his first-hand experience and his reading must have been gargantuan for him to compile such a work of reference. He followed this up with another classic, *Manuel du Sommelier* (1822). Cavoleau's *Oenologie française* was a similar work to the *Topographie*, coming from the same publisher 11 years later though limited to French wines.

The 19th century was a golden age for wine writing in Britain. Cyrus REDDING (1785–1870), a journalist whose interest in wine was stimulated during five years based in Paris, wrote *A History and Description of Modern Wines* (1833) as a result of first-hand observation of the ADULTERATION AND FRAUD which were then prevalent in the wine trade.

Many books were written by wine merchants, often criticizing the practices of their colleagues or vaunting their own specialities (a common thread through modern wine writing). Perhaps the most enjoyable to read is Thomas Shaw, whose *Wine, the Vine and the Cellar* (1863) is an agreeable blend of reminiscences, knowledge, and simple advice. He was convinced even then that 'in wine tasting and wine talk there is an enormous amount of humbug'. Another of his campaigns was against excessive DUTIES on wine, and this led to the famous Gladstone budget in 1862 in which they were considerably reduced.

Charles Tovey was a wine merchant in Bristol in south-west England, and in the introduction to *Wine and Wine Countries* (1862) he says that 'there can be no question that the Wine Trade is losing its position by the introduction into it of unscrupulous traders'. He drew heavily upon his 50 years' experience in denouncing and describing their deceits.

This same theme was continued by his London colleague James L. Denman, who wrote copiously on wine adulteration. His more particular interest, however, both commercial and literary, was the wines of Greece.

Another doctor to write on wines was John Thudichum, who had come to London from Germany, where his father had written technical books on wine. One of his particular hobby horses was the adding of gypsum to SHERRY, but his credibility within the trade was compromised by extensive research that he had carried out in Jerez, trying to produce AMONTILLADO by purely chemical means. His *Treatise on Wines* (1872), written with another doctor, A. Dupré, does, however, give a clear picture of viticulture and vinification at that time. Somerville & Ross's *In the Vine Country* (originally serialised 1890–1 and republished to great acclaim in 2021) is that rare thing, a pre-1960 book on wine by women.

Specialist books

While all these books give a general idea of the wines of Europe and, in some cases, the world, some specialist books on individual regions had also begun to appear. One of the first of these was published in London as early as 1728. This was the *Dissertation sur la situation de Bourgogne* by the French tutor to the son of a Mr Freeman. Arnoux, in this brief book, describes the various wines of Burgundy and how they are made. He also makes a plea for them to be imported into England in bottle rather than in cask. This book must have met with some success, for it was soon translated into English and was subsequently used by Philip Miller in his *Gardeners' Dictionary* and by Robert Shannon.

It was more than a century until the next two classic books on the vineyards of Burgundy appeared, and coincidentally they did so in the same year, 1831. Morelot's *Statistique de la vigne dans le département de la Côte d'Or* is largely what its title suggests, although the second half of the book deals with both viticulture and vinification in the region. The *Histoire et statistique de la vigne et des grands vins de la Côte d'Or* by Lavalle is a more readable book, for it gives many historical details concerning Burgundy and its wines, as well as more information about the characteristics of the wines from the various villages and ownership of the vineyards.

In Bordeaux, the first book of significance was the *Variétés bordelaises* of Abbé Beaurein (1784–5), which noted that the English were at last showing interest in the wines of the Médoc. The first major book dealing solely with the wines of Bordeaux, however, was the *Traité sur les vins du Médoc* of William Franck (1824), which ran into several editions. In many ways this was the forerunner of Charles Cocks's book *Bordeaux, its Wines and the Claret Country* (1846), which was translated into French four years later and became the classic reference work on Bordeaux wines, known after its original authors as 'Cocks et FÉRET'. An interesting independent view of the region is also given by the Paris merchant Charles Pierre de Saint in *Le Vin de Bordeaux* (1855).

Writing on Portuguese wines was dominated by the English. In 1787 John CROFT wrote *A Treatise of the Wines of Portugal*, and this was followed by the many works of James Forrester (1809–61), who, from his position in the trade, took a strong stance against the many adulterations that were taking place.

The 19th century saw the rapid expansion of vineyards in the NEW WORLD, and guidance was sought in Europe as to how to make the finest wines. From this came two interesting works. The first was the *Journal of a Tour through some of the Vineyards of Spain and France* by James BUSBY, which was published in Sydney in 1833. This is a fascinating account of a three-month trip, mainly by stagecoach, to find the right vine varieties for planting in Australia. The interpretation of what he learned appeared in two further books. The journey, almost 30 years later, by Agoston HARASZTHY, one of the pioneers of California viticulture, was largely by train. Perhaps because of his origins, he spent more of his time in the various states of Germany and none at all in France. His *Grape Culture, Wines and Wine-Making*, a journal of this tour, appeared in New York in 1862 and did much to establish the reputations of both Haraszthy and California wine.

A third, and earlier, New World traveller to have recorded his memories of vineyard visiting is Thomas JEFFERSON, later to become president of the United States. During his five years as minister to France (1784–9), he took advantage of his situation by visiting many of the vineyards of Europe, and his diaries leave a fascinating picture of a layman's perception of the world of wine as it then was.

One final wine writer of Victorian times was the journalist and publisher Henry VIZETELLY. His books on champagne, port, and sherry are notable for their many illustrations. These works, with their beautiful engravings, many used by modern publishers, are the forebears of the lavishly illustrated wine books published today.

Technical literature

Parallel with this growth in books on the vineyard regions and their wines, there was a considerable body of work on VITICULTURE and WINEMAKING. In France at the end of the 18th century, the Burgundian Béguillet and Parisian Maupin both wrote detailed works which were widely read.

In England, William Speechly, gardener to the Duke of Portland, wrote a *Treatise on the Culture of the Vine* (1790), which went into three editions. This dealt with both hothouse and open-air vines in ENGLAND and discusses some of the vineyards which were then planted there and the wines they produced.

Three French writers of the 19th century whose names live on in the world of wine are Jean-Antoine CHAPTAL (1756–1832), Dr Jules GUYOT (1807–72), and Louis PASTEUR (1822–95). Chaptal was the essential polymath, rising from humble beginnings to become Minister of the Interior under Napoleon. In 1799 he wrote the article on wine for the monumental *Dictionnaire d'agriculture* of the Abbé Rozier, but he is better known for his *L'Art de faire le vin* (1807) and for his support for the concept of increasing the alcohol strength of wine by adding sugar to the must, the procedure now known as CHAPTALIZATION.

Jules Guyot was instructed under the Second Empire to carry out a survey of the vineyards of France and to make recommendations as to how viticulture might be improved. His three works on viticulture in north and central France (1860), the east (1863), and the west (1866) give a vital picture of France before the arrival of PHYLLOXERA. His name lives on as a method of vine TRAINING. It is largely to him that we owe the parade-ground look of today's vineyards in place of the unruly appearance of vines subjected to the traditional practice of LAYERING.

Louis Pasteur's *Études sur le vin* (1866) deals with the question of vinification and particularly the advantages of the heat treatment, or PASTEURIZATION, of wine. His is also the first detailed work on the role

that YEASTS have to play in FERMENTATION. Another important work on the techniques of vinification was *Le Vin* (1867), by the Burgundian Comte de Vergnette-Lamotte.

Over ten years from 1901, MONTPELLIER professor of viticulture Pierre Viala, backed by industrialist Victor Vermorel, produced his unsurpassed seven-volume *Ampélographie*, a guide to 5,200 grape varieties, with the 627 most important considered in detail and 500 of them beautifully illustrated in colour by Jules Troncy and Alexis Kreÿder.

Modern wine writing

The 20th century saw a great resurgence in wine writing, particularly in Britain. Much of the credit has been laid at the door of Professor George SAINTSBURY, whose erudite miscellany of vinous reminiscences, *Notes on a Cellar-Book* (1920), was published when he was 75 years old. (It was reprinted twice within four months and has run through many editions since.)

Influential writers during this period included H. Warner Allen, a wine-loving journalist who wrote *A History of Wine* (1961), as well as Maurice Healy and Stephen Gwynn.

André SIMON (1877–1970) was extraordinarily prolific. His early writings were largely on the history of the wine trade, and he was, all his life, passionately interested in wine books, compiling a number of bibliographies on food and drink (see below). As a member of the wine trade, he introduced a degree of accuracy to his work that is missing from some of the 'gentlemen' wine writers cited above. In all he wrote more than 100 works in which his knowledge is matched by his readability.

Subsequent wine writing in Britain continued this parallel, with works coming from writers who took to wine and wine professionals who took to writing.

From the British wine trade have come such as Tommy Layton, a prolific writer on the wines of the Loire, Alsace, Spain, and Italy; his one-time office boy Michael BROADBENT, whose *Great Vintage Wine Book* and *Vintage Wine* are unrivalled collections of tasting notes on thousands of wines going back to the 17th century; Clive Coates MW on the wines of Burgundy and Bordeaux; both Anthony Hanson MW and Jasper Morris MW on Burgundy; the late John Radford on Spanish wines; Gerald Asher, long based in the United States; the late Steven Spurrier; and many others.

Representing the world of the professional writer were the biographer and founder of the Good Food Club, Raymond Postgate, whose *The Plain Man's Guide to Wine* proved so successful that it went through 16 editions in 26 years; Edmund PENNING-ROWSELL,

whose frequently revised book on the wines of Bordeaux was a masterpiece of research; the polished journalist Cyril Ray; and John Arlott, another journalist (and cricket commentator) whose enjoyment of wine and the pleasure it brings shone through his writing.

The late 20th century saw something new in the world of wine books: writers deliberately writing for their customer, the reader, rather than for their own pleasure, their work often embellished with ambitious illustration. Oz Clarke, Jamie Goode, and Tom Stevenson have been particularly prolific, Andrew Jefford regrettably less so. But the most successful and innovative of these have undoubtedly been Hugh JOHNSON and Jancis Robinson. Even more popular than the former's *Wine* and *The Story of Wine* is his *World Atlas of Wine*, which first appeared in 1971 and has sold more than 4.5 million copies. From the 5th edition, this has been co-authored by Jancis Robinson. She has written widely herself, notably producing *Wine Grapes*, with Julia Harding and José Vouillamoz, and editing the first four editions of *The Oxford Companion to Wine*.

In the rest of Europe, much of the wine literature was originally written in English, although the Dutch writer Hubrecht Duijker achieved a broad international readership. Few French writers are read outside France, although each region has had its specialized writers such as Pierre Poupon, Pierre Forgeot, and Jean-François Bazin on Burgundy, René Pijassou and Bernard Ginestet on Bordeaux. An exception, for the technically minded, is Pierre GALET's work on AMPELOGRAPHY, a worthy successor to Pierre Viala's earlier volumes. The works of Émile PEYNAUD on winemaking and wine TASTING have also been widely read outside France. In Spain, José Peñín led the growing number of writers on wine, as VERONELLI did in Italy.

In the United States, wine writing became a boom industry in the late 20th century. This was led by Alexis LICHINE, who before the Second World War joined the wine trade with Frank SCHOONMAKER, himself a successful writer on wine.

Other effective American wine authors have included Karen MacNeil, Ed McCarthy, and Mary Ewing Mulligan MW (whose books in

the 'for Dummies' series have been particularly successful), Kevin Zraly, and—the most powerful wine writer of all—Robert PARKER, who wrote several popular books and wine guides, most notably on Bordeaux and the Rhône. Kermit Lynch and Terry Theise are perhaps the most accomplished writers to have emerged from the US wine trade.

Wine writing in Australia was led by Len EVANS, followed by the even more prolific James Halliday. These vineyard owners have been followed by a host of career wine writers such as Max Allen and Peter Forrestal. In New Zealand, the field has been led by Bob Campbell MW and Michael Cooper.

It is easy to chart through wine literature the change in public perception of wine, from élitist to populist, a move encouraged by wider travel and higher disposable incomes. Annual pocket books are supplemented by specialist buyer's guides such as Bettane & Desseauve's on French wines, Peñín's on Spain, Gambero Rosso on Italy, Platter's on South Africa, and many, many more. Increasingly popular are wine-travel guides which cover specific regions and, along with recommended producers to visit, include maps, travel advice, and recommendations for places to stay, eat, shop, and explore. Other writers, such as Alice Feiring, create an almost evangelistic narrative for particular styles of wine.

The increasing interest in wine seen from the late 20th century has led to a corresponding increase in the range of wine books available and—perhaps more significantly—in the media by which wine writing is disseminated.

The biggest and most dramatic change has been the move from print to digital. Online magazines, newsletters, interactive consumer-driven apps such as Vivino and Instagram, blogs, websites, and self-published e-books mean that wine writing is no longer the exclusive domain of print publishers or wine experts. They may be self-published and/or print on demand, such as the works of Jamie Goode, Ben Lewin MW, Neal Martin, Allen Meadows (aka Burghound), and Stephen Skelton MW.

Subscription websites are seen to guarantee journalistic integrity, but consumers are used to, comfortable with, and influenced by short reads interspersed by pop-up advertising and advertorial. Opinion has proliferated, and not all of it is based on knowledge. Content on many wine websites is not fact-checked by editors.

The 21st-century style of wine writing has, in parallel, shifted from formal and didactic to casual, chatty, inclusive, multi-sensory, and interactive. Online wine writing can be immediately corrected, updated, adapted to trends, and tailored to SEO (search-engine optimization). Apps such as Twitter and Instagram encourage brevity. Visual cues such as charts and photographs are now a powerful part of the narrative. 'Story-telling' as a communication tool is recognized as a welcome alternative to pedantically presented information.

The ever-evolving literature of wine is infinite, and, as appreciation of wine spreads around the world, so will demand for words on wine. See also LANGUAGE OF WINE, MEDIEVAL LITERATURE, WINE WRITING, and INFORMATION TECHNOLOGY. C.F. & T.D.C.

Vicaire, G., *Bibliographie gastronomique* (1890, and facsimile: 1978).

Lithuania is an emerging winegrowing country despite its climate, which is nearly too cold for growing VITIS VINIFERA. The short vegetative period is framed by FROSTS in mid May and the end of September, and winter temperatures can drop to −28 °C/−18 °F.

Until as recently as 2007, most plantings were cold-resistant non-certified HYBRIDS created in the mid 20th century by local breeder Antanas Gailiunas.

However, since 2018 the country has seen a major increase in grape-growing and winemaking, with an estimated 50 ha/124 acres of vines planted by 2022. SOLARIS is now the most popular white grape variety, followed by St Pepin, Adalmiina, FRONTENAC Blanc, Muscaris, and Johanniter. There are also small plots of RIESLING, most planted close to the Baltic Sea or in the warmer centre of Lithuania.

RONDO was the first red wine grape variety planted by enthusiasts in the beginning of 21st century, but because of its low resistance to FUNGAL DISEASES it soon conceded to REGENT. The cold-hardy MARÉCHAL FOCH, FRONTENAC, LÉON MILLOT, and MARQUETTE are gaining in popularity, and some experiment with FRÜHBURGUNDER. Wasps and birds are the main threats to these early-ripening grapes. GEOTEXTILES are sometimes used to protect against WINTER FREEZE. Most plantings measure less than 3 ha/7 acres, and production facilities are modern but very small, often used for both grape- and fruit-wine production. This may soon change: with EU approval in December 2021 of Lithuania as a winegrowing country, forecasters are predicting a 30–40% increase in vineyard hectarage annually. A.S.

little leaf, a symptom of ZINC deficiency of vines. An associated symptom is a PETIOLAR sinus that is wider than normal.

Livermore Valley, California wine region and AVA spanning Alameda and Contra Costa counties, east of San Francisco Bay. As Livermore's western hills screen out nearly all the sea fogs common on the bay itself, it is quite warm and frequently windy, as evinced by the turbines blanketing the hills of Altamont Pass at the eastern edge of the valley.

Planted first in 1846 by Robert Livermore, who lent his name to the region, Livermore boomed in the 1880s, when Carl H. Wente,

James Concannon, and Charles Wetmore established a thriving wine region long before NAPA or SONOMA came on the scene. Just before the onset of PROHIBITION, it hosted more than 2,428 ha/6,000 acres of vines and 50 wineries. Livermore was the first region to produce varietally labelled Chardonnay and Sauvignon Blanc, and most of the Chardonnay planted in the state can be traced back to the region's original Wente HERITAGE CLONE.

Well-drained, stonier-than-GRAVES soils, created by an ancient riverbed, are particularly suited to BORDEAUX varieties, but Livermore's wines command little attention compared to those from Napa or even Sonoma's Alexander Valley. (The exception, perhaps, is Steven Kent Winery, whose top bottlings command Napa-like prices.) The region's primary reds are mid-priced wines made from Zinfandel and Petite Sirah; in whites, Chardonnay continues to be widely planted.

For 40 years vine acreage has been under severe pressure from urbanization, but scions of Wente Vineyards have crafted a land-use compromise with the political authorities: 10 acres of land are set aside for open space or agricultural uses whenever permits are issued for an acre of home or business development. L.M. & A.Y.

Robinson, J., and Murphy, L., *American Wine* (2013).

Lledoner Pelut or Lladoner Pelut, the downy-leaved variant of GRENACHE also known as GRENACHE Poilu or Velu in the south of France and GARNACHA Peluda or Lledoner Pelut in Spain. Both vine and wine closely resemble Grenache Noir except that it is less susceptible to COULURE and therefore yields more consistently and, usefully, reaches PHYSIOLOGICAL RIPENESS at lower sugar levels. It is officially and widely sanctioned in the Languedoc and Roussillon, often being specified in AOC regulations alongside Grenache. But by 2019 France's total had fallen to 284 ha/702 acres, largely in Roussillon, while Spain grew 538 ha/1,329 acres in 2020, mainly in Castilla-La Mancha and to a lesser extent in Cataluña. VARIETAL versions are rare.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

loam, the ideal soil for the growth of most plants, consisting of balanced proportions of clay, silt, and sand (see SOIL TEXTURE). With enough ORGANIC MATTER, loams have a friable, crumby structure (see SOIL STRUCTURE). These desirable characteristics are enhanced where CALCIUM is prominent among the ions bonded to the clay particles and organic matter. A good LOAM has a high capacity to store water and plant nutrients but, unlike stiff CLAY, is not compact enough to impede the free DRAINAGE of water. Rich, loamy soils can encourage excessive VIGOUR in vines, however, particularly in cool to mild climates with ample RAINFALL, so loams (which exist in almost all regions) are not always ideal for viticulture. J.G. & R.E.W.

locusts can damage vines. See GRASSHOPPERS for more detail.

lodge, term used by British shippers of PORT and MADEIRA for a building where wine is stored and matured, especially in Vila Nova de Gaia in OPORTO and more recently in Funchal, Madeira. It is derived from the Portuguese word *loja* meaning 'shop' or 'warehouse'. The Portuguese themselves tend to use the term ARMAZÉM. R.J.M.

Lodi, town in the CENTRAL VALLEY of California that also gives its name to a sizeable AVA. Cooler than either the northern or southern halves of the valley, this prolific farming region was populated from the late 19th century largely by German smallholders who formed CO-OPERATIVES to sell their grapes to large marketing companies such as CONSTELLATION BRANDS, Sebastiani, and JFJ Bronco in the late 1970s and early 1980s. The deep, rich-soiled valley floor was built up by ALLUVIAL deposits from rivers running out of the Sierra Nevada, then pooling before running out to the Pacific Ocean through the Central

Valley delta and San Francisco Bay. Lodi is inland from, less watery than, and thus warmer than the CLARKSBURG AVA to the north-west, but it is much less warm than Madera, Fresno, and other districts further south in the SAN JOAQUIN VALLEY.

The AVA sits 145 km/90 miles east of the San Francisco Bay and surrounds the Mokelumne and Cosumnes rivers, extending into the Sacramento–San Joaquin Delta to the west and towards the SIERRA FOOTHILLS in the east. Daily winds known locally as 'Delta Breezes' keep Lodi cooler than the rest of the Central Valley, particularly at the western end, which is the windiest and lowest in ELEVATION and has the deepest soils. Moving north and east, elevations climb, temperatures increase slightly, and soils become rockier.

The diverse growing conditions have inspired the creation of seven sub-AVAs: Alta Mesa, Borden Ranch, Clements Hills, Cosumnes River, Jahant, Mokelumne River, and Sloughhouse. They also allow Lodi to grow more than 125 grape varieties, the most in the state. The AVA has always been most famous for ZINFANDEL, but Cabernet Sauvignon is its most-planted variety. Old-vine FIELD BLENDS with Zinfandel, CARIGNAN, and ALICANTE BOUSCHET remain important, and Lodi claims what appears to be the oldest Cinsaut vineyard in the world, Bechthold, planted in 1886. In white-wine varieties, Chardonnay dominates. The AVA also has a sizeable collection of German, Austrian, and Iberian varieties. E.C.B.

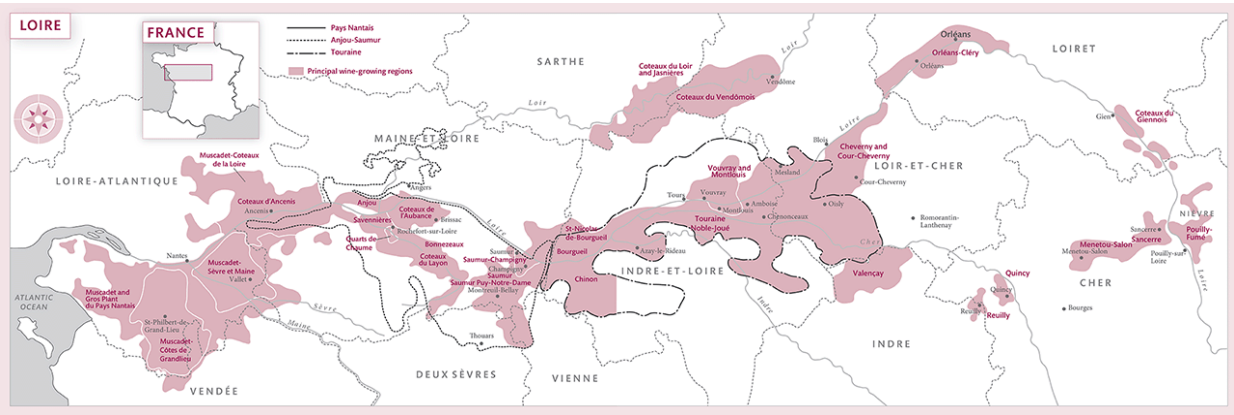
loess, an accumulation of CLAY and SILT particles that have been deposited by the wind. Loess is typically pale-coloured, unstratified, and loosely cemented by calcium carbonate. Favoured for viticulture because it is porous, permeable, readily warmed, and easily penetrated by roots, it is common in WASHINGTON state and TOKAJ and is found in some vineyards in AUSTRIA, GERMANY, and CHINA. A.J.M.

Loir, Coteaux du, northerly AOC of the greater LOIRE region on the confusingly named Loir tributary about 40 km/25 miles north of Tours in the Sarthe *département*. Viticulture dates to the Middle Ages here, but in 2019 there were just 70 ha/173 acres planted, excluding JASNIÈRES, which sits within it. All three colours of wine are made, with PINEAU D'AUNIS making up at least 65% of the reds and rosés. Cabernet Franc may stiffen reds and GROLLEAU is allowed into its light, dry rosés. Gamay and Côt (MALBEC) are allowed in both. The region's dry white wines, made entirely from Chenin Blanc, tend to be light and fresh.

See also LOIRE, including map.

Loire, France's most famous river and name of one of its most varied wine regions, which produces France's third biggest volume of wine after BORDEAUX and the RHÔNE. Loire wines are greatly appreciated locally and in Paris, but—with the famous exceptions of SANCERRE and POUILLY-FUMÉ—are still widely underrated outside France. This may be partly because the Loire's best red wines are often distinguished by their freshness and delicacy rather than by their weight and longevity and partly because so many of its finest white wines are made solely from Chenin Blanc, a grape variety associated with some rather ordinary wine outside the middle Loire.



History

We know little about the early history of viticulture in the Loire valley, but recent archaeological discoveries suggest that it was extant at least in the upper Loire in the 1st century CE (see GAUL), and it was certainly well established by the 5th century. In a letter to a friend, probably prepared for publication *c.*469, Sidonius Apollinaris (*c.*430–*c.*480), who was born in Lyons but spent a large part of his life in the Auvergne, praises the country of the Arverni (the Auvergne) for its landscape, its fertile fields, and its vineyards. In 475, ROME was forced to cede the Auvergne to the Visigoths, but the depredations of the barbarians left vine-growing safe.

In the next century, Gregory of Tours (*c.*539–94) makes frequent mention, in his *History of the Franks*, of viticulture in the Loire region. As bishop of Tours, he took a great interest in the wine of his diocese (modern TOURAINE). He tells us that, in 591, drought was followed by rain so that the grain harvest was ruined but the vines yielded abundantly. He also tells in detail of the Bretons' often successful attempts to seize the vineyards and/or grapes of the Nantes region (modern MUSCADET) in the 6th century.

The wines of the Loire continued to be held in high regard, and not only by the Bretons, who gave up plundering and bought the wines they wanted. The inhabitants of west Brittany had grown some wine themselves, but in the 13th century they quit viticulture in favour of growing grain and instead purchased their wines from Nantes. Like Nantes, Touraine produced wine of export quality, and by the end of the 11th century the wine of SANCERRE was already well reputed. In the 12th century it was exported to Flanders and sold via Orléans.

From the late 11th century onwards, the aspiring bourgeoisie of the newly rich Flemish cities wanted more and more of its chief status symbol, which was wine (see DUTCH WINE TRADE). With its excellent river connections, the Loire region was especially well placed to meet this growing demand. Some of its wine was shipped

to Flanders, or further north, or to England: some of it was carried to PARIS by river to be consumed there or sold on. Angers in particular grew rich on the Flemish guildsmen's desire for social advancement, and vines were planted even just outside its city walls. The count of ANJOU granted Angers the monopoly of carrying wine on the rivers Maine and Loire as far as the Breton port of Ingrandes; in addition, merchants could not buy their wines direct from the vineyards but had to buy them at Angers. These two privileges put the producers of SAUMUR at a disadvantage. The wines of Saumur were not fashionable in France, and Saumur was badly placed for overseas trade. In England in the late 12th century, before the rise of BORDEAUX, Anjou was the only wine to rival Poitou, shipped from LA ROCHELLE, in popularity. Anjou remained highly esteemed in England throughout the Middle Ages.

In France itself, the Loire wine that was most prized was one that has now all but disappeared from public regard: ST-POURÇAIN, made on the river Sioule in the Loire Basin. King Louis IX served it at a banquet in Saumur to celebrate his brother Alphonse's 21st birthday. St-Pourçain fetched high prices during the 14th century and was a favourite with the papal court at Avignon. The wines of the COTEAUX DU LAYON did not become famous until the 15th century.

For more historical detail, see entries under individual wine names.

Dion, R., *Histoire de la vigne et du vin en France* (1959).

H.M.W.

Geography and climate

So long is the extent of the viticultural Loire that generalizations are impossible. The Loire's vineyards vary from the CONTINENTAL climate which produces Sancerre and Pouilly-Fumé to the Muscadet region on the Atlantic coast. Loire wine regions represent today, however, the north-western limit of vine cultivation in Europe (with the exception of ENGLAND's vineyards). Spring FROST can be a serious problem, as it was in 1991, when it destroyed up to 90% of the crop in some of the Loire's wine regions; 2016, 2017, and 2019 were also frost-challenged. The character of Loire wines can vary considerably from VINTAGE to vintage, since in a cool summer the grapes may struggle to reach full RIPENESS, while a particularly hot year such as 1989, 1990, 1997, 2003, 2005, 2009, 2011, and 2018 may result in some exceptional sweet white wines, some of them BOTRYTIZED in the middle Loire, but can rob the Loire's dry white Sauvignons of their nerve and leave some MUSCADET dangerously limp.

The region is sufficiently far from the equator, however, that few of its red wines can be accused of being tannic, and the naturally high acidity associated with these latitudes, and some of its grape varieties, make much of the Loire's produce an ideal base wine for SPARKLING WINES.

Viticulture

The Loire is essentially a region of increasingly consolidated family holdings; the average holding has increased from 10 to 25 ha/25–62 acres in recent years, and many farmers have abandoned their other crops to concentrate on viticulture. In the middle Loire, RAINFALL is relatively low, but SPRAYING against FUNGAL DISEASES is still frequent elsewhere. VINE DENSITY is relatively high, between 4,000 and 5,000 plants per ha (1,600–2,000 per acre) on average, with up to 10,000 plants per ha in some Sancerre vineyards. Excess VIGOUR was a problem in the late 1980s and early 1990s and resulted in HERBACEOUS flavours in many of the red wines, although CANOPY MANAGEMENT has generally resolved this. COVER CROPS have long been the norm, and CROP THINNING was introduced in the early 1990s. MECHANICAL HARVESTING is relatively common but cannot be used for the sweet white wines of the middle Loire, where successive *tries* (see TRI) through the vineyards are needed to select only the ripest grapes.

Winemaking

White winemakers of the Loire traditionally followed very similar principles to their counterparts in Germany, assiduously avoiding MALOLACTIC CONVERSION and any new OAK influence, preferring instead to ferment and store wines in inert containers and to bottle wines early, possibly after some LEES CONTACT in the case of Muscadet. For years, Loire reds suffered from a lack of EXTRACTION.

The result of the particularly competitive wine market of the 1980s and a drop in demand for sweet wines in the late 1990s, however, was to stimulate a rash of experimentation in cellars along the length of the Loire. BARREL AGEING and in some cases BARREL FERMENTATION were introduced for both reds and whites (see ANJOU, specifically). Some producers encouraged their white wines to go through malolactic conversion, while red winemakers worked hard to extract greater colour and TANNINS from their red wine musts with prolonged SKIN CONTACT, TEMPERATURE CONTROL, and PUMPING OVER regimes. (It should be said that, in many a Loire autumn and winter, temperature control is just as likely to include heating the MUST as cooling it.) Skin contact prior to fermentation was also introduced for some white wines, especially Sauvignons.

CHAPTALIZATION has been the norm in the Loire for both reds and whites, except in exceptionally hot vintages.

Vine varieties

At the mouth of the Loire, MELON de Bourgogne and FOLLE BLANCHE predominate. The upper Loire is, in the early 21st century anyway, the terrain of Sauvignon Blanc for white wines and Pinot Noir for reds and rosés. Most of the most successful sites in the middle Loire have proved themselves suitable for either CABERNET FRANC or CHENIN BLANC, but in the thousands of hectares of vineyard planted around them, there is a greater diversity of vine varieties than anywhere else in France, including a mix of CABERNET SAUVIGNON, MALBEC, GAMAY, PINOT MEUNIER, PINOT GRIS, CHARDONNAY, and of course seas of Sauvignon and Pinot Noir. This is usually explained in terms of spheres of Bordeaux and Burgundy influence, but it indicates that, outside its most famous appellations, the regions of the Loire have been searching for their own wine identities. The vineyards of the Loire were particularly badly hit by PHYLLOXERA. The heavily CALCAREOUS soils in many regions meant that CHLOROSIS was a common problem when vines were replanted GRAFTED on to resistant ROOTSTOCKS. The Loire, with its relatively cool climate, persisted with a higher proportion of HYBRIDS longer than any other French wine region. The limits on the role of Chardonnay and Cabernet Sauvignon included in the rules of so many Loire appellations show that the authorities at least are aware of the danger of the Loire losing its own identity, and there are signs of a revival of some varieties that are exclusive to the Loire such as PINEAU D'AUNIS, MENU PINEAU, ROMORANTIN, and Meslier-St-François, although the distinctly ordinary GROLLEAU is in retreat.

Wines produced

Of all French wine regions, the Loire produces the greatest diversity of wine styles: from still through all types of sparkling wine, including the generic CRÉMANT de Loire; from bone dry and searingly tart to unctuous LIQUOREUX (although still with a high degree of acidity); and all hues from water white to deep purple. Rosés are a speciality of the Loire, whether the various VINS GRIS made well upstream, the famous Rosé d'Anjou, various pink Cabernets, or the generic ROSÉ DE LOIRE. The most common IGP wine produced in the Loire is known as Val de Loire.

Travelling upstream, the major districts, with each appellation for which there is a separate entry, are as follows (see map):

Pays Nantais: MUSCADET; GROS PLANT DU PAYS NANTAIS; Coteaux d'ANCENIS; FIEFS VENDÉENS.

Anjou-Saumur: ANJOU; SAVENNIÈRES; Coteaux du LAYON; QUARTS DE CHAUME; BONNEZEAUX; Coteaux de l'AUBANCE; SAUMUR.

Touraine: TOURAINE; CHINON; BOURGUEIL; VOUVRAY; MONTLOUIS; CHEVERNY; VALENÇAY.

Upper Loire: REUILLY; QUINCY; MENETOU-SALON; SANCERRE; POUILLY-FUMÉ.

Northern outposts: Coteaux du LOIR; JASNIÈRES; Coteaux du VENDÔMOIS.

On the bend: ORLÉANS; Coteaux du GIENNOIS.

Southern outposts: HAUT-POITOU; CHÂTEAUMEILLANT; ST-POURÇAIN; Côtes d'AUVERGNE; Côte ROANNAISE; Côtes du FOREZ (although some of these are very far from the Loire and its climatic influence). J.R. & C.P.

Lombardy, known as Lombardia in Italian, is the fourth-largest and, with over 10 million inhabitants, most populous region of Italy; it was the driving force behind the country's post–Second World War economic boom, the dynamo which has given Milan and its hinterland one of Europe's highest standards of living.

Lombardy's principal centres of viticulture are in the hills, divided among no fewer than 21 DOCs and five DOCGs which cater mainly for the many local palates. Currently the five most important areas, each producing very distinct styles of wine, are FRANCIACORTA, LUGANA, OLTREPÒ PAVESE, VALTELLINA, and LAMBRUSCO Mantovano, which is a continuation of the Lambrusco cultivation area in Emilia-Romagna.

One of Lombardy's truly indigenous varieties, GROPELLO, cultivated immediately south-west of Lake Garda, was awarded its own Valtènesi DOC in 2011 but in 2016 demoted to a subzone of the large Riviera del Garda DOC (with a provision for a ludicrous minimum of 30% Gropello), which, together with Lugana DOC, falls entirely within the Garda DOC shared with the Veneto. Its demotion suggests the Valtènesi DOC needs the association with Lake Garda for marketing reasons. W.S.

long, much-derided tasting term for wines whose impact on the PALATE is particularly persistent. A wine that is long is usually of high quality. On the basis of studies in other food systems, it is assumed that wine COLLOIDS have a role to play in lengthening the palate of a wine. This occurs through the interaction of various FLAVOUR COMPOUNDS with particular colloids resulting in some or all of the

wine's flavour compounds being retained in the mouth, along with the associated polymers, after the wine has been swallowed. Delayed release of the flavour compounds then accounts for the persistent or long palate of the wine. See also TASTING and CAUDALIE. P.J.W.

Longyan, red-skinned grape grown in CHINA whose name means 'dragon's eyes'.

Los Carneros. See CARNEROS, California wine region and AVA.

Los Olivos District, largest sub-AVA of SANTA YNEZ VALLEY, a broad, flat ALLUVIAL terrace planted mainly to Bordeaux varieties, plus some SYRAH.

lot marking. See LABELLING INFORMATION.

Loupiac, small, sweet-white-wine appellation of 264 ha/652 acres nestling between CADILLAC and STE-CROIX-DU-MONT on the right bank of the River Garonne in BORDEAUX. Slightly smaller than Ste-Croix-du-Mont and eight times smaller than BARSAC, its vineyards are situated on multifaceted exposures of clay-limestone and occasionally clay-gravel, bordering and above the wooded valleys created by streams running down to the Garonne, often dominated, as in the Médoc, by 'Folies': impressive neo-classical châteaux built as secondary residences by the 18th-century Bordeaux bourgeoisie. The wines are made primarily from SÉMILLON grapes, plus some Sauvignon Blanc and MUSCADELLE, by law harvested manually, over several passes (see TRI) when the grapes are overripened, either affected by NOBLE ROT or raisined. The minimum required pre-fermentation sweetness is one-third less than in Cadillac, accounting for a lighter style of wine, reputed locally as 'delicate and nervous'. W.J.B.

Loureiro, fine, 'laurel-scented', ancient MINHO white grape variety that is the most planted in this VINHO VERDE country in northern Portugal and the second most widely planted white variety in Portugal, which recorded 6,302 ha/15,573 acres in 2020. It is known as Loureira or Loureira Blanca over the border in GALICIA in north-west Spain. Often blended with TRAJADURA (Treixadura in Spain), it can also be found as a particularly aromatic VARIETAL wine. It can yield quite productively in the north of the Vinho Verde region and produces its best quality, usually quite low in alcohol, around Braga, Ponte de Lima, and the coast.

low-alcohol wine. Used informally, this term refers to wines with a lower than normal ALCOHOLIC STRENGTH. This may be achieved through work in the vineyard such as reducing the leaf area (CANOPY MANAGEMENT) or harvesting earlier, through the choice of YEAST strain or by BLENDING different lots of wine. Certain commercial YEAST strains and some non-*Saccharomyces* yeast (e.g. *Metschnikowia pulcherrima*) have been shown to reduce alcohol levels by between 0.2% and 1%, although the latter will not complete fermentation on its own. Higher fermentation temperatures and open-top fermenters may also decrease alcohol levels.

The most common way to produce a low-alcohol wine is to arrest FERMENTATION by refrigeration, resulting in a sweet, low-alcohol, often lightly sparkling drink. This is a particularly common technique in Italy and is conducted at all sorts of quality levels (see MOSCATO D'ASTI or LAMBRUSCO, for example).

Many countries restrict the term 'low alcohol' to wines that have been subjected to ALCOHOL REDUCTION and have a very low maximum alcoholic strength, for example 1.2% in the EU and UK or 1.15% in Australia and New Zealand. Such wines are increasingly popular as part of the fashion for NOLO wines. Owing to their reduced alcoholic strength, such wines are usually excluded from DUTY, reducing their price.

Lower Austria. See NIEDERÖSTERREICH.

Lower Murray Zone, in SOUTH AUSTRALIA, has a single but very important region, the RIVERLAND.

low-input viticulture, or low-intervention viticulture, alternatives to so-called conventional viticulture which aim to minimize inputs to the vineyard. This may be of AGROCHEMICALS, with the aim of improving the environment (see ORGANIC and BIODYNAMIC VITICULTURE), or of inputs such as LABOUR, with the aim of improving the vineyard's profitability. This latter approach was popular in Australia in the 1990s, although the philosophy is more appropriate to the production of BULK rather than FINE WINE. Reducing agrochemical input may in practice increase the labour input.

low-intervention wine is an alternative, rather more descriptive, term for NATURAL WINE.

Luberon is a sort of buffer state between the RHÔNE and PROVENCE, or more precisely between the VENTOUX appellation and that of Coteaux d'AIX-EN-PROVENCE (although French officialdom places it firmly in the Rhône). The appellation, created in 1988, produces significant quantities of wine from around 3,300 ha/8,154 acres of vines, mainly medium-bodied rosés and lightish reds based on Grenache and Syrah (at least 60% of the blend), with smaller amounts of Mourvédre, Carignan, Cinsault, and Marselan allowed. Those who try hard can produce herb-scented reds with some concentration and AGEING potential. As temperatures get rather cool at night (and in winter), the region can produce some of the crisper, more interesting white wines of the southern Rhône and even some successful Pinot Noir in the cooler spots. White wines are made from Grenache Blanc, Clairette, Bourboulenc, Vermentino, and possibly some Marsanne and Roussanne, with the proportion of Ugni Blanc limited to 50% and Viognier to 10%. Rosés may incorporate up to 20% of white grapes and have particular allure when drunk locally to the sound of cicadas. E.A.G.

Lugana, dry white Italian wine based on the grape known as Turbiana or Trebbiano di Lugana and the same as Trebbiano di Soave (VERDICCHIO), produced south and south-west of Lake Garda in the province of Brescia, straddling the provinces of Lombardy and Veneto.

From 2011 to 2020, the region saw plantings grow from 1,100 ha/2,718 acres to over 2,500 ha. Responsible for this growth is Lugana's exponential success in Germany, which takes as much as 40% of its total production. Owing to this unexpected commercial boom, and because bottling outside of the DOC is allowed, counterfeit wines began to appear, which the CONSORZIO has tried to counteract by making an official banderole applied to the neck of the bottle mandatory. At the same time, the success has inspired investment interest by outside producers.

The DOC can be divided in two parts, of which the first is a narrow band of strikingly white clay-limestone soils on the south shore of Lake Garda known locally known as *menadel*. The second, south of the Strada Provinciale 11, in the hills near San Martino della Battaglia, has sandier soils yielding less expressive wines. Differences of TERROIR are often obscured by high yields, while ageworthy versions of Lugana were not uncommon in the past, as evidenced by Ca' Lojera's version which is aged for five years and has inspired the official creation of a Riserva category. W.S.

Lunel is the centre of the Muscat de Lunel appellation for sweet, golden VIN DOUX NATUREL made from MUSCAT BLANC À PETITS GRAINS grapes grown on potentially interesting infertile inland soils between Montpellier and Nîmes. Yields are low and vinification techniques improving, although many local vine-growers have been more interested in developing lower-alcohol, dry Muscats or wines that qualify as LANGUEDOC AOC. A single CO-OPERATIVE is responsible for almost all the wine produced, which, as any geographer might suspect, tastes like a cross between the Muscats of FRONTIGNAN and those of ST-JEAN-DE-MINERVOIS. Lunel's historical claim to fame is less convincing than Frontignan's: its Muscat was dispatched to console Napoléon on the island of St Helena. The town does call itself the Cité du Muscat, however.

Lunel is also the occasional Hungarian name for a yellow-berried form of Muscat Blanc à Petits Grains grown in the TOKAJ region.

Lurtons, ramified family of property owners and winemakers in BORDEAUX, owning more wine estates in the Bordeaux region than any other single family. The original Lurton property is the modest Ch Bonnet in the ENTRE-DEUX-MERS, supplemented by Ch Brane-Cantenac

in MARGAUX in 1925. André (1924–2019) built up an empire mainly in the GRAVES while his younger brother Lucien (1925–2023) built up an impressive empire of CLASSED GROWTHS (among them Chx Brane-Cantenac, Durfort-Vivens, and Desmirail in Margaux, Bouscaut in Pessac-Léognan, and Doisy-Dubroca and Climens in Barsac) before passing them on in 1992 to his ten children.

André's son Jacques has succeeded his father, while his brother François produces wine in France, Spain, and South America.

In 1991 Pierre Lurton (son of Dominique, André and Lucien's younger brother) became the estate manager at Ch CHEVAL BLANC, the St-Émilion first growth, and, later, Ch d'YQUEM for LVMH.

Lussac-St-Émilion, large satellite appellation of ST-ÉMILION in Bordeaux with 1,414 ha/3,493 acres in 2020 making robust reds on a GRAVEL plateau in the west and cooler CLAY soils in the north.

lutte raisonnée, literally 'reasoned struggle', is a French term that describes an approach to viticulture which tries to minimize the application of AGROCHEMICALS so that they are used only when absolutely necessary and not as a matter of routine. See also INTEGRATED PEST MANAGEMENT and SUSTAINABLE VITICULTURE.

Luxembourg, or Luxemburg, was long the EU's smallest and coolest-climate wine producer before being rivalled in both respects by ENGLAND, BELGIUM, the NETHERLANDS, and DENMARK. The rarely exported wines produced are relatively dry and, depending on grape variety, reminiscent of those of Alsace or England in style. With the exception of an increasing number of light reds and rosés made from Pinot Noir and ST-LAURENT vines, the wines made on the western, Luxembourg bank of the river MOSELLE are white. In 2020 there were 1,236 ha/3,054 acres of exceptionally productive vineyard.

History

The German MOSEL, below Trier, and the Luxembourg Moselle above it had to surmount the same problems—COOL CLIMATE and political change—for centuries, but since the First World War the two regions have adopted different solutions. After the war, during which the Grand Duchy remained neutral, Luxembourg was required to break the free-tariff agreement that had been made with Prussia in 1842. Thus a ready market for Luxembourg's sharp whites made from the ELBLING grape evaporated, and Germany looked elsewhere for base wines for SEKT and suitable blending material for the Rheinpfalz's flabbiest wines. The Champagne house Mercier opened up an offshoot in Luxembourg in the late 19th century. A new economic agreement with Belgium signed in 1921 did little to soak up the surplus; Belgian taste is for the richness of POMEROL, the vinous antithesis of Elbling. Thus Elbling has been replaced by softer varieties.

Geography and climate

Luxembourg's vineyards are in two of the Grand Duchy's eastern cantons, Remich and Grevenmacher. On the ALLUVIAL plain of Remich, the heavier soils tend to produce less aromatic, heavier, earlier-maturing wines from such villages as Remich, Wintrange, and Schengen. Parts of the narrower valley of Grevenmacher to the north have been reshaped by terracing, as in the Mosel across the German border, but yields are lower, CALCAREOUS soils predominate, and wines such as the village of Ahn's fine Rieslings are particularly slow maturing. Luxembourg suffers a wide range of cool-climate-related problems such as spring FROSTS, HAIL, and COULURE, so that yields can vary substantially.

Viticulture and vine varieties

Most Luxembourg still wines are VARIETAL wines and labelled as such. Rivaner is the name used here for the MÜLLER-THURGAU that so effectively replaced Elbling in the 20th century that by the early 1980s it was planted on half of the Grand Duchy's total vineyard, being relatively easy to ripen whatever the local conditions. Its ability to yield obligingly high quantities was so abused by many growers, however, that it became synonymous with mediocrity and declined considerably to 276 ha/682 acres by 2020, about one-fifth of the country's vineyard. Much of it was replaced by Pinot Gris (195 ha/482 acres), highly regarded for its low acidity and its ripening potential. Pinot Blanc (165 ha/408 acres) and Pinot Noir (128 ha/316 acres) have also been enthusiastically planted, chiefly for CRÉMANT sparkling wine. Pinot Blanc's close relative AUXERROIS enjoys higher status in Luxembourg than anywhere else in the world (and certainly higher than in Alsace, where ten times as much is planted). Its low acidity is a positive attribute this far from the equator; when yields are curbed, BARREL-AGED Luxembourg Auxerrois can produce smoky, full-bodied wines worth AGEING. Total plantings in 2020 were 193 ha/477 acres. Although some Chardonnay and Gewürztraminer is planted, the only other significant variety is Riesling (164 ha/405 acres), whose stately ageing curve put many Luxembourg wine drinkers off for years, but a new generation of producers seems to have understood the need to pick Riesling later and achieve more consumer-friendly flavours.

Prior to the 2000s, CHAPTALIZATION was often a necessity, but CLIMATE CHANGE has made it less so. Still, the wines can be marked by relatively high acidity, and DEACIDIFICATION may be practised by some producers. An increasing number of wineries have moved to ORGANIC VITICULTURE, inspired by research led by the Stëftung Hëllef fir d'Natur (Foundation Help for Nature) as well as the success of Domaine Sunnen-Hoffmann, the country's first certified estate (2001). Today some 18 producers have taken partly or totally the same direction.

Appellations

There is just one Appellation Protégé (AOP), Luxembourg's answer to the AOC system of France: Moselle Luxembourgeoise is allowed for practically all wines, both still and sparkling, although they all must be submitted for analysis and tasting. Superior wines (excluding Pinot Noir and Elbling) may also be ranked a Grands Premiers Crus and Premiers Crus if yields do not exceed 75 hl/ha and 85 hl/ha respectively. (The maximum yield allowed for the French MOSELLE is 60 hl/ha.) Furthermore, the use of the terms 'Côtes de', 'Coteaux de,' and 'Lieu-Dit' are also regulated. Wines labeled 'Côtes de' have maximum permitted yields of 100 hl/ha (115 for Elbling and Rivaner); those labelled 'Coteaux de' and 'Lieu-Dit' must be manually harvested at less than 75 hl/ha within specifically delineated areas.

Since 1993, there has been some limited experimentation with ICE WINES and other sweet wines, with official regulation in 2001. Pinots Blanc and Gris and Riesling picked at −7 °C/19 °F with a MUST WEIGHT of at least 120 °Oechsle may be labelled *vin de glace*. The same regulations allow Auxerrois, Pinot Blanc, Pinot Gris, and Gewürztraminer with 105 °Oechsle and Riesling with 95 °Oechsle to be sold as VENDANGES TARDIVES, while the appellation VIN DE PAILLE may be used for Auxerrois, Pinot Blanc, Pinot Gris, and Gewürztraminer with at least 130 °Oechsle.

More than one-quarter of Luxembourg's total AOP wine production is in sparkling wines, both MOUSSEUX and especially TRADITIONAL METHOD. For more details, see CRÉMANT de Luxembourg.

Industry organization

As in the German Mosel, the average vine-holding is extremely small —4.77 ha/12 acres in 2020—although it is gradually increasing as more of the smallest holdings are sold to larger landowners. The number of growers more than halved during the 20 years up to 2020 to 268. Just 30% of vines are grown by independent domaines which make wine themselves. Several wine CO-OPERATIVES together function as Vinsmoselle and represent 52% of the Grand Duchy's wine production. A.D.

aop.lu/luxembourg

LVMH, scrupulously even-handed acronym for Moët Hennessy-Louis Vuitton, the French luxury goods conglomerate which has a dominant interest in the CHAMPAGNE industry, not least through its subsidiaries, which include MOËT & CHANDON, KRUG, VEUVE CLICQUOT, and Ruinart, and a leading position in Cognac through Hennessy. For more details of LVMH's champagne interests, see MOËT & CHANDON. Since the late 1950s the company has developed a substantial position in the premium SPARKLING WINE market through the creation and development of the Chandon brand in Argentina, Brazil, the US, Australia, China, and India.

LVMH's still-wine assets include CLOUDY BAY, Cape Mentelle in WESTERN AUSTRALIA, Terrazas de los Andes in MENDOZA, Numanthia in TORO, and Newton in the NAPA Valley, where the company bought a controlling stake in Colgin in 2017. In 2019 it acquired Ch Galoupet in PROVENCE and, subsequently, a controlling stake in the producer of the leading rosé brand, also in Provence, WHISPERING ANGEL. In 1998 LVMH acquired a substantial stake in Ch d'YQUEM, while its chief executive Bernard Arnault became co-owner of Ch CHEVAL BLANC. Another jewel in the crown is the GRAND CRU Clos des Lambrays in

MOREY-ST-DENIS, bought for an eye-watering sum in 2014. Ao Yun is an ambitious, small-production Cabernet blend made at ELEVATION in Yunnan, the result of a four-year search for China's most propitious red-wine-producing area.

www.lvmh.com

Lyonnais, Coteaux du, light white, pink, but mainly red wines made chiefly from about 280 ha/692 acres of vines in the hills both north and south-west of the city of Lyons, considered part of greater Burgundy by French wine authorities, and drunk mainly by its inhabitants. The red wines, all GAMAY, can be every bit as good as nearby BEAUJOLAIS, although the appellation was granted only in 1984. A small amount of white wine is also made, from Chardonnay and ALIGOTÉ. The CO-OPERATIVE at Sain-Bel vinifies three-quarters of production.

lyre, a vine-TRAINING SYSTEM whereby the CANOPY is divided horizontally into two curtains of upward-pointing SHOOTS, resembling a lyre in shape (see illustration). The system was developed in Bordeaux in the early 1980s by Dr Alain Carbonneau (see MONTPELLIER). Carbonneau was much influenced by the pioneering studies of Nelson SHAULIS in CANOPY MANAGEMENT. The lyre system improves the CANOPY MICROCLIMATE and leads to improvement in YIELD and wine quality because of better leaf and fruit exposure to SUNLIGHT. Either SPUR PRUNING or CANE PRUNING can be used. Further use of this system has been delayed by the unavailability of suitable MECHANICAL HARVESTERS. The system has been adopted in NEW WORLD vineyards in particular, especially in California, and to a lesser extent in Australia, New Zealand, Chile, and Uruguay, but it has also been implemented in some vineyards in Beaujolais.

The lyre system is essentially an inverted GENEVA DOUBLE CURTAIN, with the two adjacent curtains of foliage trained upwards rather than downwards. Both systems are used to reduce the shading of dense canopies (see SHADE). The lyre system is typically recommended for medium-VIGOUR vines, whereas the GDC can harness higher vine vigour. The lyre system has shown substantial improvements in wine quality where it has been evaluated. R.E.S.

Cross-section of **lyre**-trained vines during the growing season.

Vine training to the **lyre** system showing spur pruning (cane pruning can also be used).

lyric poetry. There are many references to wine in the lyric poets of ancient GREECE. Archilochos, writing in the middle of the 7th century BCE, describes the comfort brought by wine on a long sea journey:

Along the rowers' benches bring your cup
And lift the lids of the big wine jars up
And drain the good red wine: we can't, 'tis clear
Be sober all the time we're watching here.

Fifty years later, Alkaios of Lesbos (who knew and admired the poetess Sappho) has many references to wine, often in vigorous verse: 'Wet your lungs with wine; for the dog star is coming round, and everything is thirsty with heat.' In an early variant of not waiting for the sun to be over the yard-arm, he writes: 'Drink! Why wait for the lamps? The day is almost done!'

The curmudgeonly Theognis, writing at the same time, probably from Megara on the isthmus of Corinth, extols the value of wine and the dangers of DRUNKENNESS: 'Stand by ready to pour for those who want to drink. We cannot have a party every night. Still because I am moderate in my use of honeyed wine, I reach my house before I think of soothing sleep, and I make clear how divine a beverage for man is wine.' H.H.A.

M

Macabeo is northern Spain's second most planted white grape variety (considerably after AIRÉN), whose total had grown to 55,073 ha/136,088 acres by 2020. Around the early 19th century it spread to southern France, where, as Maccabéo or Macabeu, it was still planted on 1,714 ha/4,235 acres in 2019, mainly in ROUSSILLON. It buds and ripens too late to be grown much further north but is quite productive.

It is grown in most Spanish regions apart from Galicia and the far south with the greatest areas in CASTILLA-LA MANCHA, where it makes relatively bland dry whites, and in CATALUÑA, where it is an ingredient in CAVA, generally blended with Xarello and Parellada. Around 2,000–3,000 ha remain in each of ARAGÓN and RIOJA, where, as Viura, it replaced Malvasia Fina and Garnacha Blanca after PHYLLOXERA. Average VINE AGE is high in Rioja and can be matched by wine QUALITY if yields are restricted.

In early-picked form, in Roussillon it is either a fairly characterless white or a useful ingredient in rosé. However, in both Roussillon and Rioja it can also make fine BARREL-AGED and ageworthy whites. In the LANGUEDOC, in the white wines of Minervois and Corbières, it may be blended with BOURBOULENC, GRENACHE BLANC, and a host of other southern white varieties.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Macarthur, Sir William (1800–82), was the most influential wine pioneer in the Australian colonies during the 19th century.

Although James BUSBY is regarded as the father of the Australian wine industry, he did little to nurture it, having left New South Wales in 1833 for New Zealand. William Macarthur on the other hand fostered viticulture and winemaking throughout his lifetime through patronage, philanthropy, and grand agricultural visions for Australia.

William Macarthur was the youngest son of wealthy pastoralists John and Elizabeth Macarthur, who played an important role in developing the colony's wool and wine industries. In 1808 William and his brother James accompanied John Macarthur to England, where they were educated until 1815, when they travelled with their father to France, witnessing Napoleon Bonaparte's triumphant return to Paris. After a brief period in Switzerland during the lead-up to the Battle of Waterloo, they journeyed through the south of France and sourced grapevine CUTTINGS. After their return to Australia in 1817, the cuttings and other plant material including 'olive, fig and caper' were planted at the Macarthur's Camden Park estate, prime agricultural land south of Sydney. But it became evident once the cuttings bore fruit that a mix-up by the London nurseryman entrusted to look after the cuttings resulted in only a few new varieties being introduced into New South Wales.

A letter in 1824 from the 24-year-old William Macarthur mentions 'the first vintage at Camden is ready to be pressed and a few bottles will be sent to England'. The following year more grape varieties were imported into New South Wales. According to James Busby, John Macarthur was the first to introduce the Burgundy Grape (Pinot Noir), Miller's Burgundy (PINOT MEUNIER), VERDELHO, Sweetwater (CHASSELAS), and three types of MUSCADELLE. But it was William Macarthur who initiated and managed the importation of vine cuttings.

On learning of Busby's plan to return to Europe, James and William Macarthur partially sponsored his seminal journey through Spain and France in 1830. On his return to New South Wales in 1831, duplicate cuttings of Busby's 'great vine importation' were planted at Camden Park. In 1834 the Busby Collection planted in Sydney's Botanical Garden was appraised by Francis Forbes, Alexander McLeay, Sir John Jamison, and William Macarthur at the behest of Governor

Major General Sir Richard Bourke. Almost certainly this led to Camden Nurseries importing 'a collection of the best sorts cultivated in the Medoc' in 1837. This included the first importation of Cabernet Sauvignon. William Macarthur also claims to have brought in the first Riesling cuttings to Australia in 1838 (with the assistance of German vineyard workers from the famed Marcobrunn vineyard in the Rheingau who were employed to supervise the vineyards at Camden).

By the 1840s, Camden Park was the colony's most significant nursery of colonial vines, ornamental trees, and plant material. It supplied cuttings to Thomas Shepherd's Darling Nurseries at Darlington, Bailey's Gardens in Adelaide, and John Pascoe Fawkner and John James Rule near Melbourne. Macarthur also sold vine cuttings directly to landed farmers, including the Ryrie, Angas, Gilbert, and Reynell families. In addition, Camden Park was a renowned breeding stud of thoroughbred horses.

Wealthy, enlightened, curious, and generous in nature, William Macarthur was by far the most influential wine man of his day. 'Letters on the culture of the vine, fermentation, and the management of wine in the cellar, by Maro' (a pseudonym he used) were regularly published by newspapers (and then compiled into a book in 1844), distilling the progress of winemaking in New South Wales and inspiring settlers to grow grapes and make wine. In 1850 William Macarthur established the New South Wales Vineyard Association, which played an important role in developing a colonial wine industry.

William Macarthur's interests and achievements were much wider than viticulture and would eventually lead to a knighthood (the first Australian-born colonialist to receive this honour) and to being appointed a Chevalier of the Légion d'Honneur by Napoleon III. His practical expertise in mixed farming, economic botany, agricultural science, and winemaking helped shape the progress of colonial agriculture and the Australian wine industry during the mid-to-late 19th century. The destruction of Camden Vineyards by PHYLLOXERA around 1885 just three years after his death marked the end of an era.

H.A.C.

Macedon Ranges, fashionable Australian wine region in VICTORIA's Port Phillip Zone, with sparkling wines, Chardonnay, and Pinot Noir performing well on account of its ELEVATION-derived cool climate.

Maceratino, increasingly rare white grape grown on 39 ha/96 acres of the MARCHE in 2015. Possibly related to VERDICCHIO.

maceration, ancient word for steeping a material in liquid with or without a kneading action to separate the softened parts of the material from the harder ones. This important process in RED WINEMAKING involves extraction of the PHENOLICS (TANNINS, colouring materials, or ANTHOCYANINS, FLAVOUR PRECURSORS, and non-glycosylated FLAVOUR COMPOUNDS) from the grape skins, seeds, and stem fragments into the juice or new wine. Maceration is governed by TEMPERATURE, by contact between the solids and liquid and the degree of agitation, by time, and by the composition of the extracting liquid, in this case the grape juice as it becomes wine. Although some everyday red wines are made simply by a rapid fermentation lasting just two or three days, many winemakers encourage an additional post-fermentation maceration, particularly for long-lived wines such as red BORDEAUX. If fermentation is slow to start, possibly due to the low temperature of the grapes and/or the use of AMBIENT YEAST, the winemaker may take advantage of or even encourage the pre-fermentation maceration that results.

The maceration process should never extract all of the phenolics from red grapes, only the best part. This is why the winemaker's choices regarding the intensity, method, and duration of extraction are critical. The speed at which the anthocyanins are released from the skins depends on the vintage and the variety, starting during the aqueous phase before the tannins are released. The extraction of tannins increases as the alcohol level rises. Reactions progressively occur among the compounds newly released, leading to the

formation of PIGMENTED TANNINS. Winemakers must use trial and error, often over many years, to decide which are the optimum maceration conditions for each grape variety and season. Rapid laboratory analyses can help to estimate colour and tannins (and Ferré has shown in his *Traité d'œnologie bourguignonne* that extraction reaches a maximum of 80% of the grapes' available colouring matter on the sixth day of maceration), but the winemaker's eye and palate often prove surer guides.

Both heat and alcohol encourage the extraction of compounds, which is fortunate since both are produced by fermentation. As fermentation continues, heat is produced and the increasingly alcoholic liquid becomes a better and better solvent for the organic compounds to be extracted.

During fermentation, the bubbles of CARBON DIOXIDE gas generated tend to make the grape skins float to the surface in the FERMENTATION VESSEL to form a layer known as a CAP. For generations, winemaking ingenuity has been harnessed to devise methods of breaking up and submerging the cap to keep the skins and liquid in contact. This is relatively simple with small batches of fermenting grapes (see PUNCHING DOWN). With larger batches, a system of either grids or coarse mesh screens must be devised to keep the cap SUBMERGED, or liquid from the bottom of the tank must be pumped to the top and sprayed over the skins (see PUMPING OVER and RACK AND RETURN).

Several proprietary systems have been devised to extract the desirable organic compounds from the grape skins into the fermenting wine. Some of these use a quick high-temperature phase to disrupt the cells containing anthocyanins and liberate the desirable organic compounds (see THERMOVINIFICATION and FLASH DÉTENTE); others use mechanical stirrers or rotating tanks (see ROTOFERMENTERS) which keep the skins and liquid in contact; or some form of AUTOVINIFICATION. The use of pulsed electric fields has been found to make the cell membranes in the skins more permeable without the need to heat the must. Nanofiltration is another method that avoids the use of heat and has been successfully tested in Bordeaux. Trials

in New Zealand found that cutting up the grape skins prior to fermentation increased the speed of extraction. In general, heat and mechanical agitation systems are used for ordinary wines, while the more sensitive techniques of punching down or pumping over are preferred for finer wines, although care must be taken that any pumps used are relatively gentle. In squat tanks there is greater extraction than in tall ones because of the greater relative area of skin-to-juice contact.

Along with temperature, liquid composition, and intimacy of contact, the fourth factor influencing colour, tannin, and flavour extraction is time of contact, an aspect, albeit less than perfectly understood, over which winemakers can have total control (provided they have access to sufficient vat space). In general the longer the solids and liquids are in contact, the greater the degree of extraction, but it depends on the frequency of pumping over or punching down. It has been shown, however, that the extraction of the desirable compounds slows down considerably after the new wine approaches 10% alcohol and is at its height during the earlier phases of fermentation. The total maceration time varies according to the phenolic content of the skins (itself a function of grape variety and weather) and according to the desired style of wine. In red winemaking, maceration usually lasts at least as long as fermentation does, but it may be prolonged for a further week, sometimes longer. Punching down and pumping over are usually avoided during this later phase so as not to extract more astringent tannins. Care must also be taken to avoid the increased risk of high levels of VOLATILE ACIDITY, by protecting the cap with INERT GAS. Maintaining the temperature of the wine at 28–30 °C/82–86 °F during any post-fermentation maceration will improve the texture of the tannins.

Some wine producers favour a pre-fermentation cold maceration of red grapes rather than maceration of skins in an alcoholic liquid. This optional winemaking operation involves the maceration of grape skins with juice while the mass is held at a low temperature with the aims of extracting colour and producing more intense fruit aromas. A quite different red winemaking technique is CARBONIC MACERATION,

practised particularly in BEAUJOLAIS and for other red wines designed for early consumption.

See also BARREL FERMENTATION for an outline of a red winemaking option which dispenses with post-fermentation maceration altogether.

In WHITE WINEMAKING, maceration is usually actively discouraged by separating the juice from the skins as soon as possible in order to avoid extraction of tannins, since no colouring matter is required and the resultant ASTRINGENCY is generally viewed as a fault in white wines. However, some winemakers deliberately allow a certain period of SKIN CONTACT for white grapes before they are crushed, and in the late 1980s this technique (known as macération pelliculaire in French) was encouraged by Denis DUBOURDIEU among others in order to produce more flavourful dry white wines. Sauvignon and Gros Manseng grapes, for example, are held for 4–8 hours at about 18 °C/64 °F, resulting in juice higher in flavour compounds and flavour precursors, tannins, POTASSIUM salts, and POLYSACCHARIDES, and wines with more BODY and a slightly higher PH. Fermenting white wine on the skins has become increasingly popular, particularly but not exclusively in tandem with the use of clay fermentation vessels such as AMPHORAE, TINAJAS, TALHAS, PITHARI, and QVEVRI. See SKIN-FERMENTED and ORANGE WINE. The OIV has recently added 'white wine with maceration' to the list of 'special wines' in its International Code of Oenological Practices.

Maceration is also important in the production of fruit-flavoured spirits such as the *crème de cassis* used in making a *vin blanc cassis* or KIR, which is the aromatic and deeply coloured product of blackcurrants macerated in alcohol. V.L.

OIV, 'International Code of Oenological Practices'. www.oiv.int/en/technical-standards-and-documents/oenological-practices/international-code-of-oenological-practices.

macération carbonique, French term for CARBONIC MACERATION.

macération pelliculaire, French term for the pre-fermentation maceration of white grapes described in MACERATION and known in English as SKIN CONTACT.

macération préfermentaire, French term for pre-fermentation MACERATION. In Beaujolais, the term *macération préfermentaire à chaud* (*MPC* or *thermo*) refers to a technique involving heating just-picked grapes to about 65 °C/150 °F then chilling them back down to about 25 °C after 12 hours. The first part of fermentation is carried out on the GRAPE skins, but fermentation is completed after pressing (see THERMOVINIFICATION).

McLaren Vale, intensively planted, historic SOUTH AUSTRALIAN wine region especially noted for rich reds. These have a distinctive and often useful dash of dark chocolate in their make-up and are typically high in alcohol. An eclectic collection of winemakers makes for a vibrant cellar door scene, and many producers experiment with alternative Mediterranean varieties and innovative winemaking styles. Notwithstanding, the bulk of production is dominated by Shiraz, Cabernet Sauvignon, and Grenache. R.J.T.

Mâcon , important commercial centre on the River Saône and capital of the Mâconnais dynamic district of BURGUNDY which produces considerable quantities of white wine and some red. Unlike in the Côte d'Or to the north (see map under FRANCE), vineyards on the rolling LIMESTONE hills of the Mâconnais are interspersed with land dedicated to livestock and arable farming. Côte d'Or producers as renowned as Leflaive and Lafon have invested in this southerly region.

The climate and ambience of the region differ from the Côte d'Or however: southern tiles are used for roofs, cicadas can be heard in

summer, and the vineyards benefit from more sun, less rain, and little risk of frost. BEAUJOLAIS is to the immediate south of the Mâconnais.

Viticultural practices are broadly similar to those in the CÔTE D'OR, except for the widespread use of LYRE training systems, although yields may be a little higher, up to a permitted 66–70 hl/ha for whites and 58–64 hl/ha for reds, depending on the exact denomination. Vinification is sometimes carried out in barrels, although only the best producers use new OAK. Bottling normally takes place in the summer before the next vintage.

The appellations of Mâconnais, in approximately ascending order of quality, are, for white wines made from Chardonnay: Mâcon; Mâcon-Villages or Mâcon followed by a particular village name (for more details of which, see MÂCON-VILLAGES); ST-VÉRAN; Pouilly-Vinzelles, Pouilly-Loché, and POUILLY-FUISSÉ. Red-wine appellations are Mâcon and Mâcon followed by a particular village name. Almost all these red wines are made from the GAMAY grape since, although Pinot Noir is permitted, such wines may be sold as BOURGOGNE Rouge at a higher price than Mâcon fetches.

In 1998, the villages of Viré and Clessé, including the hamlet of Quintaine, were given their own appellation, VIRÉ-CLESSÉ. J.T.C.M.

Mâcon-Villages, appellation covering the great majority of the white wines of MÂCON. The wines may be sold either as Mâcon-Villages or as Mâcon followed by the name of the particular village. Viré and Lugny have been the best known by virtue of their CO-OPERATIVES. The full list of 27 villages or groups of villages with the right to the appellation is: Azé, Bray, Burgy, Bussières, Chaintré, Chardonnay (whence the grape may have taken its name), Charnay-lès-Mâcon, Cruzille, Davayé, Fuissé, Igé, Loché, Lugny, Mancey, Milly-Lamartine, Montbellet, Péronne, Pierreclos, Prissé, La Roche-Vineuse, Serrières (reds only), St-Gengoux-le-National, Solutré-Pouilly, Uchizy (whites only), Vergisson, Verzé, and Vinzelles.

Most Mâconnais wines are vinified in STAINLESS STEEL or glass-lined CONCRETE vats for early bottling and consumption within a year or two of the vintage. A handful of growers are producing significantly finer wines through low yields followed by BARREL FERMENTATION and BARREL AGEING. J.T.C.M.

macroclimate, also called regional climate, means a climate broadly representing an area or region on a scale of tens to hundreds of kilometres. Unlike the more precise terms MICROCLIMATE and MESOCLIMATE, 'macroclimate' approximates to what is normally meant by the word 'climate'. It is usually based on data from a long-established and topgraphically representative weather station within the region.

Macroclimatic data have to be used with caution when applied to viticulture. Informed adjustments are nearly always needed for differences in ELEVATION, slope, and ASPECT before reasonable estimates can be made for the mesoclimates of actual vineyards. This is especially so in cool regions, where small differences in local temperature can make differences in timing and completeness of RIPENING. R.E.S.

Dry, P. R., and Smart, R. E., 'Vineyard site selection', in P. R. Dry and B. G. Coombe (eds.), *Viticulture*, i: *Resources* (2nd edn, 2004).

macro-oxygenation, an umbrella term for the deliberate exposure of wine to OXYGEN that contrasts with MICRO-OXYGENATION, including the very specific technique of that name. See AERATION, PUMPING OVER, RACK AND RETURN, RACKING, BARREL FERMENTATION, and BARREL AGEING. See also TOTAL PACKAGE OXYGEN.

Macvin du Jura, powerful VIN DE LIQUEUR made in the JURA in eastern France by blending hardly fermented grape juice with MARC du Jura. This somewhat sweet but curiously earthy drink should be

served cool as an APERITIF or with ice cream dishes. A version involving spices and heated must was made as early as the 14th century. Macvin white, rosé, or red was awarded its own AOC, the 400th created by the INAO, in 1991. W.L.

Madagascar , large tropical island off the east African coast which was a French colony between 1896 and 1960 and has a wine industry that has since been run largely by Chinese immigrants. The island had about 2,704 ha/6,682 acres of vines in 2020 according to OIV figures. Due to heat and humidity, mainly HYBRID vines are grown in the central Hauts-Plateaux area at ELEVATIONS of 750–1,350 m/2,361–4,429 ft. Swiss settlers encouraged the Betsileo farmers to apply their expertise growing rice on high terraces to viticulture in the 1960s. The hundreds of vine-growers, with just a few hectares of vineyard each, are centred on Fianarantsoa and Ambalavo.

Madeira , Atlantic island belonging to Portugal, nearly 1,000 km/625 miles from the Portuguese mainland and 750 km/466 miles off the coast of North Africa, now a DOP for FORTIFIED wines. (The island's unfortified wines take either the DOP Madeirense or the IGP Terras Madeirenses; see MADEIRENSE.) Fortified madeira makes up nearly 94% of the island's production and is probably the world's most resilient and longest-lived wine.

History

Like PORT, madeira seems to have begun as an unfortified wine. There are few early records, but Madeira's strategic position in the middle of the Atlantic put the island at an advantage, and its capital Funchal became a natural port of call for ships en route to Africa, Asia, and South America. Madeira's wine industry was well established by the end of the 16th century (less than 200 years after the discovery of the island). However, the early madeira wines were unstable, and many deteriorated long before they reached their destination. Alcohol (probably distilled from cane sugar) was therefore added to some wines to help them survive a long sea voyage, although FORTIFICATION did not become general practice until the mid 18th century.

In the second half of the 17th century, ships en route to India (including many of the DUTCH EAST INDIA COMPANY fleet) called regularly at Funchal to pick up casks of wine termed *pipas* or PIPES. It was soon found that madeira somehow tasted better after pitching and rolling across the tropics in the hull of a ship. With this came a fashion for *vinho da roda*, wines that had benefited from a round trip, as opposed to *vinho canteiro*, wine which matured on the island, called after the trestles (*canteiros*) on which the pipes rested in the warehouse (ARMAZÉM). Wines continued to undergo long tropical sea journeys to induce this special flavour until the 1900s. Over the preceding century most shippers turned to using ESTUFAS, rooms or tanks in which the wine could be artificially heated to simulate the rapid maturation brought about by a long sea journey—although the finest madeiras continue to be aged naturally on *canteiros* (see below).

With the colonization of North America in the 17th century, Madeira established an important export market. By the end of the 18th century, the new North American colonies were buying one-quarter of all the wine produced on the island. Madeira was held in such high esteem that it was used to toast the Declaration of Independence in 1776. Colonial troops returning to Britain opened up

a new market for madeira there, and the drink became popular with Portuguese settlers in Africa and in Brazil as well. Demand began to outstrip supply. Then, in 1851, the first of a series of crises struck Madeira's wine industry. Oidium or POWDERY MILDEW reached the island (in the same year as it was first identified in BORDEAUX) and quickly spread through the dense vineyards, almost wiping out production in just three years.

The industry revived after it was found that oidium could be controlled by dusting the vine leaves with SULFUR, but shortly afterwards PHYLLOXERA struck, leaving the island's wine-based economy in ruins. From the mid 1870s, vines all over the island were replaced by sugar cane. Wine shippers abandoned Madeira, and many vineyards were never replanted.

Phylloxera-resistant AMERICAN VINE SPECIES were introduced a decade or so later, but many farmers, seeking a rapid return to prosperity, cultivated VITIS *labrusca*, *riparia*, *rupestris*, and hybrid vines rather than using them merely as ROOTSTOCKS on to which Madeira's traditional VITIS VINIFERA varieties could be grafted.

Madeira's wine industry returned to normal levels of production at the beginning of the 20th century, and shipments to traditional markets were restored. But the island's economy was dealt another blow by the Russian Revolution in 1917 and then by PROHIBITION in the United States. Many firms were forced to close, but a number chose to form the Madeira Wine Association, renamed as the Madeira Wine Company in 1981.

Although at the end of the 17th century there were about 30 wine shippers operating on Madeira, by the mid 2010s there were just six exporters, of which JUSTINO'S (Justino Henriques) is now the largest wine producer on the island, although the best known is probably the Madeira Wine Company comprising BLANDY, Cossart Gordon, Leacock, and Rutherford & Miles among more than 20 brand names. In 1988, the SYMINGTON family of OPORTO took control of the company and thoroughly overhauled the winemaking practices and equipment. In 2011 they sold back their stake to the Blandy family.

France, Germany, and the Benelux countries are the largest markets for modern madeira, although most of the wine destined for these countries is of very basic quality and bought for cooking rather than drinking. The United States, Japan, and the United Kingdom are the main markets for better-quality madeira.

Viticulture

Madeira is a difficult place to grow grapes. Nearly all the island's vineyards are planted on tiny step-like terraces called *poios*, carved from the red or grey BASALT bedrock. Although most of the newer vineyards are CORDON-trained, most vineyards are planted on low trellises (known as *latada*) similar to those of the VINHO VERDE region on the Portuguese mainland. These serve to raise the CANOPY above the ground, making the grapes less vulnerable to the FUNGAL DISEASES that thrive in this damp, subtropical climate. With a mean annual temperature of 19 °C/66 °F and high rainfall, powdery mildew and BOTRYTIS BUNCH ROT are constant threats.

Viticulture at this latitude is only made possible by ELEVATION. Madeira rises to over 1,800 m/5,900 ft, and the mountains are almost perpetually covered in cloud as moisture in the warm oceanic air is forced to condense. Annual rainfall on the island's summit reaches nearly 3,000 mm/117 in, over three times the total in the island's capital Funchal on the south coast. The network of IRRIGATION channels called *levadas* now extends to over 2,000 km/1,200 miles, supplying the 1,700 growers farming 420 ha/1,038 acres of piecemeal VINIFERA vineyard authorized to produce both DOP Madeira and Madeirense wines. MECHANIZATION is rendered impossible by both the terracing and the small size of the vineyard plots. As a result, cultivation costs are high; many vineyards on the south of the island have fallen prey to property speculation, while others on the north side, mostly planted with American hybrids, have been abandoned.

Vine varieties

The most planted variety by far is the red-skinned Tinta Negra or NEGRAMOLL (formerly known on the island as Tinta Negra Mole) which has been the principal *vinifera* variety on the island since phylloxera arrived at the end of the 19th century. It was long denigrated, somewhat unfairly in view of its versatility, but is now officially 'recommended'. It is sometimes blended with the more recently introduced red-skinned COMPLEXA grape. Plantings of the traditional varieties SERCIAL, VERDELHO, BUAL, MALVASIA, and TERRANTEZ are slowly increasing once again since their rout as a result of phylloxera. Other varieties planted are principally disease-resistant AMERICAN HYBRIDS such as Cunningham and Jacquet, although they are no longer permitted as ingredients in madeira and should be used exclusively in the production of the island's rustic table wine. Small quantities of ARNSBURGER and Cabernet Sauvignon are planted on the north side of the island for the production of unfortified wine. Listrão (PALOMINO) is planted on the nearby island of Porto Santo where a small quantity of FORTIFIED WINE is made, mostly for the local market.

Winemaking

Methods of production vary enormously according to the market and the price that the wine commands. Production revolves around the use of the ESTUFA system and its natural alternatives.

The *estufagem* process has been much improved in recent years with concrete tanks having been largely replaced by stainless steel (*cubas de calor*) ranging in size from 20,000 to 50,000 l/5,280–13,200 gal and widely used for large-volume production. Hot water circulates through a jacket around the tank, heating the wine to a maximum temperature of 55 °C/130 °F for at least 90 days. The process is carefully monitored by the wine industry's controlling body IVBAM (Instituto do Vinho, do Bordado e do Artesanato da Madeira) which also represents Madeira's other traditional industries, embroidery and handicrafts.

A second type of *estufagem* (once used exclusively by the Madeira Wine Company) takes place in 600-l/158-gal wooden casks or lodge pipes which are stored in warm rooms (*armazens de calor*) heated by the nearby tanks or by steam-filled hot water pipes. Temperatures would usually range between 30 and 40 °C, and the wines developed over a longer period, usually six months to a year.

Some of the smaller shippers and stockholders (*partidistas*) refuse to resort to the *estufa* to age their wines. These madeiras are left to age naturally in 600-l pipes stowed under the eaves of *armazéns* in Funchal, heated only by the sun. These *vinhos de canteiro* often mature in cask for 20 years, although some may remain in this state for a century or more before bottling and are usually destined for vintage lots.

One of Madeira's most pressing problems was a lack of good-quality base wine caused by a shortage of grapes from *vinifera* varieties. The white Sercial, Verdelho, Malvasia, and Terrantez varieties are challenging to grow and still in relatively short supply. Most madeira is therefore made from the versatile and more productive Tinta Negra.

Traditionally, shippers bought unfermented MUST direct from the growers, who trod the grapes by foot in LAGARES. Today few winemakers use *lagares*, and the main shippers buy grapes rather than must, from farmers all over the island. Most firms ferment in 25,000-l/6,600-gal vats made from stainless steel, but a few still use lined concrete or even ferment small quantities of wine in cask. Tinta Negra is usually pressed and fermented on its own; Malvasia and Bual are traditionally fermented on their skins, while Sercial and Verdelho musts are separated from the grape skins before fermentation.

Higher-quality wines (usually those made with a high percentage of the more expensive noble grapes) are made by arresting the fermentation with 95%-strength grape spirit to produce a wine with an ALCOHOLIC STRENGTH of 17–18%. Wines made from Malvasia and Bual are fortified early in the FERMENTATION process, leaving up to 7 °Baumé (see MUST WEIGHT for conversions into other measurement scales) of RESIDUAL SUGAR in the wine. Verdelho and Sercial are fermented until they are practically dry, although they may be sweetened at a later stage with either *vinho surdo* or *abafado*. *Surdo* is an intensely sweet MISTELA fortified to an alcoholic strength of 20%, often before fermentation has begun, while *abafado* is a drier wine arrested at a later stage.

In the past, producers of the cheapest wines would ferment all wines dry, leaving the fortification until after the wines have passed through the *estufa*. This saved on the cost of valuable alcohol, a few degrees of which are lost through evaporation during *estufagem*. The wines are sweetened after fortification according to style and often darkened with caramel.

The wines' age is counted from the point at which *estufagem* has been completed. Until 2002 the most basic wines were generally shipped in BULK (*granel*), but this practice has been suspended. Only so-called 'denatured' wines (usually adjusted with salt and pepper) are now permitted to be shipped in bulk.

Styles of madeira

The quality of even the most basic madeira improved greatly in the late 1990s and early 2000s. Inexpensive wines are now much fresher and cleaner, even if they are not as incisive as cask-aged examples. Finer wines are distinguished by their high-toned RANCIO aromas and searing ACIDITY. Madeira varies in colour from pale gold to deep mahogany, with a yellow-green tinge appearing on the rim of well-aged examples.

Standard blends Madeira's wines were traditionally named after the principal grape varieties grown on the island: Sercial, Verdelho, Bual (or Boal), and Malvasia (or MALMSEY), these names denoting increasingly sweet styles of madeira. But since phylloxera destroyed many of Madeira's best vineyards at the end of the 19th century, much of the island's wine has in reality been made from either AMERICAN HYBRIDS or the local *vinifera* variety Tinta Negra. The use of American hybrids has technically been illegal since 1979. From the beginning of 1993, Madeira has been made to conform to the EU requirement that a VARIETAL wine must contain at least 85% of wine made from the specified grape variety. Insufficient quantities of the traditional varieties resulted in renaming most standard blends simply 'Dry', 'Medium Dry', 'Medium Sweet', 'Medium Rich', and 'Rich' or 'Sweet'. Since 2015 wines made from Tinta Negra may be labelled as such, qualified with the sweetness designations above.

Sercial is usually grown in the coolest vineyards, at heights of up to 800 m/2,640 ft or close to sea level on the north side of the island. Many growers erroneously believed that the variety is related to Germany's RIESLING, but it is in fact the same as the ESGANA CÃO (meaning dog strangler) which grows on the Portuguese mainland, the grapes exhibiting the same ferocious levels of ACIDITY. At high ELEVATION, Sercial ripens with difficulty to make a 10% base wine which is dry, tart, and astringent when young. With fortification and ten or more years' ageing in cask, a good Sercial wine develops high-toned, almond-like aromas with a nervy character and a searing dry finish. The Sercial wines range in RESIDUAL SUGAR from 0.5 to 1.5 °Baumé. Sercial is also now used to make some interesting dry, unfortified wines.

Verdelho, which also tends to be planted on the cooler north side of the island, ripens more easily than Sercial and therefore lends itself to producing a medium-dry wine with Baumé readings of 1.5–2.5° after fortification. With age, the wines develop an extraordinary smoky complexity while retaining their characteristic tang of acidity.

Verdelho is the main grape on the island for dry, unfortified white wines.

Bual, or Boal in Portuguese, is grown in warmer locations on the south side of Madeira. It achieves higher sugar levels than either Sercial or Verdelho and, after fortification to arrest the fermentation, Bual wines range from 2.5 to 3.5 °Baumé. These dark, medium-rich, raisiny wines retain their acidic verve with age. Bual is known by the name MALVASIA Fina in mainland Portugal, and this is now its official name.

Malmsey The MALVASIA grapes which produce malmsey are usually grown in the warmest locations at low elevations on the south coast, especially around Câmara de Lobos. Varieties include Malvasia Cândida, its pink-skinned mutation Malvasia Cândida Roxa, and Malvasia Babosa. Of these, Malvasia Cândida is the most highly prized and ripens to produce the very sweetest madeira wines, gaining richness and concentration with time in cask. The most widely planted Malvasia is a more productive variety known as Malvasia Branca de São Jorge. Sugar readings in a malmsey range between 3.5 and 6.5 °Baumé, but the wines are rarely cloying as the sweetness is balanced by characteristically high levels of acidity. Like all high-quality madeira made from traditional varieties, malmseys are some of the most resilient in the world and will keep in cask and bottle for a century or more.

Historic styles Madeira's unparalleled ability to age means that styles of wine long abandoned by the island's wine shippers may still be found and enjoyed. Rainwater is a pale, off-dry or medium-dry style of madeira bottled before it is ten years old and named after wine which was supposedly diluted by rain during shipment to the United States. Still made in small quantities, Rainwater madeira is defined as being dry to medium dry (1–2.5 °Baumé) with an alcohol level of 18%. Two other styles of madeira based on the TERRANTEZ and BASTARDO grapes are rarely made since both varieties are almost extinct on the island, although Terrantez has made a modest

comeback and is much sought after. Intensely sweet wines made from three types of Moscatel (MUSCAT), usually produced for blending, are occasionally bottled on their own.

Qualities of madeira

A generally accepted hierarchy (from the youngest and most basic to the oldest and most distinguished) parallels the different styles of madeira as follows. Age designations do not refer to an exact, minimum, or average age but are effectively an indication of style.

Bulk wine (*granel*) accounted for over 20% of total sales in 2019. Since 2002, only denatured wines (usually spiced with salt and pepper for culinary use) may be exported in bulk.

Corrente, more commonly known as 'three year old', are blended wines, bottled after *estufagem* and ageing in tank, rarely in wood. All are based on the red Tinta Negra and Complexa grapes. The law stipulates that madeira wine may not be bottled before 31 October of the second year of the harvest. This puts the minimum age of bottled madeira at two to three years.

Five Year Old madeira is a blended five-year-old wine, some or all of which will have undergone *estufagem* in tank. A proportion of the blend is likely to have been aged in cask. Most are made from Tinta Negra and Complexa grapes, but some are made exclusively from the more sought-after traditional varieties (see above). They may be labelled Reserva/Reserve and Velho/Old.

Ten Year Old denotes a wine in which the youngest component in the blend will be around ten years old, having aged in cask, usually without recourse to *estufagem*. These wines are mostly varietal and are labelled accordingly. They may be designated 'Reserva Especial'/'Special Reserve' or 'Reserva Velha'/'Old Reserve'.

Fifteen Year Old denotes a blended, 15-year-old wine which may be designated Reserva Extra/Extra Reserve.

Twenty Year Old, Thirty Year Old, Forty Year Old, Fifty Year Old, and Over Fifty Years Old are officially permitted designations but rarely used, as a wine from a single year with 20 years of age qualifies as a vintage or *frasqueira* madeira. However, since the redefinition of solera (see below), some shippers have begun bottling small quantities of exceptional wine with these designations.

Solera wines were made using the SOLERA system more commonly associated with SHERRY, but, having been much abused, it was temporarily prohibited for madeira by EU law—although some very good old bottlings of 19th-century soleras can still be found. The legislation introduced in 1998 requires that the solera be based on a wine from a single year, of which not more than 10% can be withdrawn in any one year. This must be replenished with a wine of similar quality, the maximum number of additions being ten, after which all the wine in the solera must be bottled at the same time. This definition has not found favour with the madeira shippers; as of 2021, no solera wines were being bottled.

Colheita or 'Harvest' wines are from a single year, or harvest, bottled after ageing at least five years in cask. These are effectively early-bottled *frasqueira* or 'vintage' wines which share the individuality if not the concentration or the complexity of a wine aged for a minimum of 20 years (see below).

Frasqueira (Vintage) is the official term which denotes 'vintage' madeira: wine from a single year which, unlike vintage PORT, must age in cask for a minimum of 20 years. Most wines spend considerably longer in wood than this and sometimes pass their later years in 20-l/5-gal glass carboys, or *garrafões*, before bottling. The wines are extremely resistant to OXIDATION, and vintage madeira—especially Sercial with its very high level of acidity—is capable of many decades' bottle AGEING. Shippers carrying stocks of old vintages are so confident of madeira's ability to withstand oxidation that they keep the bottles standing upright so that there is no risk of CORK TAINT spoiling the wine.

Serving madeira

Madeira is probably the most robust wine in the world. Little can harm the wine after it has gone through the *estufa* or been aged for 20 or more years in cask. Most shippers storing bottles upright RECORK their most venerable vintages, say, once every 20 years. All

wines tend to throw a deposit (see SEDIMENT) with age, but madeira throws less than most. DECANTING is recommended for all older madeiras, simply to allow any BOTTLE SHOCK to dissipate. A wine that has been in bottle for many years will benefit from being decanted a day before serving. Drier Sercial and Verdelho styles benefit from being served 'cellar cool' rather than iced. Sweeter Buals and Malmseys should be served at room temperature. Once opened, a bottle of madeira can last for months, even years, on ULLAGE. R.J.M.

Madeira Wine Company. See BLANDY.

Madeirense, DOP created in 1999 for the non-FORTIFIED wines of the island of MADEIRA and Porto Santo (the small, arid island around 70 km/43 miles from Madeira itself). A VINHO REGIONAL designation, Terras Madeirenses, was created in 2004 and is much less frequently used. In 2000 a government-sponsored winery, São Vicente, began encouraging growers to vinify wines from a wide range of permitted varieties—those for Madeira but also mainland, French, and German varieties. The Madeira Wine Company (see BLANDY) led the charge for Madeira shippers with its Atlantis brand, launched in 1992. Vintages can be challenging and quantities fluctuate, however with greater experience, mainland dry-winemaking input, and a trickle of new players (including more shippers), quality is on the rise. Aromatic and salty, with vibrant acidity and tropical fruit, VERDELHO is most promising for whites and featured in the island's first ESPUMANTE in

2014, together with a splash of Sercial. TINTA NEGRA is a solid bet for rosé wines. Attempts at producing Cabernet Sauvignon, Merlot, and Syrah in the humid, TEMPERATE climate seem misconceived. Porto Santo's lead variety is Listrão (Spain's PALOMINO FINO); Caracol is exciting interest too. Two producers were commercializing light wines as of 2022 (Companhia de Vinhos dos Profetas e dos Villões and JUSTINO'S), while Barbusano is making a blend of Verdelho from its Madeira vineyards and Caracol from Porto Santo. S.A.

Mayson, R. J., *The Wines of Portugal* (2020).

Madeleine Angevine, early-ripening CROSS most common as a TABLE GRAPE but the parent of several wine grapes, including the confusingly named Madeleine × Angevine 7672, first sent to the UK from Alzey Research Institute in Germany in 1957 and now officially renamed Alzey 7672 to avoid mistaken identity. It is responsible for some light, grapey wines in England and has also been planted in WASHINGTON State, Sweden, and Denmark.

maderization, occasionally madeirization, is the process by which a wine is made to taste like MADEIRA, involving mild OXIDATION over a long period and, usually, heat. Such a wine is said to be maderized. Although this tasting term is occasionally applied pejoratively to mean that a wine is OXIDIZED, it should properly be applied only to wines with a high enough ALCOHOLIC STRENGTH to inhibit the action of ACETOBACTER, which would otherwise transform the wine into VINEGAR. Very few maderized wines are made today by simply ageing the wine at cellar temperature; the oxidation process is instead hastened by heating or 'baking' the wine as on the island of Madeira. Oxidation reactions, like most organic chemical reactions, can be roughly doubled in speed by a temperature rise of 10 °C/18 °F. For example, a wine requiring ten years at a cellar temperature of 20 °C to develop a maderized character could manifest approximately the same character after about two-and-a-half years at 40 °C or 15 months at

50 °C. Maderized wines are normally amber to brown in colour and have a distinctive cooked or mildly caramelized flavour. Wines processed at excessively high temperatures may taste burnt and harsh. Most such wines are FORTIFIED and sweetened before being marketed. Madeira and similar maderized wines were particularly popular in the 18th and early 19th centuries but have since fallen out of FASHION. See also RANCIO wines. A.D.W.

made-wine, somewhat inelegant and loosely defined name for wine made not from freshly picked grapes, which is a prerequisite for any liquid referred to as WINE, but from reconstituted GRAPE CONCENTRATE, sometimes also from other fruits. The advantages for producers are that it can be made throughout the year and that grapes can be sourced wherever they happen to be cheapest. BRITISH WINE is one popular rendition, but made-wines are also found in Japan and and Eastern Europe, for example. The produce of many HOME WINEMAKERS is made-wine.

Madiran, dynamic distinctive red-wine appellation in SOUTH WEST FRANCE which has gently remodelled its concentrated, traditionally tannic wines, GASCONY's signature red.

There are said to have been vineyards here in Gallo-Roman times, and certainly the wines of Madiran were appreciated in the Middle Ages by pilgrims en route for Santiago de Compostela. About 1,190 ha/2,941 acres south of the greater Armagnac region produce Madiran. Soils are mainly CLAY and LIMESTONE with so-called *grebb*, or *grip*, granules and pebbles strengthened with IRON and MANGANESE oxide from Pyrenean glacial ALLUVIAL deposits. The climate in Madiran is softened, and often moistened, by the Atlantic to the west, but autumn is usually dry.

The traditional grape variety is TANNAT, its very name hinting at the naturally astringent character of its high level of TANNINS. The AOC regulations require that Tannat comprises 60–80% of the vineyard,

and many top cuvées depending heavily, even exclusively on Tannat. Any balance should be Cabernet Sauvignon, Cabernet Franc, and/or FER. The wine traditionally needed long bottle AGEING, but some of Madiran's most dynamic winemakers have been experimenting with ways of softening the impact of Tannat (DESTEMMING is mandatory), including hand-picking only the ripest grapes, gentle handling, new oak, and MICRO-OXYGENATION to produce wines which have density, potential for ageing, but more charm in youth. Madiran can taste like a CLASSED GROWTH bordeaux given the sort of Gascon twist needed to cope with *magret de canard*. The leader of the appellation has been Alain Brumont, who produces both Montus and Bouscassé.

From the same area comes white PACHERENC DU VIC-BILH. Some producers use Tannat to make a sticky, near-black VIN DE LIQUEUR not unlike BANYULS and a good match for chocolate.

Madrid, Vinos de. The DOP Vinos de Madrid forms a semicircle around the southern suburbs of the Spanish capital Madrid, with 8,400 ha/20,757 acres of vines and 51 wineries in 2020. It is made up of four subzones: Arganda (the largest, in the south-east); Navalcarnero (the smallest, in south-central), San Martín de Valdeiglesias (west); and El Molar in the higher elevations to the north. White wines are made mainly from Malvar (LAIRÉN) and AIRÉN; ALBILLO Real is traditional in San Martín. For red wines, GARNACHA dominates, while Tinto Fino (TEMPRANILLO, also called Tinto Madrid here) rules in Arganda. Some INTERNATIONAL VARIETIES are also allowed. A handful of producers have shown real potential, particularly those in the western part of the region (see SIERRA DE GREDOS). V. de la S. & F.C.

Magarach, wine and vine research institute at Yalta in CRIMEA, founded in 1828, more than 50 years before DAVIS or the Institute of Oenology at the University of BORDEAUX and now known as the All-Russian National Research Institute Viticulture and Winemaking

'Magarach' RAS. Although its activities have been unusually wide-ranging, the institute has been particularly distinguished in developing HYBRID varieties and special vinification techniques.

The extent of its three experimental vineyards has been reduced from nearly 2,000 ha/5,000 acres to around 600 ha/1,482 acres, and they include a vine collection with more than 4,000 varieties from 41 countries. Some of the most successful of the 30 vine varieties designed to combine quantity with quality are Rubinovy Magaracha (CABERNET SAUVIGNON × SAPERAVI), Bastardo Magarachsky (BASTARDO × Saperavi), and Magarach Early or Ranniy Magaracha. A newer generation of DISEASE-RESISTANT VARIETIES has since been developed with specific resistances to various PESTS and DISEASES. Since 1893 the institute has collected 1,135 strains of microorganisms for winemaking.

At one time much of Magarach's effort was directed towards producing convincing copies of various classic wine styles (Magarach Malmsey, for example). The institute's own cellar harbours nearly 40,000 sample bottles, some of them containing wine from the mid 19th century.

Specific research avenues tend to have a particularly practical aspect, involving hundreds of patents. New vine varieties created by the institute grow in RUSSIA, MOLDOVA, KAZAKHSTAN, AZERBAIJAN, and elsewhere.

Magliocco. CALABRIA in southern Italy was home to a total of 674 ha/1,665 acres of dark-berried Magliocco vines in 2015: Magliocco Canino, a late-ripening likely relative of Sangiovese, and the more tannic and more common Magliocco Dolce. Librandi have made efforts to revive it as a VARIETAL, but it is also often blended with GAGLIOPPO.

magnesium, mineral element essential for healthy vine growth. It is a component of chlorophyll, and so CHLOROSIS is a common symptom of magnesium deficiency. The most conspicuous symptom

is discoloration between the main veins of the leaf, which becomes particularly noticeable around VERAISON. This zone is yellow for white varieties, red for dark fruit varieties. This deficiency can be severe in some situations, reducing YIELDS and slowing fruit RIPENING. Magnesium deficiency may be associated with BUNCHSTEM NECROSIS, in which the bunch stems and berries shrivel before ripening. Maturity is affected and wine quality suffers.

Soils high in POTASSIUM encourage magnesium deficiency. Similarly, some ROOTSTOCKS such as SO 4 and Fercal are incapable of taking up sufficient magnesium and tend to show deficiency symptoms. Magnesium deficiency is overcome by applying fertilizers to the soil or by using foliar sprays. R.E.S. & R.E.W.

White, R. E., *Understanding Vineyard Soils* (2nd edn, 2015).

magnum, large bottle containing 1.5 l/54 fl oz, or the equivalent of two bottles. It is widely regarded as being the ideal size for AGEING fine wine, being large enough to slow the ageing process but not so big as to be unwieldy or unthinkably expensive (unlike some other LARGE FORMATS). Magnums generally command a premium.

Mago, influential classical writer on agricultural, including viticultural, matters. See CARTHAGE and PHOENICIA for more details.

Maillard reaction. Named after French chemist Louis-Camille Maillard, this chemical reaction between REDUCING SUGARS and AMINO ACIDS or PROTEINS is commonly seen in the browning of untreated foods and in the taste of toast and seared meat. In wine, Maillard-reaction products are important in complex aromas of bottle-aged CHAMPAGNE and in the nutty, port-like, and bacon flavours of wine made from DRIED-GRAPE WINES. See also RANCIO.

Maipo , subregion in the north of the Central Valley in CHILE where the country's first vines imported from France were planted in the mid 19th century. It now boasts some of the country's most characterful Cabernet Sauvignon, especially from areas such as Macul, Pirque, and Puente Alto, close to the foot of the Andes and bathed by cool mountain breezes. P.T.

maître de chai, term often used in France, particularly in Bordeaux, for the cellarmaster, as opposed to the RÉGISSEUR, who might manage the whole estate, or certainly the vineyards. It means literally 'master of the CHAI'. As SCIENCE and ACADEME invade winemaking, the winemaking decisions are increasingly made by an OENOLOGIST.

Málaga , city and Mediterranean port in ANDALUCÍA, southern Spain (see map under SPAIN), which lends its name to three DOPs that cover the same geographical area: Málaga for sweet and FORTIFIED WINES; Sierras de Málaga for still wines; and Pasas de Málaga for the region's tasty traditional RAISINS.

Since the 1960s, Málaga has become more famous as the tourist gateway to the Costa del Sol, but its wine industry has a long and distinguished history dating back to antiquity. The Moors continued to make wine, calling it *xarab al Malaqui*, or Málaga syrup, probably to remove any reference to alcohol but also evoking the extraordinary sweetness of the grapes growing in the hills above the city. In the 17th and 18th centuries, Málaga, often spelt Malaga, was exported worldwide, and by the mid 19th century there were over 100,000 ha/247,000 acres of vineyard, making Málaga Spain's second-largest wine region. (See, for example, the part it played in the history of ARGENTINE wine.) Exports of Mountain, as the wine became known in Great Britain and North America, totalled 30,000–40,000 BUTTS (as much as 220,000 hl/5.8 million gal) a year.

In the mid 19th century, Málaga was dealt a double blow, first by POWDERY MILDEW and then, in 1876, by the arrival of PHYLLOXERA, which was devastating to the local economy. The terraced vineyards, then covered with Muscat grapes, to the north and east of the city were abandoned, and many families emigrated to South America. Málaga never really recovered until the 1960s, when tourism became Málaga's major industry. From a peak immediately prior to the arrival of phylloxera of 113,000 ha/279,000 acres, the region's vineyard area was only 1,200 ha in the early 21st century. Where there were once over 100 BODEGAS near the port in the centre of the city, the number of producers had risen from two in the late 1990s to 14 by 2003 and 45 by 2021.

This rugged region runs 150 km/90 miles east to west and 60 km/40 miles north to south and is almost completely mountainous, with vineyards planted up to 1,000 m/3,280 ft in ELEVATION. There are five zones. The coastal area, or Costa Occidental, comprises La Axarquía (a region of steep, SLATE-covered slopes that recall those of PRIORAT), Montes, and Manilva and has a MEDITERRANEAN CLIMATE. Further inland, the Norte and Serranía de Ronda areas experience a more extreme CONTINENTAL CLIMATE.

The principal grape variety nowadays is Moscatel de Alejandría (MUSCAT OF ALEXANDRIA), closely followed by PEDRO XIMÉNEZ, which now may be imported from MONTILLA-MORILES to the north, although according to regulations it may not exceed 10% of the volume. In the cooler mountain zone immediately north of the city, Moscatel is also used in the production of dry wines.

Traditionally, Malága was a DRIED-GRAPE WINE made by leaving the grapes in the sun on grass mats for seven to 20 days to concentrate the natural sugars. Today the wines are made using a number of different methods. Often the sweetness is obtained by arresting the fermentation with grape spirit (as for MISTELA or VIN DOUX NATRUREL), and the wine is called *vino dulce natural*.

A *vino naturalmente dulce* is made from LATE HARVEST or slightly sun-dried Moscatel in which the fermentation has stopped naturally

or has been stopped by lowering the fermentation temperature.

A third way of adjusting the sweetness is with *arrope*, unfermented grape MUST that has been boiled down to 30% of its normal volume. This may be added either before or after fermentation.

The aged, fortified wines mature in oak COOPERAGE of various sizes arranged into SOLERAS. The Consejo Regulador recognizes 16 types of wine ranging from *Seco* (dry, ≥ 4 g/l residual sugar) to Sweet (over 140 g/l RS), and *Dorado* (golden, naturally sweet, with no *arrope*) to *Negro* (black, from at least 15% *arrope*). Depending on style, Málaga may have an ALCOHOLIC STRENGTH of 15–23%. Málaga can also be classified by age:

Pálido: aged up to six months, with no *arrope* addition.
Noble: aged two to three years.
Añejo: aged three to five years.
Trasañejo: aged more than five years.

In addition, *Pajarete* denotes a fortified wine with 45–140 g/l of residual sugar, with no arrope, and aged at least two years. The rare *Lágrima* is produced solely from FREE-RUN juice without any mechanical pressing; *Lacrimae Christi* is a Lágrima aged at least two years.

While many Málaga wines are deep brown, intensely sweet, and raisiny, some tasting slightly burnt through the addition of too much *arrope*, top examples, both dry and sweet, count as some of Andalucía's most compelling and long-lived wines.

For more about the region's dry wines, see SIERRAS DE MÁLAGA.

SEE WEB LINKS

www.vinomalaga.com

Malaga Blanc, dominant grape variety in THAILAND, where it is used mainly as a TABLE GRAPE but also produces relatively soft white wine. Originally from the south of France, where it is named Panse de Provence, the grape is believed to have been introduced to Thailand in 1685 by the first Embassy of the King Louis XIV of France to King Narai the Great of Siam. The grapes' thick skins make them usefully resistant to heavy rain.

Malagousia or sometimes Malagoussia, elegant white western Greek grape variety rediscovered by Evangelos Gerovassiliou in the 1980s. It yields full-bodied, perfumed wines in many Greek regions, and total plantings have grown rapidly to reach 802 ha/1,982 acres in 2021.

Malbec, black grape variety once popular in Bordeaux, still the backbone of CAHORS but given a new lease of life by its obvious success in ARGENTINA. It has many synonyms, among them Cot, as it is known in much of western France, including the Loire, where it was once quite widely grown. In the Libournais it is known as Pressac, and in Cahors, suggesting origins in northern Burgundy, it was called Auxerrois until Argentine success encouraged adoption of the name Malbec. It also encouraged enthusiasm for the variety in France where total plantings have continued to increase since their low point in the late 1970s to 8,380 ha/20,707 acres in 2019, some 3,690 ha/9,120 acres in Cahors country. In cooler climates, Malbec has some of the disadvantages of Merlot (sensitivity to COULURE and spring FROST) without as much obvious fruit quality. Indeed it can taste like a rather rustic, even shorter-lived, version of Merlot, although when grown on the least-fertile, high, rugged LIMESTONE vineyards of Cahors it can occasionally remind us why the English used to refer to Cahors as 'the black wine'. Cahors AOC regulations stipulate that Cot must constitute at least 70% of the vineyard. Other appellations of SOUTH WEST FRANCE in which Malbec may play a (smaller) part are Bergerac, Buzet, Côtes de Duras, Fronton, Côtes du

Marmandais, Pécharmant, and Côtes du Brulhois. It is also theoretically allowed into the Midi threshold appellations of Cabardès and Malepère but is rarely found this far from Atlantic influence.

DNA PROFILING in 2009 showed that Cot is a natural progeny of Prunelard, an old variety from the Tarn, and Magdeleine Noire des Charentes, the almost extinct mother of Merlot.

Permitted by all major red bordeaux appellations, Malbec was quite popular, especially before the predations of the 1956 frosts, but total plantings fell from 4,900 ha/12,100 acres in 1968 to just over 1,000 ha/2,471 acres in 2011, mainly in Bourg, Blaye, and the Entre-Deux-Mers region. In the last decade, the variety has seen a return to popularity, with plantings up by more than 100% to 2,116 ha. Blended with Cabernet and Gamay, it is also theoretically allowed in a wide range of mid Loire appellations—Anjou, Coteaux du Loir, Touraines of various sorts, and even sparkling Saumur—but has largely been replaced by Cabernets Franc and Sauvignon.

It is in Argentina that Malbec really holds sway, planted on more than 45,657 ha/112,820 acres all over Argentina in 2019, making it the country's most-planted variety by far with more than 20% of the entire vineyard area. Varietal Argentine Malbecs have some perceptibly Bordelais characteristics, of flavour rather than structure. The wines are generally riper and more velvety than their French counterparts, although they are similarly capable of extended AGEING, and there is now a will to make rather more delicate, fragrant Malbecs. For more detail, see ARGENTINA.

The commercial success and clear appeal to modern wine drinkers of Argentine Malbec has spawned a new fashion for the variety elsewhere, not least in Chile, where varietal bottlings increased considerably in the early 21st century so that total plantings were 2,362 ha/5,837 acres in 2020. Chile's version tends to be more tannic than Argentina's and may be blended with the other Bordeaux grapes which Chile grows in such profusion. Viu, Chile's Malbec specialist, and others blend it with Cabernet Sauvignon.

Australians have so far shown no great respect for their Malbec and had been uprooting it systematically until the early 1990s,

although poor CLONAL SELECTION was probably partly to blame. Plantings totalled 562 ha/1,389 acres in 2015, and some Clare Valley producers have made fine wine from it. In New Zealand producers such as Villa Maria value it as an ingredient in BORDEAUX BLENDS, which is also its usual fate in California (see MERITAGE). Malbec was quite significant in California before PROHIBITION, and plantings have steadily increased this century, to 1,582 ha/3,909 acres by 2020.

Many of the small amounts of Malbec, Malbech, or Malbeck planted elsewhere around the world doubtless owe their continued existence to Argentina's success with the variety.

Goldin, C., *The Secrets of Argentine Malbec* (2004).

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Malepère shares many of the wine characteristics of CABARDÈS, another small AOC where the Midi and Aquitaine meet near Carcassonne in the far west of the LANGUEDOC. Climatically, it belongs even more definitively to south-west France than to the Languedoc, from which it is geographically protected by the Hautes Corbières peaks. The vineyards, mainly CLAY and LIMESTONE, are immediately north of LIMOUX. The wines, mainly red and some rosé, are made up of a blend of Bordeaux and Languedoc varieties, but in the case of Malepère, with its wetter, more Atlantic climate, it is the Bordeaux varieties that predominate. Merlot must make up at least half the blend of reds, with CABERNET FRANC and Cot (MALBEC) constituting at least 20%, but Cinsaut, Grenache, Lledoner Pelut, and Cabernet Sauvignon are also allowed as minor ingredients. Rosés are based on Cabernet Franc. Wine production is dominated by CO-OPERATIVES, particularly Les Vignobles de Vendéole.

Malibu Coast, AVA in southern CALIFORNIA approved in 2014 for a 50-mile/80-km stretch of mountainous coast north of Santa Monica

encompassing the previously established Malibu-Newton Canyon and Saddle Rock-Malibu AVAs in Los Angeles County. About 50 vineyards originally covered about 81 ha/200 acres, though WILDFIRES have hampered growth. M.D.K.

malic acid, one of the two principal organic acids of grapes and wines (see also TARTARIC ACID). Its name comes from *malum*, Latin for 'apple', the fruit in which it was first identified by early scientists. Present in nearly all fruits and berries, malic acid is now known to be one of the compounds involved in the complicated cycles of reactions by which plants and animals obtain the energy necessary for life. One of these cycles of reactions is known as the citric acid, Krebs, or tricarboxylic acid cycle, and its elucidation was one of the outstanding triumphs of biochemistry.

Another, which comes into play during the final stages of RIPENING in many fruits, including grapes, causes the decomposition of malic acid. When all of the malic acid has been used up in this latter series of reactions, the fruit becomes overripe, or senescent. The malic acid content of grapes is a very good indication of ripeness because it is specific to each variety and varies according to the climatic conditions of the vintage. The malic acid decomposing reaction is much more rapid in hot summer temperatures, probably because of the more rapid RESPIRATION of malate in the berry. This is, at least in part, one reason for the lower TOTAL ACID concentrations in grapes grown in warmer regions. It accumulates in young grape berries reaching high levels at about VERAISON—sometimes as high as 20 g/l—but, as ripening progresses, the level of malate declines to concentrations of between less than 1 and up to 5 g/l when the grapes are ripe. This large range in ripe grapes is an important source of variation in quality and style.

Tartaric acid, the other main grape acid, does not participate in several of the reaction pathways in which malic acid is an essential component, which is why the hotter the summer, the lower the likely proportion of malic acid in the grapes. Malic acid's different chemical

structure allows it to participate in many more of the enzymatic reactions involved in living systems than tartaric acid because it can be pumped across plant membranes serving as a transportable energy source. Because the concentrations of tartaric acid are relatively and desirably stable, attention is given to the tartrate/malate (T/M) ratio, which varies from about 1 to 6 and is characteristic for each grape variety. High malate varieties with a low ratio, such as SYLVANER, COLOMBARD, BARBERA, and CARIGNAN, are desirable for hot districts.

Malic acid is lost not just through the citric acid cycle and other reaction cycles during grape ripening but also in many cases as a result of MALOLACTIC CONVERSION. Temperatures of 18–22 °C/64–72 °F encourage the LACTIC ACID BACTERIA involved in malolactic conversion. The winemaker can exercise some control over this loss of malic acid if necessary, however, since the growth and activity of these organisms can be slowed or inhibited by moderate concentrations of SULFUR DIOXIDE. In addition, since the lactic acid bacteria responsible for malolactic conversion require many micronutrients (vitamins, growth factors, nitrogenous compounds), early and thorough separation of the new wine from its LEES can inhibit bacterial activity and preserve malic acid.

Malic acid is available commercially for use in acidifying foods and beverages and in numerous industrial processes. At one time it was isolated from fruits and other plant tissues but today is more usually synthesized from another organic acid. B.G.C. & V.L.

Malleco , cool, wet subregion of the Southern region of CHILE 650 km/403 miles from the capital, Santiago. Its reputation as a wine region began only in the 1990s, when Felipe de Solminihac of Aquitania winery in Maipo began planting vines in its clay and granite soils. There is now a small community of winegrowers producing excellent Chardonnay and Pinot Noir. P.T.

Mallorca , Spanish Balearic island in the north-west Mediterranean which was once the seat of the kings of ARAGÓN. In the 19th century, the island was famous for its sweet MALVASIA wines, which all but disappeared when the vineyards fell victim to PHYLLOXERA. The island has two DOPs: BINISSALEM, Spain's first offshore DOP wine region on the island's central plateau, with good, original reds from the local MANTO NEGRO grape; and PLA I LLEVANT, in the south-east, specializing in reds from the CALLET grape. Wines outside of these DOPs may take the VINO DE LA TIERRA (Vi de la Terra) Mallorca. Vino de la Tierra Serra de Tramuntana-Costa Nord covers wines grown in the high, jagged mountains at the island's northern end.

Malmesbury , ward in the SWARTLAND district of SOUTH AFRICA, and an increasingly important source of good-quality wines from often innovative wine producers, many small-scale.

malmsey, English corruption of the word MALVASIA, derived from the port of Monemvasia which was important in ancient Greece. The word was first used for (probably a wide range of) the unusually sweet, rich wines of Greece and the islands of the eastern Mediterranean, particularly Crete, then called Candia (see GREECE, medieval history). Sweet white wines were prized in the Middle Ages, particularly but not exclusively by northern Europeans, who regarded their own wines as thin and admired the longevity of these liquids, very possibly DRIED-GRAPE WINES, so sturdily high in sugar and alcohol. The acute merchants of GENOA, NAPLES, and VENICE were able profitably to capitalize on this stability in their trading links between east and west.

As European temperatures fell as a result of CLIMATE CHANGE, these richer wines held even more allure. Venetians in particular created a demand for malmsey in 15th-century England. George, duke of Clarence and younger brother of England's King Edward IV, was

popularly believed to have been drowned in a BUTT of malmsey in the Tower of London in 1478.

Malvasia vines came to be planted all round the western Mediterranean (even today, Malvasia and MALVOISIE are two of the most commonly used synonyms for various, often quite unrelated, VINE VARIETIES). Malmsey, which originally denoted any strong, sweet wine, was eventually used specifically for the sweetest style of MADEIRA, particularly that made from Malvasia grapes.

Between 2010 and 2012, a number of new PDOs were introduced in Greece for barrel-aged, sweet white wines made from sun-dried grapes, mainly from a mix of varieties, referred to under the group name of Malvasia. Malvasia of Monemvasia in the Peloponnese, Malvasia of Handakas-Candia and Malvasia of Sitia in Crete, and Malvasia of Paros are in essence Greece's modern claim to the legendary style of the Middle Ages.

malolactic conversion, widely known as malolactic fermentation and often abbreviated to MLF or malo, is the conversion of stronger MALIC ACID naturally present in new wine into LACTIC ACID (which has lower ACIDITY) and CARBON DIOXIDE. The term 'conversion' is more accurate because it is not literally a FERMENTATION process, although the release of carbon dioxide may initially give that impression. It is accomplished by LACTIC ACID BACTERIA (LAB), which are naturally present in most established wineries but may have to be cultured and carefully introduced in newer establishments where malolactic conversion is desired. This process is unrelated to and almost never precedes the main, alcoholic fermentation, for which reason it is sometimes called a secondary fermentation. Nevertheless, it is not uncommon for malolactic conversion to be complete by the end of the alcoholic fermentation.

It is written chemically thus:

$$\mathrm{COOH{-}CHOH{-}CH_2{-}COOH \rightarrow COOH{-}CHOH{-}CH_3 + CO_2}$$

malic acid→lactic acid + carbon dioxide

Malolactic conversion is conducted for three reasons: to decrease a wine's ACIDITY, to improve wine stability (see STABILIZATION), and to achieve desirable sensory (aroma and flavour) changes. It is desirable in wines which have excessive acidity, particularly red wines produced in cooler climates. It can also add flavour and complexity to both red and white wines, as well as rendering the wine impervious to the danger of malolactic conversion in bottle. Recognition and mastery of malolactic conversion (which would traditionally happen as if by accident when temperatures rose in the spring) was one of the key developments in winemaking in the mid 20th century. By the early 1990s, most fine red wines, many sparkling wines, and a small but increasing proportion of the world's white wine involved full or partial malolactic conversion, thanks either to the lactic acid bacteria present in the winery or to cultured LAB added to the wine. In hotter climates or during warmer years in cooler areas, some winemakers deliberately suppress malolactic conversion in some or all batches of a wine in order to maintain the wine's acidity. Some grape varieties seem to have a greater affinity with malolactic conversion than others. Among white grapes, Chardonnay is a generally successful candidate for the process, while most producers of Riesling and Chenin Blanc deliberately avoid it, despite the high natural acidity in these latter two. Malolactic conversion may reduce unduly the acidity of a wine made from very ripe grapes and already low in acidity, and production of the buttery-smelling DIACETYL during malolactic conversion needs to be managed since excess diacetyl can be unpleasant. Malolactic conversion's effect on decreasing TOTAL ACIDITY is often most marked on those wines which were highest in malic acid before it took place (i.e. the products of particularly cool growing seasons). In some cases, the winemaker may even have to ACIDIFY after malolactic conversion. If all of the malic acid is converted to lactic acid, the total acidity (expressed as tartaric acid) will drop by 0.56 g/l for each g/l of malic acid that was originally present in the wine.

Like most BACTERIA, lactic acid bacteria grow best in very weakly acidic solutions and at temperatures above 20 °C/68 °F. Malolactic conversion is strongly influenced not only by temperature but also by the wine's PH: if it is less than pH 3.1, it is very difficult, though still commonly practised under such conditions in Champagne and Burgundy. Lactic acid bacteria are intolerant of even moderate concentrations of SULFUR DIOXIDE and high concentrations of ETHANOL. Malolactic conversion can therefore be encouraged by adding lactic acid bacteria to the wine soon after alcoholic fermentation has finished. Alternatively, they can be added to the MUST at, or soon after, the start of alcoholic fermentation; this is often referred to as co-inoculation or simultaneous inoculation. At this point conditions are ideal for the lactic acid bacteria—the fermenting wine is warm, its alcohol content is low, the sulfur dioxide added before fermentation has already been volatilized or become bound to other wine constituents, and the dying yeast cells, or LEES, provide the necessary micronutrients. Co-inoculation is becoming increasingly popular, but some oenologists believe it to be detrimental to wine quality because it happens very quickly and at higher temperatures. If malolactic conversion has not been initiated during the alcoholic fermentation (or during post-fermentation MACERATION of reds), the new wine may be transferred to barrels or stainless-steel tanks where the malolactic conversion will take place. Barrels in which malolactic conversion has taken place in a previous vintage may encourage the onset of this process, but it is very important to know what was in the container before so that no form of spoilage is encouraged. Putting fine red wine in barrel prior to the onset of malolactic conversion became fashionable in the early 21st century because it was believed to improve the oak integration and make the wines more approachable when young (particularly useful for EN PRIMEUR tastings), although some winemakers would take the opposite view. The reliability and efficiency of malolactic conversion can also be affected by the yeast strain used for alcoholic fermentation. Some yeast may produce compounds that inhibit lactic acid bacteria, including sulfur dioxide, certain fatty acids, and proteins. Such interactions are an important

consideration for the selection of compatible pairings of yeast and lactic acid bacteria starter cultures.

Malolactic conversion may well be regarded as undesirable in some wines, particularly in certain styles of white and sparkling wine. In this case, sulfur dioxide additions and cool temperatures can prevent the activity of lactic acid bacteria. Sterile FILTRATION can insure against the commercial embarrassment of malolactic conversion taking place in bottle. If a bottled still wine starts to fizz, this is the most likely cause, most commonly encouraged by the combination of heat and residual lactic acid bacteria. See FAULTS IN WINE.

Malta , the central Mediterranean island, has a small wine industry that can trace its history back to Phoenician times, but it was the arrival of the Knights of St John in 1530 that laid the foundations of today's wine industry. Viticulture in Malta flourished until the arrival of the British in 1800, when many vineyards (and olive groves) were uprooted in favour of cotton. By the end of the 19th century, when demand for Maltese cotton had diminished, a replanting programme of sorts was started and, in spite of the outbreak of PHYLLOXERA in 1919, viticulture flourished once again. By the 1950s, 1,000 ha/2,470 acres were under vine, although most were TABLE GRAPE varieties which produced wines so low in sugar and acid that considerable adjustments were needed in wineries rarely equipped for high-quality wine production.

Some 1950s experiments with Muscat and Trebbiano were relatively successful, but it was not until the 1970s that another serious attempt was made with wine grape varieties, this time Cabernet Sauvignon planted by Marsovin at Wardija in the north of the island. TOURISM boomed in the 1980s and demand for wine grew. During the 1990s, with the help of DRIP IRRIGATION and French and Italian expertise, various other VITIS VINIFERA varieties were planted.

By 2022 only about 50 ha/124 acres of the indigenous Ġellewża (red) and 80 ha of Girgentina (white) were left; Gennarua had all but disappeared. INTERNATIONAL VARIETIES make up the rest of the country's 389 ha/961 acres of wine grapes, with Chardonnay and Vermentino providing the island's best white wines and Cabernets Sauvignon and Franc, Merlot, and Syrah dominating the reds.

Only when Malta joined the EU in 2004 were labels required to distinguish between wines made from domestic and imported grapes. In 2007 Malta introduced the wine categories DOK (equivalent to the EU's PDO) and IGT (PGI), GEOGRAPHICAL INDICATIONS with production protocols very similar to Italy's system. There are two DOKs: Malta, for wines produced on the main island, and Gozo, for those from the eponymous island. IGT Maltese Islands encompasses all the wines of the country.

Land holdings tend to be small, and most farmers sell their grapes to large wineries such as Delicata, Marsovin, and Camilleri or to the Vitimalta CO-OPERATIVE. Meridiana, wholly owned by ANTINORI since 2015, is another important winery, with 11 ha of its own vineyards.

Vineyards typically have relatively shallow, poor, LOAMY topsoil on SAND, LIMESTONE, and CLAY with richer and more fertile clayey soils in the north. Some ALLUVIAL soils can be found in the valleys. The climate is MEDITERRANEAN with long, hot, dry summers and cool, rainy winters. The average mean temperatures vary from 12.8 °C/55 °F in January to 27.7 °C/82 °F in August. Strong WIND is common throughout the year, helping to moderate temperatures and keep the vines free of FUNGAL DISEASES; at least one winery, Mar Casar, is practising BIODYNAMIC VITICULTURE. Average rainfall is 575 mm/27 in but is so concentrated in the winter months that IRRIGATION is needed. M.Ta.

Malvar . See LAIRÉN.

Malvasia, name used widely, especially in Iberia and Italy, for at least 20 different grape varieties, often unrelated. Wines produced from them are, typically, deeply coloured whites, but some are reds, usually light.

The word 'Malvasia' itself is thought to be the Italian corruption of 'Monemvasia', the name of a southern Greek port which, in the Middle Ages, was a busy and natural entrepôt for the rich and highly prized dessert wines of the eastern Mediterranean, notably those of Crete, or Candia (see GREECE, history)—although it is not known which grape varieties were responsible for these wines. They may not even have included any of the varieties known today as Malvasia of some sort. But so important was wine from Monemvasia during the time of the Venetian republic that wine shops in VENICE were called *malvasie*.

The French corruption of 'Malvasia' has been used particularly loosely (see MALVOISIE). The word was also corrupted into MALMSEY in English, which was long the name of an important style of MADEIRA, traditionally based on the Malvasia Cândida grape (also known as Malvasia di Lipari). The Germans call their various though rare forms of Malvasia Malvasier.

Italy grows more wine called Malvasia of some form than any other country, with 17 different varieties distinguished in its 2010 vine census, nine white and eight red or pink. In 2015, according to the EU's Eurostat database, most planted, with 6,983 ha/17,255 acres, was Malvasia Bianca di Candia, which produces relatively neutral wine in Lazio and throughout central Italy. The variety known as Malvasia di Candia Aromatico, quite widely planted in Italy and Greece, is apparently different and closer to Malvasia di Casorzo, a red-berried, relatively rare speciality of Piemonte. Italy's second most planted Malvasia is simply called Malvasia Bianca, with total plantings of 2,181 ha/5,389 acres. Third most common was Malvasia Bianca Lunga, with 1,135 ha/2,805 acres recorded in 2015 (although that called simply Malvasia Bianca may well be Malvasia Bianca Lunga too). This is the variety, once called Malvasia del Chianti, most common in Tuscany for both dry wines and VIN SANTO and is also grown, as Marăstina, in Croatia (which is probably close to the Croatian variety called MALVAZIJA ISTARSKA, known as Malvasia Istriana when grown in north-east Italy, where it can produce some fine VARIETAL examples).

Total plantings of Malvasia del Lazio, a CROSS of MUSCAT of Alexandria and SCHIAVA Grossa, had fallen to 676 ha/1,670 acres in 2015. The speciality of BASILICATA, Malvasia Bianca di Basilicata, may be related to Malvasia Bianca di Candia. Other, less quantitatively significant, pale-skinned grapes called Malvasia noted in the Italian vine census of 2010 included the widespread Malvasia di Lipari, which is grown on the Italian island of the same name for sweet PASSITO wines; also known as Malvasia di Sardinia (and differentiated on the Italian census) for that island's Malvasias of various sweetnesses; as Greco Bianco di Gerace for the sweet wines of the Calabrian port of

Bianco; as Malvasia Cândida to produce malmsey on the island of MADEIRA, where only tiny plantings remain; and as various Malvasias in Cataluña and the Canary Islands.

The Italian vine census also distinguished between a further eight dark- or pink-berried Malvasias, of which Malvasia Nera di Brindisi (identical to Malvasia Nera di Lecce and a cross of Malvasia Bianca Lunga and the Puglian red wine grape NEGROAMARO) is the most planted with 1,149 ha/2,839 acres in 2015, making it more common than southern Italy's other red wine Malvasia, Malvasia Nera di Basilicata. DNA PROFILING in 2021 showed that the latter is a distinct variety and a natural cross between SUSUMANIELLO (or Somarello), a rare Puglian variety, and Visparola, an old, forgotten, but (genetically speaking) key variety from southern Italy. Malvasia Nera Lunga was less quantitatively important than either and was a speciality of Asti in Piemonte. The census also referred to a variety called simply Malvasia Nera, as well as Malvasia di Schierano, which makes light, fragrant reds in Piemonte.

The variety more commonly planted to produce malmsey on Madeira today is a much newer variety called Malvasia Branca de São Jorge, whose wines are usefully high in both sugar and acidity. Portugal grows several other Malvasias of note. The most important true Malvasia is Malvasia Fina, of which there were 2,436 ha/6,019 acres in Portugal in 2020. It goes under many aliases, including the slightly confusing one of BOAL. Most important in the dry whites of DÃO, it is also widely grown in other northern Portuguese regions such as the DOURO. DNA profiling suggested that Malvasia Fina is a natural ALFROCHEIRO × Hebén cross and that dark-berried Malvasia Preta, also known as Moreto or Mureto, is a natural Alfrocheiro × CAYETANA BLANCA cross. Malvasia Preta is grown on 733 ha/1,811 acres of vineyard mainly in the Douro for port and red table wines. Pale-skinned Malvasia de Colares is the dominant grape of the shrinking COLARES region. Malvasia Rei is the Portuguese synonym for PALOMINO FINO.

In Spain, Malvasía di Sitges is Malvasia di Lipari, but Malvasía Volcánica is a historic speciality of LANZAROTE and can make full-bodied, aromatic whites of real interest. DNA profiling has shown that it is a natural cross of Malvasia di Lipari and the local MARMAJUELO. About half of all Malvasía growing in Spain is on the Canary Islands while most of the rest was Malvasia Castellana, Portugal's SÍRIA, called Cigüente in EXTREMADURA.

The aromatic, thick-skinned variety known simply as Malvasia Bianca in California and grown on 402 ha/994 acres of mainly Central Valley vineyard was brought there from Piemonte and is known strictly as Malvasia Bianca di Piemonte. It makes full-bodied, tangy, flirtatious whites there.

So common is the name Malvasia as part of a grape name or synonym that no fewer than 70 are listed in the index of the book *Wine Grapes*. J.V. & J.E.H.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Malvazija Istarska, characteristic and characterful white wine grape of the Istrian peninsula in northern CROATIA, the country's second most planted variety after Graševina (WELSCHRIESLING) with 1,626 ha/4,018 acres in 2020. Known as Malvasia Istriana in north-east Italy, it is genetically close to MALVASIA di Lipari, Malvasia Bianca Lunga, and Malvasia Nera di Brindisi.

malvidin is the PHENOLIC pigment primarily responsible for the colour of red wine. It is found in wine as malvidin 3-glucoside and various acylated derivatives.

Malvoisie is one of France's most confusing vine names, perhaps because, like PINEAU, it was once used widely as a general term for superior wines, notably those whose origins were supposed to be Greek. There is no single variety whose principal name is Malvoisie,

but it has been used as a synonym for a wide range of (usually white-berried) grape varieties producing full-bodied, aromatic whites. Despite the etymological similarity, 'Malvoisie' has only rarely been a synonym for MALVASIA. Malvoisie is today found on the labels of some Loire, Savoie, and Aosta wines made from such plantings of PINOT GRIS as remain. Malvoisie du Valais is a common synonym for (usually sweet) Pinot Gris in Switzerland. It is also sometimes used for BOURBOULENC in the Languedoc, for CLAIRETTE in Bordeaux, and for SAVAGNIN in the Austrian Tyrol. VERMENTINO is sometimes called Malvoisie in Roussillon and on Corsica.

Malvoisie Rouge d'Italie is an occasional synonym for FRÜHROTER VELTLINER in Savoie and northern Italy.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Mammolo, heavily perfumed, historic red grape variety producing wines which supposedly smell of violets, or *màmmole*, in central Italy. It seems to have played a significant genetic role in several Tuscan vine varieties. A permitted ingredient in CHIANTI and VINO NOBILE DI MONTEPULCIANO, it was planted on 26 ha/64 acres in 2015. Today it is quantitatively much more important as Corsica's SCIACCARELLU.

Manchuela, DOP of 12,478 ha/30,833 acres in 2021 on the eastern border of CASTILLA-LA MANCHA, straddling Cuenca and Albacete provinces. This is the home of BOBAL, which makes up 41% of vineyards and is mainly used for rosés and unoaked young reds. It is sometimes blended with INTERNATIONAL VARIETIES such as Syrah as well as local varieties TEMPRANILLO, MONASTRELL, GARNACHA, and GARNACHA TINTORERA (Alicante Bouschet). The white MACABEO also produces very drinkable fragrant whites in northern Albacete, while the local Albilla de Manchuela has been rediscovered as a good-quality grape. Overall this high plateau, which reaches an ELEVATION of

more than 1,000 m/3,280 ft in western Cuenca, shows great potential but has mostly lacked the investment required to develop it.

V. de la S. & F.C.

Mandilaria, distinctive speciality of various Greek islands, including CRETE, where it is often blended with the much softer KOTSIFALI, which adds BODY. The grapes have thick skins and therefore the wine produced is deeply coloured and notably high in TANNINS. It can produce harmonious dry reds such as Peza or even sweet reds. Known as Amorgiano on Rhodes. Total plantings had risen to 1,070 ha/2,644 acres in 2021.

manganese, a soil nutrient essential for vine growth but in very low quantities. Manganese deficiency causes leaf yellowing and is found most commonly on soils high in LIMESTONE and other alkaline soils. Acid soils (see SOIL ACIDITY) which are poorly drained and high in manganese can cause toxicity, reducing both vine growth and YIELD.

R.E.S. & R.E.W.

manipulation, a slightly pejorative term referring to a range of interventions made by winemakers. Wine is unusual among alcoholic drinks in that, once the grapes have been picked and put into a container, it can more or less make itself. However, winemakers closely monitor the entire process from reception of the grapes to BOTTLING and often intervene in a variety of ways to ensure quality or stylistic goals. These range from traditional techniques such as DESTEMMING, CRUSHING, SAIGNÉE, CHAPTALIZATION, BARREL FERMENTATION, LEES STIRRING, BARREL AGEING, RACKING, CLARIFICATION, and FILTRATION to more modern steps such as optical SORTING, the use of ENZYMES, FLASH DÉTENTE, cold MACERATION, CRYOEXTRACTION, cultured YEASTS, MICRO-OXYGENATION, BARREL ALTERNATIVES, REVERSE OSMOSIS, and SPINNING-CONE COLUMNS—or, more likely, a combination of these methods. Many of these practices are controlled by regulations in most wine-producing countries. In general, those that have been practised for many years

(such as chaptalization) are less controversial, even though they may be more interventionist and open to abuse than modern equivalents (such as reverse osmosis). A.O.

Goode, J., *Wine Science: The Application of Science in Wine* (3rd edn, 2021).

mannoproteins are POLYSACCHARIDES released from YEAST cells during FERMENTATION and by AUTOLYSIS during LEES CONTACT. Mannoproteins commercially prepared from yeast lees may also be added during winemaking. Mannoproteins have the potential to protect white and rosé wine from PROTEIN haze and can inhibit the growth of TARTRATE crystals, which promotes tartrate stability. They may also reduce the perception of ASTRINGENCY by interacting with both salivary proteins and TANNINS, disrupting the binding considered necessary for astringency perception. Mannoproteins released during yeast autolysis have also been demonstrated to improve the foaming properties of SPARKLING WINE. R.G.

Ramos-Pineda, A. M., et al., 'Effect of the addition of mannoproteins on the interaction between wine flavonols and salivary proteins', *Food Chemistry*, 264 (2018), 226–32.

Waters, E. J., et al., 'Preventing protein haze in bottled wine', *Australian Journal of Grape and Wine Research*, 11/2 (2005), 215–25.

Manseng Noir, Basque vine variety that DNA PROFILING suggests is identical to the Ferrón of RIBEIRO. It is genetically distinct from the white wine grapes GROS MANSENG and PETIT MANSENG.

Manto Negro, most common grape on MALLORCA, producing scented but light reds which tend to age quickly and are prone to OXIDATION. It may be best blended with a more structured grape such as CALLET.

manzanilla, a *fino* style of SHERRY made in the seaside sherry town of SANLÚCAR DE BARRAMEDA, where the particularly humid maritime air tends to result in a thicker layer of FLOR, a slower maturation process, lower alcohol content, and slightly higher acidity—especially since grapes do not get as ripe in Sanlúcar's coastal vineyards as they do inland. As the wine matures and the flor dies, a Manzanilla may develop into a Manzanilla Pasada, which is a Sanlúcar equivalent of a fino on the way to becoming AMONTILLADO. Manzanilla is typically FORTIFIED to 15% alcohol. For more details, see SHERRY. J.B.

Manzoni. See INCROCIO.

Maranges, the southernmost VILLAGE WINE appellation in the Côte de Beaune district of Burgundy, produces medium-bodied red wines of some charm when young. The vineyard stretches across the three villages of Cheilly, Dezize, and Sampigny, each of which takes 'Les Maranges' as a suffix. Formerly the wines were sold either under the village name or, much more frequently, as Côte de Beaune-Villages. Since 1988, such wines may be called Maranges or Maranges Côte de Beaune. White wines counted for slightly under 10% of vineyard area in 2018.

See also CÔTE D'OR, and map under BURGUNDY. J.T.C.M.

Maratheftiko, also known as Vamvakada, promising, dark-skinned CYPRUS grape variety gaining ground on the island, with 166 ha/410 acres planted in 2021, producing deeply coloured, fresh, cherry-fruited wines.

marc, the general French term both for grape POMACE and, more widely, for pomace brandy. It is used to distinguish the product from a *fine*, which may be made by distilling local wine. Most traditional wine regions make marc from the pomace, grape skins, and pips left after pressing. This was rarely for financial gain but often because traditional winegrowers hate to see anything they have grown go to waste.

Marche (Marches in English), the easternmost region in the central belt of Italy stretching from TUSCANY and UMBRIA to the Adriatic coast (see map under ITALY). It shares a variety of characteristics with these neighbours to the west: a TOPOGRAPHY shaped by land rising from the coastal plains to rolling hills and, westward, to the central spine of the Apennines; and a TEMPERATE climate, though, while it is marked by hot, dry summers, it is not as uniform as its western neighbours. In the north of the region west of Ancona, the climate is more CONTINENTAL, while in the south near Ascoli Piceno it is MEDITERRANEAN. Some viticultural characteristics are shared with Tuscany and Umbria: CALCAREOUS soils from the sea which once covered an important part of central Italy; HILLSIDE VINEYARDS; and large-scale plantings of SANGIOVESE, MONTEPULCIANO, and VERDICCHIO vines. The Marche has been one of the last of the central Italian regions to realize its potential for good-quality wines, however, partly because it is off Italy's main commercial axis of Milan–Bologna–Florence–Rome–Naples, and partly because of the lack of any urban centre more important than Ancona. However, the local white Verdicchio, produced in large volumes by CO-OPERATIVES and large bottlers, is a

continuous export success, although it has largely obscured the fact that high-quality wines can and are being made.

The Marche has several wine styles that are now of serious interest, and 40% of its 17,563 ha/18,688 acres of vineyards are dedicated to DOC wines. Of its 15 DOCs and five DOCGs, Verdicchio dei Castelli di Jesi with 2,200 ha of vineyards is Marche's largest. See VERDICCHIO for more information.

For red wines, Montepulciano, with 4,600 ha/11,366 acres, is the second most planted variety after Sangiovese (6,215 ha) and produces its finest expression in Conero DOCG. Rosso Conero DOC is very similar except that higher yields are allowed (13 rather than 9 tonnes/ha) and requires two years of CASK AGEING.

Sangiovese features in no fewer than six of the Marche's 15 DOCs. Traditionally it was blended with Montepulciano in the Rosso Piceno DOC, but the once-obligatory minimum 50% has been reduced to 15%, and VARIETAL Sangioveses are now allowed. Rosso Piceno Superiore indicates a smaller historic zone with marginally lower yields. Styles of both DOCs range from modest stainless steel-fermented, early-drinking versions to fine oak-aged wines. Sangiovese from the Colli Pesaresi near the coast in the north of the region can be particularly elegant. A local speciality are the medium-bodied, fresh, perfumed reds of the growing Lacrima di Moro d'Alba zone near the town of Moro d'Alba in the north-eastern corner of the Verdicchio di Castelli di Jesi zone. Offida white wines, promoted in the early 2010s from DOC to DOCG, can be produced from either PECORINO or PASSERINA grapes, while red Offida must be at least 85% Montepulciano. Offida Pecorino in particular has benefited from the ambitions of a new generation of wine producers determined to unleash its potential by lowering yields. Parallel DOC Terre di Offida is reserved for white wines made of 100% Passerina. W.S.

Merlini, P., and Silvestri, M., *Un Altroviaggio nelle Marche* (2012).

www.imtdoc.it

Marcillac, growing AOC in SOUTH WEST FRANCE whose vigorous red wines are like no other. This is the best-known wine district of the Aveyron *département* (although see also ENTRAYGUES–LE FEL and ESTAING), where growers seek to preserve the area's viticultural tradition on terraced valleys in the Massif Central at ELEVATIONS up to 600 m/2,000 ft.

Its history has been turbulent. Despite the PHYLLOXERA crisis, which was followed by hurried planting of many low-quality HYBRIDS, the vineyard thrived so as to supply wines to the miners at nearby Decazeville. The mines however were closed in 1962, and the planted area fell to a mere 23 ha/57 acres. A handful of growers set about a revival choosing to replant the local FER (here called Mansois) in the region's IRON-impregnated red earth. The vineyard now extends over 200 ha/494 acres. The local CO-OPERATIVE at Valady is an important producer, as is Domaine du Cros, which since 1984 has increased its vineyards from 3 to 34 ha.

Marcillac, usually red and sometimes rosé, must be made of at least 90% Mansois, but few growers add anything else. It is a hard-wooded vine capable of making firm, redcurrant- and raspberry-flavoured wines with excellent structure. BARREL MATURATION has been introduced to temper the acidity of the wines, but often to the detriment of their unique flavour. P.S.

marcottage, French term for the LAYERING method of vine propagation in the vineyard.

Maréchal Foch, red wine grape variety named after a famous French First World War general. This FRENCH HYBRID was bred by Eugène Kuhlmann of Alsace, who cited the VITIS VINIFERA variety Goldriesling as one parent. DNA PROFILING in 2021 identified the hybrid Millardet et Grasset 101 o.p. as the second parent. It has good winter hardiness and ripens very early. It was once widely cultivated in the Loire and is still popular in CANADA and NEW YORK, where it is spelt

Marechal Foch, is sometimes called simply Foch, and may be vinified using CARBONIC MACERATION. It produces fruity, non-FOXY wines which can stand on their own two feet. J.V.

Maremma, long, loosely defined strip of TUSCAN coastline south of Livorno extending southward through the province of Grosseto. (The Maremma also extends into LAZIO, but this is not a viticultural zone.) Since 1995 it has also been the name of an IGT which was elevated to DOC in 2011 (and legally suffixed 'Toscana' in 2020) but, perversely, without more rigorous production rules. While predominantly dedicated to the production of red wine, the DOC in 2020 owed 28% of its total production to the white grape VERMENTINO.

The DOC area is confined to the province of Grosseto. Within its borders lie no fewer than seven DOCs and two DOCGs, but, although the area is extremely extensive, in 2021 only 2,364 ha/5,841 acres were declared DOC Maremma (up from 1,665 ha in 2012). The Maremma DOC can also be used for declassifying wines from the many DOCs within the region. The Alta Maremma (Upper Maremma) is the highest part of the region, in the north between Massa Marittima and Roccastrada, where vineyards are situated at 150–500 m/490–1,640 ft in ELEVATION, providing a cooler MESOCLIMATE than the warm Maremma plain and resulting in more elegant wines.

In etymological terms, the word 'Maremma' derives from the Latin *mare*, or 'sea', and is related to the French *marais*. Like the MÉDOC in Bordeaux, the low-lying parts of the Maremma were swampy or marshy for much of their history, with chronic problems of malaria.

Production of bottled wine is consequently a recent phenomenon, and quality wine can be said to date from the first bottles of SASSICAIA in the 1970s, although the zone of Morellino di Scansano, high and relatively malaria-free, enjoyed a certain reputation in the past, which it recently has more than confirmed. Thanks to the success of Sassicaia and, later, Ornellaia, the mid 1990s saw an investment boom in the Maremma, its apparent potential for large-scale vineyards on relatively inexpensive land attracting many prestigious

producers. Because the warm climate here results in riper grapes, it quickly became a source of blending wine for beefing up other Tuscan DOCs. The history of the region is so recent that eight of Grosseto's 13 DOCs and DOCGs did not exist prior to 1989 (Bolgheri itself having been elevated only in 1983), while several small DOCs owe their status to the success of remarkably few producers, such as Suvereto, which was elevated to DOCG in 2011.

Sassicaia laid the foundation stone for successful Cabernet-based wines, and many estates tried to copy the style while often supplementing their vineyards with plantings of Merlot and Syrah, but the results often lack the elegance and age-worthiness of the prototype. BARRIQUE ageing is still the standard, although large oak CASKS are increasingly used instead. Even if almost every DOC within the Maremma has a provision for INTERNATIONAL VARIETIES, be it as an added percentage or as varietally labelled wines, Sangiovese is still the most common and mandatory ingredient in most of the wines here.

In the Maremma there are three important areas, all promoted to DOCG in 2009. Morellino di Scansano DOCG is Maremma's classic zone for Sangiovese around the town of Scansano. Vineyards rise to 450 m/1,476 ft; Sangiovese (here called Morellino) grown at lower elevations tends to be fuller bodied. Like Chianti Classico, the wines must contain a minimum of 85% Sangiovese, as do those from Montecucco Sangiovese DOCG, further inland than Morellino di Scansano. Unremarkable in the past, it has attracted newcomers unable to afford vineyards in Chianti Classico and Montalcino who have begun to produce high-quality Sangiovese wines. Montecucco DOC is for whites based on Vermentino and reds with up to 60% Sangiovese. Val di Cornia Rosso DOCG on the Tuscan coast south-east of Suvereto, on a spit of land jutting out into the Mediterranean, is for blends of Sangiovese, Merlot, and Cabernet, while the Val di Cornia Bianco DOC is for whites made from Vermentino and Ansonica (the DOC Ansonica Costa dell'Argentario on the coast near the rocky promontory of Argentario is reserved for whites with a minimum of 85% Ansonica, the same variety as Sicily's INZOLIA).

The DOC Monteregio di Massa Marittima, extending over a large area between the coast and the town of Roccastrada, features Sangiovese for reds and Vermentino for whites, complemented by international varieties. Rising to 500 m/1,640 ft, the hills here are virgin vineyard land but the few wines produced here are generally elegant and fresh, suggesting that it has an interesting future.

Bolgheri apart, the Maremma has not turned out to be the promised land it appeared to be in the mid 1990s, although it may eventually produce some excellent wines from the right varieties and CLONES planted in the best sites. W.S.

Margaret River , most important wine region in WESTERN AUSTRALIA, air-conditioned by ocean on three sides. Cabernet Sauvignon and Sauvignon Blanc dominate the region's 5,725 ha/14,147 acres of vineyards, but it is also known for first-class CHARDONNAY. Its wines, together with Margaret River's year-round TEMPERATE CLIMATE, physical beauty, and diverse attractions from surf to woodworks make it a prime centre for wine TOURISM. E.L.L.

margarodes, otherwise known as ground pearls, are a serious insect pest in some vineyards, although they are, fortunately, found only in certain restricted regions. Margarodes weaken and kill vines with a similar action to PHYLLOXERA, and afflicted vines normally die about four years after a decline in VIGOUR is noted.

While many species of margarodes occur on a wide range of host plants worldwide, the most damaging to vines is the *Margarodes vitis* of South America. There are ten species of margarodes in South Africa, five of which infest vine roots, with *Margarodes prieskaensis* being one of the most damaging. The pre-adult insect is a round cyst which attaches itself to the roots and is covered by a hard, waxy covering. The insects are conspicuous by their foul odour.

The mature cysts can remain inactive in the soil for many years. Winged male and female forms mate above the soil surface, and eggs are laid in the vicinity of vine roots in early summer. There are

no sources of resistance to margarodes within the VITIS genus which includes vines, so control by grafting on to resistant ROOTSTOCKS seems unlikely. R.E.S.

Wineland, 'Identification, control and management of grapevine margarodes' (2017). www.wineland.co.za/identification-control-management-grapevine-margarodes.

Margaux , potentially the most seductive appellation of the Haut-MÉDOC district of Bordeaux. At their stereotypical best, the wines of Margaux combine the deep ruby colour, structure, and concentration of any top-quality Médoc with a haunting perfume and a silkier texture than is found to the north in ST-JULIEN, PAUILLAC, and ST-ESTÈPHE. Mid 20th century vintages from its two finest properties Ch Margaux (see below) and Ch Palmer certainly demonstrated this and helped to develop this conception of Margaux. Margaux is the most southerly, most isolated, and most extensive of the Médoc's communal appellations (see map under BORDEAUX). Although it is made of several non-contiguous parcels of the best portions of vineyard land (inferior parcels qualifying merely as Haut-Médoc), the appellation takes in not just the substantial village of Margaux but also the neighbouring communities of Cantenac, Soussans, Labarde, and Arsac.

In total almost 1,500 ha/3,750 acres qualified for the Margaux appellation in the mid 2010s, and within its boundaries there are inevitably considerable variations in both topography and soil type. Within the apellation is LIMESTONE, CHALK, CLAY, and SAND, but most of the finest wines should come from gentle outcrops, or *croupes*, where GRAVEL predominates and DRAINAGE is good—although properties here are particularly parcellated and intermingled with one estate often comprising very different, and often distant, plots of land. Ch Margaux, for example, has vineyards in both Cantenac and Soussans.

Margaux has in the past enjoyed enormous *réclame*, and more Margaux properties were included in the 1855 CLASSIFICATION of the Médoc and Graves (more than 20) than from any other appellation. The appellation clearly still has great potential, but in the 1970s, 1980s, and even 1990s a curious number of châteaux failed to keep pace with the substantial improvements in wine quality achieved in the other three major appellations of the Médoc.

Ch Margaux itself, the FIRST GROWTH standard-bearer as well as name-bearer for the appellation, was revived only in 1978 after more than a decade of disappointing vintages (see below for more details). Of the five second growths within the appellation, Chx Rauzan-Ségla, Rauzan-Gassies, Durfort-Vivens, Lascombes, and Brane-Cantenac, the first was seriously revived only when the owners of the couture house Chanel bought it in 1994 (restoring the 'z' in its name), and the second has been one of the most notable under-performers in the whole Médoc. Among the original ten third growths, Desmirail, Ferrière, and Dubignon-Talbot were practically abandoned for years, the last apparently forever. Only Ch Palmer, officially a third growth, could be said to have represented the appellation with any glory and consistency in the second half of the 20th century. Ch Palmer, part owned and managed by the Bordeaux branch of the Sichel family, produced a wine that could without hyperbole be described as legendary in 1961.

Rauzan-Ségla and Rauzan-Gassies were originally one estate and, according to PENNING-ROWSELL, probably the first other than the first growths to establish a reputation abroad. Rausan-Ségla (as it was then spelt), the larger part, or rather many different parts, was long owned by the Cruse family then passed through several corporate hands, the last of which installed effective new winemaking equipment in the mid 1980s before the sale to the Wertheimer family of Chanel.

Ch Lascombes passed from Alexis LICHINE to a British brewer in 1971 and is now run, with considerable RIGHT BANK influence, by an American-led consortium. The large Ch Brane-Cantenac estate, like

Durfort-Vivens owned by a LURTON, has been producing lighter wines than its status in the 1855 classification suggests.

Of Margaux's many third growths other than Palmer, Kirwan has yo-yoed rather; Issan was long more famous for its romantic moated château than for its wines; Giscours has experienced a renaissance under new ownership; Cantenac-Brown was only temporarily owned by AXA; Malescot St-Exupéry, originally called St-Exupéry, is slowly taking on more flesh; Boyd-Cantenac is too often dull; while Marquis d'Alesme-Becker, originally called Becker, can be uncomfortably lean.

More care has recently been lavished on Ch Prieuré-Lichine than on Margaux's other fourth growths Chx Pouget and Marquis de Terme, although the latter is much improved since the mid 1980s. Chx Dauzac and du Tertre, Margaux's fifth growths, have seen considerable recent investment.

One of the Médoc's most famous white wines is made here, even though it qualifies only as BORDEAUX AOC (see below). J.R. & J.L.

Brook, S., *The Complete Bordeaux* (4th edn, 2022).

Ginestet, B., *Margaux* (1984).

Penning-Rowsell, E., *The Wines of Bordeaux* (6th edn, 1989).

Margaux, Château, exceptional building and the most important wine estate in the village of MARGAUX in the Bordeaux wine region, and a FIRST GROWTH in the 1855 CLASSIFICATION. There is much potential for confusion since both Ch Margaux and GENERIC wine from the commune of Margaux are colloquially referred to as 'Margaux', but the former is likely to cost many times more than the latter.

With vineyards dating back to the 16th century, Ch Margaux was one of the four New French Clarets captured in the Anglo-French wars at the beginning of the 18th century and sold in the coffee houses of the City of London (see BORDEAUX, history). Thomas JEFFERSON on his visit to Bordeaux in 1787 picked it out as one of the 'four vineyards of first quality'. Sequestered in the French Revolution

after the owner's flight to England, it was bought by the Marquis de la Colonilla in 1804 and rebuilt in the First Empire style, by L. Combes, as we know it today—the grandest CHÂTEAU of the Haut-MÉDOC. After passing through several hands, shares were bought by a Bordeaux wine merchant, Fernand Ginestet, in 1925, and the family share was slowly increased to give his son Pierre Ginestet complete ownership in 1949. Also a merchant, he was badly hit by the 'energy crisis' in the early 1970s and had to seek a buyer. The French government refused to allow the American conglomerate National Distillers to buy it, but in 1977 the château was acquired by the French grocery and finance group Félix Potin, headed by the Greek André Mentzelopoulos, domiciled in France and passionate about the property. A great deal of money was spent on restoring the neglected vineyard, *chais*, and mansion, and Émile PEYNAUD was taken on as consultant. André Mentzelopoulos tragically died suddenly in December 1980, and first his wife Laura and then his daughter Corinne took over control, assisted by the late Paul Pontallier, the young director who joined the estate in 1983 (coincidentally one of the property's most successful vintages). Between 1992 and 2003 the Italian Agnelli family of Fiat motor cars became involved in ownership of the estate, but Corinne Mentzelopoulos remained in charge and is now the sole owner with her children Alexandra and Alexis, both involved with the property. A brand-new winery designed by British architect Sir Norman Foster has been in place since 2014 with a research lab, a particular interest of Pontallier's, given pride of place.

The 80 ha/197 acres of red wine grapes are planted with roughly 75% CABERNET SAUVIGNON, 20% MERLOT, and 5% comprising CABERNET FRANC and PETIT VERDOT. Average total red-wine output has been reduced to just over 20,000 from 30,000 cases, of which the resurrected Pavillon Rouge de Ch Margaux is the excellent SECOND WINE. A third wine has been made since 1997 and offered for sale from the 2009 vintage. A hitherto somewhat uninspiring white wine Pavillon Blanc was transformed into an ambitious dry wine. It is made in a separate temperature-controlled cellar, with BARREL FERMENTATION,

exclusively from SAUVIGNON BLANC grapes planted on 12 ha/30 ha of separate vineyard. E.P.-R. & J.R.

Faith, N., *Château Margaux* (1980).

marginal climate is one in which it may not be possible to fully ripen grapes every year, typically due to insufficient heat or too little or too much moisture, and where the wines produced are often more marked by vintage variation (see RIPENING). This situation is most often encountered in cool to cold climates. However, a marginal climate for a later-maturing variety such as MOURVÈDRE would be one that is warm enough to ripen earlier-maturing varieties but often has conditions that are too cool or a growing season that is too short to ripen Mourvèdre consistently. Growing grapes in marginal climates presents significant challenges, so VINEYARD SITE SELECTION is particularly important. G.V.J.

Maria Gomes, Bairrada and Vinho Verde synonym for the Portuguese white grape variety FERNÃO PIRES.

Maria Ordoña, Galician synonym for TROUSSEAU.

Marignan and Marin are small CRUS close to the southern shore of Lake Geneva whose names may be added to the French appellation SAVOIE. The wine is typically a light, dry white made from the CHASSELAS grape.

Marin, the CALIFORNIA county and wine region most immediately to the north of San Francisco, was planted as early as 1817, though many early growers on its cold, foggy hillsides quickly realized there were more hospitable growing areas further inland and decamped to neighbouring counties. Marin's first modern winery was only bonded in 1979, but this mountainous region continues to slowly attract

plantings. More than 71 ha/175 acres of grapes, primarily PINOT NOIR, are now sourced by a number of top wineries, including the modern-day pioneer Sean Thackrey, as well as a few that focus solely on the region, such as Easkoot and Kendric. A.Y.

www.marinwine.org

maritime climate, the opposite of a CONTINENTAL CLIMATE, has a relatively narrow annual range of temperatures. Places with a maritime climate tend to be near or surrounded by oceans (MADEIRA, for example) or other large bodies of water (see LAKE EFFECT). Spring temperatures tend to be lower and autumn temperatures higher than those of nearby inland regions because water masses effectively gain and lose heat more slowly than land masses. During the summer, maritime climates also experience lower DIURNAL TEMPERATURE RANGE than areas that are further inland.

Wine regions with maritime climates tend to have longer yet cooler growing seasons with lower heat accumulation and often experience more precipitation than locations further inland. In the mid latitudes, maritime climates vary according to the ocean temperatures offshore. Many west-coast wine regions are influenced by cold ocean currents, which, combined with warmer inland temperatures, create daily incursions of marine cloud layers or fog in the coastal valleys (e.g. SONOMA and NAPA). Some west-coast wine regions with moderately warmer ocean temperatures offshore, on the other hand, tend to have slightly higher humidity and higher precipitation in the summer (e.g. BORDEAUX). With warmer ocean conditions, east-coast wine regions tend to have the highest humidity levels but also have more of a continental climate due to the westerly winds coming off the continent (e.g. VIRGINIA). See also CLIMATE AND WINE QUALITY.

marl, a CALCAREOUS rock with a significant CLAY content, and the soil derived from it. The composition is somewhere between a fine-grained LIMESTONE and a mudstone, 50–50 in a modern classification though some older schemes use different proportions. Terms such as 'clay marl' and 'limestone marl' loosely indicate greater proportions of clay or limestone. Being very fine-grained, the amounts cannot be discerned without analytical equipment: marl is no more a visible mixture of calcite and clay, as often stated, than grey is a mixture of black and white. Typically, marl is pale-coloured and featureless, sometimes splintery, and with dilute acid fizzes much less vigorously than limestone. Its most famous occurrences are in parts of CHABLIS and the CÔTE D'OR. A.M.

Marlborough , on the north-eastern tip of New Zealand's South Island, where the Polynesians first arrived via canoe more than 700 years ago, is by far the country's biggest wine region, with more than 70% of total vineyard area. There were no commercial vineyards on the island until 1973, when Frank Yukich of Montana planted a panoply of vines in Marlborough's Brancott Valley, including a small amount of Sauvignon Blanc.

Trial and error followed, but it was soon discovered that the region could produce an unprecedented expression of SAUVIGNON BLANC. The inaugural 1985 vintage from CLOUDY BAY electrified the world's wine consumers. Vineyard development has been relentless since, traversing almost 30,000 ha/74,132 acres across the region's two major catchments, the Wairau and Awatere rivers, which flow north-eastwards into the Pacific Ocean. The complex soils can be broadly divided into two categories: fertile ALLUVIUM and low-vigour CLAYS. The industry took some time to discover that the former soil is where Sauvignon Blanc thrives, while the clays host yield-sensitive Pinot Noir and Chardonnay to a far more interesting degree. Vineyards have been replanted accordingly over the past 20 years.

The impressive DIURNAL TEMPERATURE RANGE (11 °C/20 °F in summer), high sunshine hours, and low average annual rainfall (600

mm/24 in) defines the region and the styles across all varieties. Availability of water is increasingly an issue, especially for the drier Awatere Valley and Southern Valleys.

Marlborough's subregional story is still evolving. The Wairau Valley, the Awatere Valley, and the younger viticultural area to the south increasingly referred to as Southern Coast are regarded as three macro-subregions. Within these are smaller subregions. The most well-known is Southern Valleys encompassing five tributaries of the Wairau: the Waihopai, Omaka, Brancott, Ben Morven, and Taylor Pass. Here it is common to find more Pinot Noir and Chardonnay planted to the hillsides on clay, while Sauvignon Blanc and aromatic varieties occupy the gravel and loam on the valley floor.

The coastal Lower Wairau produces the most THIOL-rich expressions of Sauvignon Blanc, while the Awatere's cooler, drier climate is distinctive for its citrus and crushed herb nuances. Further south, vineyards stretch from the intensively planted Blind River to sporadic plantings around Ward and the satellite of Kekerengu.

Wine's importance to Marlborough is apparent in LABOUR statistics, where one in ten workers are directly employed by the industry. Protecting the reputation of Marlborough Sauvignon Blanc is a growing concern among producers, and in 2018 a group of wineries united under the Appellation Marlborough Wine (AMW) trademark to guarantee that basic quality parameters and provenance would be upheld in certified wines. Wines must be 100% Marlborough fruit and bottled in New Zealand.

Marlborough also has the most Pinot Noir planted (2,721 ha/6,724 acres) in New Zealand, followed by an increasing number of Pinot Gris vines (1,221 ha), while Chardonnay (1,109 ha) remains relatively static. A portion of the Pinot Noir and Chardonnay crop goes into making high-quality traditional method SPARKLING WINE. Stylistically Pinot Gris seems to have found a comfortable identity in a Northern Italian-esque mould. Riesling (240 ha) is produced in styles from dry through to lusciously botrytized (see NOBLE ROT), and the region's producers are also experimenting with alternative varieties such as SAUVIGNON GRIS, GRÜNER VELTLINER, ALBARIÑO, and PINOT BLANC.

Marmajuelo (also known as Bermejuela), rare but outstanding white grape variety grown on the CANARY ISLANDS.

Marmandais, Côtes du, Bordeaux satellite AOC in SOUTH WEST FRANCE on either side of the river GARONNE. The town of Marmande, on the Garonne, gave it its name and provided a ready means of transporting the wines to Bordeaux and then to northern Europe, especially the NETHERLANDS, from the Middle Ages until the early 19th century. The arrival of PHYLLOXERA caused many farmers to abandon viticulture, however, and vines are just one of many crops in these gentle Marmandais hills. Geographically the region is simply an extension of eastern GRAVES in the south and ENTRE-DEUX-MERS in the north. Bordeaux grape varieties CABERNET SAUVIGNON, CABERNET FRANC, and MERLOT predominate, and the cooler climate here tends to result in light versions of red, and some rosé, wines. But these varieties may not exceed 85% of a blend, and Côtes du Marmandais's distinction is in the local variety ABOURIOU, which, with FER, Cot (MALBEC), Gamay, and Syrah, must make up the rest. Total vineyard area increased sharply in the 1990s but declined again so that it now hovers around 800 ha/1,976 acres. A very small amount of white wine is made, mainly from Sauvignons Blanc and Gris.

Much of the increasingly sophisticated wine production is in the hands of CO-OPERATIVES, but Elian Da Ros has provided much-needed glamour as an ambitious individual producer.

marque, French for BRAND.

Marqués, occasional name for LOUREIRO.

Marquette, increasingly popular cold-hardy AMERICAN HYBRID bred in Minnesota and grown in Canada and various chilly American states.

Makes quite assertive, peppery red wine.

Marsala, town in the province of Trapani in western SICILY and the FORTIFIED WINE produced around it. For over 200 years one of Sicily, and Italy's, most famous products, Marsala has fallen on hard times with declining quality, evaporating markets, and plunging production levels, although there are encouraging signs of revival.

History

Marsala can said to have been born with the arrival in Marsala in 1770 of John Woodhouse, an English merchant and connoisseur of PORT, SHERRY, and MADEIRA, who noted a striking similarity between the local wines and the fortified wines of Spain and Portugal. These wines were aged in a single-cask SOLERA system but without the addition of spirit (see FORTIFICATION). Woodhouse 'invented' Marsala in 1773 by adding 8 l/2 gal of grape spirit to each of the 400-l/105-gal barrels which he shipped to England. He proceeded to open a warehouse and cellars in the township of Marsala in 1796. The victualling of Nelson's fleet in 1798 doubtlessly assisted in spreading the name of the wine, and Woodhouse was followed by another Englishman, Benjamin Ingham, who founded a Marsala firm in 1812. The largest Marsala house, Florio, whose premises once occupied a full kilometre of seafront, was founded by Vincenzo Florio from CALABRIA in 1833. Marsala's production and marketing has always been dominated by large commercial houses, although there has been little continuity over time. Of the various Italian houses founded in the 19th century, Florio, Rallo, Pellegrino, Curatolo Arini, and Martinez have remained active, while Curatolo Arini, Cantina Intorcia (founded in 1930), and Marco De Bartoli (1979) are the only producers still run by descendants of the founding family.

Winemaking and viticulture

Modern Marsala, as codified in the DOC regulations of 1969, can be fortified only by adding grape spirit. Alcohol levels will also be slightly increased by BLENDING IN *mistella* or *sifone* (see MISTELA), the must of late-picked, overripe grapes, with fermentation blocked by the addition of 20–25% pure alcohol. Modifications to the viticulture of the zone have also had an effect on the wines produced today. The traditional GOBELET vine-training system has been partially replaced by WIRES, and the traditional grapes of the region, GRILLO and INZOLIA, have been partially supplanted by the higher-yielding CATARRATTO. This and enthusiastic IRRIGATION have led to significant increases in yield (the DOC rules allow a generous 10 tons/ha for white varieties, 9 tons/ha for red) and a corresponding drop in the grapes' sugar levels. All these factors have led to poorer base wines, necessitating more routine sweetening and a loss of the intrinsic character of the wine itself.

Furthermore, in the past, the use of ancient and poorly maintained casks for ageing the better categories of wine did little for their quality. Even more damaging, however, has been the proliferation of so-called 'Marsala Speciale', cloying wines flavoured with coffee, chocolate, strawberries, almonds, or eggs, all of which enjoyed a DOC status equal to the real wine from 1969 to 1984, when the use of the name 'Marsala' for these *speciale* forms was banned. The misconception these cooking wines created persists.

Today there are three main styles of Marsala:

Fine denotes a wine made by the addition of alcohol, mistella, and *mosto cotto* to the base wine. It must measure at least 17.5% alcohol and age for at least one year; I.P. or Italia Particolare (also called L.P., or London Particolar) is a sweeter style, with a minimum of 17% alcohol and one year of CASK AGEING.

Superiore (or S.O.M., for Superior Old Marsala) allows the addition of only *mistella* to the base wine and must be at least 18% alcohol, with

two years of cask ageing. A Superiore Riserva requires at least four years of cask age.

Vergine or 'Soleras' can have only alcohol added to the base wine; it is forbidden to add either *mistella* or *mosto cotto*. Therefore, these wines are always dry. Vergine Marsalas require at least five years of ageing in a SOLERA system; Riserva or *stravecchio* versions require a minimum of 10 years.

Fine and Superiore Marsala also come in a range of sweetness levels, from Secco (a maximum of 40 g/l of RESIDUAL SUGAR) to Semisecco (40–100 g/l) and Dolce (over 100 g/l). Both can also come in three colours: Oro (golden); Ambra (amber: the colour coming from *mosto cotto*—an attempt to create the impression of a cask-aged wine by deepening its colour with concentrate); and Rubino (ruby), made from at least 70% NERO D'AVOLA, PERRICONE, and/or NERELLO MASCALESE grapes.

Although 1,526 ha/3,770 acres of vineyards were registered as DOC in 2020 (down from 1,672 ha in 2012), the production of truly fine wines as the result of long cask ageing is increasing, if at a snail's pace and still in tiny quantities. The Marco de Bartoli estate, the most innovative producer of the zone, may not state the Marsala name on the labels of its Vecchio Samperi, a prototype high-quality Marsala Vergine, as it is made without the required addition of alcohol, although it has the mandatory 18% ABV. The wine is the result of a system called *vino perpetuo*, in which the barrels are regularly TOPPED UP with younger wines, as is Intorcia's *Pre British*, referring to the ancient, and still alive, tradition of making *Alto Grado*, wines with an elevated level of alcohol, while Florio has continued to offer mature and complex Vergine and Superiore wine often sourced from enviably large historic stocks. Belfrage, N., *Brunello to Zibibbo—The Wines of Tuscany, Central and Southern Italy* (2nd edn, 2003).

Nesto, B., and Di Savino, F., *The World of Sicilian Wine* (2013).

Marsannay, northernmost appellation of the Côte de Nuits district of the CÔTE D'OR (see map under BURGUNDY). It is unique in Burgundy for having AOC status for red, white, and pink wines. The vineyards of Couchey and Chenove are included with those of Marsannay. Prior to 1987, the wines were sold as generic BOURGOGNE followed by the specification Marsannay or Rosé de Marsannay. The latter style of wine is a speciality of the village pioneered in 1919 by Joseph Clair. The small amount of white wine produced has yet to show particular character. The red wines are attractive and fruity, if lighter than those of neighbouring FIXIN. There were no PREMIER CRU vineyards in 2021, but vineyards such as Clos du Roy and Les Longeroies may yet be elevated. J.T.C.M.

Marsanne, widely dispersed pale-skinned vine variety, making full-bodied, scented white wines. Probably originating in the northern RHÔNE, it has all but taken over here from its traditional blending partner and close relative ROUSSANNE (one naturally gave birth to the other through a CROSS with another as-yet-unknown variety) in such appellations as ST-JOSEPH, ST-PÉRAY (where it is sometimes known as Roussette), CROZES-HERMITAGE, and, to a slightly lesser extent, HERMITAGE itself, where wines such as CHAPOUTIER's Chante Alouette show that the variety can make exceptionally good wines for ageing. The vine's relative productivity has doubtless been a factor in its popularity, and modern winemaking techniques have helped mitigate Marsanne's tendency to flab. It is increasingly planted in the south of France, where, as well as being embraced as an ingredient in most appellations, it is earning itself a reputation as a full-bodied, characterful VARIETAL, or a blending partner for more aromatic, acid varieties such as Roussanne, VIOGNIER, and ROLLE. The wine is particularly deeply coloured, full-bodied, with a heady, if often heavy, aroma of pears, sometimes honeysuckle, verging occasionally on almonds, sometimes bitter in youth. It is not one of the chosen varieties for Châteauneuf-du-Pape, in which GRENACHE BLANC supplies many of Marsanne's characteristics, but France's total plantings had

grown to 1,798 ha/4,443 acres by 2019—mainly in the Rhône Valley but supplemented by plantings in the Languedoc and Roussillon. A little is planted in Italy and Switzerland, where as Ermitage it produces both light, dry wines and complex sweet wines in the Valais. Interest was generated in California as part of the RHÔNE RANGERS movement, although total acreage was only 51 ha/126 acres in 2020. Australia has some of the world's oldest Marsanne vineyards, notably in the state of Victoria, and a fine tradition of valuing this Rhône import and the hefty wines it produces, which have sometimes developed relatively fast in bottle. Total plantings had fallen to 137 ha/339 acres by 2022, however.

Marselan, particularly successful CROSS of Cabernet Sauvignon and Grenache Noir made by INRA in 1961. The small-berried variety was developed specifically for the LANGUEDOC, where it copes with both wet and dry growing seasons, is resistant to FUNGAL DISEASES and COULURE, but is very sensitive to TRUNK DISEASES. It can offer respectable levels of both colour and flavour. By 2019 total French plantings had reached 6,426 ha/15,879 acres. It has also spread successfully to Spain, California, Argentina, Brazil, and China, where local WINE CRITICS have suggested that Marselan could become China's signature red variety.

Martial (Marcus Valerius Martialis) (*c.*40–103/4 CE), born in Bilbilis, in Spain; he was poor and wrote Latin poetry for a living. In his *Epigrams*, in 15 books, more than 1,500 short poems in all, he writes about the vices he sees around him in ancient ROME, but he prudently uses pseudonyms to disguise the names of those he satirizes: for instance, 'Hesterno fetere mero qui credit Acerram, fallitur in lucem semper Acerra bibit' (1. 28). ('He who thinks that Acerra reeks of yesterday's wine is wrong. Acerra always drinks until daybreak.') Since snobbery and pretentiousness are two of his main targets, he often mentions wine. Misers and the *nouveaux riches* drink OPIMIAN wine (1. 26, 3. 82, 9. 87, 10. 49), and when Martial satirizes the

classical cult of old wine (old wine was always preferred to new and was known by its consular year), he invents a wine that has not even got a consular year, because it was laid down before the Republic (13. 111). He generally presumes detailed knowledge about wine on the reader's part, as for instance in 2. 53, 4. 49, 3. 49. The reader needs to know which wines were good and which were not in order to get the point of the epigram. At the end of Book 13 (106–25) is a series of epigrams listing 21 types of wine. Martial expresses his opinions of certain wines tersely, as in the following (13. 122), 'Acetum' (Vinegar):

Amphora Nilliaci non sit tibi vilis aceti
esset cum vinum, vilior illa fuit.

(Don't think an amphora of Egyptian vinegar is mean stuff. When it was wine, it was meaner still.) H.M.W.

Griffin, J., *Latin Literature and Roman Life* (1985).

Marufo, lesser PORT grape variety, also known as Mourisco Roxo, which produces red wines relatively light in colour in northern Portugal. Favoured by a few for light tawny ports, it was grown on 1,766 ha/4,364 acres in 2020.

Marzemino, interesting, late-ripening red grape variety grown in northern Italy, from Lombardy to Friuli but mainly in TRENTINO. DNA PROFILING at SAN MICHELE ALL'ADIGE revealed parent–offspring relationships with both TEROLDEGO and REFOSCO DAL PEDUNCOLO ROSSO, thus anchoring the genetic roots of this variety in northern Italy. Once much more famous than now, it does not have particularly good resistance to FUNGAL DISEASES and is often allowed to over-produce, but it can yield lively wines, some of them lightly sparkling. A big-berried CLONE dominated plantings with just over 785 ha/1,940 acres in Italy in 2015. J.R. & J.V.

mas, southern French term for a domaine.

Masdeu, strong red wine made on and named after an exceptionally well-maintained estate near Perpignan in ROUSSILLON which found a market via London wine merchants and salerooms in the middle of the 19th century as a cheaper alternative to PORT.

Shaw, T. G., *Wine, the Vine and the Cellar* (1864).

Massandra, winery built to extremely high specifications on the outskirts of Yalta in the CRIMEA in the 1890s to supply Livadia, the tsars' summer palace. Miners were imported from GEORGIA to tunnel into the rock and create more than 3 km/1.9 m of cool, damp cellars. Prince Golitsyn (see CRIMEA) was the first winemaker and was succeeded by the first of the Yegorov family, members of which made wine at Massandra for almost a century from 1898. The most successful wines are strong and sweet, many of them VINS DOUX NATURELS as well as FORTIFIED. Many were made to mirror other famous dessert wines such as PORT, SHERRY, MADEIRA, and TOKAJI, using local varieties such as RKATSITELI and SAPERAVI as well as imports such as MUSCAT, PINOT GRIS, and MALBEC and crosses such as Bastardo Magarachsky, a BASTARDO × Saperavi CROSS originated at MAGARACH in 1949. The current buildings at Massandra are used not for winemaking but for AGEING and BOTTLING. Today the produce of nine wineries is sold under the Massandra name.

The Massandra Collection was begun by Prince Golitsyn, its oldest member being an 18th-century wine made in the image of SHERRY known as Jerez de la Frontera 1775, but it is today made up substantially of the best Crimean wines. After considerable quantities were poured into the sea before the Nazi invasion, the Collection was evacuated during the German occupation of Yalta 1941–4, some as far as to Georgia, but was back in place in time for the historic Yalta peace conference in 1945. In the early 1990s Sotheby's offered two

consignments of strong, very sweet, durable wines from the Massandra Collection at AUCTION in London as part of the auctioneer's trading arrangements with the disintegrating Soviet Union. A further sale was held in 2004. In 2014, under the Russian occupation of Crimea, the winery was nationalized and, in December 2020, put up for auction, whereupon it passed into private hands.

Massic, a white wine which was among the most famous wines of Roman Italy and was much praised by the Roman poets. The type of grape is unknown. The wine was produced on Monte Massico, the line of hills which runs down to the sea on the west coast of Italy between the rivers Garigliano and Volturno. This zone is adjacent to the territory which produced FALERNIAN, and some writers treat Massic as a subtype of that famous wine. The wine was transported to Sinuessa on the coast, where there were numerous kilns producing the AMPHORAE in which the wine was exported. J.J.P.

mass selection, *sélection massale* in French, sometimes translated as 'massal selection', is a viticultural technique used to provide buds for the PROPAGATION of vines. Field vine selection can be either by mass selection, when many vines are selected to provide BUDWOOD, or by CLONAL SELECTION, in which a single mother vine is selected to provide CLONES. In mass selection, the identity of individual vines is not maintained, which is the principal difference between the two approaches.

Mass selection can be either negative or positive. If negative, then undesirable vines in a vineyard are marked so that cuttings are not taken from them. These vines might include those with low yield, poor fruit maturity, virus disease symptoms, higher than average incidence of fungal diseases, or off-types (MUTATIONS). Negative mass selection is also a good opportunity to mark 'rogue vines' (those of another variety) to ensure that mixed plantings do not occur in the future (although see FIELD BLEND). Positive selection identifies the best

vines, for example those with good fruit set, larger and looser bunches, and good fruit maturity.

Usually the vineyard assessment is made several times over the season. For example, rogue vines and NEPOVIRUS symptoms are easier to pick out in the spring, whereas differences in grape ripening are obviously best determined just before harvest. Vines are commonly marked by paint on the trunk.

Since there is not the same detailed recording and selection of individual vines, the gains in yield or quality from mass selection are typically less than for clonal selection, but the resultant wine, made from vines with a mixture of different characteristics, may be more interesting than one made from a single clone. The benefits to be had from mass selection will depend on how heterogeneous was the field from which the selection is made. There will be little benefit of mass selection if the vineyard is genetically quite uniform, but if there is a high proportion of rogue vines, off-types, or virus diseases then the grower might expect substantial benefits.

Unfortunately, in many viticultural regions of the world cuttings are taken in winter from vineyards which have not benefited from even the most cursory inspection in the preceding summer. In the winter the dormant vines appear similar, and so mistakes of mixed plantings, off-types, and virus diseases are spread unwittingly from one vineyard to the next generation by propagation. R.E.S.

Dry, P. R., and Coombe, B. G., *Viticulture*, i: *Resources* (2nd edn, 2004).

Masters of Wine, those who have passed the examinations held every year by the Institute of Masters of Wine (IMW), the wine trade's most famous and most demanding professional qualification. The Institute had its origins in the British wine trade in the early 1950s, when a counterpart to the qualifying examinations for other professions was devised by a group of wine merchants in conjunction with the VINTNERs' Company. The first examination was held in London in 1953, and six of the 21 candidates were deemed to have

qualified as Masters of Wine. The Institute of Masters of Wine was formed in 1955. The examinations consist of five written papers and three 'practical' (i.e. wine-tasting) papers; since 1999 those who pass all of them must write an approved research paper to qualify as an MW. The examinations are distinguished by the breadth and depth of their scope. University courses (see ACADEME) offer more detailed instruction in the OENOLOGY or VITICULTURE of a particular country or region, while the MW examinations test knowledge of both subjects on a worldwide basis, as well as of such varied subjects as ÉLEVAGE, BOTTLING, transport, QUALITY CONTROL, marketing, commercial aspects of the wine trade, the effects of wine consumption on HEALTH, and general wine knowledge. Each tasting paper requires candidates to describe, assess, and, often, identify up to 12 wines served BLIND. These wines, including SPARKLING and FORTIFIED WINES, may come from anywhere in the world.

Despite a notoriously low pass rate (although it has risen markedly in recent years, and candidates have always been allowed to pass practical and theoretical parts in separate years), by 1978 the number of Masters of Wine had reached 100, including two women. In 1982 the Institute held its first, relatively academic, symposium, at Oxford, but it also lost four of its members and realized that some expansion would be necessary for its survival (it had no executives and no premises until 1987). In 1983 it relaxed its entry requirements and allowed candidates from the fringes of the wine trade, such as WINE WRITERS, to take the examinations. In 1987 the examinations were opened up to those outside the United Kingdom, and the next year the first overseas candidate, an Australian, passed the examinations, at this stage still held in London. Since 1991 examinations have been held, on the same dates, in London, Australia, and North America. By early 2022 there were 419 Masters of Wine (268 men, 151 women) based in 30 countries, and several MWs with no professional connection with wine at all; 209 members live and work outside the UK. Since 1953, 498 people have passed the exams. Numbers of candidates have grown even more rapidly than numbers of Masters of Wine. The examinations are increasingly

demanding as the wine world expands, and the standard of preparation offered by the Institute was raised considerably in the mid 1990s and early 2000s. If the aims of the Institute have at times been less clear than the status of its members, and for many years it offered examinations but remarkably little education, this has changed thanks to annual residential courses, regular seminars, tastings, online learning, and a mentoring scheme.

www.mastersofwine.org

Master Sommelier is a qualification a little like MASTER OF WINE except that it is aimed at SOMMELIERS and tests practical wine service skills as well as BLIND TASTING and theoretical knowledge (which tends to involve more rote learning than the MW). Leading up to MS level are certifications: Introductory, Certified, and Advanced. The MS qualification itself became especially celebrated in the US as a result of the 2012 film *Somm* about the trials of several candidates. But in late 2020 a substantial number of cases of sexual harassment of female MS candidates were reported, and as a result seven Master Sommeliers were stripped of their status. There are, rather confusingly, two distinct 'Courts' of Master Sommeliers: that based in the Americas also includes Korea; the other has jurisdiction over Europe, Oceania, and the rest of Asia. In late 2022 there were 269 MSs worldwide, of whom 158 were members of the American Court. In all, four people have passed both MS and MW exams.

Mataro is one of the many synonyms of MOURVÈDRE, used primarily in Australia and by those who do not realize how fashionable Mourvèdre has become.

Mateus The Palace of Mateus near Vila Real just north of the DOURO Valley in northern Portugal lent its name to Mateus Rosé. Bottled in a flask not unlike the BOCKSBEUTEL, this medium-sweet, lightly sparkling

rosé blend became one of the world's most famous wine BRANDS. It was created in 1942 by Fernando van Zeller Guedes with the aim of putting wine from this then-neutral country on the world map. Commercial production began towards the end of the Second World War (at very much the same time as that of its rival Lancers). It was originally successful in Brazil; while that market collapsed after the war, the brand proved hugely popular in post-war Britain and then in the US. At its peak in 1978, Mateus, by then supplemented by a white version, accounted for over 40% of Portugal's total table-wine exports with worldwide sales amounting to 3.5 million cases. A small quantity of Mateus Rosé is still made at Vila Real, but most of the wine is now produced by owners SOGRAPE at Anadia in BAIRRADA.

Matrasa, or Madrasa, dominant, dark-berried vine of AZERBAIJAN. It is found in other central ASIAN republics and may also be called Kara Shirei and Kara Shirai. Also spelt 'Matrassa'.

Maturana Blanca, recently revived INDIGENOUS white wine grape in RIOJA.

Maturana Tinta, a Spanish synonym for TROUSSEAU. Maturana Tinta de Navarrete, confusingly referred to on some labels in RIOJA as Maturana Tinta *tout court*, is a synonym for the French variety CASTETS.

maturation of wine. See AGEING, BARREL AGEING, and CASK AGEING. The word 'maturation' is sometimes used to refer to grape RIPENING.

mature, tasting term for a fine wine that seems to have enjoyed sufficient AGEING for it to have reached the peak of its potential. In practice it is also used by the most polite, or determinedly optimistic,

tasters to describe wines that are past that point. Any hint of orange at the rim of a red wine suggests MATURITY.

maturity, desirable state in a wine when it is consumed. In a sense, the most basic wine designed for early drinking is mature almost as soon as it is bottled, but 'mature' when applied to a wine carries with it the implication that the maturity is the result of a certain amount of AGEING. Such a (red) wine is deemed fully mature when it has dispensed with its uncomfortably harsh TANNINS and acquired maximum complexity of flavour (sometimes described as BOUQUET) without starting to decay. The period of maturity varies considerably with wine type but is probably longer than most wine consumers believe. A wine that has been followed since its youth and begins to taste mature may continue to delight, and possibly evolve for the better, for a decade or more. For more details of the process and of the difference between individual wine types, see AGEING. For maturity in grapes, see RIPENING.

Maule, southern subregion of the Central Valley of CHILE with a rich heritage of OLD VINES, especially CARIGNAN, PAÍS, and MUSCAT.

Maury, both the VIN DOUX NATUREL and Maury SEC, the TABLE WINE, come from an island of black SCHIST around the eponymous village towards the western end of the Agly Valley in France's ROUSSILLON. Summers are hot and dry though slightly cooler in the higher west of the appellation, which extends to the neighbouring villages of Tautavel, St-Paul-de-Fenouillet, and Rasiguères. Maury Sec, recognized as an appellation in 2012, is only red; any white wine is either IGP Côtes Catalanes or Côtes du Roussillon. The principal grape variety is Grenache Noir, which may be blended with Carignan, Mourvèdre, or Syrah. With the decline in popularity of the Vin Doux Naturel, there has been a considerable influx of newcomers and new estates concentrating on *vin sec.*

Maury, the VDN, comes in several varieties. Red versions make up the bulk of the production, either as Grenat or Tuilé. Both must be at least 75% Grenache Noir, with the other colours of Grenache, plus Carignan, Syrah, and Macabeo playing a subsidiary role. Grenat is presented young and fresh, aged a minimum of eight months; Tuilé is an oxidative version aged a minimum of 30 months. (See OXIDATIVE WINEMAKING.)

Blanc and Ambré come from white varieties Grenache Gris and Blanc, Macabeo, Tourbat, and both Muscats. Blanc is the fresh version, while Ambré, like Tuilé, must age at least 30 months.

Hors d'Age entails a minimum of five years oxidative ageing, but the best will spend very much longer in old barrels and maybe also glass BONBONNES exposed to the elements. A wine described as RANCIO will have developed wonderful notes of walnuts and chocolate coffee, the result of ageing for several years in barrels that are never topped up (see TOPPING UP). R.E.G.

Mauzac, or Mauzac Blanc, is a declining white grape in SOUTH WEST FRANCE, especially in its birthplace GAILLAC and LIMOUX, where it is the traditional and still principal vine variety. It produces relatively aromatic wines which are usually blended, with Len de l'El around Gaillac and with Chenin and Chardonnay in Limoux. France's total area of Mauzac had fallen to 1,479 ha/3,655 acres by 2019. Thanks to energetic winemakers such as Robert Plageoles, since the late 1980s there has been a revival of interest in Gaillac's Mauzac, which comes in several different hues, sweetness levels, and degrees of fizziness. During the 1970s and 1980s in Limoux, total plantings of Mauzac rose, but they have declined as the appellation, for both still and fizzy wines, has been invaded by Chardonnay.

The vine, whose yields can vary enormously according to site, buds and ripens late, and grapes were traditionally picked well into autumn so that musts fermented slowly and gently in the cool Limoux winters, ready to referment in bottle in the spring. Today Mauzac tends to be picked much earlier, preserving its naturally high acidity

but sacrificing much of its particular flavour reminiscent of the skin of shrivelled apples, before being subjected to the usual SPARKLING WINEMAKING techniques. Some gently sparkling Gaillacs are still made by the traditional *méthode gaillacoise*, however, just as a small portion of Limoux's Blanquette is made by the *méthode ancestrale*. Mauzac Noir is much rarer and unrelated.

Mavro means 'black' in Greek and is the common name of the dominant but undistinguished grape on the island of CYPRUS.

Mavrodaphne, dark-skinned grape variety grown particularly round Pátras in the Peloponnese in GREECE, where it is the foundation of Mavrodaphne of Pátras, a FORTIFIED dessert wine which responds well to extended CASK AGEING. This aromatic, powerful variety, also grown to a much more limited extent on the island of Kefalonia, is occasionally vinified dry but only for use in blends. There were 571 ha/1,411 acres in Greece in 2021.

Mavrotragano, increasingly appreciated, distinctive red wine grape INDIGENOUS to the Greek island of SANTORINI.

Mavroudi, meaning 'blackish', is a generic name for several Greek red wine grapes.

Mavrud, indigenous Balkan grape variety most closely associated with BULGARIA, capable of producing intense, tannic wine if allowed to ripen fully. Grown on 855 ha/2,113 acres in central southern Bulgaria in 2021 and a speciality of Assenovgrad near Plovdiv, it is small-berried, is low-yielding, and has a long vegetative period. The robust wine produced responds well to OAK AGEING and can age well for up to a decade in bottle.

Mazuelo, official Spanish name for CARIGNAN but used only in RIOJA, where it is sometimes spelt Mazuela and where the variety was historically a not particularly distinguished ingredient. For more details, see CARIÑENA.

MDMP. See METHOXY-DIMETHYLPYRAZINE.

mead, a fermented alcoholic drink, called *hydromel* in France and *Honigwein* or *Met* in Germany, made from honey, which, it is claimed, predates either wine or beer. Monks kept bees for candlewax, and any surplus honey was fermented into mead. The dissolution of the monasteries meant the virtual demise of mead-making in Britain. Since the Second World War, some larger companies have marketed a mixture of wine and honey as mead, but the tradition of genuine mead-making is experiencing a revival. Grape mead is grape juice mixed with honey before fermentation.

mealybugs, small white insects of the family Cicadellidae which suck vine sap. Young mealybugs infect new growth in the spring, typically the undersurface of leaves at the base of the shoot. They also can feed on the fruit, canes, and trunk, and one species, the vine mealybug *Planococcus ficus*, can feed on roots. Mealybugs become mature and reproduce in early summer, and there can be three or more generations a year. Mealybugs prefer a humid environment and so are mostly found in a dense vine CANOPY.

The vine mealybug, first identified in California's Coachella Valley in the early 1990s, is now widespread in the San Joaquin Valley and the Central Coast, where it is regarded as a serious problem. It is spread by infected new plantings and can be controlled by briefly dipping the dormant plants in hot water.

Mealybugs do not cause significant commercial damage by their sap-sucking action alone, but there can be two indirect effects. First, they produce copious quantities of a sugary, sticky liquid called honeydew, which collects over the bunches and foliage and on which

fungus grows, often giving it a sooty appearance, sometimes referred to as sooty mould. Grapes affected by this impart a distinctive and undesirable taste to wine, and the fruit may be fit only for DISTILLATION. Mealybugs of the genera *Planococcus* and *Pseudococcus* have been implicated in the spread of LEAFROLL VIRUS, which has serious consequences for the loss of vineyard yield and grape quality. Mealybugs have been confirmed as spreading leafroll virus in South Africa, Israel, the US, Australia, and New Zealand. They are difficult to control because they may live on vine roots and also on other vineyard plants.

Where mealybug infestations are serious, a schedule of preventive sprays is necessary, but the waxy covering of the insect makes such spraying less effective. R.E.S.

measles. For how it affects vines, see ESCA.

mechanical harvesting, harvesting by machine in place of the traditional manual HARVEST. Undoubtedly one of the greatest changes from ancient to modern vineyards has been the adoption of machine harvesting, which was first introduced commercially in the 1960s. Whereas manual grape harvesting required literally hordes of pickers to descend on vineyards and complete the harvest, now the vintage may be completed by just one harvester driver, perhaps with a supporting driver and vehicle to receive the harvested grapes.

Depending on the YIELD and vineyard TOPOGRAPHY, to harvest a vineyard by hand requires between one and ten person-days per hectare, as opposed to less than five person-hours per hectare by machine.

Mechanical harvesting has been adopted for different reasons in different parts of the world. In some of the earliest developments instigated by Nelson SHAULIS and E. S. Shepardson at CORNELL UNIVERSITY, a major consideration was potential cost savings. In Australia, one of the first countries to embrace the new technology, the scarcity of LABOUR was important. In France, the increasing bureaucracy and costs involved in employing people even temporarily added allure to machine harvesting in the 1980s and 1990s. The net effect was that seasonal workers were more difficult to find, demanded higher wages, and were also perhaps less reliable, all of these factors promoting machines over people at vintage time. Machine harvesting may have been developed in the United States, but the technology was rapidly refined in France.

History

Mechanical harvesting can either increase the efficiency of manual labour or virtually replace it. Very early attempts at mechanization emphasized the first approach, but it has been the second approach which has been the more successful, by developing machines which essentially replace most of the manual operations.

Many forms of integrated machine harvesters have been developed and evaluated. The early New York development was the 'vertical impactor', which used a metal finger to strike the vine cordon; the shock dislodged the berries. However, the most common form of harvesting now is the 'horizontal slapper', which uses fibreglass rods to strike the CANOPY and dislodge the fruit, sometimes as single berries, sometimes as bunches, catching it with horizontal conveyor belts. Recent developments include onboard SORTING and DESTEMMING.

Effect on wine quality

The effect of machine harvesting on wine quality has been the subject of much scientific study, commercial experience, and popular conjecture. The majority of studies have shown that sophisticated mechanical harvesting has no negative effect on wine quality, and some have even argued that there is a positive effect. In New Zealand, for example, it has been shown that machine harvesting of Sauvignon Blanc increases the level of THIOLS in the juice, thereby highlighting the passion fruit and grapefruit flavours that have made this variety so successful.

Certainly most forms of machine harvesting damage some grapes so that parts of berries and bunches are mixed with the juice of broken berries. However, the juice can be protected from OXIDATION by SULFUR DIOXIDE addition, especially if moved quickly in a closed container to the winery. This problem can be minimized by harvesting at night, a practice widely adopted in hotter wine regions where grapes harvested by day can arrive at the winery at over 40 °C/104 °F. Indeed, in these circumstances, machine picking at night is a bonus for wine quality in comparison with hand harvesting by day.

Another disadvantage of machine harvesting is that there can be excessive SKIN CONTACT, which, depending on its duration (usually dictated by transport times), can lead to white wines becoming too high in PHENOLICS. The skin contact involved in transporting mechanically harvested white grapes to a winery can also cause a significant increase in the concentration of PROTEINS in the wine, necessitating higher rates of BENTONITE fining. Long distances between the winery and vineyard may make a mechanical harvest for delicate white wines an impossibility. Machine-harvested grapes can also contain leaves and petioles (see MOG), which may cause taints. Despite much evidence in favour of machine harvesting, some producers will remain with hand harvesting. The gentler nature of hand harvesting (which can also involve some degree of selection, e.g. avoiding unripe bunches or those affected by BUNCH ROT) is

preferable for many top-quality wines, especially sparkling wines, for which WHOLE BUNCHES may be pressed without first crushing. However, in Australia, for example, machine harvesting of grapes for sparkling wine is being used in a limited fashion. See also ROBOTS.

R.E.S.

Allen, T., et al., 'Influence of grape-harvesting steps on varietal thiol aromas in Sauvignon Blanc wines', *Journal of Agricultural and Food Chemistry*, 59/19 (2011), 10641–50.

Coombe, B. G., and Dry, P. R. (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

mechanical pruning involves using machines for PRUNING vines in winter. Viticulture is a very traditional form of agriculture, and many who tend the vines regard the annual winter pruning as their prime opportunity to interact physically with each vine. Because of this, and because they feel that mechanical pruning cannot offer the precision of manual pruning, many vine-growers oppose mechanical pruning, even at the expense of hours of back-breaking labour in cold and sometimes wet weather.

Early experiments in mechanical pruning were carried out in Australia and New York State in the mid 1970s. The machinery was not as elaborate as that for MECHANICAL HARVESTING, consisting of reciprocating cutters or flails mounted on a tractor. In Australia circular saws were widely used, sometimes mounted on a machine harvester with the picking head removed.

Machine pruning, a form of SPUR PRUNING, is simple in the extreme: a CANE-cutting device intersects the CANOPY, typically in a straight line, so that the vine canes are cut back to near their base. Because not all canes have a common orientation, even in a vertical-shoot-positioned TRAINING SYSTEM, a horizontal cut will produce spurs with a range of bud numbers (two to ten or more). The problem is exacerbated if the existing spurs on the vine are not at the same height, which is common in older vines.

Early commercial experiments followed mechanical pruning with hand pruning to thin out spurs and cut them to a uniform two-bud length, reducing pruning time by half. Encouraged by early experiments in Australia, however, most vines are now left untended after machine pruning. Because of an increase in pruning wounds, some affecting thicker, older wood, such vines are more prone to TRUNK DISEASE.

CANE PRUNING cannot be mechanized in this way, but surplus cane removal after hand-cutting can be, and in New Zealand machines have been developed to strip last season's growth off the trellis wires, offering partial mechanization.

Mechanical pruning is now widespread in Australia, especially in the hotter wine regions, mostly using tractor-mounted circular saws or reciprocating cutter bars, with a single pass cutting through wood of various ages across the top of the vine. Other parts of the world have been slower to embrace mechanical pruning, however, especially those where LABOUR is plentiful and relatively inexpensive. Mechanical pre-pruning is becoming more widespread for the extensive vineyards of southern France. In cooler regions such as northern Europe, mechanical pruning is less useful because machine pruning leaves too many buds, tending to increase yield and slow RIPENING. ROBOTS developed for cane pruning, using 3D vision, were field tested in New Zealand in 2014 following two years' research at the University of Canterbury. Despite this and other research, robotic pruning has not become commonplace.

The 100-plus hours per hectare required for hand pruning can be reduced to less than ten hours per hectare with mechanical pruning. Some of the substantial cost savings associated with this reduction may be lost if extensive hand-pruning follows. A more extreme option is not to prune at all: so-called MINIMAL PRUNING. R.E.S.

Botterill, T., et al., 'A robot system for pruning grape vines', *Journal of Field Robotics*, 34 (2017), 1100–22.

mechanization. Most WINEMAKING operations other than TASTING and overseeing individual barrels can be fully mechanized, but mechanization has been slower to invade the vineyard. Robotic technology is used, for example, in the production of PORT, in the movement of pallets around the winery, and in the preparation of grape samples. For more details of viticultural mechanization, see ROBOTS, MECHANICAL HARVESTING, MECHANICAL PRUNING, TRIAGE, and, most importantly, LABOUR.

medals from wine COMPETITIONS and other JUDGINGS are coveted by many wine producers and used mercilessly as sales aids. There is a certain hierarchy of medals, however. State and national wine shows are important to the wine trade in AUSTRALIA, but a Hobart gold medal may be reckoned less glamorous than a Canberra silver. In France, medals awarded by the fairs in Paris and Mâcon are usually indications of real quality.

medical aspects of wine consumption. See HEALTH.

medical profession. See DOCTORS.

medicine, wine in. From ancient times to the 18th century, wine enjoyed a central role in medicine (see LITERATURE OF WINE). The earliest practitioners of medicine were magicians and priests who used wine for healing as well as religious purposes (see RELIGION). Receipts for wine-based medicines appear in papyri of ancient EGYPT and the tablets of SUMER in about 2200 BCE, making wine humanity's oldest documented medicine.

The beginnings of systematized medicine are commonly attributed to the Greek Hippocrates (*c.*450 BCE), who recommended the use of wine as a disinfectant, a medicine, a vehicle for other drugs, and part of a healthy DIET. He experimented with different wines in order to

discover how each might be most appropriately used—whether diluted or not, for example—to cure a specific ailment, from lethargy or diarrhoea to easing difficult childbirth.

The most famous physician of ancient ROME was GALEN (2nd century CE), whose medical experience was shaped by treating injured gladiators in Asia Minor, although Aurelius Cornelius Celsus (25 BCE–37 CE) had already written extensively about the medical uses of various wines from different regions of Greece and Italy. Galen learned (like the Good Samaritan of the BIBLE) that wine was the most effective means of disinfecting wounds, even soaking exposed abdominal contents in wine before returning them to the abdominal cavity in the case of severe stomach wounds. His post as imperial physician involved tasting the emperor's wines in order to select the best and most healthy.

Ancient Jewish civilization prized wine for its medicinal properties. In the Talmud it is stated: 'Wine is the foremost of all medicines: wherever wine is lacking, medicines become necessary.'

The Qurʾān presented Arab doctors with a dilemma. The likes of Avicenna (11th century CE) recognized the importance of wine in healing, but since its consumption was forbidden throughout the world of ISLAM he had to be careful to prescribe it as a dressing only (although he noted boldly that 'wine is also very efficient in causing the products of digestion to become disseminated through the body'). Arabs studied medicine from Greek sources then transmitted it back, slightly amended, to the west. The works of Galen, for example, reached medieval Europe partly via the great medical school of Salerno in Italy, where they were translated from Arabic to Latin, and partly through direct translation from Greek. It was then that the notion of wine as an essential element in a healthy diet gained ground.

The medicinal use of wine continued throughout the Middle Ages, in MONASTERIES, hospitals, and universities. The earliest printed book on wine is by a doctor, one ARNALDUS DE VILLANOVA of the University of MONTPELLIER, who had written at the beginning of the 14th century.

Building on the observations of his classical forebears, he offers not only remedies for curing human ailments with appropriate wines but also recipes for curing 'sick' or bad wines too.

A new dimension was added to the role of wine in medicine with the introduction of DISTILLATION in the western world in the 12th century. Hieronymus Brunschwig, the German pharmacologist, wrote in the 15th century that '*Aqua vitae* [the water of life, or ALCOHOL] is commonly called the mistress of all medicines', but warned that 'it is to be drunk by reason and measure'.

Medicinal attitudes towards wine began to change in the latter half of the 19th century—although wine was still being added to sterilize water as late as the 1892 cholera epidemic of Hamburg (vindicated by modern research indicating that wine contains substances which make it a more effective anti-bacterial agent than pure alcohol), and strong, sweet wines such as PORT and BANYULS were still being prescribed as aids to recuperation in the early 20th century. Alcoholism was defined as a disease, and the injurious side-effects of excessive drinking studied. The appearance of temperance societies, sometimes supported by the medical establishment, caused many to re-evaluate the role of wine in DIET and medicine.

One further aspect of the conjunction of wine and medicine is the great influence that DOCTORS have had since ancient times, not just as wine consumers (and producers) but also in promoting or damaging the commercial potential of certain wines. Undoubtedly Roman connoisseurs took note of the recommendations of Galen and others, while in 17th-century France the commercial battle between wine regions reached new heights when Louis XIV's physician prescribed burgundy in preference to champagne. Other examples of vinous prescriptions abound.

For a modern view of the medical effects of wine consumption, see HEALTH.

medieval literature. The only medieval successor to the Roman AGRICULTURAL TREATISES is PETRUS DE CRESCENTIIS' *Liber ruralium commodorum* of *c.*1304; otherwise there are few medieval authors who wrote specifically on wine.

One of these is Henri d'Andely, whose *Bataille des vins* dates from just after 1223, and it belongs to the genre of the medieval debate poem. The king of France, Philip Augustus, wants to know which is the best wine: his preference is for whites. Some 70 wines are tasted, and the crown of victory passes all the French wines by, for it goes to the wine of CYPRUS.

Another Old French poem about wine is *La Disputoison de vin et de l'iaue* ('The Debate between Wine and Water'), written sometime between 1305 and 1377, when the papal court was at Avignon. The debate reflects the changing FASHIONS of the time, including those for the wines of BEAUNE, GASCONY, LA ROCHELLE, ST-POURÇAIN-sur-Sioule, and PARIS.

Of the Middle English poets, Chaucer is the one who displays the most knowledge of wine, although he tends to mention different wines only briefly. Chaucer's father and grandfather were among the most important VINTNERS in London and held the office of deputy to the king's butler, who was the person responsible for the collection of taxes on imported wines. Jugs of MALMSEY ('malvasye') and VERNACCIA ('vernage') are, for example, the extravagant presents that the monk in 'The Shipman's Tale' gives his friend the merchant, whom he is about to cuckold.

Wine is just wine in the medieval drinking songs, too. Most of them are in Latin, and they are not in praise of drinking so much as of DRUNKENNESS. The 9th-century poem about Adam, abbot of Angers, for example, has an address to BACCHUS as its refrain. One of the *Carmina Burana*, 'Potatores exquisiti' (*CB* 179), asks all serious topers to banish moderate drinkers from parties and to drink until speech

becomes impaired and walking impossible. Even when one is on one's own, the object of drinking should be inebriation. H.M.W.

Mediterranean, famous sea, wine-producing climate, diet (see HEALTH), and many other things besides. By classical times, vines were grown for wine in almost all the countries bordering the Mediterranean sea and on many of the islands; from Spain in the west to Byblos in the east, from northern Italy to Egypt, the vine made inexorable progress, with AMPHORAE of wine traversing the sea regularly. Historically the Mediterranean was the focus of viticulture, and most wine was produced in MEDITERRANEAN CLIMATES. In the Middle Ages, particularly when temperatures rose overall (see CLIMATE CHANGE) and when consumers were accustomed to very light, acid wines, viticulture spread much further north than the shores of the Mediterranean (see PARIS, ENGLAND, and GERMAN HISTORY, for example).

Mediterranean climate, a climate type characterized by warm, dry, sunny summers and mostly mild, wet winters. It occurs throughout the Mediterranean basin, on the west coast of the United States, in Chile, in southern and south-western Australia, and on the Cape of South Africa. The autumn and spring seasons range from mostly dry (on the hot, equatorial fringes bordering deserts) to wet at the poleward fringes, where Mediterranean climates merge into those with a more or less uniform rainfall distribution as in central and western Europe.

Mediterranean climates have some distinct advantages for viticulture over uniform- or summer-rainfall climates, provided that IRRIGATION can be given as needed. Sunshine is mostly sufficient, and there is less risk of rainfall in the growing season and of excessive rainfall during ripening and harvest. As a result of these rainfall patterns, the risk of FUNGAL DISEASES is generally lower. And to the extent that many Mediterranean climates can have the disadvantages of high TEMPERATURES during the ripening period, VINEYARD SITE SELECTION can help to minimize these disadvantages, by seeking out cooler coastal or high-ELEVATION sites, for example.

Further favouring Mediterranean climates is the fact that some of the main advances in vineyard management have particular application there. DRIP IRRIGATION in a summer-dry climate, for example, allows a high degree of control over SOIL WATER availability and vine VIGOUR. J.G. & R.E.S.

Mediterranean fruit fly, *Caratitis capitata*, can be a grape pest in some areas such as parts of Australia and South Africa. Infestations of grapes are often due to a build-up in other soft fruits such as figs, apricots, peaches, nectarines, or citrus. Despite being a major destructive pest for many fruit crops, it is not regarded as serious for vineyards. See also DROSOPHILA. R.E.S.

Méditerranée , IGP covering the entire Provence-Alpes-Côte-d'Azur region of FRANCE. Of the approximately 9,000 ha/22,000 acres in production in 2020, 60% was devoted to rosé. Grenache, Syrah, and Cinsaut are major blending components, alongside Merlot and CALADOC. E.A.G.

Médoc, the most famous red-wine district in Bordeaux and possibly the world. The Médoc stretches north-west from the city of Bordeaux along the left bank of the Gironde estuary, a virtually monocultural strip of flat, unremarkable land sandwiched between the *palus*, or

coastal marshes, and the pine forests which extend for miles south into the Landes. The vineyard strip is about 5–12 km/3–8 miles wide and runs northwards, with various intermissions for scrub, pasture, polder, and riverbank, more than 70 km/50 miles from the northern suburbs of Bordeaux to the marshes of the lower, more northerly part of the Médoc, the so-called Bas-Médoc (see map under BORDEAUX). Wines produced in the Bas-Médoc use the Médoc appellation, while those on the higher ground in the south-eastern section are entitled to the Haut-Médoc appellation, although many of them qualify for the smarter individual village, or communal, appellations. From south to north, these are MARGAUX, MOULIS, LISTRAC, ST-JULIEN, PAUILLAC, and ST-ESTÈPHE.

As outlined in BORDEAUX, history, the Médoc is a relatively recent wine region. Before the Dutch diligently applied their drainage technology to the polders of the Médoc in the mid 17th century, the region was salt-marsh, of interest for grazing rather than vine-growing. The ditches were so effective, and Bordeaux merchants so keen to supply vinous rivals to GRAVES and the powerful Portuguese wines that had been shipped in great quantity to the important British market, that New French Clarets were born, and great estates established in the Médoc on the back of their commercial success. In the mid 19th century, the Médoc enjoyed a period of prosperity unparalleled until the 1980s.

The climate on this peninsula is Bordeaux's mildest, moderated both by the estuary and by the Atlantic ocean just over the pines. These forests protect the vineyard strip from strong winds off the ocean and help to moderate summer temperatures, but it is only in the Médoc and the Graves district further south that Bordeaux vignerons are confident of ripening Cabernet Sauvignon grapes with any frequency. The Médoc is also Bordeaux's wettest region, which makes ROT a constant threat and SPRAYING a habit.

A typical estate, or CHÂTEAU, in the greater Médoc district hedges its viticultural bets and grows at least three grape varieties: a majority of Cabernet Sauvignon, supplemented principally by Merlot, together with some Cabernet Franc with, perhaps, a little late-

ripening Petit Verdot and occasionally some Malbec. However, Merlot often predominates in the damper, cooler soils of the Bas-Médoc as it is easier to ripen in lesser vintages, and Cabernet Sauvignon comprises only about half of all the vines planted in the district. In 2021, in reaction to concerns posed by CLIMATE CHANGE, the INAO also approved six new varieties for experimental, limited use in AOC Bordeaux wines: red varieties CASTETS, the Portuguese grape TOURIGA NACIONAL, and the French crosses ARINARNOA and MARSELAN; and the white varieties LILIORILA and ALVARINHO.

While the Médoc possesses few distinctive geographical features, many hours have been spent charting the subterranean Médoc. It has long been argued that its great distinction is its soil, in particular its GRAVEL. Many a geological theory has been employed to explain exactly how, and whence, these gravel deposits arrived in the Médoc, and efforts have been made to correlate exact soil and rock types with the quality of wine produced from vines grown on them. Dr Gérard Seguin of the University of BORDEAUX was one of the first to show that the soil's physical attributes are very much more important than its mineral composition and that one of the most important soil attributes is good DRAINAGE (see SOIL AND WINE QUALITY). The gravels of the Médoc are ideal in this respect and are particularly important in such a damp climate—although in hotter vintages mature vines can benefit from the extensive root systems encouraged by the gravel. The gravels of the Médoc are also good at storing valuable heat, thereby promoting RIPENING.

It is traditionally said that the best vines of the Médoc are those which grow within sight of the Gironde, and certainly this is true of all the district's FIRST GROWTHS. Some argue that this is because the gravels deposited here are younger and more effective for vine maturation, others that the MESOCLIMATES of coastal vineyards tend to be slightly warmer, and others still that vines on higher ground have to establish more complex root systems.

About 800 vine-growers farm this land, about one-quarter of which constitutes the CLASSED GROWTHS ranked in the famous 1855

CLASSIFICATION of the Médoc (and Graves).

The Haut-Médoc appellation

The landscape of the Haut-Médoc may not be remarkable, but it is peppered with grandiose château buildings erected and embellished with the money to be made from selling CLASSED GROWTH red bordeaux. Certainly the Haut-Médoc today is nothing if not stratified, thanks largely to the effects of the 1855 CLASSIFICATION of its most famous estates, which recognized 60 of them as first, second, third, fourth, and fifth growths, commercial and social positions from which none but Ch MOUTON ROTHSCHILD has so far been able to escape.

Most of these classed growths are entitled to a village appellation such as Pauillac or Margaux (see map under BORDEAUX), but five of them are in communes without their own appellations and qualify merely as Haut-Médoc. The most highly ranked of these is the third growth Ch La Lagune in Ludon just outside the city, a property which has retained its reputation for robust, concentrated wines. Just north of this well-run property is the fifth growth Ch Cantemerle. The commune of St-Laurent, inland from ST-JULIEN on the main road through the forests of the Médoc, boasts the steady fourth growth Ch La Tour-Carnet and two improving fifth growths, Chx Belgrave and Camensac.

The area classified as Haut-Médoc as opposed to any more specific commune totalled 4,741 ha/11,710 acres in 2020. Many of these vineyards are CRUS BOURGEOIS offering some of the best value to be found in Bordeaux. The top wines share the deep colour, the concentration, the TANNINS, and some of the AGEING potential of the classed growths and are made in a very similar fashion, with the average YIELD hovering around 42 hl/ha, and a leap of faith and selling price is needed to justify the use of new BARRELS. Some other particularly ambitious properties include Chx Agassac, Arnauld, Beaumont, Belle-Vue, Bernadotte, Cambon La Pelouse, Citran, Coufran, Labat, Lamothe-Bergeron, Lanessan, Malescasse, Sénéjac, and Sociando-Mallet.

The Médoc appellation

The total area qualifying for the basic Médoc appellation increased dangerously fast in the 1990s and early 2000s and reached nearly 5,700 ha/14,000 acres by 2004, 1,000 ha more than in 1996 and considerably more than that of the generally finer Haut-Médoc. It was still 5,653 ha in 2020. Growers were encouraged by what they thought would be a steady increase in worldwide demand for red bordeaux. They were wrong, however, and many found themselves in severe financial difficulties by the mid 2000s. Permitted yields are generally the same as for Haut-Médoc, and a high proportion of the wines are dominated by Merlot. Much of the wine produced on these lower, less well-drained, heavier soils is solid if uninspiring CLARET sold in bulk to CO-OPERATIVES or to the BORDEAUX TRADE for blending into GENERIC Médoc, if the growers are lucky. Estates on which an effort is made to produce something more distinctive than this, usually by restricting yields and refining winemaking, include Chx Clos Manou, Les Ormes Sorbet, Poitevin, Potensac, Preuillac, Rollan de By, La Tour de By, Tour Haut-Caussan, and Vieux Robin. Goulée is a Médoc from the owners of Ch Cos d'Estournel of ST-ESTÈPHE. J.R. & J.L.

Melnik , firm, even austere, ancient late-ripening BULGARIAN red grape variety grown on 197 ha/487 acres in 2021 exclusively in the Struma Valley around the historic town of Melnik, close to the Greek border, in what was then Thrace. It may therefore have been cultivated here for many centuries (see GREECE, ancient). Many producers have given up making varietal red wine due to the difficulty of getting the grapes ripe enough, but it is proving useful for

traditional-method SPARKLING WINE and even rosé thanks to its notable acidity. Its full name is Shiroka Melnishka Loza, or 'broad-leaved vine of Melnik', and its berries are notably small with thick, blue skins, though the wines are not usually deep in colour. OAK AGEING and several years in bottle bring out a warmth and style not unlike a NEBBIOLO. Its earlier-ripening offspring Ranna Melnishka Loza (Early Melnik or Melnik 55) yields wines with rounder fruit and softer TANNINS.

Melon, or Melon de Bourgogne, the most planted grape variety in the Loire Valley, planted on 8,436 ha/20,845 acres in 2019 and famous in only one respect and one region, MUSCADET. As its full name suggests, its origins are Burgundian, and this is one of the many progeny of Pinot and Gouais Blanc (see PINOT). Melon was outlawed from Burgundy just like Gamay at various times during the 16th and 17th centuries. While not as highly regarded as fellow white Burgundian and sibling Chardonnay, several of whose synonyms include the word 'Melon', it does resist cold well and produces quite regularly and generously. It had spread as far as ANJOU in the Middle Ages, according to Bouchard, and so it was natural that the vine-growers of the Muscadet region to the west might try it. It became the dominant vine variety of the Loire-Atlantique in the 17th century, when DUTCH traders encouraged production of high volumes of relatively neutral white wine, in place of the thin reds for which the region had previously been known, as base wines for Holland's enthusiastic distillers.

Melon's importance today rests solely on MUSCADET, although it is also grown to a limited extent in Vézelay in northern Burgundy.

Many of the older cuttings of the variety called PINOT BLANC in California were in fact Melon.

Bouchard, A., 'Notes ampelographiques rétrospectives sur les cépages de la généralité de Dijon', *Bulletin de la Société des Viticulteurs de France* (1899).

Galet, P., *Dictionnaire encyclopédique des cépages* (2nd edn, 2015).

Mencía, increasingly valued red grape variety grown so widely in north-west Spain that in 2020 plantings totalled 8,375 ha/20,695, notably in BIERZO, RIBEIRA SACRA, and VALDEORRAS (see map under SPAIN). DNA PROFILING laid to rest the once-popular theory that Mencía and Cabernet Franc were related but has more recently shown that the variety called JAEN, or Jaen du Dão, in Portugal is Mencía, while Mencia is most likely a natural CROSS between ALFROCHEIRO and the obscure Patorra. In addition, the rediscovery by young winemakers of old, forgotten, low-yielding hillside plots of Mencía on deep SCHISTS has started a PRIORAT-like revolution in the region. The concentration and COMPLEXITY of their wines dispel the notion that this variety necessarily produces light reds. It was the fertile plains on which Mencía was replanted after PHYLLOXERA, with resulting high YIELDS, that gave the variety its reputation for dilution. J.V.

Mendocino County is CALIFORNIA's largest and most northerly wine-producing region. Part of the even larger NORTH COAST AVA, the region is framed by Sonoma County to the south, the Pacific Ocean to the west, and the Mayacamas to the east. Its distance from San Francisco, which is about 100 miles south, kept its 19th-century vineyards small and delayed their impact outside the county. The same isolation kept wine for surreptitious resale there throughout PROHIBITION. Today that distance acts to slow development of the region's oeno-TOURISM and direct-to-consumer sales, though more nimble producers can clear that hurdle.

The vast majority of Mendocino's 7,700 ha/17,470 acres of vineyards are in its southern half. Even so, the meteorological range between the coastal Anderson Valley AVA and the interior appellations is extraordinary. As a result, the county has two distinct viticultural faces: the more famous coastal area, with its sparkling and aromatic

whites and Pinot Noirs; and the less known hot interior, planted to broad swaths of inexpensive Cabernet and Chardonnay and peppered with pockets of OLD VINES.

The region includes 12 AVAs. The coverall Mendocino AVA includes, from south to north, the sub-AVAs Yorkville Highlands, McDowell Valley, Anderson Valley, Cole Ranch, Pine Mountain-Cloverdale (shared with SONOMA), Redwood Valley, Potter Valley, Eagle Creek, Covelo, and Dos Rios. It also includes Mendocino Ridge, the only non-contiguous AVA in the US, which applies only to vineyards at 1,200 ft/366 m in ELEVATION or higher. Chardonnay is the region's most planted vine variety, at 4,466 acres/1,807 ha in 2020; Cabernet Sauvignon follows at 3,271 acres, with Pinot Noir just behind. ZINFANDEL, PETITE SIRAH, BARBERA, and CARIGNAN (spelt Carignane here) from third-generation Italian-American growers on the benchlands (see BENCH) can reach great heights in the hands of an artisan winemaker. Fetzer and its sibling Bonterra, which practise ORGANIC VITICULTURE, are the dominant wineries by size; Frey is notable as a producer of ORGANIC WINE, from grape to bottle. See also ANDERSON VALLEY.

K.A.W.

Mendoza , the most important wine-producing province in ARGENTINA, with over 70% of the country's vineyards and wine production. In the rain shadow of the Andes Mountain on the western fringe of the country, Mendoza has been the heartland of Argentine wine since the 19th century. The region's 151,233 ha/373,705 acres of vineyards (2020) encompass a wide variety of MESOCLIMATES and soils, with ELEVATION a major factor, as vineyards range up to 2,000 m/6,562 ft.

Provinces, such as Mendoza, are divided into departments, which are subdivided into districts and, in turn, into single vineyards. An IG (Indicación Geográfica, or GEOGRAPHICAL INDICATION) can represent a department, district, or smaller regional zone. The most important wine-producing areas in and around Mendoza are the following:

Luján de Cuyo The heartland of MALBEC, and the country's first CONTROLLED APPELLATION for Malbec, created in 1993, is where most of the traditional and renowned wineries of Mendoza are located—even if most also have vineyards in other areas. Running just south of Mendoza city to the Uco Valley, Luján's wine regions range 690–1,300 m/2,264–4,265 ft in elevation. Average rainfall is about 190 mm/7.2 a year, and the mean annual temperature is 15 °C/37.5 °F. The main districts within Luján de Cuyo are Las Compuertas, Vistalba, Agrelo, Perdriel, Ugarteche, Chacras de Coria, and Mayor Drummond. UNGRAFTED VINES of Malbec and Cabernet Sauvignon, some over 100 years old, are particularly treasured here.

Maipú Just east of Luján, Maipú is slightly warmer because of its lower elevation and renowned for its richer, jammier red wines. The main districts are Cruz de Piedra, Barrancas, Russell, Coquimbito, Lunlunta, Fray Luis Beltrán, and Maipú (as in Luján, there is a department and a district within it with the same name). Together with the department of Luján de Cuyo, they form what the locals call *Primera Zona,* or 'first zone', Mendoza's most traditional high-quality region.

San Rafael and General Alvear The southernmost wine regions of Mendoza balance lower elevation with higher LATITUDE, focusing on classic VARIETAL wines.

Valle de Uco/Uco Valley Arguably the most fashionable wine region in South America Valley de Uco comprises the departments of Tupungato (with its districts El Peral, Anchoris, La Arboleda, Tupungato, and Gualtallary), Tunuyán (Vista Flores, Los Árboles, Los Sauces, Los Chacayes), and San Carlos (Paraje Altamira, La Consulta, Eugenio Bustos, Pampa El Cepillo). Elevations range from 850 m/2,789 ft?1,990 m/6,529 ft. The combination of cool temperatures, very poor soils (many CALCAREOUS), good DRAINAGE, and continuous breezes results in full-bodied wines with high natural ACIDITY. Malbec, Chardonnay, and Cabernet Franc excel.

Eastern and Northern Mendoza Comprising Lavalle, Las Heras, Santa Rosa, La Paz, San Martin, and Rivadavia departments, these vast, mostly low-elevation, warm areas specialize in large volumes

and entry-level wines—although some high-quality wines are also made, mostly with TEMPRANILLO and BONARDA. There are some exciting new vineyards in the Andes foothills of Las Heras making fresher, tauter wines from Malbec and Pinot Noir.

Red wines account for almost two-thirds of Mendoza's production, with Malbec accounting for over one-quarter of all plantings—some 38,644 ha/95,491 acres in 2020—followed by Bonarda (CHARBONO) at roughly 10%. Cabernet Sauvignon, Syrah, and Tempranillo are the next most planted varieties, but Cabernet Franc and Pinot Noir are probably the more lionized. In white wines, white Criolla grapes lead in plantings, but it is Chardonnay, Sauvignon Blanc, Torrontés, and Sémillon that lead in quality, especially from the cooler heights of the Uco Valley. Pink-skinned grapes, notably CRIOLLA GRANDE and CEREZA, account for about one-fifth of all Mendoza plantings and are used for inexpensive wine and GRAPE CONCENTRATE. Over 150 grape varieties are planted in Mendoza, and winemakers are ever more adventurous, now making interesting and excellent wines from varieties ranging from MONTEPULCIANO to FIANO. A.B.

Barnes, A., *The South America Wine Guide* (2021).

Menetou-Salon is just west of, and very much smaller than, the much more famous SANCERRE, near the city of Bourges, producing a not dissimilar range of red, white, and rosé wines which can often offer better value—from 602 ha/1,487 acres of vines in 2019, encompassing ten villages. Sauvignon Blanc grown here can make wines every bit as refreshingly aromatic as Sancerre. Soils in the appellation are mainly LIMESTONE from the Upper Jurassic period and can be very similar to those in the more famous zone to the east, although Menetou's vineyards are flatter and less compact, resulting in a less favourable MESOCLIMATE. The best zone is around the village of Morogues, a name used on the labels of producers such as Henry Pellé. The village of Parassy also has a high concentration of vineyards. Sauvignon Blanc represents about 75% of the appellation's total production, while Pinot Noir grapes are responsible for scented,

light reds and pinks for early consumption, this lightness owing much to relatively high permitted YIELDS (59 hl/ha for reds and 63 hl/ha for rosés)—yet more evidence of the similarity between Sancerre and Menetou-Salon.

See also LOIRE, including map. J.R. & C.P.

Méntrida , Spanish town and DOP south-west of Madrid in CASTILLA-LA MANCHA (see map under SPAIN) traditionally producing robust red wines from GARNACHA grapes. The producer who first brought international attention to this part of Spain, Marqués de Griñon, grows CABERNET SAUVIGNON, CHARDONNAY, SYRAH, and PETIT VERDOT in his vineyard at Malpica de Tajo, which used to be just outside the denomination but has now been incorporated within it. He spurned the opportunity to jump rank from what was then the lowest to the local DOP and was rewarded in 2002 with his own VINO DE PAGO, Dominio de Valdepusa. Meanwhile, a number of producers in Méntrida proper and in its mountainous northern area, part of the GREDOS region, are turning out delicate Burgundy-style Garnacha and making significant progress with ALBILLO Real grapes as well as with Syrah and Cabernet Sauvignon. R.J.M., V. de la S. & F.C.

Menu Pineau, an old LOIRE white wine grape sometimes called Arbois Blanc and officially known in France as Orbois, is a progeny of the prolific GOUAIS BLANC. Just 157 ha/388 acres remained in 2019, producing such wines as VALENÇAY, CHEVERNY, and occasionally one labelled TOURAINE. A vigorous vine, its wines are softer than those of CHENIN BLANC.

menzione geografica aggiuntiva. See MGA.

Meranese, or Meraner in German, red wines based on SCHIAVA grapes, from around the town of Merano in ALTO ADIGE.

mercaptans, VOLATILE SULFUR COMPOUNDS typically referred to as THIOLS when they contribute positive flavours to a wine. The term mercaptans is generally used in relation to FAULTS IN WINE, for example excessive REDUCTION or when a compound such as methanethiol (asparagus-like) is at a level that dominates the wine and masks its fruit. Such faults typically become worse post-bottling because of the anaerobic environment. V.F.

Blanchard, L., et al., 'Formation of furfurylthiol exhibiting a strong coffee aroma during oak barrel fermentation from furfural released by toasted staves', *Journal of Agricultural and Food Chemistry,* 49/10 (2001), 4833–5.

Ferreira, V. E., et al., 'Elusive chemistry of hydrogen sulfide and mercaptans in wine', *Journal of Agricultural and Food Chemistry*, 66/10 (2018), 2237–46.

merchants are almost as important to the wine world as producers and consumers, and may have been for at least four millennia. Several different types of wine merchant are considered below, but they share a dependence on the vine and the attractions its produce has for the consumer.

Britain

The British wine merchant is, almost necessarily, an importer, or a customer of one. Wine merchants were important in medieval England and Gascony, when they were known as VINTNERS in English. Even today, a wine merchant in Britain enjoys a social standing perceptibly higher than that of, for example, a grocer. This is somewhat ironic since the majority of the wine sold in Britain has been sold by grocers, as opposed to specialists, since at least 1987. This was largely due to the efforts of the licensed supermarkets to improve the range and quality of wines they sell, although it is also simply a function of the fact that so many Britons pass through a supermarket every week. The independent specialist wine merchant, or indie, has to compete with the low margins funded by the sheer quantity of wine a supermarket chain can sell. They do so by offering more personal service, advice, sale-or-return facilities, credit, glass loan, and so on, with the supermarkets and such specialist chains as have survived the onslaught of competition from supermarkets hot on their heels. Hybrids that are a cross between shop and wine bar are increasingly popular.

France

The French term most often translated as merchant is *négociant*, most often a producer/bottler rather than a specialist retailer (known as a *caviste* in French and still a relatively rare phenomenon), since so many wine purchases in France, as in other European wine-producing countries, have been made direct from the producer (*vente directe*) or, increasingly, at the supermarket (*grande surface*). See NÉGOCIANT and BORDEAUX TRADE for more details.

US

As American wine enthusiasts proliferate, so do wine retailers in the US, even though they have to deal with the constraints of the THREE-TIER SYSTEM and, in many states, compete with large supermarket groups. Unlike their British counterparts, the best routinely sell mature FINE WINE by the single bottle rather than by the CASE.

See also E-COMMERCE and wine TRADE.

Mercurey, most important village in the Côte CHALONNAISE district of Burgundy. While most of the production is in red wines made from Pinot Noir, a small quantity of unusually scented white wine from Chardonnay is also made. With 650 ha/1,600 acres under vine, Mercurey produces almost as much wine as the other principal Côte Chalonnaise appellations Givry, Rully, and Montagny combined. The appellation, including the commune of St-Martin-sous-Montaigu, includes 32 PREMIER CRU vineyards making up over 20% of the total.

The red wines tend to be deeper in colour, fuller in body, more capable of AGEING, and half as expensive again as those of the neighbouring villages. Maximum yields for Mercurey are the same as those for VILLAGE WINES in the CÔTE D'OR, unlike the other appellations of the Côte Chalonnaise.

Mercurey is said to have been the favourite wine of Gabrielle d'Estrées, although her lover Henry IV preferred neighbouring Givry. Leading producers include Ch de Chamirey, Faiveley, Michel Juillot, Lorenzon, Raquillet, and de Villaine. J.T.C.M.

Merenzao, relatively rare red grape in VALDEORRAS in north-west Spain, sometimes known as María Ordoña, and a synonym for TROUSSEAU.

meristem culture. See TISSUE CULTURE.

Meritage (rhymes with 'heritage') is a name created by a group of North American winegrowers in 1988 for wines made in the image of a BORDEAUX BLEND, devised to distinguish these wines from VARIETAL wines. This trademarked name is legally available for use on labels only to wineries that belong to the Meritage Alliance and for wines that are made exclusively from two or more of the varieties Cabernet Sauvignon, Cabernet Franc, Merlot, Malbec, and Petit Verdot for red wines (the less widely planted St-Macaire, Gros Verdot, and Carmenère are also allowed) and Sauvignon Blanc, Sémillon, and Muscadelle for whites. In 2022, the Alliance had more than 350 member wineries globally, the majority in CALIFORNIA, NEW YORK, and VIRGINIA.

www.meritagealliance.com

Merlot, or Merlot Noir, black grape variety originally associated with the great wines of ST-ÉMILION and POMEROL, but it has become so popular worldwide that by 2010 it was the second most planted variety overall, not far behind CABERNET SAUVIGNON. Its late 20th century increase in popularity may be most readily associated with a short-lived FASHION for it in the United States, but in reality total American Merlot plantings lag behind those of Cabernet Sauvignon by quite a margin, and it is in Bordeaux, and in France overall, that earlier-ripening Merlot is so decisively the most planted red wine grape with a total that had reached 114,785 ha/283,640 acres by 2019 (when Cabernet Sauvignon's total had fallen to 46,971 ha).

It was already documented as a good-quality vine variety in the Libournais in 1784, according to the historian Enjalbert, and in 1868 was noted by A. Petit-Laffitte as the Médoc's premier variety for blending with the much younger grape variety Cabernet Sauvignon. DNA PROFILING has shown it is the progeny of CABERNET FRANC and an obscure western French variety recently named Magdeleine Noire des Charentes. In consequence, Merlot turns out to be the probable half-

brother of Cabernet Sauvignon, which helps to explain why Merlot-dominant red bordeaux can taste so like Cabernet-dominant red bordeaux. Merlot the wine is generally plumper, fruitier, and softer than Cabernet, but its flavour is arguably much less emphatic. If any single wine promoted TEXTURE rather than flavour to the front rank of concerns for American winemakers it was Merlot, 'Cabernet without the pain' (cf. ASTRINGENCY).

Throughout Bordeaux and SOUTH WEST FRANCE and, increasingly, much of the rest of the world, Merlot plays the role of constant companion to the more austere, aristocratic, long-living Cabernet Sauvignon, providing a more obvious complement to Cabernet Sauvignon's attributes than the CABERNET FRANC that often makes up the third ingredient in the common BORDEAUX BLEND. It also provides good viticultural insurance in more MARGINAL CLIMATES as it buds, flowers, and ripens at least a week before Cabernet Sauvignon (although this makes Merlot more sensitive to FROST, as was shown dramatically in 1991 when some RIGHT BANK properties hardly produced any wine at all). Its early flowering makes it particularly sensitive to COULURE, which weaker ROOTSTOCKS can help to prevent. Merlot is not quite so vigorous as Cabernet Sauvignon, but its looser bunches of larger, notably thinner-skinned grapes are much more prone to ROT. It is also more sensitive to DOWNY MILDEW. (SPRAYING can be a particularly frequent phenomenon in the vineyards of Bordeaux.) Merlot responds much better than the late-ripening Cabernet Sauvignon to damp, cool soils, such as those of St-Émilion and Pomerol, that retain their moisture well and allow the grapes to reach full size. In very well-drained soils, dry summers can leave the grapes undeveloped. Unlike Cabernet Sauvignon, Merlot is extremely sensitive to the timing of HARVEST, and acid levels can be dangerously low if picking is delayed too long. Merlot arguably reaches its apogee in the finest wines of Pomerol such as PETRUS and LE PIN.

For the vine-grower in anything cooler than a warm or hot climate, Merlot is much easier to ripen than Cabernet Sauvignon and has the further advantage of yielding a little higher. It is not surprising

therefore that, in France and northern Italy, total Merlot plantings have long been greatly superior to those of Cabernet Sauvignon.

This is particularly marked in Bordeaux, where Cabernet Sauvignon dominates Merlot only in the famously well-drained soils of the Médoc and Graves—and even here Merlot plantings increased considerably in the late 1990s, typically at the expense of Cabernet Franc. Elsewhere, not just in St-Émilion and Pomerol but also in Bourg, Blaye, Fronsac, and, importantly, those areas qualifying for basic Bordeaux or the rest of the so-called Bordeaux Côtes appellation, Merlot predominates.

Merlot is also more widely planted than either sort of Cabernet in the rest of SOUTH WEST FRANCE. Wherever in this quarter of France the AOC regulations sanction Cabernet Sauvignon (see CABERNET SAUVIGNON for details), they also sanction Merlot, although the latter is favoured in the Dordogne while the Cabernets are preferred in Gascony.

With Syrah, Merlot has been a major beneficiary of the Languedoc's replanting with 'improving' grape varieties. Total plantings in the Languedoc more than doubled between 1988 and 1998 and stood at 27,124 ha/67,025 acres in 2019. Most of this is destined for fruity, easy, early-drinking Pays d'Oc wines, for the only Languedoc appellations to sanction Merlot within their regulations are CABARDÈS and MALEPÈRE.

Merlot has long been grown in Italy, and the country's national total had reached 24,057 ha/59,446 acres by 2015. It is planted particularly in the north-east, often alongside Cabernet Franc, where vast quantities of the wine pronounced 'Merlott' are grown on the plains of both FRIULI GRAVE and PIAVE, even if better, more concentrated wines come in smaller quantities from higher vineyards. In FRIULI, there is even a Strada del Merlot, a tourist route along the Isonzo River. Individual denominations for Merlot abound in FRIULI, VENETO, and TRENTINO-ALTO ADIGE. Merlot is also planted on the Colli BOLOGNESI in Emilia-Romagna. The variety is planted in almost all of Italy's 20 regions. In general, little has been expected from, or

delivered by, the sea of light, vaguely fruity Merlot from northern Italy, which makes it all the more remarkable that the variety is being taken seriously by a handful of producers in Tuscany and Umbria and, more recently, in Friuli. Ornellaia in BOLGHERI and the Fattoria di Ama in CHIANTI CLASSICO were some of the first to show that Italy could provide something more in the mould of serious Pomerol, with Masseto and L'Apparita respectively. Many Italian producers still in thrall to INTERNATIONAL VARIETIES prefer Merlot to Cabernet Sauvignon, both for ripening more easily and for being a less dominant blending component with native Italian varieties. In the south of Italy it can be a challenge to give Merlot definition because it ripens too early in the heat.

Merlot is vital to the wine industry of Italian SWITZERLAND and is made at a wide range of quality levels, including some very fine wines indeed.

In eastern and central Europe Merlot plays a very important role. It has also been popular over Italy's north-eastern border in western SLOVENIA and all down the Dalmatian coast in CROATIA, where it can be attractively plummy when yields are restricted. It is also known in HUNGARY, notably around Eger in the north-east and Villány in the south, but (as in AUSTRIA) Cabernet Franc is much more highly regarded. It is also the most widely planted red wine variety in ROMANIA, where total plantings had grown to 11,151 ha/27,555 acres by 2021, and it just behind Cabernet Sauvignon over the border in MOLDOVA and in BULGARIA, particularly the south of the country, where it is often blended with Cabernet Sauvignon.

The fact that it is slightly lower in acidity as well as international *réclame* may have hindered its progress in some warmer climates such as Iberia and most of the eastern Mediterranean, where it is not generally as common as the more structured Cabernet Sauvignon. For example, in 2020, Spain grew 18,651 ha of the latter and less than 11,890 ha of Merlot, most successfully in Penedès.

In the 1990s, and until SIDEWAYS punctured its reputation, Merlot was suddenly regarded as 'the hot varietal' in the Cabernet-soaked

state of California, and it demonstrated decisively that it had a particular affinity with the conditions of Washington State and those of Long Island in NEW YORK State.

In 1985, California had a total of hardly 800 ha/2,000 acres of Merlot. This had already risen to about 83,250 ha by 1992 when the faddish American mass market discovered the variety as softer and milder than the state's Cabernet Sauvignons, and demand soared. By 2003 there were 21,000 ha in the ground in California, although the intensity of the FASHION for Merlot led to stretching and over-enthusiastic IRRIGATION for a while. Plantings in all but the coolest regions of the state seem to have settled down, with 15,017 ha/37,107 acres in 2020. See CALIFORNIA for more detail of the wine style.

Merlot has had little success in Oregon's vineyards, where the much cooler climate makes coulure too grave a problem, but in WASHINGTON's sunny inland Columbia Basin Merlot has produced consistently fine, fruity, well-structured reds. Merlot is the state's second most popular black grape variety with 3,671 ha/9,071 acres in 2017, although its susceptibility to WINTER FREEZE can occasionally prove disastrous in this desert climate. Merlot is also grown increasingly in other North American states, notably in NEW YORK's Long Island.

In South America, Merlot has become extremely important to Chile's prolific wine exports. Vines called Merlot have done particularly well in the damper soils of the more southerly wine regions in Chile's Central Valley, although it took some time to distinguish satisfactorily between true Merlot Noir and CARMENÈRE (which almost equalled Merlot's total Chilean plantings of 11,366 ha/28,086 acres by 2020). See CHILE for more detail. Merlot is also planted to a more limited extent in ARGENTINA, URUGUAY (where it can blend well with the local TANNAT), BRAZIL, and BOLIVIA.

Merlot has never really taken off in AUSTRALIA, where plantings in the irrigated interior proliferated in the 1990s to satisfy US demand. From a peak of 10,737 ha/26,532 acres in 2008, the area has been

slowly falling, down to 8,115 ha/20,053 acres in 2022, less than one-third as extensive as those of Cabernet Sauvignon.

Merlot clearly has potential in New Zealand, particularly in Hawke's Bay, and plantings were 1,077 ha/2,661 acres in 2022, making it by quite some distance the country's second most planted red wine grape after Pinot Noir and far more popular than the late-ripening Cabernet Sauvignon. South Africa has produced some interesting varietal Merlots and is using it to good effect in various BORDEAUX BLENDS, but it is only the fourth most popular red wine variety after Cabernet Sauvignon, Shiraz, and Pinotage.

Merseguera, lacklustre Spanish white grape variety (Esquitxagos in Penedès) widely grown in ALICANTE, JUMILLA, and VALENCIA.

Merwah, or Merweh, INDIGENOUS VARIETY of LEBANON traditionally used in the making of arak (local spirit), sacramental wines, and Chateau Musar's white blend. Like OBEIDEH, it is increasingly popular among wine producers, who value its body and acidity. M.R.K.

Meslier St-François is, like MENU PINEAU, a white grape variety that is a local speciality of the Loir-et-Cher *département* in the westward bend of the Loire but has been disappearing at an even faster rate. DNA PROFILING revealed it as a natural cross of GOUAIS BLANC and CHENIN BLANC.

mesoclimate, a term of climatic scale, intermediate between regional climate, or MACROCLIMATE, and the very small-scale

MICROCLIMATE. It encompasses the more specific terms TOPOCLIMATE and SITE CLIMATE and has largely replaced both in specialist usage (although the word 'microclimate' is widely and incorrectly used by non-specialists to mean 'mesoclimate'). The usual scale of a mesoclimate is in tens or hundreds of metres, so one speaks correctly of the mesoclimate of a particular vineyard or potential vineyard site.

The full definition of a mesoclimate requires detailed on-the-spot records, but these are seldom available over the long periods (conventionally 30 years or more) needed to iron out short-term climatic fluctuations and, thus, to be fully representative. The process can be considerably shortened if site records can be calibrated continuously against those of a nearby and reasonably comparable older climate-recording station. The differences, once established as consistent over a number of seasons, can be applied to the longer-term records of the latter.

In the absence of any local temperature measurements, it is still possible to make fair estimates by interpolating within known regional trends and then allowing for differences in ELEVATION at the rate of 0.6 °C/1.1 °F per 100 m/330 ft. Following that, individual mesoclimates can be approximated more closely still by allowing for features of TOPOGRAPHY such as slope and ASPECT and even SOIL TYPE. J.G.

Iland, P., et al., 'Climate and the vine', in *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

Mesopotamia. In ancient Mesopotamia, which lay in the fertile land between the rivers Tigris and Euphrates and is often thought of as the cradle of civilization, the most widely consumed alcoholic drink during all periods was probably beer. However, grape wine is already mentioned in cuneiform texts preserved on clay tablets from Ur dating to approximately 2750 BCE. Vines do not grow so well in the low-lying and humid south of Mesopotamia, and wine seems to have been imported from the more mountainous north. This is probably the origin of the poetic Mesopotamian name for wine, 'beer of the mountains'.

By the first millennium BCE, wine was as widely used as beer, at least in privileged circles. Unfortunately, little information is available about the methods of production. Some wines, such as the so-called 'bitter wine' of Tupliash, an area lying to the east of the river Tigris, seem to have been drunk FLAVOURED with herbs.

From the beginning of the first millennium BCE, however, it appears that wines were more commonly identified by their place of origin than by their type. These are mostly regions in the north or north-west of Mesopotamia (in modern northern Iraq and northern Syria) but also including Suhu (a region in modern Iraq on the middle course of the river Euphrates, downstream from the modern Syrian border). In an inscription detailing offerings made to the god Marduk in his temple at Babylon, King Nebuchadnezzar II (r. 604–563 BCE) mentions 'beer of the mountains', 'clear wine', and the wines of eight different named regions.

A few documents (in the form of clay tablets) survive from the early 8th century BCE from the Assyrian capital Kalhu (modern Nimrud). These are the remnants of a once-vast archive detailing the administration of wine rations to the 6,000-strong palace household, from the king and queen down to assistant cooks and shepherd boys. It has been estimated that the *pithoi* in the Fort Shalmaneser magazine could have held as much as 15,000 litres. The storeroom of the North West Palace was on the same scale, and, combined with other cellars that remain to be discovered, the wine supplies must have been adequate to meet the needs of the palace. The king's wives received the largest daily allotments, perhaps as much as a litre a day. By comparison, six skilled workers or ten ordinary workers had to share the same amount. A harem of women from Arpad, a city of the realm, were given a *sappu* of wine each day, but the number of women and size of the jar are unknown.

Wine and beer were frequently offered, among many other foods and drinks, to deities as part of the cult, and the practice of LIBATION was widespread in temple ritual.

Among the Babylonians and Assyrians, wine was widely used, as was beer, for medicinal purposes (see MEDICINE), especially as a

vehicle for various concoctions often of rather dubious, if not frankly revolting, ingredients.

metabisulfite, often added to freshly picked grapes to prevent OXIDATION of the must. See SULFUR DIOXIDE.

metals. See MINERALS and LEAD.

metatartaric acid. See TARTRATES.

métayage, French word for a system of sharecropping particularly common in the CÔTE D'OR whereby a vine-grower, or *métayer*, rents a vineyard or, more likely in Burgundy, part of a vineyard and pays rent in the form of wine or grapes.

methanol, another name for methyl alcohol, also known as wood alcohol, is the member of the chemical series of common ALCOHOLS with the lowest molecular weight. Methanol is highly toxic. The immediate risk of ingesting any quantity of methanol is blindness, but

consumption of 25–100 ml/1–4 fl oz can be fatal. As recently as the mid 1980s, some Italian wines were found to have been contaminated with methanol (see ADULTERATION).

Wines naturally contain very small quantities of methanol: about 0.1 g/l, or less than one-hundredth of the normal concentration of ethanol. Some methanol is naturally present in grapes, and further traces are formed during FERMENTATION, but most is formed by demethylating the pectin materials that are naturally present in the grape (see COLLOID and ENZYMES). Red wines, and particularly those subjected to prolonged MACERATION, are likely to have higher methanol concentrations than average. Brandy in general has rather higher levels of methanol than wine because the DISTILLATION process concentrates it. And wines and brandies made from fruits other than grapes tend to have higher methanol concentrations because grapes have fewer pectins than most other fruits. It would be impossible to ingest a dangerous level of methanol from such drinks, however, without ingesting a fatal amount of ethanol long beforehand.

Methanol is often encountered in everyday life because it is a common solvent for household products as well as being used as fuel for chafing dishes. A.D.W.

méthode ancestrale, sometimes called méthode artisanale or méthode rurale, very traditional and now FASHIONABLE way of making a lightly sparkling wine. For more details, see SPARKLING WINEMAKING.

méthode champenoise, French term for the intricate traditional method described in detail in SPARKLING WINEMAKING. From 1994 the term was outlawed by EU authorities in favour of one of the following: méthode traditionnelle; méthode classique; or méthode traditionnelle classique. English-language equivalents are ‘fermented in this bottle’ and TRADITIONAL METHOD.

méthode classique, EU-approved term for the traditional method of SPARKLING WINEMAKING.

méthode dioise ancestrale, SPARKLING WINEMAKING process used for CLAIRETTE DE DIE.

méthode gaillacoise, GAILLAC's version of the MÉTHODE ANCESTRALE. See SPARKLING WINEMAKING.

méthode traditionnelle, méthode classique, and méthode traditionnelle classique, alternative EU-approved terms for the traditional method of SPARKLING WINEMAKING.

methoxy-dimethylpyrazine, more properly 2-methoxy-3, 5-dimethylpyrazine, or MDMP, is a compound identified by aromas of fresh cork or woody and dusty smells. It exists in cork and becomes a TAINT in wine at concentrations above the perception threshold of approximately 2–4 ng/l in red and white wines.

An AWRI study in 2004 isolated this compound and confirmed that it is responsible for a taint described in Australia as 'fungal must'. It has been suggested that this may prove to be second only to TCA as a cause of CORK TAINT in Australian wine, but further research has been hampered by the difficulty involved in measuring the compound.

Simpson, R. F., et al., 'Isolation and identification of 2-methoxy-3,5-dimethylpyrazine, a potent musty compound from wine corks', *Journal of Agricultural and Food Chemistry*, 52/17 (2004), 5425–30.

methoxypyrazines, FLAVOUR COMPOUNDS which result in HERBACEOUSNESS. They contain nitrogen and are secondary products of AMINO ACID metabolism. Three methoxypyrazines have been identified

for Cabernet Sauvignon and Sauvignon Blanc grapes: ISOBUTYL-METHOXYPYRAZINE (IBMP), secbutyl-methoxypyrazine (SBMP), and isopropyl-methoxypyrazine (IPMP). Sensory evaluation has confirmed the contribution of IBMP, which has a very low threshold of 215 ng/l in white wine, to the aroma described as characteristic of capsicum or bell pepper and green gooseberries. It is generally the most dominant of the three. IPMP, the most abundant of the three, has a more earthy aroma, characteristic of cooked or canned asparagus (found in some New Zealand Sauvignon Blanc).

Related studies have demonstrated that the levels of IBMP and IPMP compounds in grape berries matches what is known commercially about the herbaceous wine character. First, the berry concentrations of IBMP drop markedly during ripening, as does the herbaceous character, and more so with increased sun exposure. Secondly, concentrations of IBMP are higher for grapes grown in cooler climates; Australian samples have been found to have much lower levels of IBMP than French or New Zealand samples, for example. In wine, methoxypyrazines are particularly stable against OXIDATION. Their sensory impact may be influenced through binding with other wine components. D.D. & R.E.S.

Methuen Treaty, accord signed between Britain and Portugal in 1703 which gave Portuguese goods preferential treatment in Britain and encouraged the imports of Portuguese wine, at the expense of wine from the rest of Europe, notably France, at a time when PORT was evolving into the strong, sweet drink we know today.

metodo classico, metodo tradizionale, and metodo classico tradizionale, Italian terms for SPARKLING WINES made by the traditional method.

método tradicional, método clásico, and método tradicional clásico, Spanish and Portuguese terms for SPARKLING WINES made by the traditional method.

Meunier, how PINOT MEUNIER is known in FRANCE.

Meursault , large and prosperous village in the Côte de Beaune district of Burgundy's CÔTE D'OR producing mostly white wines from the Chardonnay grape (see map under BURGUNDY). Although Meursault contains no GRAND CRU vineyards, the quality of white burgundy from the best of its 19 PREMIERS CRUS is rarely surpassed.

The finest vineyards are Les Perrières, Les Genevrières, and Les Charmes. Between them and the village of Meursault are three more premiers crus: Le Poruzot, Les Bouchères, and Les Gouttes d'Or. Another group by the hamlet of BLAGNY are sold as Meursault-Blagny if white or Blagny premier cru if red, while, at the other end of the village, Les Santenots is sold as Meursault Santenots if white and Volnay Santenots if red, as it usually is. Apart from Les Santenots and the lean but fine red wines of Blagny, the other red wines of Meursault tend to be grown low on the slope and do not feature among the best of the Côte de Beaune.

Les Perrières was cited as a 'tête de cuvée' vineyard in the original CLASSIFICATION of 1861 and might well have been classified as a grand cru. The name derives from medieval quarries, and the vineyard retains a quantity of stones, which reflect the sun back on to the vines. If Les Perrières is regularly the richest wine in Meursault, Les Genevrières comes close in quality, producing particularly elegant wines. Les Charmes is the biggest of the three major vineyards and produces the most forward wines, seductive even in their youth.

Meursault also enjoys a wealth of good wines from other named vineyards such as Chevalières, Tessons, Clos de la Barre, Luchets, Narvaux, and Tillets. These are frequently more interesting than the village wines of PULIGNY-MONTRACHET, where the water table is higher. Furthermore, it is possible to dig cellars significantly deeper in Meursault, which enables many growers to prolong BARREL AGEING through a second winter, which improves the depth, stability, and AGEING potential of the wines. Meursault comprises 283 ha/699 acres of village-appellation vines and 109 ha of premier cru vineyards. A tiny fraction of both is red.

Meursault also hosts one of the three glorious feasts of Burgundy during the third weekend in November (see TROIS GLORIEUSES). On the Monday after the HOSPICES DE BEAUNE sale, some 600 local growers and guests gather at noon for the Paulée de Meursault, an end-of-harvest feast revived in the 1920s by Comte Jules Lafon. Everybody brings their own bottles to share with other tables. The occasion slightly belies the local proverb that he who drinks only Meursault will never be a drunkard. Fine Meursault producers include Ballot-Millot, Boisson-Vadot, Bouzereau, Coche-Dury, Ente, Fichet, various Jobards, Comte Lafon Mikulski, Prieur, Roulot, and others in a village rich with individual domaines. J.T.C.M.

Mexico is the oldest wine-producing country in the Americas. The southernmost point of North America, it has undergone a massive wine renaissance in the past 40 years, with wineries in 15 states

taking advantage of the country’s long coastlines and mountainous terroir to produce a wide variety of wines.

History

Mexico has been producing wine since 1521, the year Spanish conqueror Hernán Cortés succeeded in subjugating the Mexica state. Travellers and missionaries soon followed, bringing European vines with the intention of producing SACRAMENTAL wine; in 1524, Cortés decreed that all new settlers must plant 1,000 vines for every 100 natives on the lands granted to them. Plantations were established in the territories now occupied by the states of Puebla, Michoacán, Guanajuato, and Querétaro. The movement accelerated in 1531, when King Carlos V of Spain ordered every ship sailing to the New World to bring grapevines. By 1554, New Spain had become a colony formally dedicated to wine production, and vineyards had spread north to San Luis Potosí, Zacatecas, Coahuila, and Sonora.

The industry experienced a setback in 1595, however, when Spain's King Felipe II banned new plantations and ordered the large-scale uprooting of Mexican vines in an effort to protect the Spanish wine industry. Yet some winemakers persevered: Bodegas San Lorenzo, today Casa Madero, became the country's first winery dedicated entirely to the production and commercialization of wine in 1597.

In the 17th and 18th centuries, missionaries continued to spread viticulture as they moved north, with the Jesuit Juan de Ugarte credited for planting the first vineyard in Baja California in the early 1700s. The Franciscan friar Fray Junípero Serra followed, propagating Misión grapes (see MISSION) along the Pacific coast.

Efforts to develop viticulture flourished during the second half of the 19th century. In 1843, the Escuela Nacional de Agricultura opened, teaching the cultivation and management of vines; in 1870, in the town of San Luis de la Paz, Guanajuato, the San Luis Rey winery was founded; and in 1888 the first winery in Baja California was created, taking its name from the mission of Santo Tomás.

Thanks to PHYLLOXERA, Mexico's vineyards covered but a few hundred hectares at the beginning of the 20th century, but locals worked to quickly reestablish production. In 1928 L.A. Cetto was

founded, today the country's largest winery with 1,200 ha/3,000 acres of vines; in 1948 15 producers created the Asociación Nacional de Vitivinicultores. The industry received a further boost in 1973 with the launch of a national viticulture programme; by 1979 the Ministry of Agriculture reported 56,295 ha of grapevines.

By the late 1980s the demand for brandy and wine grapes had fallen, and by 1996 only seven wineries were left. However, projects focused on premium wines—such as Monte Xanic, founded in 1987—ploughed ahead, setting the scene for the plethora of new wineries that would blossom in the new millennium. By 2022 Mexico boasted 35,825 ha/88,525 acres of vineyards, 8,633 ha of which were dedicated to the production of TABLE WINES and grape MUST. There were also 400 wineries in 15 states, the majority in Baja California, Coahuila, and Querétaro, followed by Aguascalientes, Baja California Sur, Chihuahua, Durango, Guanajuato, Hidalgo, Jalisco, Nuevo León, Puebla, San Luis Potosí, Sonora, and Zacatecas.

Geography and climate

Winegrowing is focused in the north and central parts of the country, where mountainous terrain and cool Pacific influences temper the abundant sun and warmth.

Baja California, a narrow peninsula sandwiched between the Gulf of California and the Pacific Ocean, is responsible for 70% of Mexico's production. This is where L.A. Cetto, Mexico's largest winery, and Monte Xanic, its first premium winery, are based. Most of its 4,500 ha/11,100 acres of vineyards and 260 winemaking projects are concentrated at its northern end, from Tecate at the US border down through the Guadalupe, Ojos Negros, Santo Tomás, and San Vicente valleys.

The climate is marked by hot days, exceeding 40 °C/104 °F in the summer, and cool nights created by Pacific fog and wind. Annual rainfall does not exceed 300 mm/12 in, so VINE DISEASE pressure is low; the SANDY soils, mixed with small proportions of CALCAREOUS and GRAVELLY soils, keep phylloxera at bay.

Although the region is home to about 40 grape varieties, the local industry is based on Chenin Blanc, Chardonnay, Sauvignon Blanc, Cabernet Sauvignon, Merlot, Syrah, Petite Sirah, Tempranillo, Zinfandel, and Nebbiolo. The latter, also called Nebbiolo de Baja, differs from Piedmontese Nebbiolo in colour, structure, and tannins; in 2018 the University of California at DAVIS Plant Identification Lab associated three samples of Nebbiolo from Valle de Guadalupe with the Italian grape Lambrusca di Alessandria (see LAMBRUSCO). However, there are also many wines produced with certified Nebbiolo clones.

Coahuila is Mexico's second most extensive wine region, with about 900 ha/2,200 acres planted to vines. Far east of Baja California, along the border with Texas, it has a CONTINENTAL CLIMATE, with a DIURNAL TEMPERATURE RANGE of up to 25 °C/77 °F, and poor soils high in calcium carbonate and other MINERALS. The vine thrives in the subregions of Cuatro Ciénegas, San Buenaventura, General Cepeda, Ramos Arizpe, Saltillo, Sierra de Arteaga, Valle de Parras, and

Torreón, the plantings concentrated at elevations of 700–2,300 m/2,297–7,546 ft. The dominant grapes are Chardonnay, Chenin Blanc, Cabernet Sauvignon, Malbec, Pinot Noir, and Syrah. Many of Mexico's most well-known wineries are based here, including Casa Madero, America's oldest commercial winery.

Querétaro, Mexico's southernmost wine region, is part of the Mesa del Centro, a large plain at 1,700–2,300 m/5,570–7,546 ft above sea level. The vines are concentrated in San Juan del Río, Tequisquiapan, Ezequiel Montes, Colón, and El Marqués, where hot days, radically cool nights, and abundant summer rains define the climate. Chardonnay, Sauvignon Blanc, MACABEO, and XARELLO grown on the calcareous and clay-loam soils lend themselves well to vibrant whites and traditional-method SPARKLING WINES, styles pioneered by Finca Sala Vivé de Freixenet (HENKELL FREIXENET). Producers also find good results in rosés and reds from MARSELAN, Merlot, Malbec, and Syrah.

In the last decade, the remaining states in the Mesa del Centro have experienced a flourishing of small wineries. The TEMPERATE climate, high elevation, and sandy CLAY and calcareous soils are particularly favourable for white wines from Sauvignon Blanc, Viognier, Macabeo, Riesling, and Grenache Blanc and for reds such as Grenache, Caladoc, Cabernet Franc, Malbec, and Syrah.

Chihuahua, Mexico's largest state, is where the future lies. Bordering the US, it boasts a diverse array of climates, allowing for quality wines to be made from a wide range of grapes, from Gewürztraminer and Malvasia Bianca to Cabernet Sauvignon, Malbec, and Syrah. Investors such as L.A. Cetto, based in Baja California, are betting on Chihuahua for new vineyards, while wineries such as Encinillas, Pinesque, Tres Ríos, Casa Establo, and Santa Clara are already demonstrating the region's potential. C.B.S.

MGA, *menzione geografica aggiuntiva*, meaning 'additional geographical mention', a term used in BAROLO and BARBARESCO to refer to a registered vineyard that may be mentioned on the label, for example Bussia (Barolo Bussia) or Asili (Barbaresco Asili). MGAs are

also used in ALTO ADIGE and ROERO. Similar to the French term DÉNOMINATION GÉOGRAPHIQUE COMPLÉMENTAIRE but generally covering a smaller area. See also UGA.

Michigan , Midwestern state in the United States whose boundaries are defined by four of the Great Lakes, the largest freshwater lakes in the world. Ninth in the US for wine production in 2020, it has a well-established wine industry that has jumped from 90 wineries in 2012 to over 150 in 2021, with more on the way as cherry and peach orchards are regularly converted to vineyards.

Geography and climate

Michigan has two parts: the Upper Peninsula, on the north end of Lake Michigan, bordering Wisconsin; and the Lower Peninsula, a large, mitt-shaped land mass surrounded by Lake Michigan to the west, Lake Huron to the east, and INDIANA and OHIO to the south. While wine grapes are grown statewide, the Lower Peninsula holds all of Michigan's five AVAs. The oldest is Fennville, the nation's third AVA when it was established in 1981. It nests into Lake Michigan Shore in the state's south-west corner. Classified as Region II on the Winkler Index (see CLIMATE CLASSIFICATION), the region benefits from westerly winds off the lake that moderate the temperature year-round. Harvest here often begins one to three weeks earlier than in the northern AVAs.

About 322 km/200 miles north of Fennville, Leelanau Peninsula and Old Mission Peninsula jut into Grand Traverse Bay, the surrounding waters tempering the Region I climate. Soils are sandy LOAM and GRAVEL, a contrast to the CLAY found further south. Directly east, the emerging Tip of the Mitt AVA covers the entire top of the state's Lower Peninsula.

Vine varieties

Of Michigan's 3,375 wine-grape acres in 2020, 2,325 are planted to VITIS VINIFERA. Riesling leads the way in hectarage, producing impressive dry examples in both the north and the south. Pinot Blanc is also well established; PINOT GRIS, AUXERROIS, GEWÜRZTRAMINER, ALBARIÑO, and SAUVIGNON BLANC are on the rise.

In red wines, Pinot Noir, long hoped to be the standard for red wine in northern Michigan, offers a lighter style at its best or, in colder vintages, contributes to excellent dry sparkling wine and rosé. Bordeaux varieties and Syrah ripen more dependably in the south-west, though fine examples of Merlot and Cabernet Franc continue to be produced up north. Increased attention to matching site to grape varieties has winegrowers looking also to GAMAY, GRÜNER VELTLINER, and BLAUFRÄNKISCH. Also notable are the many experimental plantings of varieties such as REFOSCO, TEROLDEGO, LAGREIN, FRIULANO, and TEMPRANILLO, efforts guided in part by Michigan State University's Department of Horticulture.

Viticulture

Research has shown that Michigan's growing season has grown warmer and longer by almost a month in the last 60 years. At the same time, CLIMATE CHANGE bring challenges, such as extreme and persistent WINTER FREEZE that can damage or destroy vines. Rainfall has also increased at the end of the season, although Michigan's dependable Indian summers continue to be a plus. HYBRID grapes are often grown to hedge against humid conditions in the south-west and against cold spells in the north. SUSTAINABLE and innovative farming practices have become a priority for many winegrowers, such as Karma Vista on the Lake Michigan Shore and Mari Vineyards on Old Mission Peninsula. Despite the climatic challenges, the state's industry continues to grow in size as well as reach, with increasing out-of-state distribution. M.T.

microbes, or microorganisms, extremely small living beings, a few of which are capable of causing VINE DISEASES and FERMENTATION. Those affecting wines and vines are usually referred to as YEASTS and BACTERIA. Microbiology is the study of such microorganisms, which need micronutrients as well as nutrients for growth. See also MICROBIAL TERROIR and SOIL BIOTA.

microbial terroir. While there is now greater understanding of the roles played by SOIL, GEOLOGY, CLIMATE, and VITICULTURE in TERROIR and its expression in wine, the study of vineyard microbiology in the soil and on the berries and its influence on wine QUALITY and FLAVOUR is just beginning.

Recent research suggests that fungi and bacteria found on grape skins, including the YEASTS that play a part in SPONTANEOUS FERMENTATION, may also contribute to terroir. In many grape-growing regions, research has shown that region and site—notably MESOCLIMATE and soil—as well as grape variety, ROOTSTOCK, and vineyard management play a role in determining the fungal and bacterial populations found in grapes and MUST. Research by Gayevskiy and Goddard and by Taylor et al. in New Zealand revealed regional differences both in fungal communities on ripe Chardonnay and in indigenous *Saccharomyces cerevisiae* populations found in spontaneous ferments. Subsequent and related research has suggested a link between these regionally distinct yeasts and wine composition. Other recent research by Hall and Wilcox detected non-*Saccharomyces* yeast species and other microbes within healthy, undamaged fruit, raising the possibility that endophytic microbiomes that vary among varieties and locations might also affect wine composition.

ORGANIC MATTER may also play an important intermediary role between vineyard GEOLOGY and what we smell and taste in a wine. Given the at-best indirect relationship between geology and wine flavour, notwithstanding the common use of tasting terms such as MINERAL or 'stony', bacteria and fungi in vineyard soils may bridge the gap between odourless, flavourless ROCKS and the organoleptic distinctiveness of wines from specific origins. For example, as Maltman explains, the smell of wet or warm earth and stones known as petrichor and the earthy odour called GEOSMIN are derived not from the stones themselves but from the release by wetting or warming of volatile organic compounds that form a film on soil and rock surfaces. microbullage. See MICRO-OXYGENATION.

microclimate, the climate within a defined and usually very restricted space or position. In viticulture, the term typically refers to a small and specific part of the CANOPY.

Common use of the term 'microclimate' to describe the climate of a vineyard site, hillside, or valley is clearly wrong. The correct term for these is usually MESOCLIMATE or possibly 'site climate' or TOPOCLIMATE. Microclimate distances are normally measured in millimetres to a maximum of a few metres; those of mesoclimate from a few to tens or hundreds of metres.

CANOPY MICROCLIMATE is that within and immediately surrounding the vine canopy. There are microclimates on or close to the surfaces of individual leaves, grape bunches, or even berries. Microclimates also exist at various positions or depths within the soil. All these distinctions are important in understanding vine responses to environment.

Microclimate is potentially influenced by management practices such as vine TRELLISING, vine TRAINING systems, and TRIMMING; vine VIGOUR and the factors affecting it; and SOIL MANAGEMENT and mulching. In this respect it differs in important ways from climatic definitions of greater dimension, such as MACROCLIMATE and mesoclimate, which are wholly or largely uninfluenced by vineyard management. J.G. & R.E.S.

micro-oxygenation, a term that refers generally to the exposure of wine to very small amounts of OXYGEN (the opposite of MACRO-OXYGENATION) but also to a specific vinification technique known in French as *microbullage* that was initiated in 1990 by winemaker Patrick Ducournau in MADIRAN to control the AERATION of wines in tank. The method was authorized by the European Commission in 1996 and is used mainly but not exclusively on red wines. Its guiding principle is that all wines require OXYGEN to a greater or lesser extent, its aim being to enable the winemaker to deliver precise and controlled levels at various stages in the WINEMAKING process. It also addresses the issue of wine storage, effectively transforming large inert storage vessels into selectively permeable containers of infinitely variable dimensions.

Micro-oxygenation can be used during the early stages of alcoholic FERMENTATION to build a healthy YEAST population and help avoid a STUCK FERMENTATION. It also helps to maintain yeast viability, thus minimizing the production of SULFIDES, which may later cause REDUCTION problems. Injections of oxygen during ÉLEVAGE can also help counter the problem of reduction. But, proponents believe, its chief attribute is that it mirrors the effects of oxygen on wines treated to BARREL AGEING: wines in barrel are exposed to oxygen passively and continually, whereas wines stored in tank are exposed to significant amounts of oxygen only during RACKING, with less control. Used in conjunction with OAK CHIPS or INNER STAVES, the technique can provide an efficient, cost-effective alternative to oak barrels. Micro-oxygenation seems to favour POLYMERIZATION of tannins and the retention of PIGMENTED TANNINS resulting respectively in a softer taste and more stable colour. Some Bordeaux producers use micro-oxygenation on new wine during maceration before PRESSING as a way to begin this process while the MUST has all its constituents available. In such instances, a higher dose of oxygen is used. Proponents claim that it is also an effective remedy for GREEN or vegetal characters that are the result of slightly underripe fruit, but research suggests this is due to an uplift in fruity characters that mask the green notes. Too much oxygen, on the other hand, may spoil the fruit aromas. It has been suggested that the introduction of oxygen in this way appears to accelerate the ageing process, but this is contested by those who make the equipment and promote its use. In fact, the effect of micro-oxygenation depends very much on the amount of oxygen, the rate of application, and the period over which it is added.

The micro-oxygenation apparatus consists of a system of two chambers and valves connected to a cylinder of oxygen. The gas is moved into a first chamber that is calibrated to the volume of wine. It then moves into a second chamber and is delivered into the wine, a timer controlling the injection of a predetermined dose. Different devices are used to deliver the oxygen, including a ceramic or stainless-steel diffuser that periodically injects oxygen into the wine

as a stream of bubbles or special plastic tubing that allows oxygen to diffuse through the tube wall into the wine in a continuous process. A typical dosage rate is 0.75–3 cc of oxygen per litre of wine per month, and the treatment might take four to eight months. In the absence of good methods to monitor the real-time impact of oxygen addition, the application rate and timing are determined by taste and experience. There are no firm guidelines for how much micro-oxygenation a wine can take, but most winemakers will replicate the oxygen ingress of a barrel (approximately 1–2.5 mg/l/month), adjusted according to grape variety.

The technique was first developed as a response to the fierce TANNINS of Madiran's TANNAT grape and seems particularly well suited to tannic grape varieties. It has also been used on wines high in tannins but relatively low in ANTHOCYANINS—some SANGIOVESE, for example, or PRESS WINES.

Micro-oxygenation does not necessarily preclude barrel ageing. A variation on this technique is used in barrel as a gentler alternative to racking, and one which binds less SULFUR DIOXIDE, for example. This method of adding a measured amount of oxygen into the wine in barrel has been dubbed *cliquage*. The wine is otherwise aged conventionally in barrels, which allow continuous micro-oxygenation due to the structure of the wood and produce big, rich red wines that remain relatively supple. But without racking, the risk of contamination—with BRETTANOMYCES, for example—is much greater. More recently, micro-oxygenation has been used in conjunction with barrel ageing in an effort to shorten the time in barrel. Oxygen rates are typically low (1–2 mg/l/month) and applied for several months depending on perceived wine evolution.

Micro-oxygenation is widely used throughout France, particularly in BORDEAUX, as well as in many other countries. Perhaps its largest take-up, however, was in Chile, where it is particularly appreciated for its ability to moderate the greenness of tannins sometimes found in some Chilean red wines. Results so far suggest the technique is particularly suitable for fashioning wines for short- to medium-term consumption from tannic or potentially reductive grape varieties.

Midi, common name for the south of France. Like 'Mezzogiorno' in Italy, it means literally 'midday' and refers to regions where midday is a time of extreme heat and inactivity, at least in summer. The name is often used synonymously with LANGUEDOC and ROUSSILLON, although strictly speaking the Midi encompasses PROVENCE as well.

mildew. See DOWNY MILDEW and POWDERY MILDEW.

Milgranet, rare, recuperated vine speciality of French vineyards north and west of Toulouse producing particularly firm red wine. Probably a GOUAIS BLANC x Négret du Tarn CROSS.

Millau, Côtes de, AOC of just 55 ha/136 acres of vines in the Gorges du Tarn in the far east of Aveyron, SOUTH WEST FRANCE, making reds and some rosés mainly from Gamay and Syrah, and the odd white based on Chenin, sometimes with Mauzac. Pre-PHYLLOXERA, the region's vineyards covered more than 15,000 ha/37,066 acres, an area larger than the whole of present-day BERGERAC. Attempts at revival were thwarted by the First World War. Today there are but half a dozen or so independent growers. The Aguessac CO-OPERATIVE dominates production. The wines are popular within the region but rarely seen outside. P.S.

millerandage, a form of poor FRUIT SET, is a condition of the grape bunch in which there is an excessively high proportion of seedless berries and 'live green ovaries' (LGOs) relative to seeded berries. Poor fruit set in the vine is a consequence of either COULURE or millerandage. Seedless berries are sometimes known as chicken berries (normal seeded berries are the hens). Whereas seedless berries will mature normally, LGOs do not and remain firm and green. They have been known as shot berries in the past, but this nomenclature is inappropriate because they do not fit the definition of a berry. The condition is due either to inclement weather at FLOWERING, which affects some varieties (MERLOT, for example) more than others, or alternatively to BORON deficiency, or FANLEAF DEGENERATION.

Millerandage can cause a major loss of YIELD. Some winemakers believe that millerandage is good for wine quality because of the widely held view that small BERRY SIZE makes better-quality wine. This is based in part on experience with certain CLONES, for example the so-called Mendoza clone of Chardonnay in Australia and New Zealand that typically displays a high proportion of seedless berries. A Millerandage Index (MI) was defined for the first time in 2009—the higher the numerical value, the greater the expression of the condition. P.R.D.

Iland, P., et al., 'Flowering and fruit set', in *The Grapevine: From the Science to the Practice of Growing Vines for Wine* (2011).

millésime is French for VINTAGE. A vintage-dated wine is therefore said to be millésimé.

minerality, imprecise tasting term and elusive wine characteristic that, along with the descriptor mineral, became common currency in the early years of this century. Although descriptors such as 'flinty/gunflint' (*pierre à fusil*), 'stony', and 'chalky' have been in circulation for many years, particularly with reference to white wines

such as those from SANCERRE and CHABLIS, the term 'minerality' was adopted much more recently by winemakers, marketers, and WINE WRITERS. If there is little agreement as to its exact meaning, there is even less as to its causes, but it is particularly useful for describing not only an aroma and flavour but sometimes also a TEXTURE that is undeniably present in some wines from a wide range of regions and varieties, especially, but not exclusively, in COOL-CLIMATE whites. It is easier to say what it is not—fruity, vegetal, or animal—than what it is. Other descriptors that are often associated with minerality include 'wet stones', 'smoky', 'oyster shell', 'struck match', 'salty', and 'iodine'. As Parr et al. (2013) point out, the term has also become, for many, an indicator of quality.

Although many TASTING TERMS are metaphorical (there are no blackcurrants in wine made from Cabernet Sauvignon and no brioche in a well-aged champagne), there is a strong temptation to interpret 'mineral' rather more literally, suggesting or presuming that aromas and flavours thus described are derived from the vineyard site and that they are therefore a demonstration of the concept of TERROIR.

However, geologists and soil scientists are clear that there can be no direct connection between the flavour of a wine and the GEOLOGICAL minerals in the rocks that underlie a vineyard or the MINERAL elements in the soil that are nutrients for the vine. In any case, the minerals found in wine are below the threshold of sensory perception. This has not deterred researchers such as Ballester, Parr, and Heymann from trying to elucidate the meaning, reference, and underlying causes of what Ballester describes as 'an ill-defined sensory concept', although there has so far been little progress in identifying compounds in wine that are associated with the perception of minerality.

It has been suggested by both sensory and chemical analysis that the wine components giving rise to the term 'minerality' include high ACIDITY and low PH (possibly due to an alkaline soil such as LIMESTONE or chalk) as well as VOLATILE SULFUR COMPOUNDS. As Heymann et al. point out, the exception to this lack of precision is the identification

by Tominaga et al. of the aroma compound benzenemethanethiol (benzyl mercaptan), which is said to give Sauvignon Blanc wines, in particular, a flinty or smoky aroma (see SULFIDES).

Given these suggested connections, it is not possible to determine whether minerality is a TERROIR or a WINEMAKING effect. In any one wine it could easily be either or both. Whereas once New Zealand Sauvignon Blanc wines were typically described and appreciated as FRUIT-DRIVEN and Loire Sauvignons as flinty, the former, almost exclusively sealed under SCREWCAP, are now sometimes considered more sophisticated and complex than they were due to the perception that they are more 'mineral'.

While research has found some common ground among tasters who use this term, there may never be an agreed, precise definition, and further research into the chemical composition of wines perceived as mineral is in progress. Perhaps once we are able to describe and explain the mechanisms that translate vineyard site and viticultural practices into wine characteristics (see, for example, SOIL BIOTA, SOIL AND WINE QUALITY, YEAST), we will also be able to use the word 'minerality' with greater precision.

See also LANGUAGE OF WINE and TASTING-NOTES LANGUAGE.

minerals in the geological sense are the typically complex, rigid, crystalline compounds (see GEOLOGY) that make rocks and soils, but in the nutrient sense (see VINE NUTRITION) they are the dissolved single elements that the vine requires in order to grow. Wine writings often blur and confuse the two meanings. The term is also used metaphorically in wine tasting (see MINERALITY).

The vine's essential nutrients are often called mineral nutrients or simply minerals because they are fundamentally derived from geological minerals, for example by weathering and CATION EXCHANGE. In practice, though, a vine gets most of its annual nutrients from ORGANIC MATTER, and this is certainly true of NITROGEN, PHOSPHORUS, and SULFUR, which are sparse or absent in rocks. About a dozen other mineral nutrients are essential to vine metabolism.

Vine roots have mechanisms aimed at selecting and balancing their optimal nutrient uptake, but in practice they can be compromised, for example by a low soil PH or interference by some predominant element. Also, there is usually some passive uptake, which can include traces of inert elements not involved in vine metabolism but which might give the grape juice, and possibly the wine, some fingerprint or chemical characteristic of the soil from which it came. Otherwise, in view of differing viticulture and winemaking practices, not to mention possible CONTAMINANTS in the

vineyard and winery, the mineral content of a finished wine has no obvious relationship with its vineyard geology. (See also SOIL AND WINE QUALITY.)

Unsurprisingly, analyses of the mineral content of wine are highly varied, though concentrations are always small. POTASSIUM is the exception, with reported values generally between 500 and 1,500 mg/l. The other essential nutrient minerals include CALCIUM and MAGNESIUM, expressed usually in tens of mg/l, and IRON, ZINC, MANGANESE, and COPPER, typically in mg/l or less. A.J.M.

mineral vine nutrition. See VINE NUTRITION.

Minervois, improving western LANGUEDOC appellation for characterful reds, generally suppler than those from CORBIÈRES to the south, together with some rosé and a little white, whose total vineyard area had fallen to 3,245 ha/8,015 acres produced on varied inland terrain in the Aude and eastern Hérault *départements* (see map under LANGUEDOC). The appellation takes its name from the village of Minerve, scene of one of the bloodiest sieges of the Cathar sect in the 13th century. There is considerable archaeological evidence that the Romans practised viticulture here. Cicero records the dispatch of wine to Rome from the *pagus minerbensis*; La Livinière, the first Minervois village to be accorded its own appellation, Minervois-La Livinière, is said to take its name from *cella vinaria*, Latin for 'wine cellar'. More recently, the vineyards of Minervois were invaded first by PHYLLOXERA and then by the CARIGNAN vine.

Since 1985, when Minervois was granted AOC status, strenuous efforts have been made to upgrade overall quality, and a number of both CO-OPERATIVES and individual wine producers have made considerable investments both in winery equipment and in planting better vine varieties. Mourvèdre and Syrah must account for at least 20% of the blend, and these two plus Grenache and LLEDONER PELUT

must make up a minimum of 60%. Various combinations of Bourboulenc, Rolle (Vermentino), Macabeo, Roussanne, Marsanne, and Grenache Blanc are responsible for the varied quality and character of white Minervois, the first two being best suited to the south-eastern part of the appellation closest to the Mediterranean, while the last two perform best in western, Atlantic-influenced sites. White Minervois is increasingly aromatic and sophisticated.

The appellation can be divided into five climatic zones: Les Côtes Noires in the far north-west on the coolest, most Atlantic-influenced foothills of the Montagne Noire; La Clamoux on ALLUVIAL terraces and flatter land in the south-west towards Carcassonne; La Zone Centrale in the middle of the appellation at an ELEVATION of around 400 m/1,312 ft; La Causse on high land and poor, dry soils in the north-east where yields are lowest; and Les Serres in the warmest, most MEDITERRANEAN south-east.

In the extreme north-east of the region, some of France's rarest and most delicate VIN DOUX NATUREL is produced: MUSCAT DE ST-JEAN-DE-MINERVOIS.

Minho, VINHO REGIONAL in north-west Portugal named after the Minho province, itself named after the river (called Miño in Spain, with which it forms the boundary—see map under PORTUGAL).

Its boundaries are identical to those of VINHO VERDE, but producers may use different grape varieties and make wines with higher alcohol levels than the 11.5% maximum of Vinho Verde. Some producers prefer Minho to Vinho Verde because of the latter's historic reputation for low-quality wines, but this is slowly changing with the rising overall quality of Vinho Verde. S.A.

minimal pruning, a viticultural technique developed by CSIRO in Australia whereby vines are essentially left without any form of PRUNING from one year to the next. The technique has particular application to higher-yielding, low-cost vineyards in warmer areas but

was also used in some cooler regions producing high-quality wines, especially where there was a shortage of LABOUR.

The technique was developed and popularized in the late 1970s and 1980s, but its scientific interest can be traced back to a difference of opinion between two eminent viticultural scientists in the late 1960s. When Professor Nelson SHAULIS of CORNELL UNIVERSITY in New York State was visiting CSIRO at Merbein in Victoria, Australia, he debated with Dr Peter May and Allan Antcliff whether an unpruned vine might die. To settle the question a SULTANA (Thompson Seedless) vine was left unpruned; to general surprise, it produced a large crop that ripened satisfactorily. At this time there was interest in MECHANICAL PRUNING, and in many ways minimal pruning is a natural extension of that method. The technique has now been extensively evaluated for vine varieties for both wine production and RAISINS and in both hot and cooler climates.

One might imagine that an unpruned plant would exhaust itself and die if its growth and cropping were not controlled by pruning. Interestingly, the opposite is true. The production of Sultana vines, which have now not been pruned for almost 40 years, has continued to be satisfactory. Although vines are not killed by pruning, it has been shown to have a weakening effect on them. Furthermore, minimal or zero winter pruning is what vines experience in their natural state, and primitive vines survived in the wild for millions of years before they were first cultivated by man and were pruned. A feature of unpruned, or minimally pruned, vines is that there are many short shoots, whereas a pruned vine has fewer shoots which in turn grow more vigorously. A minimally pruned vine typically produces more fruit than one conventionally pruned, especially in the first year or so of minimal pruning. Significantly, a minimally pruned vine establishes a large leaf area earlier in the growing season, which is advantageous for PHOTOSYNTHESIS.

Ripening of this increased crop can be delayed, and if RIPENING is inadequate, due to cool weather for example, then wine quality can be reduced. In hot regions a harvest delay of a week or so is of little consequence, but in cooler climates the delay may be disastrous.

Research by Rousseau et al. over a seven-year period in the Languedoc found that minimally pruned vines had higher yields and ripened seven to 25 days later or, for later-ripening varieties such as Mourvèdre, not at all.

Minimally pruned vines look extremely wild and untidy compared with vines pruned by hand. After several years, old wood builds up in the centre of the canopy that is an unpruned vine, and this can exacerbate the threat of pests such as MEALYBUG. During the growing season, however, the vine's appearance may not be too different from that of normally pruned vines. Where minimal pruning is practised in hotter, dry climates, shoots stop growing quite early in the summer, and so the CANOPY can be relatively open with good fruit exposure, a requirement of a good CANOPY MICROCLIMATE. Where the climate is cooler and more humid and the vines are growing in fertile, moist soil, however, shoots may continue to grow, and the bunches of grapes may effectively be buried under several layers of leaves. This shaded canopy may then result in reduced colour and flavour in the grapes and eventual wine. R.E.S.

minimum-intervention wine. See NATURAL WINE.

Minnesota , an Upper Plains state in the United States which has benefited from the creation of cool-climate HYBRIDS, many bred at the University of Minnesota. These grapes, such as LaCrescent, Itasca, Frontenac, Marquette, Edelweiss, and many others, are growing in importance both in the northern United States and CANADA. Almost 50 wineries operate in Minnesota. D.F.

Minutolo, very aromatic Puglian white wine grape once known as Fiano Aromatico but unrelated to both FIANO and any Muscat, even though it can taste quite like MUSCAT OF ALEXANDRIA. It was rescued from extinction in the early 21st century.

Miousat, light-berried vine rarity of GASCONY which has been rescued from oblivion there but is still grown in very limited quantities. According to DNA PROFILING, it is HUMAGNE BLANCHE.

Mireval is the large village that gives its name to Muscat de Mireval, the sweet, golden VIN DOUX NATUREL appellation that adjoins and is somewhat overshadowed by FRONTIGNAN to the west of it. Production, from about 260 ha/640 acres of MUSCAT BLANC À PETITS GRAINS, has been almost exclusively in the hands of the CO-OPERATIVE, called La Cave de Rabelais in honour of the only well-known writer to have mentioned it. The wine is virtually indistinguishable from Frontignan, and to those who live outside Mireval there seems little justification for Muscat de Mireval's independent existence, although soils here may be a little more CALCAREOUS than those of Frontignan.

mis en bouteille is French for 'bottled', while *la mise en bouteille*, or *la mise*, is French for 'bottling'. A wine that is mis en bouteille au château is CHÂTEAU BOTTLED, while mis en bouteille au domaine is DOMAINE BOTTLED. Producers may use these terms even if they use a mobile bottling line.

Misket, name for several different perfumed white wine grapes in BULGARIA, including the old, pink-skinned Misket Cherven, by far the most important of the Miskets, which makes soft, grapey, dry wines in the south of the country. Misket Varnenski is a Dimiat × Riesling CROSS developed for the eastern Varna province, while Misket Vrachanski is a more aromatic but even rarer cross.

Mission, California name for the Misin grape of Mexico, PAÍS of Chile, and CRIOLLA CHICA of Argentina, both synonyms for Spain's Listán Prieto, which can still be found on the Canary Islands. Historically very important as a survivor from the earliest VITIS VINIFERA vine varieties to be cultivated in the Americas, this was the original black grape variety planted for sacramental purposes by Franciscan MISSIONARIES in MEXICO, the south-west of the United States, and CALIFORNIA in the 17th and 18th centuries. Mission was an important variety in California until the spread of PHYLLOXERA in the 1880s, and 154 ha/381 acres persist, mainly in the south of the Central Valley. A vineyard planted in 1854 survives in the SHENANDOAH VALLEY, and renewed enthusiasm for the variety has led to new plantings in Sonoma, Napa, and Santa Barbara counties.

Pinney, T., *A History of Wine in America* (1989).

missionaries have doubtless played a role in the establishment of viticulture all over the world and, particularly, in documenting these achievements. Missions and missionaries have had a particularly profound effect, however, on the history of wine production in much of Latin America, in California, in New Zealand, and, to a certain extent, in Japan.

Soon after European colonization of South and Central America, missionaries, particularly Jesuit missionaries, established missions alongside more commercial ventures. Whatever the commercial interest in establishing viticulture, the missionaries grew vines to provide some wine for the EUCHARIST (although see SOUTH AMERICA, history). Both Argentina and Chile date their wine industries from the first successful attempts to cultivate the vine at missions in the foothills on either side of the Andes in the late 16th century; by the 17th century, Peru's viticulture, which probably predated that of both Chile and Argentina, was concentrated around Jesuit missions in coastal valleys. Mexico, however, is the Americas' oldest wine-producing country, and grape seeds were planted almost as soon as

Cortés had landed there. Jesuit missionaries are believed to have been the first to cultivate vines for the specific purpose of winemaking in Baja California (northern Mexico) in the 1670s. It was not until the late 18th century that they established their series of missions up the west coast of what is now the American state of CALIFORNIA and brought with them the so-called MISSION grape from Mexico.

Two centuries earlier, in 1545, Portuguese Jesuit missionaries had introduced wine to the feudal lords of southern JAPAN, who developed a taste for wine and continued to import it. Much more recently, it was Jesuit missionaries who sowed the seeds of the modern wine industry in CHINA.

At much the same time or even earlier, in the early 19th century, French Marist missionaries played a significant role in New Zealand's wine history by introducing vine CUTTINGS from Europe, brought expressly to provide sacramental wine. The first Catholic bishop of the South Pacific, from Lyon, arrived with cuttings in 1838, and by 1842 they were reported to be performing well. Mission Estate in Hawke's Bay is still in production, but the Marist seminary has moved to Auckland.

Seward, D., *Monks and Wine* (1979).

Mission Haut-Brion, Château La, important GRAVES wine estate now under the same ownership as its long-standing rival Ch HAUT-BRION.

Four wines are now produced here: Ch La Mission Haut-Brion red and white (the latter known as Ch Laville Haut-Brion until 2009), the red SECOND WINE La Chapelle de La Mission Haut-Brion, and a second white produced in common with Ch HAUT-BRION over the road, under the same ownership.

La Mission's winemaking history is as old as its neighbour's. In 1540 Arnaud de Lestonnac, brother-in-law of Jean de Pontac (founding father of Ch Haut-Brion) acquired the first plot of what would become La Mission Haut-Brion. His granddaughter Olive de Lestonnac—also owner of Ch MARGAUX, and the richest woman in Bordeaux at the time—played an important role in the history of the vineyard. She devoted her life and fortune to various philanthropic and religious acts, and the legacy of La Mission Haut-Brion was transferred to the Pères Lazaristes in 1682. Throughout the 18th century, they worked to restore the property to its rightful worth. The property became well known in part thanks to the patronage of the Maréchal de Richelieu. The property was revitalized by the Woltner family, who acquired it in 1919 and in many subsequent vintages managed to make even more concentrated, long-lived wines than their FIRST GROWTH neighbour, typically fermented at much lower temperatures than Ch Haut-Brion. In 1983, however, La Mission was sold to the Dillons, so that both these famous estates, the flagships of the newer PESSAC-LÉOGNAN appellation (although much of La Mission is in fact in the Bordeaux suburb of Talence rather than Pessac), are run by the same team, while still retaining their quite distinct premises and characters. La Mission's red-wine vines are planted on 25.4 ha/62.8 acres of vineyard. White wine grapes are planted on 3.7 ha/9.1 acres, planted with slightly more Sémillon grapes than Sauvignon to produce approximately 600 cases.

Missouri, Midwestern state in the United States which has played an important part in the country's wine history. In the 1860s, Missouri made more wine than CALIFORNIA and NEW YORK combined. Wine production blossomed under a heavy influx of Germans in the Missouri river valley, west of St Louis, and today this area is billed to its many wine TOURISTS as 'the Rhineland of Missouri'.

When the AVA system was initiated in the 1980s, a Missouri area application was rapidly created, and America's first AVA was therefore Augusta, the site of many of Missouri's best vineyards today. Nearby, Hermann AVA, granted a few years later, also reflects the region's

historical importance as much as it does any specific climatic or terroir qualities.

Missouri remains one of America's top 20 wine-producing states and enjoys robust support from the state government, with agricultural stations, experimental wineries, and researchers, marketers, and consultants. While in the past fruit and sweet wines dominated their output, many of Missouri's 129 wineries now produce dry and semi-sweet wines from HYBRIDS and AMERICAN VINE SPECIES. Due to the climatic challenges of the CONTINENTAL extremes, VITIS VINIFERA-based wines remain unusual. The most successful VARIETAL Chambourcin, Norton, Seyval Blanc, Traminette, Valvin Muscat, Vidal Blanc, and Vignoles have set a standard for these varieties in other states. D.F.

mistela is the Spanish term, mistelle the French, and mistella (or *sifone*) the Italian for a mixture of grape juice and alcohol. The FERMENTATION process is arrested by the addition of alcohol, leaving a sweet, stable, alcoholic liquid arguably less complex than an equivalent wine that owes its alcohol content to fermentation. It was the commercially vigorous and adaptable Dutch who developed this sort of drink, so much more stable over long journeys than wine (see DUTCH WINE TRADE). In Spain, such usefully stable sweetening agents are used in blending wines such as SHERRY and MÁLAGA but are also sometimes sold, like France's PINEAU DES CHARENTES, for drinking as an APERITIF. See also VIN DE LIQUEUR, VIN DOUX NATUREL, and Australia's TOPAQUE AND MUSCATS, some of which may comprise or include *mistelle*.

mites, minute insects which feed on leaf surface cells and which can be a significant grapevine pest worldwide. Those that feed on the leaves include grape (or grapeleaf) rust mite (*Calepitrimerus vitis*); Pacific spider mite (*Tetranychus pacificus*), which is the most destructive; two-spotted spider mite, which is only occasionally found

on grapes; and Willamette mite (*Eotetranychus willamettei*). Mite feeding slows PHOTOSYNTHESIS and can reduce grape RIPENING.

In Europe, red mite (*Panonychus ulmi*) and two types of yellow mite (*Eotetranychus carpini* and *Tetranychus urticae*) cause the most damage. They feed on green parts of the vine and can affect FRUIT SET and CANE RIPENING, as well as reducing leaf health.

Predatory mites often keep these mites sufficiently under control, so it is important not to destroy them with other sprays. SULFUR sprays applied for erinose or POWDERY MILDEW are effective on some types of mite. White oil applied before BUDBREAK or miticides during summer can control mites. See also ERINOSE MITE. M.J.E.

Mittelburgenland, wine region whose 2,035 ha/5,029 acres of vines in 2022 make up 4.5% of AUSTRIA's total. It runs from just south of the city of Sopron to just north of Koszeg, both in HUNGARY but long pre-eminent urban centres of this German- and Croatian-speaking area that, until the creation of Austrian BURGENLAND in 1921, was known as German West Hungary. Mittelburgenland began styling itself Blaufränkischland even before the potential for this ageworthy red wine grape here and elsewhere in Burgenland emerged in the late 1980s and 1990s; now BLAUFRÄNKISCH represents 52% of Mittelburgenland vines. The varied geological underpinnings of Mittelburgenland's hillsides and plateaus—featuring SCHIST and occasional BASALT, plus LOESS, CLAY, and LIMESTONE—play a role in the diversity and complexity of its Blaufränkisch wines. Especially important wine communes include—in a band along the region's northern edge—Neckenmarkt, Horitschon (with contiguous Raiding), and Deutschkreuz, as well as, in its extreme south, Lutzmannsburg. ZWEIGELT, Merlot, and Cabernet Sauvignon are also common, often blended with Blaufränkisch, and there is some Pinot Noir (Blauburgunder), ST-LAURENT, and a bit of Syrah. Such Blaufränkisch pioneers as Albert Gesellmann and Franz Weninger focused on showcasing top individual vineyards, beginning with Horitschon's

Hochäcker. Early in the new millennium, Roland Velich—from a family of growers of sweet and dry white wines in NEUSIEDLERSEE—staked Blaufränkisch claims of avowedly Burgundian stylistic inspiration but combined with multi-site blending modelled on J. L. CHAVE. His Moric wines showcasing OLD VINES in Neckenmarkt and Lutzmannsburg soon achieved internationally coveted status.

Mittelburgenland DAC is the official appellation for Mittelburgenland Blaufränkisch. The KLASSIK and Reserve versions specify successively higher minimum alcohol and a later release date. Ageing in new wood is in principle restricted to Reserve bottlings. QUALITÄTSWEIN that does not qualify for the Mittelburgenland DAC or is not successfully submitted for inclusion can only be labelled for its state of origin, Burgenland. D.S.

Mittelrhein, second-smallest wine region in GERMANY better known to the outside world for its cliffs and castles than its Rieslings, which however can be outstanding. Most of the 468 ha/1,156 acres of vines planted in 2019, 65% of them RIESLING, grow within sight of the river RHINE, often looking down upon it from a considerable height (see map under GERMANY). The first commercial vineyards start just south of Bonn, and none is found on the west bank of the river until Koblenz, 58 km/36 miles upstream. Thereafter they climb both sides of the Rhine gorge, wherever site, MESOCLIMATE, and much hard work make vine-growing a more or less viable exercise. The Mittelrhein also incorporates the remnants of once-flourishing vineyards around Bad Ems and Nassau on the Lahn. There is usually enough rain during the growing season to maintain the health and strength of the vines on their porous, steep, heat-trapping SLATE and QUARTZITE slopes.

The prime Mittelrhein sectors are about 12 km south of Koblenz, around Boppard (the vineyards sharing the name Hamm), and from the far south near the RHEINGAU at Oberwesel and especially Bacharach and adjacent Steeg, whose most notable vineyards are Hahn, Posten, Wolfshöhle, and St Jost. Because of CLIMATE CHANGE,

top growers have been relying on vineyards at higher ELEVATIONS or in side valleys such as Oberdiebach to produce dry Rieslings of 12% alcohol or less, thus saving some of the region's dwindling treasure of OLD VINES. Other signs of the times are increasingly impressive SPÄTBURGUNDER and experimental pockets of Syrah. At their best, Mittelrhein Rieslings combine the mineral notes and tension of Mosel wines with the tropical fruit of Nahe Rieslings. While the region's top growers make up in quality for what they lack in numbers, it is TOURISM that sustains the Mittelrhein's part-time vine growers in a wine region that has been shrinking for a century. D.S.

MJT, mean January/July temperature. See CLIMATE CLASSIFICATION.

moelleux, French term meaning literally 'like (bone) marrow', or 'mellow'. Wines described as *moelleux* are usually medium sweet, while very rich BOTRYTIZED wines may be described as LIQUOREUX.

Moët & Chandon, Champagne house producing the single most important champagne BRAND in the world, and part of the vast LVMH group. The Champagne house was founded by Claude Moët, born in 1683 to a family which had settled in the Champagne district during the 14th century. He inherited vineyards and became a wine merchant, establishing his own firm in 1743. He was succeeded by his son Claude-Louis Nicolas and his grandson Jean-Rémy Moët, who used his impressive connections to open up international markets for his wine. Jean-Rémy was a close personal friend of Napoleon Bonaparte and was awarded the cross of the Légion d'Honneur in the final years of the emperor's rule. In 1832, Jean-Rémy handed over the firm to his son Victor and his son-in-law Pierre-Gabriel Chandon. At the same time, the company acquired the Abbey of Hautvillers and its vineyards (see PÉRIGNON, DOM). In 1962, Moët & Chandon's shares were quoted for the first time on the Paris Stock Exchange, leading to a period of considerable expansion. First Moët bought shares in

Ruinart Père et Fils, the oldest Champagne house, in 1963. Five years later it acquired a 34% stake in Parfums Christian Dior, increasing this to a 50% stake shortly afterwards. In 1970 Moët took control of Champagne Mercier, a popular brand in France, and capped it all by buying out Dior and merging with the cognac house of Hennessy in 1971 to form the holding company Moët Hennessy. The acquisitions continued unabated, including, in 1981, a stake in the American importers Schieffelin. At one stage the company's American investment also involved the Simi winery in Sonoma, Moët having established Domaine Chandon, the seminal sparkling wine producer, in the Napa Valley in 1973.

This was by no means the company's first venture into the New World. Bodegas Chandon was established in Argentina in 1960, and Provifin, now Chandon do Brasil, followed in 1974, both companies making considerable amounts of wine for the domestic market, much of it sparkling. In Germany, too, a SEKT business was established in the form of Chandon GmbH in 1968. In 1985, the group founded Domaine Chandon in Australia's Yarra Valley and in 1987 established a company in Spain for the production of a CAVA, subsequently sold to HENKELL FREIXENET.

In 1987, Moët Hennessy merged with the Louis Vuitton Group, makers of luxury leather goods and then owners of Champagne houses VEUVE CLICQUOT, Canard-Duchêne, and Henriot, and Givenchy perfumes. The LVMH group's composition continues to evolve, but in 2005 it owned five Champagne houses: Moët & Chandon, Mercier, Ruinart, Veuve Clicquot, and KRUG (having once also owned Pommery, and Lanson briefly while stripping it of its extensive vineyard holdings before selling it on). Of these, Moët & Chandon and Mercier are run most closely in tandem.

Moët, the brand, continues to sell at over twice the rate of its nearest competitors and claims that one in four bottles of Champagne exported comes from the house. It is the leading brand of champagne in most world markets with a share of the champagne market in the United States that can be as high as 50%. By 2020 the

non-vintage Brut Impérial had been restyled to be drier with longer AGEING in bottle.

The house prestige cuvée is named after Dom Pérignon, the legendary figure of the Abbey of Hautvillers, and broke new ground in terms of packaging, pricing, and qualitative ambitions when it was launched in 1936. S.E.A.

MOG, or material other than grapes, refers to leaves, canes, vines, and other debris picked inadvertently with the grapes at harvest. The amount of MOG is increased by MECHANICAL HARVESTING.

Moldavia . See MOLDOVA.

Moldova , in full the Republic of Moldova, may have been one of the smallest states of the former Soviet Union, but it produced more wine than any other, with its biggest winery (Agrovin Bulboaca) the largest wine factory in the USSR. Independent since 1991, it is one of Europe's poorest countries, but wine remains an important part of the economy, and the country still has more grapevines per person than anywhere else in the world, with 122,000 ha/301,469 acres of vineyard in 2020. The country has real potential for wine quality, thanks to its extensive vineyards, temperate CONTINENTAL CLIMATE, and gently undulating landscape. It is effectively landlocked between eastern ROMANIA and UKRAINE, with a short 'coastline' on the river Danube, giving it access to the Black Sea. The Republic of Moldova today has the same borders as its predecessor state, the Moldavian Soviet Socialist Republic, though since 1992 the eastern part of the country has been the breakaway territory of Transnistria. This accounts for around 11% of Moldova's population but is not recognized internationally.

History

Fossil leaves of *Vitis teutonica* dated to the Miocene era confirm that the vine was widely grown in this area around 10 million years ago. The earliest records of domesticated vines occur in Neolithic sites from 6th–5th millennia BCE and on multiple Cucuteni-Trypillia sites in the region from 5200–3500 BCE. Later, there are Iron Age traces of grapes near Etulia, then the Roman province of Dacia left its mark, sharing much of this period of history with today's Romania.

The principality of Moldavia (covering land that is today's eastern Romania and the Republic of Moldova) was founded in 1359, when Bogdan I wrested the territory from Hungarian control. There are several 15th-century records of vineyards and wine from these lands, and wine became significant under the great leader Stefan Cel Mare (1457–1504). In the 16th century, Moldavia became a vassal state to the Ottoman empire, though wine production continued, linked to Christianity and monastic vineyards. Five wars between 1711–1812 with the Russian Empire appears to have slowed down winemaking, until the eastern part beyond the river Prut was annexed to become the Russian province of Bessarabia in 1812.

Russia encouraged vines in the new province, and Tsar Alexander I set up a campaign to repopulate the empty steppe in Southern Bessarabia, requiring colonists (from Germany, Switzerland, and Bulgaria) to be agriculturalists or winemakers in return for exemptions from taxes and military service. Around this time, it became fashionable for Russian aristocrats to own vineyards, often bringing in vines and expertise from France, and in 1842 the School of Viticulture, Gardening, and Viniculture was opened in Stăuceni, possibly the first such school in Europe. The 19th century also saw the founding of several of Moldova's earliest estates, such as Vinaria Purcari in 1827, Romănești winery in 1850, and Castel Mimi in 1893. In 1878, a bottle of Negru de Purcari famously won a gold medal in Paris, bringing it to the attention of the Russian royal family. By 1883, 20% of the Russian Empire's wine came from Bessarabia, with exports to the West also strong as PHYLLOXERA took hold. By the early

20th century 180,000 ha/444,790 of vines had died. In 1940 the country was annexed by the Soviet Union, becoming the Moldovan Soviet Socialist Republic (MSSR) in 1944. By this time, vineyards were typically less than 5 ha and planted either to French varieties or HYBRIDS by poor peasants who couldn't afford expensive GRAFTED VINES. The post-war period saw large-scale collectivization into collective farms called *kolkhoz* and state-owned farms called *sovkhoz.* The policy was to develop the MSSR for agriculture, with a drive to increase wine production, as wine was seen as a prestige product that could be displayed to the world. MECHANIZATION, heavy AGROCHEMICAL use, and modernization of the grape assortment were part of the plan, alongside research into more cold-tolerant vine varieties. Peak vineyard area reached 224,000 ha/553,516 acres between 1971 and 1980, and in 1983 MSSR was the sixth-largest wine producer in the world, producing one-quarter of the USSR's wine.

The arrival of GORBACHEV with his anti-alcohol campaign in 1985 saw uprooting of 75,000 ha, then further losses followed as a consequence of Moldova's complex land reform in the 1990s after independence was declared. It wasn't until well into the 2000s that wineries started to buy up vineyards to improve fruit quality and consistency. Wine reached 9% of total GDP by 2005, but the following year Russia banned all Moldovan wine, causing devastating losses of at least 200 million USD. A further ban followed in 2013, coincidentally around the time Moldova signed free trade agreements with the EU. The sudden need to find other markets required a change of wine style towards dry wines with improved winemaking. Considerable international aid has gone into educating winemakers and modernizing equipment, as well as helping to change legislation to allow the establishment of small independent wineries, quality standards, and PGIs.

Climate and geography

Moldova lies between 46 and 48° N and is low and hilly, averaging 147 m/482 ft above sea level with its highest point reaching just 430 m/1,411 ft. The climate is good for viticulture, with average summer temperatures of around 20 °C/68 °F, and while winters can be extremely cold (−25 °C/−13 °F), freezing damage is unusual. Moldova has a high proportion of humus-rich black soils, but the relatively dry climate forces vines to root deep into the LIMESTONE bedrock. The country has three PGI wine regions covering 9,600 ha/23,722 acres in 2019: Codru in the centre of Moldova is bordered by Leova, Cimiștlia, and Tighina, and since 2016 it has included Bălți and vineyards in Transnistria. It has a CONTINENTAL CLIMATE with moderate winters, thanks to the forested hills to the north, and 79% of its vineyards are on slopes. Annual rainfall is 450–550 mm/18–22 in with 2,100–2,200 sunshine hours. It is noted for fresh, floral whites and structured, COOL CLIMATE reds that can age well. Valul Lui Trajan in the south-west is Moldova's warmest region, with a more MEDITERRANEAN CLIMATE, low elevation (5–310 m/16–1,017 ft), and well-drained soils with clay and sand that make it best regarded for rich, structured reds. Ștefan Vodă in the south-east has a TEMPERATE continental climate, with influence from the Black Sea. Annual rainfall averages 450–550 mm/18–22 in, elevations are just 120 m/394 ft, and annual sunshine hours are 2,200–2,300. Its most famous district is Purcari, noted for long-lived reds. Moldova also has a national PGI for wine distillates called Divin. There are plans to establish PDOs, but none were in place in 2022.

Viticulture

Moldova is able to grow the great majority of its vines without WINTER PROTECTION. Most vines are CORDON-trained on medium-height TRELLISES. Most vineyard work is done by hand due to low wages, though LABOUR availability is an increasing problem as so many working-age Moldovans work abroad. Privately owned vines tend to be old and may be in poor condition, while wineries have invested in substantial plantings since mid 2000s to ensure consistent fruit quality. Important viticultural concerns include increasing risk of DROUGHT stress, given the dry climate and lack of IRRIGATION, while PHYTOPLASMA is present and DOWNY MILDEW, POWDERY MILDEW, and GREY ROT can be a problem in more humid seasons.

Vine varieties

Of the 74,400 ha/183,846 acres of vines in commercial production in 2020, 55,200 ha are VITIS VINIFERA wine varieties, 7,000 ha are HYBRIDS (notably Isabella), and the rest are TABLE GRAPES. The country's top red wine varieties by volume in 2020 were Cabernet Sauvignon (31%) and Merlot (26%), Pinot Noir (4%), SAPERAVI (4%), and FETEASCĂ Neagra (3%). Top white varieties were Sauvignon Blanc (17%), Chardonnay (16%), Aligoté (8%), Pinot Gris (8%), and Riesling (5%). Local varieties (many shared with Romania) including Fetească (Alba, Regală, and Neagră) and Rara Neagră (BĂBEASCĂ NEAGRĂ) had virtually disappeared in the previous era, but there is increasing interest in replanting them, though total area under local varieties is only an estimated 1,300 ha/3,212 acres. Other local reds that may have quality potential include Codrinschii, Kopchak/Copceac, and Negru de Căușeni (in 2023 the latter two were awaiting approval for planting). SAPERAVI also produces good results in Moldova—it was originally cultivated as part of the Negru de Purcari blend in 1950s but has now spread to the south-west and is appearing in both VARIETAL wines and premium blends. Several wineries are also working with genuinely Moldovan white varieties including Viorica, Alb de Onițcani, Floricica, and Riton. These are varieties developed for cold- and disease-resistance in the Soviet era but capable of producing good-quality wine and expected to play an increasing role as Moldova is making moves towards developing industry-wide SUSTAINABILITY practices. Certified ORGANIC VITICULTURE is limited to a handful of producers.

Wines produced

Modern Moldovan wine styles usually show fresh natural ACIDITY and relatively moderate alcohol levels with good varietal expression. In 2020, white wines led production at 40.2 million litres/10,619,717 gal while reds comprised 36 million litres, rosé 10 million litres, and sweet wines 2.5 million litres. Negru de Purcari may be Moldova's most famous wine. This blend of Cabernet Sauvignon, Saperavi, and Rara Neagră was famously the only wine exported with an English label from Moldova in Soviet times. It was revived as a brand belonging to Vinaria Purcari in 2003, based on historic records, and has inspired several other premium red blends. Moldova continues to make some FORTIFIED WINES, notably Pastoral (previously Cagor), a partially fermented red from heat-treated MUST, often based on Cabernet or Saperavi. There are also a few good ICE WINES from Riesling, Traminer, or Muscat Ottonel. SPARKLING WINE production, both tank- and bottle-fermented, dates to 1950s, with state-owned Cricova the most notable producer.

Modern industry structure

Prior to the first Russian ban in 2006, wine quality across Moldova was often distinctly poor, as old Soviet winemaking technology was commonplace, with little attention paid to HYGIENE or controlling OXIDATION. Today modern equipment is more widespread among key players whose vineyard ownership allows them to control grape quality—and quality can be very high. Bureaucracy has been reduced, and this has encouraged the establishment of small boutique wineries, many of whom have tourism facilities too. By 2021 the country had 226 registered wine producers and 51,000 growers. Wineries are all fully privatized apart from state-owned enterprises Cricova and Mileștii Mici (famous for the largest collection of bottled wine in the world and for the largest network of underground cellars, measuring 200 km/124 miles). In 2020 there were 42 members of the small wineries' association, who must own 1–40 ha/2.5–99 acres to distinguish them from HOME WINEMAKERS.

The wine industry is a strategic and economically important sector for Moldova, creating 16% of the value in the agricultural sector and 3% of total GDP in 2020, and employing around 150,000 people. Production in 2020 was the smallest for 10 years at 0.91 million hl/nearly 20 million gal (although average production has typically been closer to 1.5 million hl). The vast majority is exported, to 63 countries led by Belarus, Georgia, Romania, Russia, Czechia, the UK, and Poland. Inexpensive BULK WINE continues to be the majority by volume of exports, but value in the bottled wine export sector has increased. This has been helped by strong marketing activities and concepts such as the Wine of Moldova country brand launched in 2014. Several aid organizations have been working in Moldova to help restructure and modernize the wine industry. Viticultural research is also underway, and the strategic vision to 2030 includes a move towards a consumer-led, quality-focused industry with sustainability at its heart. C.G.

Gilby, C., *The Wines of Bulgaria, Romania and Moldova* (2018).

www.wineofmoldova.com

Molette is a common white grape variety, yet another progeny of GOUAIS BLANC, used particularly for the sparkling wines of SEYSSEL in SAVOIE. The base wine produced is neutral and much improved by the addition of some ALTESSE.

Molinara, red grape variety grown in 2015 on 605 ha/1,495 acres, mainly in the Veneto region of north-east Italy, particularly for VALPOLICELLA. Its wines tend to be high in acidity, light in colour, and prone to OXIDATION, so the variety is losing ground to CORVINA, RONDINELLA, and INTERNATIONAL VARIETIES in the zone.

Molise , Italy's second smallest and least populated region, is a mountainous area south of ABRUZZO in south-east Italy. Impoverished by a continuous emigration of LABOURERS for almost a century, the region has only 5,374 ha/13,279 acres of vineyards, of which less than one-tenth is devoted to DOC wine production. Production is almost entirely in the hands of CO-OPERATIVE wineries, which sell much of the wine in BULK.

The proximity of Abruzzo—to which the Molise was joined administratively until the 1960s—has left its mark on Molise's viticulture: the two predominant vine varieties are MONTEPULCIANO d'Abruzzo and TREBBIANO d'Abruzzese. There have been attempts to diversify, however, with the planting of grape varieties from southern Italy, especially neighbouring Campania, such as FIANO, GRECO di Tufo, and AGLIANICO. INTERNATIONAL VARIETIES have also been planted. The region has one overarching DOC, Molise, and three other DOCs within it: Biferno, Pentro d'Isernia, and Tintilia del Molise. While this last is based on one of the very few INDIGENOUS VARIETIES of any commercial

significance in Molise (and which may only be planted in vineyards of at least 200 m/656 ft ELEVATION), all other DOCs are catch-all denominations based on Trebbiano Toscano and Montepulciano d'Abruzzo and including VARIETAL bottlings, notably of Cabernet Sauvignon and Aglianico.

In the past the region's best wines, produced by the Di Majo Norante winery, were bottled under the IGT in response to the world's lack of interest in Molise's DOCs, but that is changing—evidence that, however slowly, things are moving forwards for Molise. W.S.

Belfrage, N., *Brunello to Zibibbo—The Wines of Tuscany, Central and Southern Italy* (2nd edn, 2003).

Moll, robust but potentially interesting white grape grown on the Spanish island of MALLORCA, also known as Prensal.

Mollar. See NEGRAMOLL.

molybdenum, trace element important for plant growth. A deficiency in vineyard soils is extremely rare but may contribute to poor FRUIT SET and symptoms of NITROGEN deficiency, particularly on acidic soils (see SOIL ACIDITY) and with some varieties, including Merlot. This can be effectively treated with foliar sprays; since such sprays are inexpensive, they often applied as a prophylactic at FLOWERING.

Kaiser, B., et al., 'The role of molybdenum in agricultural plant production', *Annals of Botany*, 96/5 (2005), 745–54.

monasteries. See MONKS AND MONASTERIES.

Monastrell, Spain's fourth most important black grape variety, known in France as MOURVÈDRE, grown on 37,881 ha/93,606 acres in

2020, mainly in Murcia and CASTILLA-LA MANCHA.

The origins of the variety are almost certainly Spanish. Murviedro is a town near Valencia (Mataro, another name for the variety, is another near Barcelona). It is certainly easier to grow in Spain than in the cooler reaches of southern France, for it buds and ripens extremely late, later even than CARIGNAN. Provided the climate is warm, the upright, vigorous Monastrell adapts well to a wide range of soils and recovers well from spring FROST. (It is sensitive to low winter temperatures, however.)

The wine produced from Monastrell's small, sweet, thick-skinned berries tends to be heady stuff, high in alcohol and tannins, with a somewhat gamey, almost animal, flavour when young and well capable of AGEING, provided both OXIDATION and REDUCTION, to which it is particularly prone, is carefully avoided in the winery. It is the principal black grape variety in such DOPs as ALICANTE, ALMANSA, JUMILLA, VALENCIA, and YECLA.

See MOURVÈDRE, its more usual name outside Spain, for more details of where else it is grown.

Monbazillac, serious sweet-white-wine AOC (since 1936) within the BERGERAC district in SOUTH WEST FRANCE. The region's reputation for sweet wines predates the influence of the DUTCH WINE TRADE, going back to the Middle Ages, when Benedictine MONKS farmed the land and discovered the positive aspects of *Botrytis cinerea*. (See NOBLE ROT.)

Like SAUTERNES, Monbazillac is made from Sauvignons Blanc and Gris, Sémillon, and, particularly successful here, MUSCADELLE grapes. These vines grow immediately south of the town of Bergerac on the left bank of the DORDOGNE, close to its confluence with a small tributary, the Gardonette. This environment produces autumn morning mists followed by hot sunshine, a combination that encourages the development of noble rot, particularly on north-facing slopes.

In the past, Monbazillac was too often a sweetened, heavy, often sulfurous wine, but since 1993 there has been a clear distinction between serious sweet Monbazillac and early-picked dry white wine which is sold as Bergerac Sec. In a determined quest for quality, MECHANICAL HARVESTING was banned and at least two TRIES through the vineyard insisted upon. Basic maximum permitted yields here are 40 hl/ha (2.3 tons/acre), as opposed to the 25 hl/ha in Sauternes, but in a good vintage, the average yield in Monbazillac is around 26 hl/ha (as opposed to Sauternes' 22.5 hl/ha). At 2,700 ha/6,672 acres planted (out of a potential 3,600 ha), the AOC is considerably larger than Sauternes.

There is also now a further clear division between the basic MOELLEUX wines and those that bear the title SÉLECTION DE GRAINS NOBLES, which are much richer and at their best six to 20 years after the vintage. The top wines (particularly those of Ch Tirecul-la-Gravière) can rival even the finest SAUTERNES. The active CO-OPERATIVE is based in the majestic Ch de Monbazillac on the crest of a hilltop overlooking the Dordogne. P.S.

Monção e Melgaço, inland DOC subregion of VINHO VERDE in north-west Portugal on the left bank of the river MINHO best known for VARIETAL wines made from the ALVARINHO grape which flourishes in its relatively warm, dry, sheltered location. The vineyards rise from the river into the hills on stony alluvial and (predominantly) GRANITIC soils; a leading producer has planted a trial hectare on SCHIST at a dizzying 1,100 m/3,609 ft above sea level. Alvarinho wines here tend to be more muscular and fruity than Albariño from RÍAS BAIXAS across the river, yet they retain impressive freshness because there is no need to lower acidity with MALOLACTIC CONVERSION. Being the speciality, Alvarinho is made every which way, including aged in oak, chestnut, and clay vessels and in sparkling and LATE HARVEST styles. S.A.

Mondavi, important family in the recent history of CALIFORNIA wine, with Robert Mondavi (1913–2008) in particular having done more than anyone to raise awareness of the civilizing influence of wine in general and of California as a source of top-quality wine in particular.

Robert's father Cesare came to the US in 1906 from the MARCHE on Italy's east coast. He and his Italian wife Rosa ran a boarding house for miners in Minnesota before moving to LODI in California's San Joaquin Valley in 1922, whence, throughout PROHIBITION, they shipped grapes back east to America's temporarily swollen band of HOME WINEMAKERS. Immediately after Repeal, Cesare turned to winemaking and was joined in the late 1930s by his sons Robert and Peter.

As early as 1936, the Mondavis made their crucial move out of the hot Central Valley (leaving GALLO to build up the world's largest winery there) into the cooler NAPA Valley where they were determined to make TABLE WINES, rather than dessert wines which were then much more popular. The Mondavis acquired the nearby Charles KRUG winery in 1943. Robert Mondavi's obsession with constant fine-tuning of wine quality grew here, inspired by old bottles from the Inglenook winery and guided by oenologist André TCHELISTCHEFF. During the 1950s, he became increasingly fascinated by the CABERNET SAUVIGNON grape, and in 1962 he travelled to BORDEAUX for the first time, a seminal visit which was to convince him of the necessary conjunction between fine wine and gracious living.

This led to disputes with his younger brother Peter which were exacerbated by Cesare's death in 1959. By 1965 Robert was excluded from the Charles Krug winery, where Peter and his descendants remain, and won compensation only after a long and bitter lawsuit. The opening of the Robert Mondavi winery on the Oakville highway in 1966—strikingly Californian, in the mission style, thanks to architect Cliff May—marked the beginning of a new chapter not just for the Mondavis but for California wine. There was restless experimentation with different BARRELS, TOAST, FINING, and FILTRATION regimes; special RESERVE bottlings; comparative tastings with France's most famous

wines; wine TOURISM; and cultural events associated with the winery and its wines. In 1979 a groundbreaking JOINT VENTURE was announced between Robert Mondavi and Baron Philippe de ROTHSCHILD: Opus One, with its own lavish winery since 1992. Also in 1979 the company bought a CO-OPERATIVE in Lodi which, producing the high-volume, lower-priced range of Woodbridge wines then known as 'fighting varietals', became its single most profitable venture by far.

During the 1990s, Robert Mondavi extricated himself from day-to-day operations, which then also included joint ventures in Chile and Tuscany, a controlling interest in Ornellaia, an ambitious venture in the Languedoc, and the Byron winery in the Santa Maria Valley.

Although the Robert Mondavi winery had considerable assets in the form of 1,500 acres/607 ha of prime Napa Valley vineyard, and though its annual production of Napa Valley wine peaked in the early 1990s at about 500,000 cases (more than any other producer), borrowings, family squabbles, and the prospect of significant inheritance taxes resulted in a public share issue in 1993. In 2004, amid much acrimony, the board voted to sell the company, and it was purchased by CONSTELLATION BRANDS, which disposed of all joint ventures except for Opus One.

Mondavi, R., *Harvests of Joy* (1998).

Mondéjar , DOP in northern CASTILLA-LA MANCHA, Spain, created in 1996 and producing TABLE WINES of modest distinction. TEMPRANILLO is the main variety in the 425 ha/1,050 acres of vineyards.

Mondeuse Blanche is a light-berried vine found in SAVOIE, producing a dry, relatively soft white wine. DNA PROFILING has shown that it is not a white MUTATION of MONDEUSE NOIRE but is, with TRESSOT, one of its progenitors. It is also a parent, with DUREZA from the Ardèche, of the famous SYRAH. J.V.

Mondeuse Noire, one of the oldest and most distinctive red grape varieties of SAVOIE, bringing an Italianate depth of colour and bite to the region in contrast to the softer reds produced by the GAMAY imported only after PHYLLOXERA. The juicy, peppery wines are powerfully flavoured and are some of Savoie's few to respond well to careful OAK AGEING (although, when grown prolifically on Savoie's more fertile, lower sites, Mondeuse can easily be a dull wine too, which may explain why the variety has been underrated).

Total French plantings of Mondeuse Noire fell sharply in the 1970s and were barely 200 ha/500 acres in 2000, but they had reached 302 ha by 2019, showing signs of a renaissance. Most Mondeuse is sold as a VARIETAL Vin de Savoie, sometimes with a CRU name added. It is also grown in the Vin du BUGEY region, and from the 2010s it underwent a small revival in Switzerland, where it was once well respected. It is grown on Etna in Sicily and in California. It was long confused with REFOSCO DAL PEDUNCOLO ROSSO in California, where it is a relative rarity, as it is in Australia. DNA PROFILING suggests that it is a natural progeny of MONDEUSE BLANCHE and TRESSOT. J.V.

Monferrato, extensive DOC in the hills east of Turin in the provinces of Asti and Alesssandria in PIEMONTE. The region is traditionally known for light and often sparkling Barbera del Monferrato, which has gained in quality since the creation of the Barbera del Monferrato Superiore DOCG, for still red wines with a minimum 14 months of ageing and 13% alcohol. While Monferrato serves as an overarching DOC, also for INTERNATIONAL VARIETIES (which, however, cannot be mentioned on labels), the region boasts a handful of interesting smaller denominations dedicated to local varieties. Long considered a workhorse variety, DOLCETTO produces some complex wines in DOCG Ovada, and GRIGNOLINO del Monferrato Casalese DOC is experiencing a renaissance, its pale and tannic reds now proving to be ageworthy as well (and just in time to halt the DOC's demise, as it measured just 270 ha/667 acres in 2020). RUCHÈ

di Castagnole Monferrato DOCG is a rare, aromatic red wine with classic Piemontese tannic structure, and Monferrato Casalese is a dry white made from CORTESE and not unlike GAVI, which also lies within Monferrato. Although the region is overshadowed by its more illustrious neighbours, notably the LANGHE, Monferrato's highly original wine styles deserve more attention. W.S.

Monica , basic red grape variety grown in 2020 on 1,203 ha/2,073 acres of SARDINIA, where some varietal Monica di Sardegna is thus labelled. DNA PROFILING recently indicated that it is a natural progeny of Hebén, an old and rare wine and TABLE GRAPE from Spain, suggesting that it was initally brought to the island from Spain when Sardinia was part of the Aragón kingdom. Its wines are generally undistinguished and should be drunk young, although with lower YIELDS the variety could produce a pleasurable, if not always memorable, wine.

monks and monasteries. Wine has always had spiritual and religious significance (see RELIGION AND WINE), and monks and monasteries have long been regarded as playing a crucial part in wine history.

While wine and the vine played a prominent role in most religions of the eastern Mediterranean during prehistory and antiquity, it was in Christian religious symbolism and practice that it achieved particular significance, as an essential element of the EUCHARIST. Such Christian symbolism built on earlier Jewish beliefs in which the vine or vineyard was used in the Old Testament as one of the favourite symbols for the nation of ISRAEL. The adoption of Christianity as the state religion of the Roman Empire during the 4th century CE (see ancient ROME) led to wine attaining the utmost ideological prominence in European society. While monasteries in the eastern Mediterranean and northern Africa continued to make wine in late antiquity, as evidenced in particular by their wine PRESSES, the religious

significance of wine is widely regarded as of particular importance at two main periods in its history: first, in ensuring the survival of viticulture following the collapse of the western Roman Empire; and second in the introduction of viticulture and winemaking to the Americas.

It has generally been argued that Christian communities' need for grape-based wine with which to celebrate the Eucharist was one of the main factors enabling viticulture and winemaking to survive in western Europe following the fall of Rome in 476 CE. It is assumed that when transport was difficult, it was easier for isolated Christian communities in northern Europe to cultivate their own vines rather than import wine. Moreover, monks are widely regarded as the only individuals capable of nurturing viticultural and winemaking traditions.

There is, however, little firm evidence for this hypothesis. The Germanic tribes which overran the western Roman Empire were known to be fond of wine, and there is little reason to suppose that they consciously destroyed vast expanses of European vineyards. This is supported by the evidence of surviving elements of the Gallo-Roman aristocracy, who recorded the continued cultivation of vines during the second half of the 5th century in areas of GAUL such as Clermont-Ferrand. Bishops and monks certainly did own vineyards and organized the production of wine throughout the period from the 6th to the 10th century, but in most instances they appear to have been given their vineyards mainly as grants from royalty or the secular nobility. This implies that substantial non-monastic vineyards survived and were developed in the aftermath of the Germanic invasions of the 5th century. The real role of monasteries seems not so much to have been in the preservation of a tradition of viticulture following the collapse of Rome but rather in building up substantial holdings of vineyards and, thus, in being among the most important winemakers of medieval Europe (see also CHARLEMAGNE).

During the Middle Ages, monastic houses came to possess some of the most renowned vineyards of Europe. The Benedictines (who, like the Carthusians, are now popularly associated with a high-quality

liqueur based on distilled wine and whose Rule included a daily wine allowance) thus owned extensive vineyards. In BURGUNDY the monks of Cluny owned most of the vines in what is now GEVREY-CHAMBERTIN, while the abbey of St-Vivant owned vineyards in what is now called VOSNE-ROMANÉE. Along the Loire, the Benedictine abbey of St-Nicolas held vineyards in what is now ANJOU, and Benedictine monasteries at BOURGUEIL and La Charité also produced quantities of wine. Further south, the Benedictine abbey at ST-POURÇAIN produced what was one of the most renowned wines in medieval France. In CHAMPAGNE, the Benedictines held six monasteries in the diocese of Reims, while in the RHÔNE they held vineyards at both CORNAS and ST-PÉRAY. In BORDEAUX, they owned such properties as Ch Prieuré in Cantenac (now carrying the suffix of a more recent owner, Alexis LICHINE) and Ch Carbonnieux in GRAVES. In Germany, the abbey at St Maximin in the RUWER was producing about 9,000 l/2,370 gal of wine a year towards the end of the 8th century. Although they also owned many German vineyards, especially in RHEINHESSEN and FRANKEN, the Benedictines' best-known German wine estate was SCHLOSS JOHANNISBERG in the RHEINGAU (see GERMAN HISTORY).

The more ascetic Cistercians, likewise, owned numerous important vineyards throughout Europe. Clairvaux Abbey had extensive vineyards in CHAMPAGNE, and the Cistercians of Pontigny are reputed to have been the first to plant the CHARDONNAY vine in CHABLIS. Their most famous vineyard, however, was the extensive, walled CLOS DE VOUGEOT, and their other holdings in Burgundy included vineyards in MEURSAULT, BEAUNE, and POMMARD. Cistercians also produced fine wines in SANCERRE and PROVENCE. Their most important wine-producing abbey in Germany was KLOSTER EBERBACH in the RHEINGAU, but there were many others, notably at Himmerod and Machern in the MOSEL and Maulbronn in WÜRTTEMBERG. As major landowners throughout Europe, other monastic orders also owned extensive vineyards; the Carthusians, for example, had particular interests in CAHORS, SWITZERLAND, and Trier in the Upper Mosel. (See also PRIORAT.)

The second main viticultural role widely attributed to the monks was their influence on the development of vineyards in the Americas. In the 17th century, the Jesuits were major wine producers on the coastal plain of PERU, and in the 18th century, with the expansion of Spanish interests in CALIFORNIA, the Franciscans, particularly under the leadership of Júnipero Serra, played an important part in introducing viticulture and winemaking to Alta California. Most of the missions established in California during the 1770s and 1780s thus cultivated vines and made wine, with the Mission of San Gabriel becoming particularly famous for its wines, although the majority of mission vineyards nevertheless remained very small.

In the 21st century, monastic winemaking continues, despite the earlier effects of the Reformation in northern Europe. Abbeys and monasteries still producing wine include Göttweig, Heiligenkreuz, and KLOSTERNEUBURG in Austria and Muri-Gries near Bolzano in ALTO ADIGE, while at St Hildegard above Rüdesheim in the German Rheingau almost all the work is actually done by the sisters. Perhaps the most unexpected wine-producing monastery is Cremisan, sandwiched between Israel and PALESTINE.

Quite apart from the general role played by monastic orders in the history of wine, certain individual monks and monasteries enjoy vinous fame on their own account. The classic example of this is the work of Dom PÉRIGNON in improving the quality of the wines of Hautvillers in CHAMPAGNE at the end of the 17th century.

monopole, Burgundian term for a wholly owned vineyard or CLIMAT.

monopolies. State, province, or national exclusive controls over the sale, and occasionally production, of all alcoholic drinks have a long history. In INDIA, the manufacture of the sort of wine drunk in the immediately pre-Christian era was a state monopoly. In countries such as ALGERIA and (until relatively recently) EGYPT, the state has controlled wine production as well as distribution. The administrators of many ancient civilizations saw the economic and social advantages of exercising a monopoly over the distribution of wine and beer (the only alcoholic drinks known in antiquity). State monopolies on selling alcoholic drinks have been features in many Scandinavian countries, Pennsylvania in the United States, and much of Canada, although some of these monopolies were broken in the 1990s. The disadvantage for consumers can be a restriction of choice and, in many cases, severe restrictions on where and how wine is sold, sometimes with all the safeguards and ignominy associated with the distribution of dangerous drugs. The advantage for producers can be that a sale to a monopoly represents a relatively high-volume order. The two biggest monopolies in terms of volume of wine sold are the Liquor Control Board of Ontario (LCBO) in Canada, which sold about 172 million litres of wine in the twelve months to 31 March 2021, and Systembolaget in Sweden—a fervent advocate of SUSTAINABILITY, especially in packaging—which sold 223 million litres in 2021.

monoterpenes have ten carbon atoms and are members of the group of natural products called TERPENOIDS. Monoterpenes are major contributors to the characteristic flavour properties of MUSCAT grapes and wines and also play a part in the floral aromas of many non-Muscat wines such as RIESLING. Individual monoterpenes that are found in grapes and contribute to the attractive flavour properties of wines include the ALCOHOLS geraniol, nerol, linalool, and citronellol, although more than 40 have now been reported. Monoterpenes were

among the first grape and wine FLAVOUR COMPOUNDS to be elucidated and the first to be discovered in glycosylated form (see GLYCOSIDES) as FLAVOUR PRECURSORS. P.J.W.

Strauss, C. R., et al., 'Role of monoterpenes in grape and wine flavor', in *Biogeneration of Aromas*, American Chemical Society (1986).

Montagne de Reims, the 'mountain of Rheims', or the forested high ground between the CHAMPAGNE towns of Rheims and Épernay. Its lower slopes are famed for the quality of PINOT NOIR base wine they produce.

Montagne-St-Émilion, the largest satellite appellation of ST-ÉMILION in Bordeaux with 1,570 ha/3,878 acres in production in 2020. Most soils are some mixture of CLAY and LIMESTONE with GRAVEL and SAND.

Montagnieu , CRU on a steep, south-facing LIMESTONE-scree slope above the Rhône river whose name can be added to the eastern French appellation BUGEY. Montagnieu reds must be from the local MONDEUSE grape. The name may also be used for fine white TRADITIONAL METHOD sparkling wines made principally from ALTESSE, CHARDONNAY, and Mondeuse. The cru name may also be added to AOC ROUSSETTE du Bugey. W.L.

Montagny, the appellation for white burgundy produced in the communes of Montagny-lès-Buxy, Jully-lès-Buxy, Buxy, and St-Vallerin in the Côte CHALONNAISE. The wines have a little more body and more acidity than other whites from this region. Of its 352 ha/870 acres of vineyards, 211 are classified as PREMIER CRU. Much of the production passes through the excellent CO-OPERATIVE founded in 1929 at Buxy,

which boasts the motto ‘with the good wines of Buxy everyone sings and everyone laughs’. J.T.C.M.

Montalcino , town in TUSCANY in central Italy famous for its long-lived red BRUNELLO DI MONTALCINO. Rosso di Montalcino is also made of 100% Brunello grapes but needs be aged for only one, rather than four, years.

Montecucco, source of promising Sangiovese in the MAREMMA.

Montefalco , small DOC zone in UMBRIA between Assisi and Terni best known for the DOCG Montefalco SAGRANTINO. It is used mainly for the earlier released Montefalco Rosso (60–80% SANGIOVESE, 10–25% Sagrantino); some Montefalco Bianco (a blend with minimum 50% TREBBIANO Spoletino) and varietal GRECHETTO is also made. W.S.

Montenegro , or Crna Gora, meaning ‘black mountain’, is a small country on the Adriatic coast to the south and east of CROATIA, also bordered by BOSNIA AND HERZEGOVINA, SERBIA, KOSOVO, and ALBANIA. Formerly part of YUGOSLAVIA, it became independent in 2006; in 2022 it was a candidate country for EU membership. Its wine culture dates back to pre-Roman times, supported by finds from the city of Budva dated to the 4th century BCE. The industry declined under the Ottomans and PHYLLOXERA, recovering in the early 20th century with the first wine CO-OPERATIVE in 1911.

Wine regions

Montenegro's wine regions lie between latitudes 41.5 and 42.5° N, with ELEVATIONS reaching 600 m/1,970 ft. In the warm MEDITERRANEAN CLIMATE, drought can be a threat, and most commercial vineyards have IRRIGATION. Montenegro had 2,992 ha/7,393 acres of vineyards in 2019 with an average annual production of 103,076 hl/2,722,980 gal of wine.

In 2017, the country was divided into four winegrowing regions: Crnogorski Basen Skadarskog Jezera (Montenegrin basin of Lake Skadar); Crnogorsko-Primorski (Montenegrin coast); Nudo; and Crnogorski Sjever (northern Montenegro). Seven PDOs and two PGIs are in place, though EU registration had not been completed in 2022. The PDOs are Crmnica, Podgorički subregion, Ulcinjski subregion, Boka Kotorska, Nudo, Katunska Nahija, and Bjelopavlići. PGI regions are Crnogorski Basen Skadarskog Jezera, and Crnogorsko Primorje.

The national register records 313 grape-growers and 88 wine producers, though the country's dominant producer is 13 Jul-Plantaže which makes 96% of Montenegrin wine. It claims Europe's largest single-plot vineyard at 2,310 ha/5,683 acres, the Ćemovsko Polje, in a karst valley close to Lake Skadar.

Red wine grapes account for 72% of vineyards, whites 26%, with the remainder in mixed vineyards. The country grows at least 60 varieties, with the deep-coloured and richly flavoured local VRANAC making up 52% of plantings, while Kratošija (ZINFANDEL) is just 3.6% of plantings. Some research suggests Kratošija may have originated here before it reached Croatia and that it is the male parent of Vranac, along with Duljenga. INTERNATIONAL VARIETIES account for just under 14% of plantings, led by Chardonnay and Cabernet Sauvignon. Of the white INDIGENOUS VARIETIES Krstač is most important. Considerable research is going into rescuing old indigenous varieties from small-holder plots. Extensive work on CLONAL SELECTION is also being carried out, aimed at raising the quality of Vranac. C.G.

Maraš, V., Tello, J., Gazivoda, A., et al., 'Population genetic analysis in old Montenegrin vineyards reveals ancient ways currently active to generate diversity in *Vitis vinifera*'. *Scientific Reports* 10, 15000 (2020).

Montepulciano , name of a vigorous red grape variety planted in much of central Italy, and the name of a Tuscan town at the centre of the zone producing the highly ranked red wine VINO NOBILE DI MONTEPULCIANO (which is not made from this grape variety).

On a 2015 total of 32,724 ha/80,863 acres of vineyard, the grape variety is allowed, alone or as part of a blend, in no less than 3 DOCGs, 36 DOCs, and 88 IGTs, but it is most widely planted in ABRUZZO, where it is responsible for the often excellent-value Montepulciano d'Abruzzo, and in the MARCHE, where it is a principal ingredient in such reds as Rosso Conero and Rosso Piceno. It is also grown in MOLISE and PUGLIA. At its best, it produces wines that are deep in colour with ripe, robust TANNINS. Both the colour and the tannins make it a favoured blending ingredient among producers looking to boost their more feeble efforts. Unfortunately, high YIELDS and a tendency to REDUCTION in the wines have ensured that general quality is not as high as it should be. A DOCG for Montepulciano d'Abruzzo Colline Teramane—Montepulciano grown in the hills in the area around Teramo in the northern part of Abruzzo—came into effect with the 2003 vintage and produces some of the region's best wines.

The variety ripens too late to be planted much further north, although Montepulciano has recently shown it can yield dependable quantities of deep-coloured, well-ripened grapes with good levels of alcohol and extract in UMBRIA and the Tuscan MAREMMA. It is sometimes called Cordisco, Morellone, and Uva Abruzzese. DNA PROFILING has suggested a parent–offspring relationship with BOMBINO BIANCO. A tiny amount is grown in Argentina, California, Australia, and New Zealand.

Monterey , one of the major agricultural counties south of San Francisco in CALIFORNIA, with a reputation as 'America's salad bowl'. The coast may be exceptionally picturesque, while the county's inland Salinas Valley is planted with vast stretches of lettuces, broccoli, artichokes, carrots, tomatoes, capsicum/bell peppers, and strawberries which have their own kind of beauty, as described in the novels of John Steinbeck, notably *The Grapes of Wrath*. Chardonnay, Pinot Noir, and some Riesling were the varieties in FASHION in the second decade of the century, although there remained plenty of once-dominant Cabernet Sauvignon in its 18,581 ha/45,915 acres in 2021.

As a wine region, Monterey is not cut from the normal cloth. Rainfall is so low that grapes cannot be grown there without IRRIGATION. Water supply is ample, however, from the underground Salinas River, which defines the large valley so open to the Pacific Ocean that sea fogs and bracing winds cool and darken its northern end, permitting few or no grape varieties to ripen there. Into this contradictory situation came an army of would-be growers who, in 1968–75, took Monterey from one isolated vineyard to the most heavily planted county on the American west coast, with a peak of 14,980 ha/37,000 acres. Plantings have yo-yo'd since, ranging from 8,093 ha to nearly 28,328 ha/70,000 acres between 1975 and 2010 before settling at around 18,600 ha/46,000 acres in 2021.

The first Monterey wine successes came from near the towns of Soledad and Greenfield, and that area—now the AVA of ARROYO SECO—remains near the forefront, although it has since been eclipsed by the Santa Lucia Highlands (see below), a more recent AVA that flanks Arroyo Seco and reaches further north along the western foothills. Monterey County also physically contains the wine regions of CARMEL VALLEY, San Antonio Valley, and most of CHALONE (shared with SAN BENITO County), though all these AVAs remain outside the boundaries of the Monterey AVA itself.

Monterey AVA

The blanket AVA for most of Monterey County, located within the larger CENTRAL COAST AVA, encompasses the AVAs of Arroyo Seco, San Lucas, Hames Valley, Santa Lucia Highlands, and San Bernabe, as well as all other vineyards not included in these more specific regions. The San Lucas AVA was sponsored by the vast Almaden Vineyards when it owned a large amount of land; it has not been actively used on labels since Almaden left the region, although it contains a hefty percentage of Monterey's total acreage in vines. The borders of the AVA are overlapped by the largest contiguous vineyard in the world, San Bernabe's 5,261 ha/13,000 acres owned by Delicato, which also has bases in the Central Valley and Napa Valley and pushed through AVA status for San Bernabe in 2004. Both Hames Valley and San Lucas would be considered hot by the overall standards of Monterey County.

Arroyo Seco AVA

A fairly coherent district within the vastness of Monterey County's Salinas Valley has its anchor point at the scruffy farm town of Greenfield. Most of its vineyards lie to the west of town, on either bank of the dry wash for which it is named in Spanish, but some range east and north to the even scruffier precincts of Soledad. Chardonnay, which has been planted in the region since the 1960s, is the mainstay for most of the wineries who draw upon it, but some cleave resolutely, and less successfully, to Cabernet Sauvignon. Riesling and Rhône varieties have also had some success. Large swaths of the region's vineyards are owned by a few large wine companies such as JACKSON FAMILY WINES, J. Lohr Vineyards and Wines, and Wente Family Estates.

Santa Lucia Highlands AVA

On the western side of the Salinas Valley, Santa Lucia Highlands' Chardonnay, Pinot Noir, and Syrah vines grow on terraces at up to 365 m/1,200 ft in elevation, looming over the row crops on the valley floor. On well-drained, ALLUVIAL soils of decomposed GRANITE, the region's 2,590 ha/6,400 acres of vineyards experience a remarkable fog-influenced DIURNAL TEMPERATURE RANGE, along with fierce marine WINDS that can turn grape leaves inside-out. Consistently cool-to-moderate weather makes for largely uneventful and rather long growing seasons, with harvest consistently three or more weeks later than other North Coast regions. The wind contributes to berries with thicker skins that are also praised for their tendency to retain high levels of natural ACIDITY. Consequently, the region is arguably Monterey's most celebrated AVA, its grapes, especially Pinot Noir, prized and purchased by wineries throughout California. The best examples of the region's wines strike a balance between ripeness and freshness, with a character that sets them apart from the somewhat generic wines made elsewhere in the county. www.santaluciahighlands.com

Monterrei, the smallest DOP in GALICIA, on Spain's border with Portugal, with a history of wine production dating back to Roman times, as suggested by archaeological finds of stone wine presses. Its 500 ha/1,234 acres of vineyard are planted to a bevy of red and white INDIGENOUS VARIETIES. The most planted white grapes are GODELLO and TREIXADURA, which are often blended together; red wines

depend mainly on MENCÍA and BASTARDO. 'Superior' designates a wine made with at least 85% any local variety.

Monthelie, village producing red and occasionally white wine in the Côte de Beaune district of Burgundy's CÔTE D'OR (see map under BURGUNDY). It is so dominated by wine production that one local saying has it that a chicken in Monthelie is likely to die of hunger at harvest time.

The wines resemble those of VOLNAY without reaching the same heights of depth and elegance, although they age well and are more powerful than those of AUXEY-DURESSES, the neighbouring appellation to the south with which the PREMIER CRU vineyard Les Duresses is shared. Most other premier cru vineyards of Monthelie (which were expanded considerably in 2006) such as Meix Bataille and Champs Fulliot lie adjacent to Volnay. Increasing amounts of Chardonnay have been planted since the 1980s, for Monthelie also borders the white-wine village of MEURSAULT. La Goulotte, Combe Danay, and the top of Les Duresses are good vineyards for white grapes. J.T.C.M.

Montilla-Moriles, Spanish DOP in ANDALUCÍA, 40 km/25 miles south of Cordoba (see map under SPAIN), producing both FORTIFIED and unfortified wines in the style of SHERRY, usually known simply as Montilla. For many years wine from the country around the towns of Montilla and Moriles found its way into sherry SOLERAS. The practice largely ceased in 1945 when the area was awarded its own DOP, although wines made from the PEDRO XIMÉNEZ grape, some of them very fine, are still legally exported to JEREZ and neighbouring MÁLAGA for blending. Since it became a region in its own right, Montilla has had to contend with a popular image as an inferior, cheap alternative to sherry. However, it is remarkable that the region's two most outstanding bodegas, Alvear (founded in 1729) and Pérez Barquero (1905), are at the same level of quality as the three or four best bodegas in the Sherry district.

The soils in the centre of the region associated with lower YIELDS and better wines resemble the chalky ALBARIZA of Jerez, although most of Montilla-Moriles is SANDY and parched. The climate is relatively harsh, with summer temperatures rising to 45 °C/113 °F and short, cold winters. The Pedro Ximénez vine, which accounts for over 95% of the region's 4,655 ha/11,503 acres of vines, seems to thrive in the hot conditions, yielding extremely sweet grapes.

The wines therefore achieve ALCOHOLIC STRENGTHS of 14–16% without FORTIFICATION. Other grape varieties include VERDEJO, Baladí (CAETANA BLANCA), and MUSCAT OF ALEXANDRIA, which tend to produce lighter wines for blending. The PALOMINO vine, which is the basis for most sherry, has not been successful in Montilla.

Winemaking practices in Montilla parallel those for sherry. Pale, dry FINO and AMONTILLADO style wines are made from FREE-RUN juice, while heavier styles similar to OLOROSO are made from the subsequent pressings.

Pale Dry Montilla matures under a film of FLOR, initially in concrete or earthenware TINAJAS, then in a SOLERA similar to those in Jerez. However, in the hot climate of Montilla-Moriles, far removed from the cooling winds of the Atlantic, the flor is usually thinner than in Jerez, and the wines tend to have less finesse as a result (see SHERRY). Heavier oloroso styles are fortified and aged for longer in soleras, where they become dark and pungent. Around half the region's wines are not fortified, which puts them at an advantage in certain markets where duties are levied on alcoholic strength. The region is now most celebrated for its PX wines, which are very sweet but not that strong, and of which some producers make young, vintage-dated examples.

Liem, P., and Barquín, J., *Sherry, Manzanilla & Montilla—A Guide to the Traditional Wines of Andalucía* (2012).

Montlouis, or Montlouis-sur-Loire as it is officially known, is a dynamic white-wine appellation in the TOURAINE district of the Loire finally out of the shadow of the much larger and more famous

VOUVRAY across the river. As in Vouvray, the CHENIN BLANC grape is the sole variety of this historic AOC (1938) which allows wine production in all degrees of sweetness and FIZZINESS according to each VINTAGE's peculiarities. The 450 ha/1,100 acres of vineyards grow on plateaus rolling south-west towards the cooler valley of the Cher. The TUFFEAU is covered by *perruches* (flinty clay), *aubuis* (chalky clay), and Miocene GRAVEL, resulting in a sandier topsoil than in Vouvray. About two-thirds of the region's production is MOUSSEUX, while dry, BARREL AGED, SINGLE-VINEYARD WINES are becoming increasingly popular, a trend started by visionary growers such as François Chidaine and Jacky Blot. In 2020, Montlouis trademarked the term 'Originel' to describe sparkling wines made from a single fermentation in the bottle with no added YEAST nor *liqueur de* TIRAGE. After mandatory DISGORGEMENT, it is topped up with the same wine before the bottle is sealed. The wine may be sold as either *mousseaux* or *pétillant* depending on the pressure in the bottle.

See also LOIRE, including map, and SPARKLING WINEMAKING.

P. Le.

Montonico Bianco, ancient light-berried table and wine grape, probably of Greek origin, grown mainly in central Italy. It should not be confused with Mantonico Bianco, another old variety from southern Italy. Montonico Nero is a synonym for GAGLIOPPO.

Montpellier, University of. The agricultural component of Montpellier University is known as the Institut Agro, created under the name École d'Agriculture de Montpellier in 1872 in response to the viticultural crises caused by PHYLLOXERA, POWDERY MILDEW, and DOWNY MILDEW in France. The first Professor of Viticulture, Gustave Foëx, established a collection of European (VITIS VINIFERA) and AMERICAN VINE species (VITIS RIPARIA, VITIS LABRUSCA in particular) and varieties, which remains the world's most comprehensive repository, with more than 7,500 accessions. Pierre Viala was Professor of Viticulture at the end of the 1880s, bringing back from the US

phylloxera-tolerant vine species suitable for CALCAREOUS soils. Thanks to his effort, *Vitis berlandieri* was used to obtain rootstocks such as 41 B, which allowed the replanting of the Cognac and the Champagne regions. Viala's successor was Professor Louis Ravaz, who became one of the first vine physiologists in the wine world. During the 20th century, several famous scientists took the position of Professor of Viticulture of the Montpellier school: Jean Branas, Denis Boubals, and Alain Carbonneau, this last being a specialist in CANOPY MANAGEMENT. Since the Foëx period, AMPELOGRAPHY has been a speciality at Montpellier. Until his retirement in 1985, Pierre GALET helped to establish the scientific bases of ampelography. His successor, Jean-Michel Boursiquot, has been one of the major players in the development of molecular ampelography over the last 20 years.

In 2005, the Institut des Hautes Études de la Vigne et du Vin (Institute for Higher Education in Vine and Wine Sciences), or IHEV, was created to organize the education, research, and extension activities of the Institut Agro Montpellier, today led by Professor Laurent Torregrosa. With 40 permanent staff, including 27 professors and associate professors, the institute offers eight training programs (300 students) dedicated to vine management, wine production or wine economics, from Bachelor to PhD, including the renowned Diploma of Oenology. For research in the wine sector, l'Institut Agro Montpellier, INRAE, and Montpellier University are organized into 12 joint research units, with 300 staff, including 25 PhD students. Extension activities are supported by four industrial chairs, three joint technology units, and three experimental estates (Domaine du Chapître, Centre Expérimental INRAE de Pech-Rouge, and Centre de Ressources Biologiques de Vassal).

The main research topics at Montpellier are vine and yeast genetics, fermentation monitoring, ecophysiology, viticulture management, digital viticulture, and VINE BREEDING. Such research aims to address the main challenges of the sector: product innovation, input reduction in vine management and wine production (see SUSTAINABILITY), and adaptation to CLIMATE CHANGE.

Montpeyroux, high-elevation CRU within the LANGUEDOC and strong favourite to be the next Languedoc subregion to receive its own AOC. The region encompasses around 300 ha/740 acres of rocky CLAY and LIMESTONE some 40 km/25 miles north of Montpellier in the foothills of the Larzac mountains, within the AOC TERRASSES DU LARZAC. Wines must be a blend of at least three grape varieties, primarily Syrah, Grenache, and Mourvèdre, with Carignan and Cinsaut in a supporting role. DROUGHT is a common summer problem, and yields on these rocky slopes are notably low, while ELEVATION and WINDS such as the tramontagne help retain freshness in these full-bodied reds. M.S.

Montrachet, or Le Montrachet, the most famous GRAND CRU white burgundy, the apogee of the Chardonnay grape produced from a single vineyard in the Côte de Beaune district of the CÔTE D'OR. Claude Arnoux, writing in 1728, could find no words in either French or Latin to describe its qualities, though he noted that it was very expensive and that you needed to reserve the wine a year in advance. Dr Lavalle's view (see BURGUNDY, history), expressed in 1855 and not necessarily valid today, was that whatever the price for a good vintage of Le Montrachet, you would not have paid too much.

Le Montrachet covers just under 8 ha/20 acres straddling the borders of Puligny and Chassagne, two communes which have annexed the famous name to their own (see PULIGNY-MONTRACHET and CHASSAGNE-MONTRACHET). Part of the secret lies in the LIMESTONE, part in its perfect south-east ASPECT, which keeps the sun from dawn till dusk. Curiously, the vines in the Puligny half run in east–west rows, while most in Chassagne run north–south, reflecting the contours of the land.

The principal owners and producers of Le Montrachet are the Marquis de Laguiche, Baron Thénard, DOMAINE DE LA ROMANÉE-CONTI, BOUCHARD PÈRE ET FILS, Domaines Lafon and Prieur in Meursault, and Domaines Ramonet, Colin, and Amiot-Bonfils in Chassagne. Domaines Leflaive and d'Auvenay have also purchased smallholdings. The

largest slices belong to the Marquis de Laguiche, whose wine is made by Joseph DROUHIN and Baron Thénard, some of whose wine is distributed by NÉGOCIANTS.

Four more grands crus are associated with Le Montrachet: Chevalier-Montrachet (7.48 ha) is situated directly above the Puligny section of Le Montrachet, on thin, stony soil giving wines which are not quite as rich as the latter. Particularly sought after are the wine from Domaine Leflaive; the Chevalier-Montrachet Les Demoiselles from Louis LATOUR and Louis JADOT; and Chevalier-Montrachet La Cabotte from Bouchard Père et Fils.

Bâtard-Montrachet (10.27 ha), on the slope beneath Le Montrachet, also spans the two communes, producing rich and heady wines not quite as elegant as a Chevalier-Montrachet. In the Puligny section of Bâtard is a separate enclave, Bienvenues-Bâtard-Montrachet (3.43 ha), while an extension of the Chassagne section is the rarely seen Criots-Bâtard-Montrachet (1.57 ha).

See CÔTE D'OR for details of viticulture and winemaking.

Montravel includes three AOCs in the extreme west of the BERGERAC district in SOUTH WEST FRANCE bordering on Bordeaux's eastern satellites. The appellations Côtes de Montravel and Haut-Montravel are used for small quantities of sweet wines, with the former generally denoting a MOELLEUX wine and the latter for a sweeter version. Montravel *tout court* is mainly a dry white, although in 2001 the appellation was extended to reds based on Merlot.

For the whites, each of SÉMILLON and the two Sauvignons must make up at least one-quarter of the blend. MUSCADELLE is also

approved, as is up to 10% ONDENC. The overall quality of the dry wines increased considerably in the late 1980s, though they remain rarely found outside the area of production. P.S.

Montsant, DOP created in CATALUÑA in 2001 which used to be known as the Falset subregion of the TARRAGONA DOP. Its 1,900 ha/4,700 acres of vineyards were given their own identity in order to highlight their superior quality. It has less of the SCHIST soils of its neighbour PRIORAT, but otherwise its old GARNACHA and CARIÑENA vineyards on steep slopes enable it to produce wines of very similar style and quality at lower prices.

Moon Mountain District , high-ELEVATION California AVA in the Mayacamas foothills famed for structured ZINFANDEL and Cabernet Sauvignon. See SONOMA.

Montù, also known as Montuni, late-ripening white grape indigenous to the plains of EMILIA in Italy.

Moravia, Eastern part of CZECHIA whose wine region lies just north of Austria's WEINVIERTEL. Moravia Agria is the name of a grape making refreshing reds in MANCHUELA, while Moravia Dulce is MARUFO.

Morellino di Scansano, particularly successful Sangiovese in Italy's MAREMMA, now suffixed 'Toscana' to increase international brand awareness.

Moreto do Alentejo, undistinguished red grape variety, a natural CROSS of ALFROCHEIRO × CAYETANA BLANCA, that is planted mainly in Portugal's ALENTEJO as well as in BEIRAS.

Morey-St-Denis, important village in the Côte de Nuits district of BURGUNDY producing red wines from Pinot Noir grapes (see map under BURGUNDY). Morey suffers, perhaps unfairly, in comparison with its neighbours CHAMBOLLE-MUSIGNY and GEVREY-CHAMBERTIN because its wines are usually described as being lighter versions of Gevrey or firmer than Chambolle, according to which side of the village they are located. Indeed, in the past, the wines were often sold under those names. Geologically there is no need for Morey-St-Denis to feel inferior as the same stratum of LIMESTONE which runs from the Combe de Lavaux in Gevrey through Morey to the Combe d'Antin in Chambolle.

There are four GRAND CRU vineyards, moving southwards from the border with Gevrey-Chambertin: Clos de la Roche (16.9 ha/42 acres), Clos St-Denis (6.5 ha), Clos des Lambrays (8.7 ha), and Clos de Tart (7 ha), plus a small segment of Bonnes Mares overlapping from Chambolle.

Although Morey chose to append 'St-Denis' to its name in 1927, Clos de la Roche is probably the finest vineyard. The soil is rich in MARL, giving greater depth, body, and AGEING ability than most other vineyards.

Clos St-Denis, sandwiched between Clos de la Roche and the village itself, may be the quintessential wine of Morey-St-Denis—a touch lighter than Clos de la Roche, supple and succulent, the more charming of the two early in life, with a trace of austerity, but the pinnacle of finesse.

Excellent examples of both Clos de la Roche and Clos St-Denis have been made by Domaine Ponsot, Domaine Dujac, and various Ligniers. While Domaine Ponsot was one of the first to bottle their own wines in Burgundy, Domaine Dujac is the comparatively recent creation (in 1968) of Jacques Seysses, an inspirational grower whose example significantly influenced the generation taking over their family domaines in the 1980s.

Clos des Lambrays, all but a monopoly, was promoted from PREMIER CRU to GRAND CRU. Clos de Tart, singled out by Dr Lavalle in

1855 as the only *tête de cuvée* vineyard in Morey, has always been a MONOPOLE: founded by the Cistercian sisters of Notre Dame de Genlis in 1250, it remained in their hands until the French Revolution, when it was auctioned in one piece. In 1932 one of the Marey-Monge family sold it to the Mommessin family, and thence in 2018 to ARTÉMIS DOMAINES.

Successful premier cru vineyards in Morey-St-Denis include Les Ruchots, Clos de la Bussière (monopole of Domaine G Roumier), Les Millandes, Clos des Ormes, and Les Monts Luisants. Domaine Ponsot also produces a rare and curious white wine from the last, based on a plot of ALIGOTÉ planted in 1911.

See also CÔTE D'OR. J.T.C.M.

Morgon, historically the most prominent cru in BEAUJOLAIS, encompassing about 1,100 ha/2,717 acres of vines around the commune of Villié-Morgon. The wines from the ex-VOLCANIC cone known as Côte de Py are the most reputed, although those of Grand Cras and Douby play important, if different, roles. Classic Morgon soil is the degraded 'blue stone' SCHIST found on Py, but other schists and shallow GRANITE sands also appear. The wines can be denser and longer lived than many cru Beaujolais, depending on the parcel, and the appellation has even been used as a verb, as in describing the process by which a young Beaujolais channels a Pinot Noir-dominated red burgundy with age: *il morgonne*. Villié-Morgon has been home to some of the region's well-known provocateurs, including Marcel Lapierre and Guy Breton. J.F.B.

Morillon is an old north-eastern French name for PINOT NOIR and is still a common name for the powerfully aromatic CHARDONNAY of STYRIA in southern Austria. It was a widely used Burgundian vine variety name in the Middle Ages and was, for example, an old name for Chardonnay in CHABLIS country.

Morio-Muskat was once Germany's most popular MUSCAT-like vine variety, particularly with the eager blenders of the PFALZ and RHEINHESSEN in the late 1970s, when its total German area reached 3,000 ha/7,410 acres and demand for LIEBFRAUMILCH was high. Total plantings are falling fast, however, and Germany had only 333 ha by 2020 as this aggressively blowsy cross has undoubtedly had its day. Although Peter Morio's cross was introduced as SILVANER × WEISSBURGUNDER, DNA PROFILING has shown it to be Silvaner × MUSCAT BLANC À PETITS GRAINS, explaining both its name and its grapey flavour.

Moristel, light, loganberry-flavoured speciality of SOMONTANO in northern Spain, also known as Juan Ibáñez. The light red wine produced oxidizes easily (see OXIDATION). It may be better in a blend than as a VARIETAL.

Mornington Peninsula, MARITIME, cool-climate wine region south-east of Melbourne in the Australian state of VICTORIA with 80-odd producers in 2021. Site climate varies widely across this long east–west peninsula, and the differences are notably apparent in the varied styles of its wines, particularly Chardonnay and Pinot Noir.

Morocco , with its high mountains and cooling Atlantic influence, has arguably the greatest potential for producing high-quality wine in North Africa. Viticulture, which existed in the Roman era, was probably introduced by Phoenician settlers. But it was the French colonists who brought large-scale wine production, so that Morocco played a significant part in the world's wine trade in the 1950s and 1960s, although it never produced as much as neighbouring ALGERIA. At independence in 1956, Morocco had 55,000 ha/135,850 acres of carefully husbanded vineyard. With the departing French colonists went winemaking expertise, capital, and a large proportion of domestic consumption. This was compounded in 1967 by new EEC (now EU) quotas which literally decimated Morocco's exports. Frozen

out of European markets and faced with stiff competition from other over-producing Mediterranean countries, most producers GRUBBED UP their vineyards and replaced them with cereal crops. Between 1973 and 1984 most vineyards were taken over by the state, which by 1984 had also established a firm grip on the sale of wine, including grape price-fixing regardless of quality.

By the early 1990s, only about 13,000 ha of the nation's 40,000 ha of vines were planted with wine vines, over half of them, many virused, 30 years old or more and therefore economically unproductive. Average yields were well under 30 hl/ha (1.7 tons/acre). The state had a virtual monopoly on the domestic market. The only independent producer to prosper in this post-colonial climate was Brahim Zniber, head of North African wine giant Les Celliers de Meknès and also owner of its main domestic competitor, Thalvin/Domaine Ouled Thaleb. Zniber, who bought his first vineyards from departing French producers in the 1950s and started bottling wines in 1976, encouraged the introduction of a CONTROLLED APPELLATION system and pioneered VARIETAL wines.

In a bid to revive Morocco's rural economy, the late King Hassan II successfully attracted foreign investment in viticulture during the 1990s. Several large Bordeaux groups, including CASTEL, William Pitters, and Taillan, took up the offer of long leases on prime vineyard land from the state holding company SODEA. This policy of seeking inward investment, continued by King Mohammed VI, had a galvanizing effect on the industry from the mid 1990s, and thousands of hectares were replanted with better-quality grape varieties.

Historically CARIGNAN dominated Moroccano's vineyards, but CINSAUT is now the country's most planted variety, with Grenache and Syrah gaining ground. Cabernet Sauvignon and Merlot are also popular. Well over 77% of Moroccan wine is red. Rosé and VIN GRIS account for another 16%. What little white is made tends to be heavy versions of CLAIRETTE and MUSCAT, although there are laudable exceptions, such as the ROUSSANNE of Domaine Val d'Argan, a pioneer

in the ORGANIC VITICULTURE movement on the southern coast near Essaouira.

Most vine-growing, however, is concentrated in the north, where the Atlas Mountains and the Atlantic Ocean create cool MESOCLIMATES in a country otherwise largely described as having a semi-arid MEDITERRANEAN CLIMATE. Even so, summer temperatures can reach 35–38 °C/95–100 °F; rainfall between May and October is very low; and DROUGHT cycles and SUNBURN are worsening due to CLIMATE CHANGE. The prevailing WINDS from the Atlantic, which can blow at up to 65 km/40 miles per hour, can also be challenging. Vine TRELLISING and careful row orientation have become more common, and all the major producers now practise DRIP IRRIGATION.

Morocco's appellation system, closely modelled on the French AOC, is called Appellation d'Origine Garantie. AOG rules delimit the geographical area of production and set maximum YIELDS but do not dictate grape varieties. The system, which has yet to achieve any real significance in terms of guaranteeing quality, includes 14 AOG zones, most in the country's cooler, fertile north:

The East: Beni Sadden, Berkane, Angad
Meknès/Fès region: Guerrouane, Beni M'tir, Saiss, Zerhoune
The Northern Plain: Gharb
Rabat/Casablanca region: Chellah, Zemmour, Zaër, Zenata Sahel Sahel
El-Jadida region: Doukkala

Of these regions, Meknès is the centre of Moroccan viticulture. Here in the Middle Atlas, at an ELEVATION of around 600 m/1,968 ft, the vines benefit from moderate rainfall, abundant sunshine, and a mix of SANDY and CLAY and LIMESTONE soils. Domaine de la Zouina, established in 2002 by Bordelais winegrowers Gérard Gribelin and Philippe Gervoson, leads the way.

There are also vast new plantings around Benslimane, outside of Casablanca, and Beni Mellal, north-west of Marrakech, including

grapes such as ARINARNOA, MALBEC, MARSELAN, TANNAT, TEMPRANILLO, and VERMENTINO.

Morocco also has three AOCs. Coteaux de l'Atlas covers the clay–limestone terroir at the foot of the Atlas Mountains. At 700 m/2,297 ft in elevation, its climate is mild and sunny. Chardonnay is the only variety permitted for white wines; reds can be made from Cabernet Sauvignon, Cabernet Franc, Syrah, and Merlot. Crémant de L'Atlas is reserved for TRADITIONAL METHOD sparkling wines from Chardonnay. Côtes de Rommani is located south of the Coteaux de l'Atlas, in the Zaër highlands. Domaine la Ferme Rouge is the sole producer, its 300 ha/741 acres of vines growing on sunny hillsides of clay and limestone at an elevation of almost 450 m/1,476 ft. The AOC authorizes the cultivation of 16 grape varieties with an average yield of 60 hcl/ha.

By 2020, Morocco's wine production remained modest, with an annual output of around 600,000 hl, although the local market is buoyed by strong demand from the tourist industry and the country's affluent urban elite, as well as by the high duties on imported wines. Moroccan law prohibits the sale of alcohol to Muslims, but in practice the law is seldom if ever applied. Alcohol is freely available in all the main cities outside the holy month of Ramadan. Not everyone approves of this permissive approach—least of all Morocco's growing ISLAMIST movement, which seeks to ban or limit alcohol consumption.

See also CORKS, of which Morocco is the world's third largest producer, after Portugal and Spain. J.R. & R.Z.

Joy, R., *A Survey of Moroccan Wine* (2003).

morphology. See VINE MORPHOLOGY.

Morrastel is the main French synonym for Rioja's GRACIANO. Morrastel-Bouschet is a much lesser CROSS that produced substantial quantities of notably deep red wine in France's LANGUEDOC in the mid 20th century.

Mortágua , confusing western Portuguese red wine grape synonym with multiple meanings: for CAMARATE in Arruda, for TRINCADEIRA in Torres Vedras, and, occasionally in Dão and Setúbal, for TOURIGA NACIONAL.

Moscadello, sometimes Moscadelleto, name for the MUSCAT BLANC À PETITS GRAINS grown in and around MONTALCINO in central Italy. Moscadello was the major wine of Montalcino for centuries, being cited by English travellers in the 17th and 18th centuries, long before anyone even noted the presence of important reds. The firm Villa Banfi made an important investment in selling this sweet grapey, fizzy white wine in the 1980s, hoping to repeat the commercial success of LAMBRUSCO, but to little avail.

Moscatel, Spanish and Portuguese for MUSCAT. The term may be applied to both grape varieties and wines. Thus Moscatel de Grano Menudo is none other than MUSCAT BLANC À PETITS GRAINS, while Moscatel de Alejandría, Moscatel de Málaga, and Moscatel Romano are MUSCAT OF ALEXANDRIA. Moscatel Rosado, on the other hand, may be a South American speciality (see below). Most of the vines known simply as Moscatel in Spanish- and Portuguese-speaking countries are Muscat of Alexandria, although northern Spain has some of the superior small-seeded variety.

Inexpensive wines labelled Moscatel abound in Iberia and are in general sweet and grapey.

See also Moscatel de SETÚBAL.

Moscatel de Alejandría, Spanish name for MUSCAT OF ALEXANDRIA.

Moscatel de Austria, grape variety grown on more than 1,700 ha/4,200 acres in Chile but used mostly in the production of the

national aromatic brandy PISCO. Identical to Argentina's TORRONTÉS Sanjuanino.

Moscato, Italian for MUSCAT and the name of a sweetish VARIETAL wine style for which there was a FASHION in certain quarters towards the end of the first decade of the 21st century (see ASTI for details), which resulted in an increase in plantings of Muscat even in California. The Italian vine census of 2010 identified seven different Moscatos. Moscato Bianco is the finest Muscat grape variety MUSCAT BLANC À PETITS GRAINS and is that most commonly encountered in Italy, with total plantings of 13,334 ha/32,949 acres in 2015, making it one of the country's most planted white wine grapes, cited in almost 20 DOCs. This is the Moscato responsible for all the light, usually sweet and sparkling wines of Asti and MOSCATO D'ASTI. Moscato Rosa del Trentino is a very much rarer red-skinned grape found in TRENTINO and ALTO ADIGE, often called Rosenmuskateller. The golden-berried Moscato Giallo (Goldmuskateller) is more widely planted, on 1,108 ha/2,738 acres in 2015, and has a parent–offspring relationship with Moscato Bianco. Moscato di Terracina is a recently revived aromatic white grown in Lazio. Moscato di Scanzo is a dark-berried speciality of Bergamo which makes small quantities of decadently aromatic, sweet PASSITO reds. Moscato Nero di Acqui is a synonym for MUSCAT OF HAMBURG.

Few of Italy's regions lack their own Moscato-based wines. The majority of these are low in alcohol and at least lightly sweet, ideal accompaniments to fruit and fruit-based desserts. In the south and, especially, the islands, they are typically golden and sweet.

SICILY, and southern Italy more generally, was once renowned for its Moscato wines, many of them made from MUSCAT OF ALEXANDRIA, more commonly known as ZIBIBBO in Italy. The revived popularity of Moscato di PANTELLERIA in the 1980s coincided with, and perhaps influenced, new attempts to achieve a more luscious style of Moscato in Piemonte, and a new category of passito wines, far sweeter than

Moscato d'Asti and frequently given BARREL AGEING, began to emerge in the late 1980s. Small quantities of Moscato passito have long been made in the Valle d'AOSTA, principally near the township of Chambave.

Moscato d'Asti, fragrant and lightly sweet, gently fizzy DOCG wine made in the PIEMONTE region of north-west Italy. It is produced from MOSCATO Bianco, Italy's name for MUSCAT BLANC À PETITS GRAINS, whose production in and around the town of ASTI increased enormously in the 20th and early 21st centuries. Canelli, where in 1865 Carlo Gancia produced the first sparkling Moscato and where the historic underground cellars now have UNESCO World Heritage status, is considered the cradle of Moscato in Piemonte. At the end of the 19th century, almost 80% of all Moscato was grown in the CALCAREOUS soils in the triangle formed by Castiglione Tinella, Canelli, and Santo Stefano Belbo, still considered the classic zones for fine Moscato, although expansion of the zone has revealed a real vocation for Moscato on the slopes of Cossano Belbo, Mango, Neviglie, and Trezzo Tinella. Moscato d'Asti is therefore something of a misnomer, since much of the production is not in the province of Asti but in the province of Cuneo (stretching as far as Serralunga Alba in the eastern part of the BAROLO zone), and a significant proportion is in the province of Alessandria.

As a wine, Moscato d'Asti is often lumped together with ASTI, although the two are discernibly different. With a maximum of 2 atmospheres of pressure in the bottle—less than one-third that of Asti—Moscato d'Asti is only slightly frothy, while Asti is fully sparkling. Its ALCOHOLIC STRENGTH is considerably lower (maximum 6.5% as opposed to Asti's 6.5–11%), and Asti can taste sweeter than the more flavourful Moscato d'Asti, even if its RESIDUAL SUGAR is usually slightly lower.

The ripest, and best, MOSCATO grapes are used to produce Moscato d'Asti. The 'wine' is classed as 'partially fermented grape must', for the juice is chilled and filtered immediately after pressing and fermented only when required, ensuring that Moscato's beguiling

aromas are not lost. Fermentation is stopped when the wine reaches 5.5% alcohol; the unfermented sugar lends a hedonistic grapey character to the wine and helps to exalt the Moscato's heady perfumes.

Within the Asti DOCG there are two subzones, Santa Maria d'Alba and Strevi, in which only Moscato d'Asti and not Asti Spumante can be produced. Both decree 100% Moscato, lower yields of 9 tons/ha, and 11% minumum potential potential alcohol. (Confusingly, Strevi is also a DOC for a still sweet wine made of LATE HARVEST or dried Moscato grapes).

Moscato d'Asti is not a classic dessert wine, its chief virtues being delicacy, intense aromas, and a sweetness that is as much suggested as forthrightly declared. Moscato d'Asti Vendemmia Tardiva, in contrast, is a full-blown, still, sweet DRIED-GRAPE WINE.

Moscato d'Asti production may have grown enormously but is less than Asti's (33 million bottles compared to 50 million bottles of Asti). It is a classic and unusually refreshing expression of one of the world's most popular grape varieties, even if wines with residual sweetness are considered out of fashion. In an effort to halt Moscato d'Asti's slow decline, a group of young Asti producers specializing in dry Moscato has registered the brand 'EsCamotage' to promote their dry wines. W.S.

www.astidocg.info

Moscato di Sardegna, relatively new (1979) DOC in SARDINIA for sweet, still or sparkling white wines made in the image of MOSCATI D'ASTI.

Moscato di Scanzo, or Scanzo, is a DOCG from the area east of Bergamo in LOMBARDY for an increasingly rare, sweet PASSITO of the dark-berried MOSCATO di Scanzo. The grapes must be dried for at least

21 days or until a minimum of 280g/l of RESIDUAL SUGAR has been obtained. By law the wine must be aged for at least two years. W.S.

Moscato di Strevi. See STREVI.

Moscato Spumante, often the simplest form of light, sparkling Italian white wine made in the style of ASTI but usually with the most basic, industrial ingredients. Not to be confused with the infinitely superior MOSCATO D'ASTI, nor with METODO CLASSICO versions.

Moschofilero, vine variety with deep pink-skinned grapes used to make strongly perfumed, delicate white wine in GREECE, particularly on the high plateau of Mantinia in the Peloponnese, where conditions are sufficiently cool that harvest is often delayed until well into October and alcohol levels are typically low. There are strong flavour similarities with fine MUSCAT, but the origins of this distinct vine variety are as yet obscure. Smaller quantities of fruity light-pink wine are also made from this spicy variety, which is also increasingly used for sparkling wines. So popular has it become that Greece had 1,220 ha/3,015 acres planted by 2021.

Mosel, formerly known as Mosel-Saar-Ruwer, is a major German growing region famed for RIESLING (62% of vine share), the best examples being long-lived, delicate, and dynamic, including some of the world's finest sweet wines. The total area planted, at 8,744 ha/21,607 acres in 2019, has been declining slowly and, except in the best-known vineyards, Riesling grapes command a price that only just covers the costs of farming the generally steep, stony, sheer slopes with their densely planted and often archaically trained vines. (See GERMANY, viticulture.)

As the River Mosel twists from Trier to Koblenz, the vineyards are at their steepest on the outer edge of the curve. Those on the flatter inner edge are frequently planted with varieties other than Riesling.

TOPOGRAPHY is all important here, but SOIL, too, is critical. An overwhelming majority of top Mosel, Saar, or Ruwer sites is dominated by Devonian SLATE, which has been used in the region for hundreds of years as a building material and has traditionally been renewed, redistributed, or added to vineyards to promote heat retention. Some of the vineyards between the almost vertical spurs of rock were created in the 16th century with the aid of explosives, a dangerous operation when there was a wine village below. Vineyards have been subjected to the wholesale renovation (known as FLURBEREINIGUNG) later and to a lesser extent than those of most other German regions, the principle obstacle being sheer steepness and difficulty of access to the slopes for earth-moving equipment. Vineyards associated with some of the Mosel's most important villages also proved resistant to the late 19th and early 20th century ravages of PHYLLOXERA, and a few productive stands of vines still date to the 19th century. In those places where phylloxera never penetrated, many vines are UNGRAFTED, and, until the new outbreaks of phylloxera in the early 21st century, could be replanted without grafting, a dwindling but arguably precious legacy.

The Mosel traditionally enjoys a warm summer with an average temperature in July of 18 °C/64 °F, but summer temperatures in the upper 30s °C are no longer a rarity. Today, autumn or winter FROST DAMAGE is rare, but spring frost has become more dangerous due to progressively earlier BUDBREAK. Nights cold enough for EISWEIN production are no longer a given and come increasingly late in the year, while marauding wild boar remain a major impediment to that genre, with a reputation for Christmas or New Year's feasting on any grapes still left hanging.

In the 18th century, many villages produced red wine (see GERMAN HISTORY). By the early 19th century, white wine dominated, and the ELBLING vine was planted on nearly two-thirds of the Mosel vineyard area, but Riesling had become the touchstone of quality. Riesling's prevalence peaked in 1954 with a 90% share of Mosel vineyards before succumbing to the allure of more easily ripened HYBRIDS and,

for a decade from the late 1990s, to that of DORNFELDER, in response to increased domestic demand for red wine. None of these non-Rieslings excel, although tiny pockets of SPÄTBURGUNDER (Pinot Noir) and WEISSBURGUNDER (Pinot Blanc) do.

A key to a fine Mosel Riesling is enlivening acidity (especially TARTARIC ACID), which balances any RESIDUAL SUGAR present, along with a frequent if vague impression of wet stone. A low-alcohol Mosel Riesling often tastes merely off-dry even when it has 20–30 g/l residual sugar. TROCKEN wine is increasingly common, representing a return to dryness such as characterized Mosel Riesling when it achieved international acclaim in the late 19th century, albeit in an era with later growing seasons and lower MUST weights than today's. As a result some dry Mosel Rieslings may be 13% or more natural alcohol, but the quintessential Mosel remains for many non-Germans a delicate (7–9% alcohol) Riesling that is fresh and subtly sweet yet invigorating. Only a minority of Mosel growers (notably along the Saar) seriously pursue the goal of non-trocken but far-from-sweet Riesling. (Throughout Germany, most prominent growers have given up on HALBTROCKEN as a concept.) Yet, at levels of residual sugar hardly detectable as such, ravishing dry-tasting Mosel Riesling of 10–12% alcohol is possible.

Processing close to one-fifth of its region's fruit and half of that Riesling makes Moselland CO-OPERATIVE in Bernkastel the world's largest producer of Riesling. Much of the rest—especially from grapes other than Riesling—is bottled by merchant houses. But although the standing of Mosel wine in Germany was debased in the late 20th century by over-production and price warfare, not to mention by the legal adoption of names of famous villages and vineyards to designate GROSSLAGEN, the small upper tier of estate-bottled wine has guaranteed Mosel Riesling a high profile and devoted following abroad, which has affected the German market as well.

Geography

The Lower Mosel, also known as Terrassen Mosel, boasts the highest percentage of Riesling vines in the Mosel, if only a minority of its top sites. Curving downstream from Zell to the confluence of the Rhine and Mosel at Koblenz, it incorporates many small, steep vineyards whose terraces often date back centuries and which can be maintained only by hand. Monorails have been installed in many places to ease access. Labour intensity as well as the susceptibility of these sheer rocky slopes to DROUGHT have historically put this subregion at a commercial disadvantage relative to its neighbours upstream. Variations on Devonian slate, frequently rich in QUARTZITE, dominate the soils, though SANDSTONE and occasionally CALCAREOUS rock put in appearances. The precipitous walls of slate outside Koblenz at Winningen—most notably the Uhlen and Röttgen vineyards—are regaining a reputation for high ripeness and excellence that was essentially forgotten for nearly a century, a revival led by the Heymann-Löwenstein estate. Upriver from Winningen, in Kobern, Gondorf, Lehmen, Kattenes, and Hatzenport, several estates are demonstrating Riesling's delicious potential. Numerous villages above and below Cochem still harbour significant Riesling plantings, although their wines are scarcely recognized by name even inside Germany. At Bremm, the terraced Calmont rises 200 m/656 ft from the river. With a 65% incline, it is one of the world's steepest vineyards and, like sites immediately upstream in Neef, St Aldegrund, and Alf, its potential is being demonstrated and its vine presence hanging on for dear life thanks to a few intrepid growers able to access their vineyards using sure, stout feet and hair-raising monorails.

Of perhaps 100 EINZELLAGEN with outstanding potential in the Mosel, over half are in the Middle Mosel, which extends upstream from Pünderich with its complex, slatey, crenulated Marienburg, a long, steep wall accessed by boat from the village. A roster of towns and their top sites, nearly all dominated by Devonian slate, includes Enkirch (Batterieberg, Ellergrub, Steffensberg, Zeppwingert), Wolf

(Goldgrube), Kröv (a different Steffensberg), and Kinheim (Hubertuslay, Rosenberg). Along the bow of the Mosel between Enkrich and Wolf is the traditionally important merchant base and winegrowing centre of Traben-Trarbach, some of whose once-renowned sites (notably Traben's Gaispfad and Zollturm) cling to the Mosel's right bank. Others (Hühnerberg, Ungsberg, Schlossberg), happily subject to some ambitious recent reclamation, hug the steep, narrow valley of the Kautenbach as it rushes down to meet the Mosel at Trarbach. The red slate of Erden (Treppchen and Prälat) generates some of the Mosel's most celebrated Rieslings, with a prominent citrus and green herb character, and the potential of adjacent Lösnicher Försterlay has recently been demonstrated by prolific winegrower Ernst Loosen (Weingut Dr. Loosen). Neighbouring Ürzig, where virtually all of the top vineyards are united under the name Würzgarten, gives the best Erdeners a run for their money with frequently spicy and strawberry- or kiwi-scented Rieslings from diverse soils prominently including iron-rich, finely eroded Permian sandstone unique in the Mosel.

Below Ürzig the Mosel inscribes one of its periodic tight turns and then enters a straight stretch whose south-facing slopes enjoy international fame—Zeltingen (Himmelreich, Schlossberg, Sonnenuhr), Wehlen (Sonnenuhr), Graach (Himmelreich, Domprobst), and Bernkastel, renowned for its Doctor vineyard—but whose wines from other vineyard sites, including Graben and Lay, are more often labelled for the GROSSLAGE Badstube. Apple, citrus, vanilla, and nut-oil notes typify many of the wines from these sites, as well as, in the case of Bernkastel, a characteristic black-cherry note.

After another twist, the river flows past Lieser (Niederberg Helden) and a side valley at Mühlheim (Sonnenlay) and Veldenz (Elisenberg, Grafschafter Sonnenberg), all three towns getting well-deserved recent exposure in the hands of talented winegrowers. Next comes Brauneberg (Juffer, Juffer Sonnenuhr), whose unusually well-watered walls of south-east–facing slate enjoyed an eminent position in the Mosel pecking order throughout the 19th century. The late 20th century revival of their reputation for stunningly rich yet refined Rieslings (and, indeed, of the reputation of Mosel Riesling as a whole)

owes much to the viticultural and promotional labours of Wilhelm Haag (1937– 2013), proprietor of Weingut Fritz Haag and president of the VDP-Mosel from 1984 to 2004. Kesten (Paulinsberg, Paulinshofberg) and Wintrich (Geierslay, Ohligsberg) are also producing impressive Rieslings.

Astride a tight loop in the Mosel hang the amphitheatrical slopes of Piesport, whose Goldtröpfchen site is among the region's best and internationally best-known (although the adjacent Domherr, Grafenberg, Kreuzwingert, and Schubertslay have first-rate potential as well). Tropical and black fruit flavours characterize the best Piesport wines, but this village's name has been tarnished by mass volumes of mediocre wine labelled with the intentionally deceptive GROSSLAGE designation Piesporter Michelsberg. The clay- and iron-rich slate of Dhron, deployed along a tiny, eponymous tributary of the Mosel, is re-establishing a reputation for longevity and distinctive complexity that Riesling labelled Dhroner Hofberger commanded through the mid-20th century. One of the Mosel's narrowest switchbacks and most vertiginous walls of blue slate occurs upstream from Piesport at Trittenheim (Altärchen, Apotheke) and neighbouring Leiwen (Laurentiuslay), wines from the former being characteristically richer and from the latter sleeker and more distinctly mineral. Thanks to a bevy of winegrowing talents, the reputation of these sites is itself now steeply ascendant. Upstream, Thörnich (Ritsch), Detzem (Maximiner Klosterlay), and Pölich (Held) offer in the hands of a few winegrowers glimpses of superb potential. The same is true of vineyards just below Trier at Longuich (Herrenberg, Maximiner Herrenberg), where the abbey of St Maximin, arguably the pre-eminent medieval viticultural institution of the Mosel, established its main press house and planted a forest that has served successfully as a hail shield for five centuries. Some sites just below Longuich at Mehring (Blattenberg, Zellerberg) have potential, although their high CLAY component tends to result in a broader, less dynamic style of Riesling. Numerous historically prestigious sites in Trier are also being revived.

The Mosel tributaries Saar and Ruwer make up a mere 11% of the official Mosel growing region, but their reputation is out of proportion to their surface area. The higher elevation of their vineyards as well as the Saar's predominance of wind-open side valleys make for generally cooler conditions than in the Middle Mosel, and wine from these subregions traditionally derived its renown from brightness, animation, and clarity, preserved even in rich and BOTRYTIZED sweet wines. The traditional handicap was how often Riesling simply failed to adequately ripen, but there have been at most three vintages since 1987 that could be described in those terms.

The Ruwer vineyards begin at Eitelsbach and Mertesdorf and end barely 8 km/5 miles upstream. A long legacy of high quality combined with MONOPOLE vineyard status has made Eitelsbach's Karthäuserhofberg and Mertesdorf's Maximin Grünhaus (with its famed Abtsberg and Herrenberg vineyards) the Ruwer's best-known estates outside Germany, but Kasel, immediately upstream, boasts excellence and historical renown (from Nies'chen and Kehrnagel), while the potential of higher, cooler sites at Waldrach is being rediscovered. The Ruwer vineyards, dominated by grey and red slate, tend to promote flavours of red fruits, pungent green herbs, and brown spices.

Travelling upstream from the Saar's confluence with the Mosel near Trier comes a hairpin turn with outstanding vineyards along its right bank at Filzen and Kanzem, the latter's Altenberg among the Mosel's finest sites. Across the river at Wawern, the Herrenberg and Goldberg—perpendicular to the river—are being revived. The Saar straightens to north–south orientation just upstream from Kanzem at Wiltingen, whose Braune Kupp, Gottesfuss, Kupp, and Hölle are all first-rate. But Wiltingen's towering Scharzhofberg—its fame nowadays rightly associated with the superb custodianship of successive Egon Müllers, and for centuries cited as one of the Mosel-area's greatest vineyards—does not lie along the Saar. Rather, with the neighbouring Braunfels, it faces south at the edge of an ancient bed of that river (or perhaps of the Mosel itself), which inscribes a roughly 10-km eastward crescent of important vineyards—some revived since the

late 20th century, some still neglected—at Oberemmel (Agritiusberg, Hütte, Raul), Krettnach (Altenberg, Euchariusberg), Niedermennig (Herrenberg, Sonnenberg), and Falkenstein (Hofberg). Upstream from Wiltingen come Ayl (Kupp), Schoden (Herrenberg), and Ockfen (Bockstein). In a side valley, Geisberg—a site long deemed second only to Scharzhofberger and Bockstein—was reclaimed from scrub in 2015–17 by Weingut Van Volxem.

The EINZELLAGE Ayler Kupp is so large and heterogeneous that only recent registration of various cadastral designations has permitted labels to reflect a useful degree of specificity, while steep, elongated, uniquely cobbled, riverside Saarfeilser Marienberg straddles three communes, with consequently diverse labelling. Saarburg's dominant Rausch vineyard is another geological anomaly, for incorporating diabase as well as slate. Furthest upstream of the Saar's vineyards are those of Serrig (Herrenberg, Schloss Saarsteiner, Würtzberg) and, across the River Kastel, the tiny Maximiner Prälat, once among the gems of the medieval St Maximin abbey's necklace of vineyards, condemned in the early 21st century by its steepness and poor access to largely return to scrub.

Parallel to the vineyards along the Saar are those of the Upper Mosel, which hug that river's right bank above Trier. Here the Elbling grape dominates (with close to 500 ha/1,236 acres); Riesling is rare; and the soils are calcareous, like those in the adjacent left bank Moselle vineyards of LUXEMBOURG, whose prevalent AUXERROIS, PINOT GRIS, and PINOT BLANC are also planted on these German shores, along with Chardonnay that has recently displayed serious potential.

Carlberg, L., *Mosel Wine* (2022)

Pigott, S., *Wein Spricht Deutsch: Weine, Winzer, Weinlandschaften* (2007).

Reinhardt, S., *The Finest Wines of Germany* (2012).

Steinberg, E., *Understanding Mosel Wines* (2012).

Moselle, French name for the river known in German as MOSEL which rises in the Vosges Mountains of France, forms the border between LUXEMBOURG (in which it plays a key part in wine production) and Germany, and joins the River Rhine at Koblenz in Germany, 545 km/340 miles later.

In the far north of France, the Moselle AOC, with Côtes de TOUL, constitutes what the French call their *vins de Lorraine*, the last remnants of what was once an important and flourishing Lorraine wine industry. Extensive vineyards around Metz supplied PINOT NOIR grapes to Champagne in the 19th century, and Sparkling Moselle was a popular partner to Sparkling HOCK. After the region became German following the Franco-Prussian war of 1870, it provided base wine for SEKT. PHYLLOXERA did not arrive until 1910, but the poor-quality HYBRIDS chosen for replanting, together with industrialization (see RAILWAYS), the proximity of the First World War battlefields, and the end of the German outlet for the wines, hastened the decline of this wine region. Reduced to 10 ha in 1983, the vineyard is slowly recovering, reaching in 2021 almost 80 ha/198 acres and growing, as CLIMATE CHANGE has brought more warmth to this cool CONTINENTAL region, making it easier to achieve full grape RIPENESS. Today AUXERROIS, PINOT GRIS, and MÜLLER-THURGAU are the most common vine varieties; Pinot Blanc, Gewurztraminer, and Riesling are also permitted. Reds must be made entirely of Pinot Noir; rosés may incorporate GAMAY.

As a result of the success of some German wines in the English-speaking world, Moselle became a GENERIC name for any light, medium-dry, faintly aromatic wine.

Mosel-Saar-Ruwer, from 1971 to 2007 the official name, incorporating the names of two major tributaries, that appeared on all labels of wine from the German growing region now known simply as MOSEL.

mother vine, an identified, preferred individual vine from which CUTTINGS or other vegetative propagation materials are taken. They are normally the consequence of CLONAL SELECTION and VINE improvement programmes. Such vines, including fruiting varieties and ROOTSTOCKS, are certified only if they have been tested for VIRUS DISEASES. The manager of the mother vines must be on guard for changes in mother-vine disease status, due to insect-vectored virus diseases or fungal infection in pruning wounds leading to TRUNK DISEASE, for example. The latter is the common explanation for the continuing spread of trunk diseases by BENCH GRAFTING. R.E.S.

moths, the larval stages of one or several small leafroller (tortricid) moth species, damage grapes in almost all winegrowing regions of the world. Despite the name, most of these species do not 'roll leaves' but mainly feed on flowers and fruit, resulting in yield reductions of up to 10%, often multiplied by secondary infections. In Europe the main species are the European grapevine moth (*Lobesia botrana*), also known as eudemis, and the vine moth (*Eupoecilia ambiguella*), also known as cochylis, with occasional outbreaks of the grape tortrix (*Argyrotaenia ljungiana*) and the long palped tortrix (*Sparganothis pilleriana*); in North America the grape berry moth (*Paralobesia viteana*), the orange tortrix moth (*Argyrotaenia citrana*), and the omnivorous leafroller (*Platynota stultana*), which does form the leaf into a roll, restricting the exposed leaf surface; and in Australia the light brown apple moth (*Epiphyas postvittana*) and in New Zealand the grapevine moth (*Phalaenoides glycine*). Most of these species can also develop on other (wild) host plants around the vineyard and transfer to the vines.

These species generally have several generations per season, the first generation attacking flowering stages or leaves and later generations the fruit stage. The larval feeding causes little direct damage, but feeding punctures in berries can increase the risk of BOTRYTIS BUNCH ROT or other infections, including several fungi of the genus *Aspergillus* that can produce a mycotoxin (OCHRATOXIN A).

Accidental introductions of several of these species have occurred worldwide, even in the recent past: European grapevine moth to Japan, Chile, Argentina, and California (2009, Napa Valley, eradicated 2014); light brown apple moth to North America (2007), Hawaii, and New Zealand.

A few other species of moths (Tortricidae but also from the Sphingidae, Pyralidae, Zygaenidae, and Noctuidae families) that mainly feed on the leaves or buds can be found in vineyards, but these are generally considered of minor importance.

Leafroller damage is very variable depending on the climate, seasonal weather, surrounding landscape (other vineyards and vegetation), and control by different natural enemies such as parasitic wasps (egg parasitoids and pupal parasitoids) and flies and predatory lacewings, BEETLES, true bugs (hemiptera), spiders, harvestmen (daddy longlegs), bats, etc.

Monitoring of these pests is a key factor for successful INTEGRATED PEST MANAGEMENT. Adults are generally monitored using PHEROMONE or food traps; eggs and larvae can be counted. Long-running area-wide surveillance networks such as in the St-Émilion region of France (SEE WEB LINKS www.gdon-libournais.fr) are very successful in monitoring risks, determining observation periods, and improving sustainable management.

Intervention thresholds are very difficult to establish because of the risk of secondary infection (botrytis) and the influence of climatic conditions on both all insect stages and the associated secondary fungal infections.

When population levels are high enough to require control, the measures are mainly based on mating disruption or insecticides (see PESTICIDES). In ORGANIC VITICULTURE, disrupting mating as well as organic pesticides such as BT (*Bacillus thuringiensis*) allow sufficient control if applied at the right developmental stage, between egg-hatching and the caterpillars entering the berries. Attempts at biological control using natural enemies such as egg parasitoids have been largely unsuccessful. The use of the sterile insect technique to

eradicate incursions in new areas is being studied, but mass rearing of tortricid is difficult.

See also BEETLES for a European insect which causes leaf rolling.

Moueix, important family in the BORDEAUX TRADE, notably, but by no means exclusively, in ST-ÉMILION and POMEROL. The Moueix family came from the Corrèze, a severe district in central France, noted for its hard-headed men. Jean Moueix (1882–1957) bought Ch Fonroque in St-Émilion in 1930, and his son Jean-Pierre (1913–2003) joined him that year, with the purpose of selling only the hitherto somewhat neglected wines, nearly all red, produced on the RIGHT BANK of the Dordogne, from the Côtes de CASTILLON downstream to BLAYE. In 1937, Jean-Pierre formed Établissements Jean-Pierre Moueix on the quay in LIBOURNE. Increasingly successful in the post-war period, it became from 1970 the major NÉGOCIANT there selling the finer châteaux wines, at a time when the traditional merchants were failing.

In 1956, the 70-year-old firm of Duclot in the city of Bordeaux was acquired to deal mainly with the 'left bank' districts (MÉDOC, GRAVES, etc.), as well as selling direct to private customers in France. As Duclot Export it is prominent in the export trade. From 1968 Duclot has been headed by Jean-Pierre's elder son Jean-François (b. 1945), now aided substantially by his son Jean (b. 1987).

In 1970, the younger son, Christian (b. 1946), became a director of J. P. Moueix, with special responsibilities, along with the firm's OENOLOGIST Jean-Claude Berrouet, for the 17 estates owned or farmed by the firm. In 1982 Christian started a JOINT VENTURE in

Yountville, NAPA Valley, with two daughters of John Daniel, former owner of Inglenook, before buying them out in 1994. From a 50-ha/124-acre vineyard and an architectural landmark winery opened in 1998, a Bordeaux-style wine named Dominus is produced. He now runs the Libourne négociant with his son Edouard, who lives in what was Ch Belair in St-Émilion and is now Bélair-Monange, incorporating the vines of Magdelaine next door.

In the 1950s, Jean-Pierre Moueix began to acquire châteaux on the right bank: La Fleur-Pétrus (1950 and now much expanded), Trotanoy (1953), Lagrange (1953), La Grave (Trigant de Boisset) (1971), and Certan-Giraud, renamed Hosanna (1999), in Pomerol; and Magdelaine (1952) in St-Émilion.

In the 1970s and 1980s, the firm expanded into FRONSAC, acquiring Canon, Canon de Brem, La Croix-Canon, and Canon-Moueix in the superior Canon-Fronsac appellation and La Dauphine in Fronsac. These properties were sold en masse in 2000.

A number of other properties are farmed on behalf of their owners, including Chx Lafleur-Gazin, farmed since 1976 and purchased in 2021, and Latour-Pomerol in Pomerol. However, much the most important acquisition was a half-share of PETRUS in 1964. Jean-François Moueix and his children now own it all.

Jean-Pierre Moueix, a man of great probity and courtesy, was a notable collector of art and books, and the château in which he lived beside the river Dordogne on the edge of Libourne was once full of the works of such leading modern artists as Picasso and Francis Bacon, some of them fetching record prices at auction after his demise. E.P.-R. & J.R.

mouldy, pejorative tasting term to describe an aroma or flavour that permeates a wine and reduces the fruity, fresh character. The most common source of the mouldy flavour is disease-infected fruit that has not been properly sorted or treated during processing to remove such flavour. See ROT, FUNGAL DISEASES.

Another source of mouldy character is COOPERAGE. When barrels are left empty, it is important to preserve them from mould growth or bacterial spoilage. Generally this is managed by using SULFUR DIOXIDE as an antimicrobial agent, and the barrels must be carefully checked before refilling. See BARREL MAINTENANCE. The word 'mouldy', along with 'musty' or 'mushroomy', is also used to describe a wine that is affected by CORK TAINT. K.C.

Moulin-à-Vent means 'windmill' in French, and the name describes the landmark that denotes one of the most famous BEAUJOLAIS crus. Originally it denoted a small, highly ranked CRU within Romanèche-Thorins, but it has expanded to include 632 ha/1,561 acres in Chénas and Romanèche, as much as anything a reflection of the market power of the name. A vein of MANGANESE running through GRANITE near the two towns' border has often explained the stiffer TANNINS and bite of the wines, as well as their ability to age, but the soils are more varied than usually described, with variations in the granite as well as deep colluvium. The reputation has prompted higher prices for both wine and vines—€100,000 per hectare in 2019, making it the hardest cru in which to acquire land. Nonetheless, long-time properties like Ch des Jacques, owned by Louis JADOT, have been joined by recent arrivals such as Thibaut Liger-Belair and Richard Rottiers. J.F.B.

Moulis, or Moulis-en-Médoc, smallest of the six communal appellations of the HAUT-MÉDOC district of Bordeaux (the others being MARGAUX, ST-JULIEN, PAUILLAC, ST-ESTÈPHE, and neighbouring LISTRAC). Although it includes only about 600 ha/1,500 acres of vineyards, Moulis has a considerable diversity of TERROIR, in terms of both topography and soil composition. Countryside that is positively rolling by Médoc standards, and soils that include various GRAVELS, CLAYS, and LIMESTONE, result in wines as varied as the occasionally brilliant Ch Chasse-Spleen, the good-value Ch Maucaillou, and a host of

properties whose names include the word 'Poujeaux'. The finest of these is usually long-lived Ch Poujeaux itself. Like Listrac, Moulis is not CLASSED GROWTH country. Perhaps because of this, the best wines can offer good value, being as well structured as any Haut-Médoc, often with some of the perfume of Margaux to the east.

Brook, S., *The Complete Bordeaux* (4th edn, 2022).

Mountain, 19th-century English term for MÁLAGA, which is indeed flanked by mountains. The name is no longer used (except by Spain's roving winemaker Telmo Rodriguez for his sweet golden Málaga) but is commonly found on DECANTER labels produced before PHYLLOXERA devastated the Málaga region in 1876.

Mount Barker , cool subregion of the Great Southern region, WESTERN AUSTRALIA, with a strongly CONTINENTAL climate especially suited to Riesling, Shiraz, and Cabernet Sauvignon. (Also a town in Australia's ADELAIDE HILLS.)

Mount Benson, cool-climate seaside wine region in the Limestone Coast Zone of SOUTH AUSTRALIA awarded its GEOGRAPHICAL INDICATION in 1997, the same year Michel CHAPOUTIER of the Rhône Valley began planting here. The region makes elegant, light- to medium-bodied wines, particularly Shiraz.

Mount Harlan , California wine region and AVA. See SAN BENITO.

Mount Lofty Ranges Zone encompasses the Adelaide Hills, Adelaide Plains, and Clare Valley wine regions in SOUTH AUSTRALIA.

Mount Veeder, California wine region and AVA on the NAPA side of the Mayacamas known for STRUCTURED, long-lived Cabernet

Sauvignon.

Moura, DOC subregion of the southern part of Portugal's ALENTEJO with an extreme CONTINENTAL CLIMATE.

Mourisco, or Mourisco do Minho, minor dark-skinned Portuguese variety grown in the Beiras and Minho regions, known as Tinta Castañal over the border in Spain's Galicia. Mourisco Branco is CAYETANA BLANCA. Mourisco Roxo is MARUFO.

Mourvèdre, warm-climate red grape variety whose considerable fortunes in Spain have been declining (see MONASTRELL) while it has become markedly more fashionable elsewhere. Plantings in France, where it is enjoying a resurgence of popularity in the south, had grown to 9,385 ha/23,191 acres by 2019, the second biggest national total after Spain's. It cannot be grown successfully much further north than the southern Rhône, however, since it is so late ripening. It is the characteristic grape variety of BANDOL and is increasingly popular with producers of CHÂTEAUNEUF-DU-PAPE because it ripens at lower sugar levels than GRENACHE. In California and Australia it was often called Mataro but has been enjoying a new lease of life as either VARIETAL Mourvèdre or in a blend with Grenache and Syrah/Shiraz, sometimes called GSM.

Mourvèdre dominated Provence until the arrival of PHYLLOXERA and the search for productive vines to supply the burgeoning market for cheap TABLE WINE. For many decades it marked time in its French enclave Bandol (in 1968 total French plantings were as little as 900 ha) but is now regarded as an extremely modish and desirable 'improving variety' throughout the Languedoc and Roussillon, especially now that CLONES have been selected which no longer display the inconveniently variable YIELDS once resulting from degenerated vine stock.

In southern France, Mourvèdre produces wines considered useful for their STRUCTURE, intense fruit, and, in good years, perfume often redolent of blackberries. The structure in particular can be a useful foil for Grenache in Provence and for Cinsaut further west. In Bandol, it is typically blended with both of these, and the statutory minimum for Mourvèdre is now 50%. Mourvèdre is condoned in a host of AOC regulations all over the south of France from GRIGNAN-LES-ADHÉMAR to COLLIOURE, including CHÂTEAUNEUF-DU-PAPE and environs. It usually plays a useful supporting role, being fleshier than Syrah, tauter than Grenache and Cinsaut, and more charming than Carignan. Somewhat belatedly, Australia realized it had all the wherewithal to produce authentic Rhône blends, despite the loss of precious old-vine Grenache and Mourvèdre in South Australia in the late 1980s (due to an ill-advised VINE-PULL SCHEME). Old-vine Grenache–Shiraz–Mourvèdre (or any combinations thereof) have proliferated since the 1990s as resources have been moved from fortified to table-wine production, although plantings of Mourvèdre, still called Mataro in official statistics, had fallen to 751 ha/1,856 acres by 2015.

Although grown at least since the 1870s, California's unfashionable Mataro was fast disappearing until the RHÔNE RANGERS made the connection with Mourvèdre and pushed up demand for wine from these historic stumps, notably in Contra Costa County between San Francisco and the Central Valley, where there were considerable new plantings in the early 1990s thanks to demand from the likes of Bonny Doon and Cline Cellars. By 2020 the state's total plantings had risen to 483 ha/1,194 acres. Rhône mania spread north to Washington, where there were 165 acres in 2011, but this fell back down to 126 acres in 2017. South Africa had 495 ha/1,223 acres in 2020. It is also grown on Cyprus.

mousse, French term for FIZZINESS.

mousseux, French for 'sparkling'. Some *mousseux* wines are made by the traditional method (see SPARKLING WINEMAKING), while others

may be made by the much less painstaking TANK METHOD.

mousy, TASTING TERM commonly associated with a wine FAULT that is extremely difficult to recognize. It cannot be detected aromatically, only when the wine is tasted, and sometimes the flavour of a dirty mouse cage does not develop until after the wine has been swallowed. About one-third of the population are unable to taste the compounds responsible, making it an extremely elusive fault.

The three main chemicals responsible for the fault are 2-acetyltetrahydropyridine (ACTPY), 2-ethyltetrahydropyridine (ETPY), and 2-acetylpyrroline (ACPY). It is difficult to measure in wine, and according to the AWRI the chemicals are present in micrograms per litre.

Research has shown this fault to be microbial in origin and most closely linked with species from the *Lactobacillus* family, responsible for MALOLACTIC CONVERSION. Current studies are also looking at a separate chemical pathway, but this will require further work to fully understand the mechanism.

Although it is not known why some wines are affected and others not, it is clear that those made using winemaking practices that create an environment conducive to microbial activity will be more vulnerable to mousiness. This includes using low levels of SULFUR DIOXIDE or adding SO_2 only after MALOLACTIC CONVERSION, wines with high PH or with high levels of solids after fermentation, and poor control of a wine's exposure to oxygen during ageing. With the increase in low-SO_2 wines and extended LEES CONTACT, it appears that this fault is on the rise. K.C.

Goode, J., *Flawless: Understanding Faults in Wine* (2018).

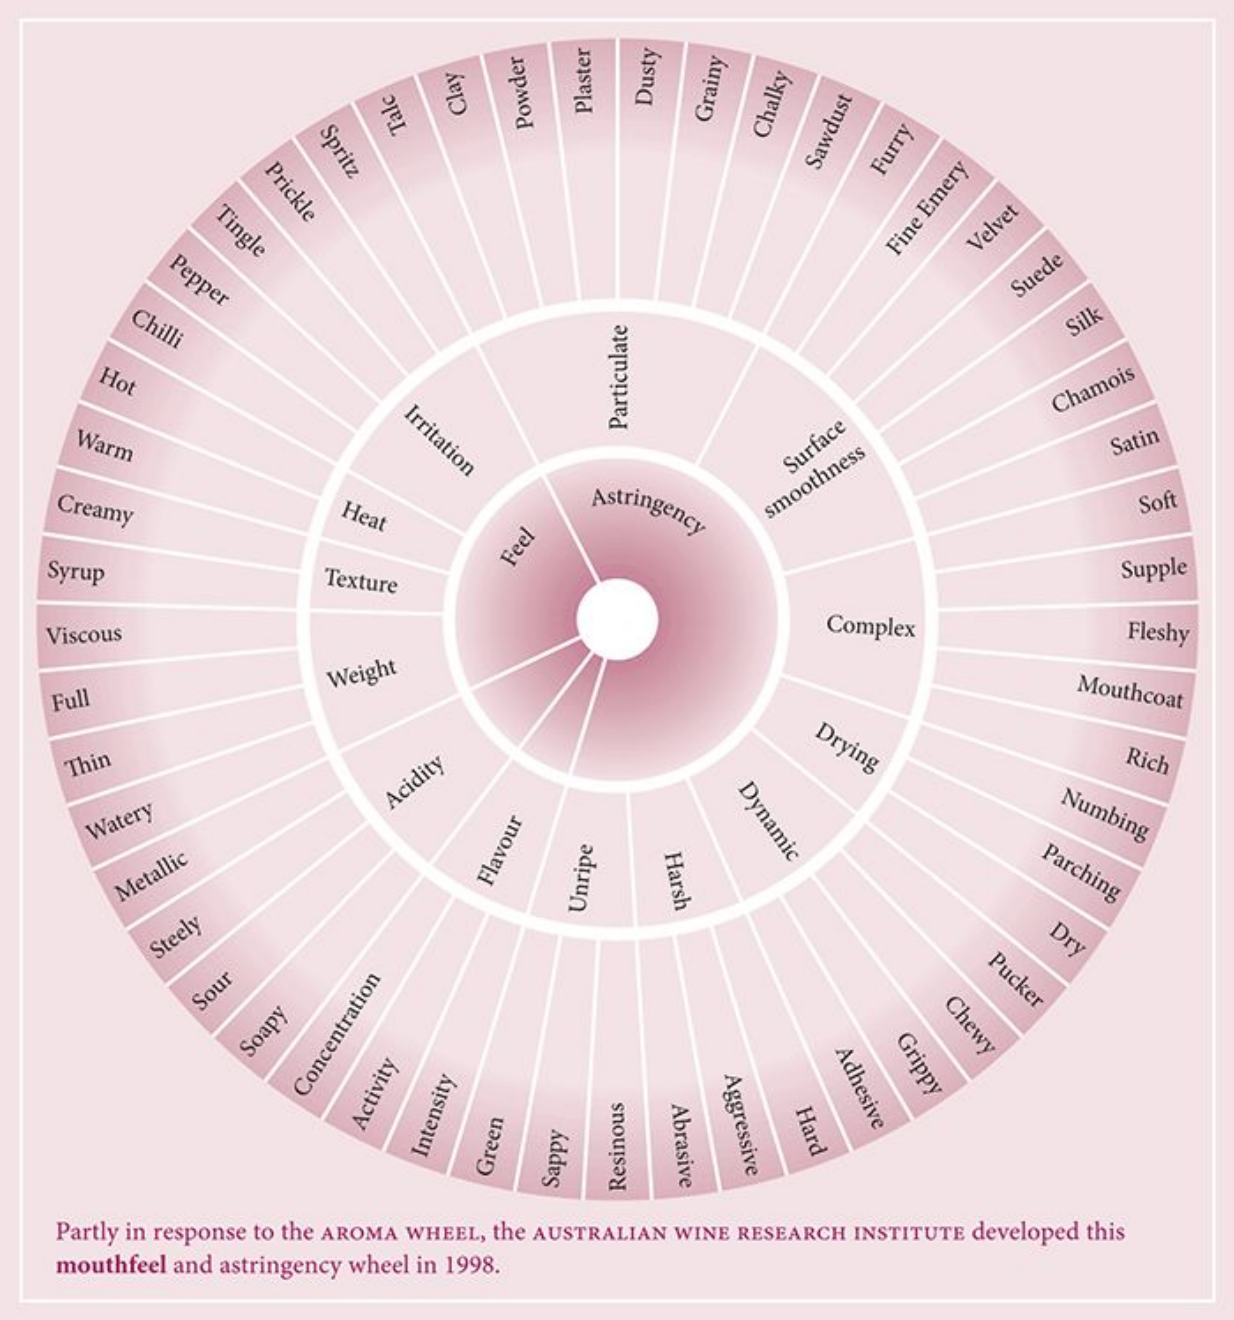
moût de raisins partiellement fermenté issu de raisins passerillés is the cumbersome French name for partially fermented grape must extracted from raisined grapes and is a term used on labels of some French SWEET WINES, since ALSACE, JURANÇON, and GAILLAC have exclusive rights to VENDANGES TARDIVES. According to EU regulations, the must has to have a total sugar content of at least 272 g/l and the finished wine at least 8% alcohol.

mouthfeel, non-specific tasting term, used to refer to tactile attributes such as smoothness but also to heat (see ALCOHOLIC STRENGTH), VISCOSITY, and the sensation of weight in the mouth. For more detail, see diagram and TEXTURE.



Partly in response to the AROMA WHEEL, the AUSTRALIAN WINE RESEARCH INSTITUTE developed this **mouthfeel** and astringency wheel in 1998.

Gawel, R., et al., 'A mouth-feel wheel: terminology for communicating the mouth-feel characteristics of red wine', *Australian Journal of Grape and Wine Research*, 6 (2000), 203–7.

Mouton Cadet, the most successful Bordeaux BRAND, began life in 1927, a poor vintage in which Baron Philippe de ROTHSCHILD created

what was effectively a SECOND WINE called Carruades de Mouton for Ch MOUTON ROTHSCHILD, but it was not a success. Its successor in 1930 was named Mouton-Cadet, since Philippe was the *cadet*, the youngest, of the family. Eventually, as Mouton Cadet, it developed a prosperous life of its own, and demand was so great that the flexibility of the BORDEAUX AOC appellation was needed.

Today Mouton Cadet is available in red, white, rosé, and organic versions, having been repackaged and reblended in 2004 to rely predominantly on FRUIT-DRIVEN Merlot and Sauvignon Blanc, with tighter control over the 250 growers and seven winemakers involved in its production.

Mouton Rothschild, Château, important wine estate in PAUILLAC in the BORDEAUX wine region and the only one ever to have been promoted within the 1855 CLASSIFICATION, to FIRST GROWTH.

Originally part of the LAFITE estate with which it is intermingled, it became in the middle of the 18th century a separate entity, owned by the de Brane family. In the first half of the following century, Baron Hector de Brane (or Branne) became known as 'the Napoleon of the vines' for his work in developing the Médoc vineyards and, in company with his neighbour Armand d'Armailhacq, in supposedly introducing the CABERNET SAUVIGNON vine. In 1830, he sold Mouton to a M. Thuret and retired to his Ch Brane-Cantenac in the commune of MARGAUX. At this time, Mouton had little international repute, and the first entry in a Christie's AUCTION catalogue was in 1834. In 1853, Thuret sold it to Baron Nathaniel de ROTHSCHILD, of the English branch of the family, two years before the 1855 classification which placed Mouton Rothschild at the top of the second growths, a position unsatisfactory to the family but not seriously contested until Baron Philippe de Rothschild took over the running of it from his father in 1922. He startled Bordeaux by employing a poster artist, Carlu, to design an art-deco label, including the Rothschild arrows, for the 1924 vintage and then proposing CHÂTEAU BOTTLING of all the first

growths (and Mouton Rothschild). He also instigated what was initially a SECOND WINE, called MOUTON CADET.

On his return in 1945 after the Second World War, Baron Philippe initiated the series of ARTISTS' LABELS, each year designed by a well-known artist, including Cocteau, Braque, Dali, Bacon, and Henry Moore. He also began a campaign to elevate Mouton to first-growth status, which he achieved in 1973. He and his American wife Pauline created a magnificent Musée du Vin, or wine museum, filled with *objets d'art* and open to the public since 1962 on application. In 2013 a new vat room was inaugurated as well as an exhibition space for the artworks which have illustrated the Mouton labels so famously and have been exhibited around the world.

The 80-ha/200-acre vineyard is planted with 80% CABERNET SAUVIGNON grapes, 16% MERLOT (much increased in the late 1990s), 3% CABERNET FRANC, and 1% PETIT VERDOT. Average production is 13,000–16,000 cases. After she succeeded her father Baron Philippe de Rothschild in 1988, Baroness Philippine de Rothschild introduced a second wine, Petit Mouton de Mouton Rothschild, in 1994 and a dry white AOC Bordeaux, Aile d'Argent, in 1991. Since her death in 2014, the estate has been owned by her three children. The wine is famously concentrated and intensely aromatic in good vintages. See ROTHSCHILDS for details of other wine investments and JOINT VENTURES.

movies about wine. See FILMS ABOUT WINE.

Moza Fresca, GALICIAN name for the grape known as SÍRIA in Portugal.

MRL. See RESIDUES and AGROCHEMICALS.

MS. Abbreviation for MASTER SOMMELIER.

Mtsvane, name of two distinct light-skinned, high-quality varieties grown in GEORGIA: the more widely planted Mtsvane Kakhuri, meaning 'green from Kakheti', often referred to simply as Mtsvane, and Goruli Mtsvane, meaning 'green from Gori', planted in Kartli and Imereti.

Mudgee , inland wine region in NEW SOUTH WALES. The name is an Aboriginal word meaning 'nest in the hills', and indeed the region is perched at about 450 m/1,500 ft up the western slopes of the Great Dividing Range. The cooler temperatures at this ELEVATION and the wide DIURNAL TEMPERATURE RANGE allow for harvests up to four weeks longer than in neighbouring Hunter Valley. The region is most known for generous, bold Cabernet Sauvignon and Shiraz, yet it is also capable of making crisp, ageworthy Riesling. Forward-thinking producers are also focusing on Italian and Mediterranean varieties including Zinfandel, Tempranillo, Graciano, Touriga Nacional, Nebbiolo, Sangiovese, and Barbera. A.R.P.

mulch, materials put on the vineyard soil surface to assist vine growth. Mulch is useful because it keeps soil damp, stops it becoming too hot, and hinders the growth of weeds. Mulches are generally composed of ORGANIC MATTER, providing NUTRIENTS for the vine's growth as the mulch decomposes. Organic mulches have a desirable effect on SOIL HEALTH, by increasing microbial populations and diversity. A common indicator of this is more EARTHWORM activity, related to improved SOIL STRUCTURE and better water infiltration.

Animal manure and straw were common mulches of the past, but in some modern vineyards these have been replaced with thin plastic film. Young vines are planted through the plastic. The response of young vine growth to plastic is often remarkable, especially for vineyards which rely on rainfall rather than IRRIGATION for their water supply. The film controls weed growth, stops water evaporating from

the soil surface, and in spring warms the soil, promoting root growth. After a few years the plastic film rips and is blown around the vineyard, possibly presenting disposal problems.

A major disadvantage to straw mulch has been the cost of placing a sufficiently deep mat below each vine. This cost can be reduced by modern techniques of mechanically unrolling bales of hay or, alternatively, by throwing the straw under the vine as the COVER CROP is mown.

Organically farmed vineyards use mulches of living plants as well as dead material. The main disadvantage of living mulches for the young vines is that there may be too much competition for water and nutrients, and so the living mulch may need to be killed off. However, when a thick plant mulch breaks down, then nutrients are released and the soil is improved. Both living and dead organic mulches can cause problems because of INSECTS and FUNGI which can be harboured in the litter around the vine trunk. Generally speaking, however, mulch has more positive than negative effects in the vineyard. R.E.S.

Elmore, C., et al., 'Four weed management systems compared: mulch plus herbicides effectively control vineyard weeds', *California Agriculture*, 51/2 (1997), 14–18.

mulled wine is wine that has been heated with sugar and spices and also, sometimes, slices of fruit and even brandy. This was a particularly common way of serving wine in the Middle Ages, since honey and spices helped to compensate for any shortcomings in wine QUALITY (which were likely to be considerable as the months since the HARVEST wore on, in an age when wine was served directly from the barrel). The verb 'mull' was current at least from the beginning of the 17th century. Recipes vary but red wine is almost invariably used, and cinnamon and cloves are common. It is far less difficult to make good mulled wine than to find DRINKING VESSELS that retain the heat but are not uncomfortably hot to hold.

Müllerrebe, meaning 'miller's grape', is the common, and logical, name for Germany's selection of PINOT MEUNIER, also misleadingly known as Schwarzriesling, grown on 1,807 ha/4,465 acres, mainly in Württemberg, southern Germany, where it is a local speciality.

Müller-Thurgau, waning white grape variety which could fairly be said to have been the bane of German wine production. This cross was developed in 1882 for entirely expedient reasons by a Dr Hermann Müller, born in the Swiss canton of Thurgau but then working at the German viticultural station at GEISENHEIM. His understandable aim was to combine the quality of the great RIESLING grape with the viticultural reliability, particularly the early ripening, of SILVANER. Most of the variety's synonyms (Rivaner in Luxembourg and Slovenia, Riesling-Silvaner in Switzerland, Rizlingszilvani in Hungary) reflect this combination. Late 20th century DNA PROFILING by researchers at Geilweilerhof established that the variety is actually Riesling × Madeleine Royale, a now-extinct TABLE GRAPE of unknown parentage obtained from a cross made in 1845. The variety is all too short on Riesling characteristics, typically smelling vaguely peachy with a fat, flaccid mid PALATE, too often with a slight suspicion of rot, to which its rather large, thin-skinned berries are prone.

The vine certainly ripens early, even earlier than Silvaner. Unlike Riesling, it can be grown anywhere, producing prodigious quantities—sometimes double Riesling's common yield range of 80 to 110 hl/ha (4.6–6.3 tons/acre)—of extremely dull, flabby wine.

Müller-Thurgau was not embraced by Germany's growers until after the Second World War, when the need to rebuild the industry fast presumably gave this productive, easily grown vine allure. In the early 1970s, it even overtook the great Riesling in total area planted (having for some time produced far more wine in total) and remained in that position throughout the 1980s. Typically blended with a little of a more aromatic variety such as MORIO-MUSKAT and with a great deal of SÜSSRESERVE, Müller-Thurgau was transformed into oceans of QUALITÄTSWEIN sugarwater labelled either LIEBFRAUMILCH or one of the

internationally recognized names such as Niersteiner, Bernkasteler, or Piesporter (see GROSSLAGEN). But by the late 1990s, Riesling was once again Germany's most planted grape variety—although at more than 11,453 ha/28,301 acres in 2020, total plantings of Müller-Thurgau in Germany are arguably still (too?) significant.

The wood is much softer than Riesling's and can easily be damaged by hard winters. The grapes rot easily (as can be tasted in a number of examples from less successful years), and the vine is susceptible to DOWNY MILDEW, BLACK ROT, and, its own bane, ROTBRENNER, but it will presumably continue to flourish while there is a market for cheap German wine.

Outside Germany it can be much more exciting. In northern Italy's ALTO ADIGE, where extensive acreage of ancient vines testifies to the promotional success by early proponents of Dr Müller's cross, bottlings from easily a score of today's best domaines and grower CO-OPERATIVES testify to the refinement, MINERALITY, COMPLEXITY, and sheer refreshment value that is possible with Müller-Thurgau—just not, it seems, in Germany. Most of the best Alto Adige wines are grown on very steep, stony, high-ELEVATION sites of which Tiefenbrunner's Feldmarschall is one extreme example, but there are others in the VALLE ISARCO. Italy's total area planted in 2015 was 1,296 ha/3,202 acres.

The variety thrives all over central and eastern Europe. It is planted, appropriately enough, in SWITZERLAND, playing an important role in the vineyards of the German-speaking area in the north and east, notably in the canton of Thurgau. In AUSTRIA (where it is sometimes called Rivaner) total area planted had fallen to 1,311 ha/3,240 acres by 2021, mainly in the Weinviertel, where it makes generally light, inconsequential wines. Across Austria's southern border, it is also grown in eastern SLOVENIA (as Rizvanec) and is even more important to the east and north of Austria in CZECHIA and HUNGARY. As Rizlingszilvani, it covers more than a thousand hectares of vineyard around Lake Balaton and produces lakesful of flabby Badacsonyi Rizlingszilvani. In the 1970s Müller-Thurgau was planted

enthusiastically by New Zealand grape-growers on the recommendation of visiting German experts as a preferable substitute for the HYBRIDS that were all too prevalent in the country's nascent wine industry, but it has now virtually disappeared.

Elsewhere in the New World, most growers are not driven by the need for early-ripening varieties (and would find the flab in the resultant wine a distinct disadvantage), although some Oregon growers have had success with it (28 ha/69 acres in 2018), and credible examples have been produced in the cooler vineyards of western Washington State, for example in the Puget Sound AVA.

Two of Northern Europe's smallest and coolest wine producers, ENGLAND and LUXEMBOURG, have in their time depended heavily on Müller-Thurgau, and it is still the most widely planted variety in the latter.

Munson, T. V. (1843–1913), Texan credited with putting PHYLLOXERA-resistant roots on French vines and saving Europe's vineyards from devastation. Thomas Volney Munson was a lifelong student of viticulture, especially AMERICAN VINE SPECIES. At Kentucky University he became interested in TEXAS and its grapes and journeyed tens of thousands of miles in 40 states gathering WILD VINE specimens and studying soils and climates. He travelled by horseback and train, hunting from rail cars and jumping off to collect specimens whenever the train stopped. In 1876, Munson settled on the Red River near Denison in Texas, which he described as a 'grape paradise' because of the six or eight species of wild vines there. He developed a vineyard and NURSERY business as well as becoming the authority on the wild grape species of North America. Munson's passion was for VINE BREEDING, and he produced about 300 varieties using local VITIS species *lincecumii*, *champini*, and *candicans*. None, however, became commercially important.

Being aware of phylloxera's predations in Europe, Munson began GRAFTING European vines to American species as ROOTSTOCKS to grant resistance. He passed on the results of his research to Viala,

Planchon, and other French experts. In the 1880s and 1890s, French growers accordingly imported huge quantities of American species for use as rootstocks, especially from Texas and Missouri. The French government made Munson a Chevalier du Mérite in 1888, only the second American to have achieved this honour (Thomas Edison having been the first). R.E.S.

Murray Darling, Australia's third largest winegrowing region straddling the Darling River and both sides of the Murray river in VICTORIA and NEW SOUTH WALES. The hot, dry region is dependent on IRRIGATION (the soils have little water-holding capacity, and growing-season rainfall is negligible) and high yields of low-cost grapes, the quality of which has risen as demanded by large companies competing internationally. Chardonnay, Shiraz, and Cabernet Sauvignon are mainstays, but the fraught issue of water availability has prompted interest in recent years in less water-intensive Italian and Mediterranean varieties. E.N.H.M. & A.R.P.

Muscadel, or Muskadel, South African name for MUSCAT BLANC À PETITS GRAINS, used mainly when the variety is made into very sweet but not very modish JEREPIGO.

Muscadelle is the famous also-ran third grape variety responsible, with SÉMILLON and SAUVIGNON BLANC, for the sweet white (and often duller dry white) wines of Bordeaux. By 2019 France's total plantings had fallen to 1,399 ha/3,457 acres, 704 ha of them in the Gironde, where the majority of Muscadelle vines are not in the great sweet white-wine areas of SAUTERNES but in the unfashionable and vast ENTRE-DEUX-MERS, including the fringe sweet-white appellations of PREMIÈRES CÔTES DE BORDEAUX, CADILLAC, LOUPIAC, and STE-CROIX-DU-MONT. Muscadelle is relatively more important to BERGERAC than to Bordeaux, and it is valued as the finest ingredient in some of the best MONBAZILLAC.

Unrelated to any member of the MUSCAT group, the variety shares a vaguely grapey aroma with them but has its relatively ancient origins in SOUTH WEST FRANCE. DNA PROFILING has shown a parent–offspring relationship with the prolific GOUAIS BLANC. The usefully productive Muscadelle leafs late and ripens early and has rarely demonstrated great subtlety in the wines it produces. The occasional VARIETAL French Muscadelle can demonstrate a certain 'green' tang, but its use is almost exclusively in blends, adding the same sort of youthful fruitiness to south-western sweet whites as PINOT MEUNIER does to the north-east sparkling whites called CHAMPAGNE.

The variety known as Sauvignon Vert in California is Muscadelle. In only one corner of the wine world does Muscadelle produce sensational varietal wine: TOPAQUE in Australia. For years Australians thought the grape they called Tokay, which produced these dark, syrupy, wood-matured concentrates for after-dinner drinking, was Hungarian, but the French AMPELOGRAPHER Paul Truel identified it as Muscadelle in 1976. Total national plantings stood at 92 ha/227 acres by 2015, one-third of them in RUTHERGLEN.

Muscadet, one of France's dry white commodity wines currently undergoing revolution while trying to survive. The Muscadet region extends east and south of Nantes near the mouth of the Loire on a shrinking vineyard area of 7,900 ha/19,500 acres in 2020 of gently rolling, Atlantic-dominated countryside that is 95% devoted to one grape variety, MELON de Bourgogne, also nicknamed Muscadet. Known in Burgundy since the 13th century, this vigorous yet subtle variety came to prominence in the Pays Nantais after the terrible 1709 winter revealed its cold hardiness, and the DUTCH WINE TRADE understood its suitability as distilling material for their *brandewijn*. This, doubled by the hastily made, diluted production of the 1980s and 1990s, delayed to recent times the recognition of Melon for TERROIR-driven, long-lived wines.

All Muscadet appellations combined produce the largest quantity of dry white wines in the entire Loire, with Muscadet Sèvre-et-Maine

representing 75% of the planted surface (6,000 ha/14,800 acres) and of the volume when not depleted by FROST and MILDEW. Named after two small rivers which flow through this, the oldest AOC of the region (1936) is a geological mosaic of metamorphic mica-SCHIST, GNEISS and amphibolite, igneous GRANITE and gabbro, and quaternary SAND and CLAY, leading to a wide spectrum of expressions from crisp and fresh to concentrated and ambitious. To the north-east, Muscadet Coteaux de la Loire, also created in 1936, covers 170 ha/420 acres around Ancenis producing a more generous style from steep SLATE slopes, while to the west the 220 ha/540 acres of the flatter and sandier Muscadet Côtes de Grandlieu (1994) make briny and vivid wines on the shore of the eponymous lake in the south-west of the region. Muscadet is the basic appellation, second in area (1,600 ha/3,960 acres) and volume, producing more generic wines authorized since 2020 to include 10% CHARDONNAY in the blend while forbidding SUR LIE on the label.

Strictly regulated, 'sur lie' requires the wine to be kept on the LEES and bottled between March and November of the year following the harvest, a practice inherited from the tradition of the 'wedding barrel' kept over the winter. The LEES CONTACT helps to balance the high-acid verve of Melon as MALOLACTIC CONVERSION is historically prevented in the large, underground concrete tanks commonly used. Some PRIMEUR wine is also made.

Since the mid 1980s, in reaction to the wine's poor reputation, the most dynamic producers have been experimenting with such techniques as BARREL FERMENTATION, LEES STIRRING, and, more recently, malolactic conversion, vinification in AMPHORA, and SKIN CONTACT. Yet the most substantial evolution of the Muscadet de Sèvre-et-Maine appellation has been the approval of the *crus communaux* in 2011. These geologically identified plots are subject to lower YIELDS (45 hl/ha) and extended ageing (18–24 months minimum depending on the cru, thus prohibiting the use of the 'sur lie' designation). Gorges (where the movement begun), Clisson, and Le Pallet were the first recognized, later joined by Goulaine, Château-Thébaud, Monnières

St-Fiacre, and Mouzillon-Tillières, Vallet, La Haye-Fouassière, and Champtoceaux. While these crus represent a tiny minority of the production, they prove the region's potential for unique, long-lived, high-quality Muscadets while remaining great values.

Other wines produced in the Pays Nantais are GROS PLANT, Coteaux d'ANCENIS, and FIEFS VENDÉENS. See also LOIRE, including map.

P.Le.

Muscadinia, a section of the botanical genus VITIS, although some botanists have suggested that it should be considered a separate genus rather than a section of *Vitis*. *Muscadinia* includes the two species *Vitis rotundifolia* (including *Vitis rotundifolia* var. *munsonia*) and *Vitis popenoei*, according to recent PHYLOGENIES. *Vitis* contains the true grapevine, also called *Euvitis*, as outlined in BOTANICAL CLASSIFICATION. *Muscadinia* and *Vitis* differ in chromosome number and morphology.

Members of the *Muscadiniae* occur only in the south-eastern United States and Mexico but seem related to *Vitis ludwigii* found as fossil seeds in Tertiary sediments of northern Europe. There is speculation that *Muscadinia* can be regarded as transitional between the temperate genus *Vitis* and *Ampelocissus*, which is adapted to tropical climates. Species of the three genera have similar characteristics.

The Muscadines, as they are called, typically have small bunches of large, thick-skinned berries and high yields. The better-known of the two species is *Vitis rotundifolia*, of which only SCUPPERNONG was grown commercially for winemaking until the second half of the 20th century. It has been supplanted by purple-skinned Noble and bronze-skinned Carlos. The very thick skins and musky flavour of Muscadines produce fruit and wine quite different from that of European VITIS VINIFERA vines. The berries have a thick, slippery pulp that is difficult to press, and excessive pressure brings bitterness from the skins. Muscadines are typically low in sugar concentration, usually requiring CHAPTALIZATION, but have medium to high ACIDITY and relatively high levels of antioxidants (see HEALTH).

A few thousand hectares of Muscadine grapes are grown in the cotton belt in the south-eastern United States.

The Muscadines have natural resistance to PIERCE'S DISEASE and can therefore be planted in some areas unsuitable for VITIS species and HYBRIDS of them. They are also usefully resistant to PHYLLOXERA, NEMATODES, DOWNY MILDEW, and POWDERY MILDEW, which makes Muscadine germplasm valuable in VINE BREEDING. The different chromosome numbers of *Vitis* (2n = 38) and Muscadines (2n = 40) is a barrier to crossing the two sections, since progeny (2n = 39) are typically infertile. However, the development of rare, fertile *Euvitis* × *Muscadinia* interspecific hybrids has made possible their use in VINE IMPROVEMENT programmes. R.E.S., J.V. & P.C.

Muscardin, red grape variety occasionally making a light, crisp, floral contribution to CHÂTEAUNEUF-DU-PAPE blends.

Muscat , one of the world's great and historic names, of both grapes and wines, that benefited from a FASHION in the early 2010s for wines labelled MOSCATO. Muscat grapes—and many different Muscat varieties, several closely related, in several hues of berry—are some of the very few which produce wines that actually taste of grapes. MUSCAT OF HAMBURG and MUSCAT OF ALEXANDRIA are grown as

both wine grapes and TABLE GRAPES (although Hamburg is much better in the second role). MUSCAT BLANC À PETITS GRAINS is the oldest and finest, producing wines of the greatest intensity, while MUSCAT OTTONEL, paler in every way, is a relative parvenu. See also various MOSCATELS and MOSCATOS.

Muscat grapes were probably the first to be distinguished and identified and have grown around the Mediterranean for many, many centuries. With such strongly perfumed grapes (thanks to a particularly high concentration of MONOTERPENES), described in French as MUSQUÉ as though they were actually impregnated with musk, Muscat grapes have always been attractive to bees, and it was almost certainly Muscat grapes that the Greeks described as *anathelicon moschaton* and PLINY the Elder as *uva apiana*, 'grape of the bees'.

Muscat wines, carrying many different labels including Moscato (in Italy) and Moscatel (in Iberia), can vary from the refreshingly low-alcohol, sweet and frothy ASTI Spumante through Muscat d'ALSACE and other bone-dry Muscats, made for example in Roussillon, to sweet wines with alcohol levels of 15–20%, usually by MUTAGE (as in the VINS DOUX NATURELS of southern France and Greece). Since a high proportion of the world's Muscat is dark-berried, and since a wide variety of wood-ageing techniques are used, such wines can vary in colour from palest gold (as in some of the more determinedly modern Muscats de FRONTIGNAN) to deepest brown (as in some of Australia's sweet, fortified Muscats. (See TOPAQUE AND MUSCAT.)

Most Muscat vines need relatively hot climates (although see MUSCAT OTTONEL and GERMAN HISTORY, in which the medieval cultivation of both light- and dark-berried Muscat vines is documented). There are or have been many famous Muscats around the Mediterranean. See MOROCCO, GREECE, SICILY, and SARDINIA.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Muscat Bailey A, A Japanese HYBRID (Bailey × MUSCAT OF HAMBURG) grape that is becoming a major variety for wine in JAPAN, producing a broad range of wines from rosé to medium-bodied reds. Sudo Wine and Takeda Winery in Yamagata Prefecture have the oldest wine-producing vines, 70–80 years old.

Muscat Blanc à Petits Grains is the cumbersome but descriptive full name of the oldest and most respected variety of Muscat with the greatest concentration of fine grape flavour, hinting at orange-flowers and spice. Its berries and seeds are, as its name suggests, particularly small, and they are round as opposed to the larger, oval berries of MUSCAT OF ALEXANDRIA—another synonym for this superior variety being Muscat à Petits Grains Ronds. But its berries are not, as its principal AMPELOGRAPHICAL name suggests, invariably white. In fact there are pink-, red-, and black-berried versions (although the dark berries are not so deeply pigmented that they can produce a proper red wine), and some vines produce berries whose colour varies considerably from vintage to vintage. Many synonyms for the variety include reference to the yellow or golden (*gallego, giallo, gelber*) colour of its berries. 'Brown Muscat' is one of Australia's names for a Muscat population that is more dark than light, resembling South Africa's Muscadel in that respect (thereby providing more evidence of early viticultural links between these two southern-hemisphere producers). *Wine Grapes* lists no fewer than 60 synonyms of this ancient variety, including Muscat of Frontignan, Frontignac, Muscat Blanc, Muscat d'Alsace, Muskateller, Moscato Bianco, Moscato d'Asti, Moscato di Canelli, Moscatel de Grano Menudo, Moscatel de Frontignan, Moscatel do Douro, Moscatel Galego Branco, Muscatel Branco, White Muscat, Muscat Canelli, and Muscadel. Any Muscat with the words 'Alexandria', 'Gordo', 'Romain', 'Hamburg' or 'Ottonel' in its name is *not* this superior variety.

This particular Muscat may well be the oldest known wine grape variety and the oldest cultivated in France, having been established in Gaul around Narbonne, notably at FRONTIGNAN, by the Romans—and possibly even before then brought to the Marseilles region by the

Greeks. DNA PROFILING has found close genetic relationships between this Muscat and several modern Greek and Italian varieties such as MOSCHOFILERO and MALVASIA respectively. Muscat Blanc also seems to be a parent of several other varieties with Muscat in their name, including Muscat of Alexandria. Muscat Blanc has clearly been established for many centuries round the Mediterranean, where its early budding poses few problems. It was certainly already widely esteemed in the vineyards of Roussillon by the 14th century. It is Piemonte's oldest documented variety; is recorded as growing in Germany, as MUSKATELLER, as early as the 12th century; and is the first documented variety grown in Alsace, in the 16th century, suggesting that spring frosts may have been less common then, for the variety has now been replaced by the more accommodating Muscat Ottonel in Alsace.

Muscat Blanc also yields more conservatively than other Muscats and is sensitive to a wide range of diseases, which has naturally limited its cultivation—although it has travelled for so long and so widely that it is particularly widely distributed.

This is the Muscat that predominates in Italy, which has the single biggest area planted with it (see MOSCATO). In France, contrary to most other white grape varieties, this Muscat has been steadily gaining ground over many years but appears to have plateaued, with 7,357 ha/18,180 acres in 2019, plus just under 100 ha of the pink-berried mutation, mainly in the LANGUEDOC and ROUSSILLON, partly because of the development of dry, unfortified Muscat wine there. It has overtaken Muscat of Alexandria to become the most common white wine grape in Roussillon, and it is also important in the Hérault *département*. This is the Muscat solely responsible for France's golden sweet Muscats of BEAUMES-DE-VENISE, FRONTIGNAN, LUNEL, MIREVAL, and ST-JEAN-DE-MINERVOIS. Muscat has also benefited from the development of a virtually CLAIRETTE-free grapey (Tradition) version of the Rhône's fizzy CLAIRETTE DE DIE. This is the predominant Muscat of CORSICA.

As Moscatel de Grano Menudo it is still grown in Spain but to a limited extent; most Spanish wines labelled Moscatel are made from Muscat of Alexandria. In Portugal, there were 859 ha/2,123 acres of Moscatel Galego Branco in the Douro region in 2020. In Eastern Europe, MUSCAT OTTONEL with its shorter growing season is generally more popular, but Muscat Blanc is grown in Slovenia as Rumeni Mušcat, in Hungary as Sárga Muskotály (the third ingredient in TOKAJ), in Romania where it is known as TĂMÂIOASĂ Alba, and in Bulgaria and Russia, where it is called Tamyanka. It was almost certainly this Muscat that was responsible for the famous, long-lived Muscats of CRIMEA.

See MUSKATELLER for more on Muscat in Germany and Austria.

If anywhere could be said to be Muscat's homeland it is GREECE, and its total area of Muscat Blanc à Petits Grains, at 1,692 ha/4,181 acres in 2021, is more than twice as much as that of Muscat of Alexandria (the prime Cypriot Muscat). The small-berried Muscat is accorded the honour of being the only variety allowed in Greece's most rigidly controlled Muscats such as those of Samos, Patras, and Kefalonia. For the moment, Greek Muscat, like its many variations on the MALVASIA theme, is almost invariably sweet, alcoholic, and redolent of history, but drier versions more suited to drinking with food are on the increase. See GREECE for more details.

Outside of Europe, the variety reaches its apogee in Australia, where it has been known as Brown Muscat and Frontignac with all manner of colour of grape skins. Its most glorious incarnation is RUTHERGLEN Muscat. Australian 2022 grape-variety statistics distinguished between a stable total of about 265 ha/655 acres of dark-skinned, small-berried Muscat, also known as Muscat à Petits Grains Rouges, and a total of light-skinned, small-berried Muscat that had increased to 1,057 ha, thanks to plantings in RIVERLAND and RIVERINA, presumably in response to the FASHION for MOSCATO. This was probably also the explanation for the newer plantings in California's SAN JOAQUIN VALLEY, where Muscat of Alexandria has been very much more important than this finer Muscat, which was planted

on 1,137 ha/2,810 acres in 2020. In South Africa, the name most often seen on labels is Muscat de Frontignan, although it is also known simply as Muscat Blanc and as MUSCADE. The total area planted in 2020 was 852 ha/2,105 acres, mainly in inland Robertson. This was the Muscat chiefly responsible for the famous 18th-century CONSTANTIA dessert wine.

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Muscat d'Alsace is an Alsace synonym for the vine variety MUSCAT BLANC À PETITS GRAINS. For more details of what to expect of a wine labelled Muscat d'Alsace, see ALSACE.

Muscat de Beaumes-de-Venise is the often delicate VIN DOUX NATUREL from the southern Rhône village of BEAUMES-DE-VENISE, under whose name there are more details.

Muscat de Frontignan is the old name for the once internationally famous wine of FRONTIGNAN. It is also a synonym used in both France and South Africa for the grape variety solely responsible for it, MUSCAT BLANC À PETITS GRAINS.

Muscat de Lunel. See LUNEL for details of this southern Languedoc VIN DOUX NATUREL. It is yet another synonym for the grape variety solely responsible for it, MUSCAT BLANC À PETITS GRAINS.

Muscat de Mireval. See MIREVAL for details of this relatively unimportant southern Languedoc VIN DOUX NATUREL.

Muscat de Rivesaltes is by far the largest MUSCAT appellation of France, covering 90 villages in the Pyrénées Orientales, as well as

nine in the Aude—although the drop in plantings, from 4,809 ha/11,883 acres in 2000 to 3,033 ha/7,495 acres in 2020, illustrates the sharp decline in popularity of sweet wines in general and Muscat in particular. The Muscats of 'Perpinyà' and 'Clayrà' (Claira is a neighbouring village of Rivesaltes) were already sought out by 14th-century wine buyers from as far away as Barcelona and Avignon. Today Muscat de Rivesaltes, recognized as an appellation in 1956, is the only Muscat VIN DOUX NATUREL which may be made from MUSCAT OF ALEXANDRIA as well as the finer MUSCAT BLANC À PETITS GRAINS. Average YIELDS of these low-trained vines, often on difficult-to-work dry TERRACES, can be as little as 17 hl/ha (1 ton/acre) (the official upper limit is 30 hl/ha). Since the 1980s, more skilled vinification has helped improve quality, with temperature-controlled fermentations and perhaps some SKIN CONTACT and MUTAGE *sur marc* (on the skins). The skill lies in judging the right moment for mutage, when the wine will be neither too sweet nor too dry. The wines, usually picked with a minimum sugar level of 100 g/l, are bottled at a minimum of 15° alcohol. Generally, Muscat de Rivesaltes is released the spring after the harvest, and Muscat de Noël even earlier, in time for Christmas. It is generally drunk when it is young and fresh, either as an APERITIF or with fruit or creamy desserts, but it can age well. With its decline in popularity, wine producers have turned to Muscat Sec as an alternative dry TABLE WINE, usually sold as IGP Côtes Catalanes, and some have experimented with sweet unfortified Muscat from LATE HARVEST grapes. R.E.G.

Muscat de St-Jean-de-Minervois, a VIN DOUX NATUREL produced in the northern LANGUEDOC. See ST-JEAN-DE-MINERVOIS.

Muscat du Cap Corse, Corsican VIN DOUX NATUREL. See CORSICA.

Muscat of Alexandria is a Muscat almost as ancient as MUSCAT BLANC À PETITS GRAINS and also has dozens of synonyms, but its wine

is usually distinctly inferior. In hot climates it can thrive and produce a good yield of extremely ripe grapes, but their chief attribute is sweetness. (In cooler climates, its output can be seriously affected by COULURE, MILLERANDAGE, and a range of FUNGAL DISEASES.) Wines made from this sort of Muscat tend to be strong, sweet, and unsubtle. The aroma is vaguely grapey but can have slightly feline overtones of geranium rather than the more lingering bouquet of Muscat Blanc.

Some indication of its lack of finesse as a wine producer is the fact that a considerable proportion of the Muscat of Alexandria grown today is destined for uses other than wine: Chile, for example, distils most of its thousands of hectares of Muscat of Alexandria to make PISCO; it is even grown under glass in Britain and the Netherlands to provide grapes for the fruit bowl.

Its name suggests origins in Egypt, but genetics suggests Greece and also that it is a progeny of Muscat Blanc à Petits Grains. It was disseminated around the Mediterranean by the Romans, hence its common synonym Muscat Romain. Its southern Italian synonym is ZIBIBBO, under which details of its Italian incarnations can be found.

Today it is most important to wine industries in that old arc of maritime history Iberia, South Africa, and Australia, where it may be known respectively as Moscatel, Hanepoot, and Muscat Gordo Blanco or Lexia, a particularly Australian contraction of the word Alexandria. Spain's total plantings had grown to 10,759 ha/26,586 acres by 2020, more than three times as much as of the other major Muscat, called Moscatel Grano Menudo here. It is not known, however, exactly how much of this serves the wine industry, typically with sweet MOSCATELs of various sticky sorts. Muscat of Alexandria's various Spanish synonyms include Moscatel de Alejandría, Moscatel de Málaga, Moscatel de España, Moscatel Gordo (Blanco), Moscatel Blanco, and Moscatel de Chipiona.

In Portugal its most famous incarnation is Moscatel de SETÚBAL, but Portugal's Muscat of Alexandria grapes, often called Moscatel Graúdo, have also been harnessed to produce aromatic, dry Muscats, much lower in alcohol. This is also the fate of the majority of Australia's relatively static total of 2,210 ha/5,461 acres of Muscat Gordo Blanco,

the country's dominant Muscat, once used mainly for FORTIFIED WINES, although from cooler vineyards it can produce sound, unfortified wines that are sweet because they are LATE HARVESTED. Dry wine produced from the Gordo Blanco grown in Australia's irrigated Riverland is typically used for blending with, and often softening, more glamorous grape varieties.

Muscat of Alexandria is the dominant Muscat in South Africa—HANEPOOT is its traditional Afrikaans name—and was the country's fourth most planted white wine variety in the late 1990s, but it is in marked decline; by 2020 there remained 1,560 ha/3,855 acres, mainly in hotter inland regions. For years it provided sticky, raisiny wines for FORTIFICATION, as well as everything from GRAPE CONCENTRATE to RAISINS. Today some drier, lighter wines are also made from it. Muscat of Alexandria is widely grown in California (1,678 ha/4,146 acres) and still grown to a relatively limited extent in Argentina, Peru, Colombia, Ecuador, and even Japan. Although Muscat Blanc is more important in GREECE, Muscat of Alexandria is grown widely there and is the Muscat that predominates in Türkiye, Israel, and Tunisia, although in much of the Near East nowadays these grapes are eaten rather than drunk. In France, total plantings of Muscat d'Alexandrie, or Muscat Romain, have decreased to about 2,166 ha, almost exclusively in Roussillon, where it was introduced for Muscat de Rivesaltes.

Muscat of Frontignan is a common synonym for MUSCAT BLANC À PETITS GRAINS, and this is the Muscat variety that is solely responsible for the VIN DOUX NATUREL of the same name. See also FRONTIGNAN for details of the wine that justifies this synonym.

Muscat of Hamburg is the lowest quality of the wine-producing MUSCATS. DNA PROFILING at CONEGLIANO showed that it is a natural cross of MUSCAT OF ALEXANDRIA and TROLLINGER (also called SCHIAVA Grossa). It comes exclusively in black-berried form and is far more common as

a TABLE GRAPE than a wine grape. Its chief attribute is the consistency of its plump and shiny dark-blue grapes, which can well withstand long journeys to reach consumers who like black-skinned Muscat-flavoured grapes. In France it was grown on 3,324 ha/8,214 acres in 2019 and was the most important table grape. It is also relatively important as a table grape in Greece, eastern Europe, and Australia. It was extremely popular as a greenhouse grape in Victorian England, where it occasionally took the name of Snow or Venn, two of its more successful propagators.

In the world of wine production its importance is limited, but it does produce a fair quantity of light, grapey red throughout eastern Europe and some 'Black Muscat' in California; in CHINA, crossed with the indigenous VITIS AMURENSIS, it has spawned a generation of varieties adapted for wine production.

Muscat Ottonel is the palest of all the Muscats, both in terms of the colour of wine produced and in terms of its character. Its aroma is altogether more vapid than the powerful grapey perfumes associated with MUSCAT BLANC À PETITS GRAINS and MUSCAT OF ALEXANDRIA. It was bred in 1839 from CHASSELAS and the no-longer-cultivated Muscat d'Eisenstadt (also called Ingram's Muscat, after its breeder) and released in 1852 in the Loire as a TABLE GRAPE.

Its tendency to ripen earlier than these other two Muscats has made it much easier to cultivate in cooler climates, and nowadays Muscat Ottonel is the dominant Muscat cultivated, on fewer than 200 hectares, in ALSACE. This low-vigour vine, which does best in deep, damp soils, is also grown throughout eastern Europe, notably in AUSTRIA, where it is planted in Burgenland and spelt Muskat Ottonel. It may well be that it is at its best as a late-harvest wine, for there are some fine, apparently long-living examples from both HUNGARY and ROMANIA (where the variety is often known, respectively, as Ottonel Muskotály and TĂMÂIOASĂ Ottonel). Romania and Bulgaria, where it is often labelled MISKET, probably have the biggest areas of the variety: 3,100 ha and 5,124 ha respectively.

Muscat Romain, or Roman Muscat, is a common name for MUSCAT OF ALEXANDRIA in Roussillon.

Muschelkalk, literally 'shell limestone' in German, is the time-honoured name used in Germany and neighbouring countries for a particular group of CALCAREOUS rocks deposited during a precise geological interval in northern mainland Europe. Muschelkalk consists mainly of LIMESTONE, together with various argillaceous and dolomitic limestones, and MARLS, each with distinctive fossils. Parts of southern PFALZ, RHEINHESSEN, and central FRANKEN in Germany, as well as LEITHABERG in Austria's Burgenland, are sited on Muschelkalk, as are a number of grand cru vineyards in ALSACE.

Classically and internationally, Muschelkalk is the name for the middle division of the three that originally defined the Triassic period of geological time. However, rocks formed at this time away from northern Europe are quite different from those lauded by German producers. See GEOLOGY for more. A.J.M.

mushroom root rot, vine disease. See ARMILLARIA ROOT ROT.

Musigny, Le, great red GRAND CRU in Burgundy's CÔTE D'OR. For more details, see CHAMBOLLE-MUSIGNY.

Muskateller, German for MUSCAT, almost invariably the superior MUSCAT BLANC À PETITS GRAINS or some mutation of it. Gelber Muskateller, for example, is the gold-skinned version which is increasingly recognized as superior to MUSCAT OTTONEL in Austria, where 1,480 ha/3,657 acres were planted in 2022 (including the pink-skinned MUTATION Roter Muskateller). The variety is popular in STYRIA for light, dry wines and makes both dry and sweet wines in other parts of the country. In Germany, Gelber Muskateller is a distinctly

minority interest, but it remains popular in the Pfalz. Roter Muskateller has all but disappeared.

Muskat Ottonel is what German-speaking countries call their MUSCAT OTTONEL.

Muskat-Silvaner, or Muskat-Sylvaner, was once, tellingly, the common German-language synonym for SAUVIGNON BLANC used in Germany and Austria.

Muskotály, name used in HUNGARY for Muscat, either Ottonel Muskotály (MUSCAT OTTONEL) or Sárga Muskotály, the yellow-berried form of MUSCAT BLANC À PETITS GRAINS.

musqué is a French term meaning both 'perfumed', as in musky, and 'muscat-like'. Many vine varieties, including CHARDONNAY, have a Musqué mutation which is particularly aromatic and may add to the variety's own characteristics a grapey scent reminiscent of MUSCAT.

must is the name used by winemakers for a thick liquid that is neither GRAPE JUICE nor WINE but a mixture of grape juice, stem fragments, grape skins, seeds, and pulp that comes from the DESTEMMER-CRUSHER that smashes grapes at the start of the winemaking process, although it is also sometimes used loosely to refer to GRAPE JUICE. The French equivalent is *moût*, the Italian is *mosto*, the Spanish is *pasta*, and the German is *Maische*. Confusingly, Spanish *mosto* refers to the juice once it has been pressed off the skins (see PRESS), and Italian *mosto* can refer to both the juice without the skins and to must. The word 'must' has been used in English for at least a thousand years to refer to fruit being prepared for, or undergoing, FERMENTATION.

must chilling, important WHITE WINEMAKING operation, particularly in WARM CLIMATES, which delays the onset of fermentation until after pressing and helps prevent OXIDATION. See REFRIGERATION and TEMPERATURE. France's first must chiller was installed, by Australians, in the Languedoc in the early 1990s.

must weight, important measure of grape RIPENESS, indicated by the concentration of dissolved compounds in grape juice or must. Since about 90% of all the dissolved solids in grape juice are the fermentable SUGARS (the rest being acids, ions, and a host of other solutes), any measurement of these solids gives a reliable indication of the grapes' ripeness and therefore the POTENTIAL ALCOHOL of wine made from them (see FERMENTATION).

Must weight may be measured approximately in the vineyard before harvest using a REFRACTOMETER or in the winery using a refractometer or a HYDROMETER, calibrated according to one of several different scales used in different parts of the world for measuring the concentration of dissolved solids. This variation is not so surprising when one considers how crucial this statistic is to the winemaking process and therefore how early in the evolution of each country's wine industry a scale will have been adopted. Each scale merely requires a different calibration of the hydrometer, usually with a reading of zero indicating that the DENSITY of a solution is exactly one, as in pure water.

BAUMÉ is the scale most commonly used in much of Europe, including France, and in Australia. The number of degrees Baumé indicates the concentration of dissolved compounds in a solution calibrated so that it indicates fairly well the potential ALCOHOLIC STRENGTH of a wine made by fermenting the must to dryness, although the figures in the table above are approximate.

In the United States, and increasingly in Australia, ripeness is most commonly measured in degrees BRIX, also sometimes called Balling, both terms borrowed from the sugar-refining industry. The Brix

reading simply indicates the percentage of solids (of which about 90% are sugars) by weight.

Winemakers in Germany most commonly use the OECHSLE scale, which simply indicates the density of the juice: a grape juice with a specific gravity of 1.085 is said to be 85 °Oechsle. Austria has its own, similar scale, devised at KLOSTERNEUBURG, which measures ripeness in degrees KMW (or Babo).

Baumé (degrees)	Brix/ Balling (degrees)	Oechsle (degrees)	Potential alcohol (% vol)
10	18.0	75	10
11	19.8	84	11
12	21.7	93	12
13	23.5	101	13
14	25.3	110	14
15	27.1	119	15

Since it takes about 16.5 g/l (0.6 oz/1.76 pt) of sugar to produce 1% alcohol by fermentation (in white wines, closer to 18 g/l in reds, depending on the efficiency of the YEAST strain), it is possible to calculate approximately the potential alcohol using any of these scales. All of these must-weight measurements can be roughly converted among themselves, with Baumé values about five-ninths of Brix/Balling values, and 14.7 °Brix/Balling equalling 60 °Oechsle. Some equivalences are outlined in the table, although, according to published scales, the relationship between the different measurements is not a strict one (as illustrated in Hamilton and Coombe).

A typical dry wine is made from grapes which measure 12–14 °Baumé, 22–25 °Brix or Balling, and 93–110 °Oechsle. Grapes grown in ENGLAND in particularly cool years, however, may reach a natural must weight of around 50 °Oechsle, while some grape varieties in the SAN JOAQUIN VALLEY of California can easily reach 30 °Brix, as they gradually dehydrate under the intense heat. One German wine harvested at Nussdorf in the PFALZ in 1971 was picked at 326

°Oechsle and was still fermenting 22 years later, having reached just 4.5% alcohol; another picked in 2011 in Rheinhessen came in at 338 °Oechsle, but the volume was too small and the sugar too high to ferment. B.G.C.

Hamilton, R. P., and Coombe, B. G., 'Harvesting of winegrapes', in B. G. Coombe and P. R. Dry (eds.), *Viticulture*, ii: *Practices* (2nd edn, 2006).

mutage is the process of stopping GRAPE JUICE or MUST from fermenting, sometimes by adding SULFUR DIOXIDE but usually by adding alcohol, thereby creating an environment in which YEASTS can no longer work. Mutage transforms fermenting must into a vin muté such as a VIN DE LIQUEUR or a VIN DOUX NATUREL. The alcohol may be added before or after the grape juice has been separated from the skins (*sur grains* or *sur jus*). Mutage plays a crucial part in making PORT, where the process is known as *fortificação* or occasionally *aguardentação*.

mutation, spontaneous change to genetic material occurring during cell division in organisms such as grapevines. Since so many of today's VINE VARIETIES were selected over the last several centuries, they may have accumulated a substantial load of mutations. WILD VINES are invariably dark-skinned; light-skinned varieties are therefore the result of mutation. Generally mutations are either innocuous or deleterious, but people have had many centuries in which deliberately to select those vines which perform best (a process now formalized as CLONAL SELECTION), so beneficial mutations have been maintained.

Mutation is particularly common among vine varieties with a long history of cultivation such as PINOT NOIR, CARIGNAN, SAVAGNIN, GRENACHE, and TERRET. Although mutation is not always as spectacular as a change in berry colour, most of these varieties have forms called variously Noir (black), Gris (grey), Blanc (white), Rose (pink), Vert (green), Rouge (red), and sometimes more.

Mutations commonly seen in grapevines include leaf, berry, and pulp colour, berry size, seedlessness, compactness of bunches, productivity, flavours, date of ripening, leaf lobation, very large INFLORESCENCES, and absence of inflorescences. Mutation can also cause polyploidy (multiple sets of chromosomes), which leads to 'giant' plants and berries. The two Gamay TEINTURIERS, Gamay Teinturier de Fréaux and Gamay Teinturier de Chaudenay, are thought to be mutations of Gamay de Bouze. A mixture of normal and mutant tissue is known as a chimera, and the varieties Pinot Noir and Pinot Meunier are partners in a so-called periclinal chimera. Such plants are essentially composed of a mutant 'skin' enclosing a 'normal' interior. Pinot Meunier is essentially similar to Pinot Noir, with the exception of white hairs on the shoot tip and young leaves.

Mutation can be induced by chemicals such as colchicine and by ionizing radiation. A form of genetic variation known as somaclonal mutation is induced during TISSUE CULTURE, and it is thought that this will be a useful means of increasing clonal variation among existing varieties. R.E.S. & J.V.

muzzle, the wire which holds a SPARKLING WINE cork in place. Known in French as a muselet.

MW, abbreviation for MASTER OF WINE.

Myanmar (formerly Burma), tropical South East Asian nation, bordered by THAILAND, Laos, CHINA, INDIA, and Bangladesh, had two

wineries focused on classic VITIS VINIFERA wine styles in 2023. Myanmar Vineyard Estate has 6 ha/17 acres of vineyards at ELEVATIONS of 1,200 m/3,937 ft on LIMESTONE slopes on the southern extension of the Himalayan ranges, west of the Shan State capital Taunggyi. Shiraz makes up 65% of the vineyards; the rest is planted to DORNFELDER, TEMPRANILLO, and Sauvignon Blanc. Red Mountain Estate is further south, on the shores of Inle Lake, a popular tourist resort. The 74-ha/185-acre property grows mainly INTERNATIONAL VARIETIES, plus MUSCAT BLANC À PETITS GRAINS for a LATE HARVEST white and CARIGNAN for a rosé. D.G.

mycoderma. See FILM-FORMING YEASTS.

mycoplasma. See PHYTOPLASMA.

mycorrhiza, the symbiotic relationship between vine ROOTS and arbuscular mycorrhizal fungi in the soil that increases the surface area of the roots and allows the vine to access and utilize NUTRIENTS in the soil more effectively. The fungi, which thrive in soils high in ORGANIC MATTER, have been shown not only to improve the uptake of nutrients but also to increase resistance to plant pathogens and to improve SOIL STRUCTURE. Enterprising companies are selling mycorrhizal fungi that can be used to inoculate vineyard soils, and there is a growing market for so-called biostimulants that are said to activate indigenous populations of mycorrhizal fungi. See BIOLOGICALS.

N

Nagyburgundi, occasional Hungarian synonym for BLAUFRÄNKISCH, although Kékfrankos is more common.

Nahe, wine region in GERMANY with 4,202 ha/10,383 vine acres in 2019 scattered over a wide area on either side of the river Nahe (see map under GERMANY). The region was defined in its current form as part of the German wine law of 1971, bringing together several geologically and climatically distinct areas.

By turns bucolic and geologically dramatic, the stretch of the river between Monzingen and Bad Münster am Stein features steep and often terraced slopes yielding world-class RIESLING on a geologically complex mix including SANDSTONE, porphyry, and SLATE. A single vineyard, such as the renowned Niederhäuser Hermannshöhle, can incorporate five fundamentally different soil types, and it does not seem to be mere imagination that such geological complexity is mirrored in the flavour of the wines. The general climatic tendency is to warm as the Nahe meanders downstream. Excellent ventilation, low precipitation, and balmy autumnal temperatures, in addition to the steep, southward ASPECT of vineyard slopes, offer ideal circumstances for late-ripening Riesling.

The foremost wine villages (with their most notable vineyards) along this stretch of the Nahe, travelling downstream, are Monzingen (Frühlingsplätzchen, Halenberg), Meddersheim (Rheingrafenberg), Schlossböckelheim (Felsenberg, Kupfergrube), Oberhausen (Brücke, Leistenbreg), Niederhausen (Hermannshöhle, Kerz, Klamm), Norheim (Dellchen, Kirschheck), and Traisen (Bastei, Rotenfels). Wines of pronounced, often pungent spice and mineral inflection with frequent red fruit notes are characteristic for many of the best vineyards in this

area. The Rheinland-Pfalz (originally Prussian) viticultural school in Bad Kreuznach and State Domaine of Niederhausen-Schlossböckelheim founded in 1902 (privatized in 1998 and impressively revived in 2009 as Gut Hermannsberg) greatly helped to establish what reputation Nahe Riesling enjoyed prior to the 1980s, while the efforts of Helmut Dönnhoff in Oberhausen and Werner Schönleber at Weingut Emrich-Schönleber have done much to secure the Nahe's current high standing.

On the northern outskirts of Bad Kreuznach, immediately adjacent to the city, the vineyards are substantially LOESS and CLAY, on gentler slopes than those elsewhere along the Nahe, but in certain sites, notably Kahlenberg and Krötenpfuhl, GRAVEL offers excellent drainage and Riesling potential. Immediately west of Bad Kreuznach, Roxheim, dominated by red SANDSTONE, enjoys historical and recently renewed renown for both Pinot Noir and Riesling. Viticulture around Bad Kreuznach, limited by late 20th century urban development, was traditionally dominated by large landholders who also had important holdings in the Middle Nahe, most notably the Anheuser family and the Reichsgraf von Plettenberg.

The Lower Nahe, near its confluence with the Rhine at Bingen, features outstanding steep-slope Riesling from a wide range of soils, notably quartzite-rich SLATE. Top sites include a trio along the Troll-Bach at Dorsheim just west of the Nahe elevated to late 20th century prominence by winegrower and wine journalist Armin Diel (Schlossgut Diel): Burgberg, Goldloch, and Pittermännchen. There are also two standout sites along similar tributary streams at Münster-Sarmsheim, Dautenflänzer and Pittersberg, and another at Bingerbrück—Abtei, a vineyard farmed in the Middle Ages by the Ruppertsberg Abbey.

The aforementioned areas by no means exhaust the historic or current sources of excellent Nahe wine. These include the Alsenz near its confluence with the Nahe at Bad Münster (in particular the Altenbamberger Rotenberg and Ebernburger Schlossberg), as well as a number of villages located several miles north and west of the Nahe, most notably Bockenau, whose towering Felseneck and

Stromberg were virtually unknown prior to the 21st-century efforts of Weingut Schäfer-Fröhlich. Sporadic vineyards occur along the Nahe's tributary Glan, from Oberhausen's Leistenberg south to Meisenheim more than 12 km away. Among these, the dramatically terraced Kloster Disibodenberg in Odernheim harbours not only outstanding wine potential but also Germany's oldest known vine vestiges, conceivably dating back within a century or so to the eponymous cloister's most famous resident, sainted Nahe native Hildegard of Bingen.

White wines make up three-quarters of the Nahe's wines, with Riesling dominating in both reputation and plantings, at 29% share of vine surface. MÜLLER-THURGAU comes in number two at 12%, but qualitatively more important is the nearly 16% collective share of WEISSBURGUNDER (Pinot Blanc) and GRAUBURGUNDER (Pinot Gris). SILVANER, dominant in a once flourishing Alsenz Valley, has slipped to 6% Nahe-wide. In red wine varieties, DORNFELDER boasts more acreage, but the Nahe's serious reds are issued from SPÄTBURGUNDER (Pinot Noir). D.S.

Pigott, S., et al., *Wein Spricht Deutsch: Weine, Winzer, Weinlandschaften* (2007).

Reinhardt, S., *The Finest Wines of Germany* (2012).

Namibia in southern AFRICA was first planted to wine grapes in the late 1800s by German colonists. The climate is arid and subtropical, forcing most grape-growing into cooler, higher ELEVATIONS. By 2022 there were four wineries producing grape wines: Thonningii in the north, in the Otavi Mountains; Kristal Kellerei and Erongo Mountain Winery on the banks of the Omaruru River in west-central Namibia; and Neuras further south, in the Naukluft Mountains.

nanofiltration, a membrane separation technique which is looser than REVERSE OSMOSIS and tighter than ULTRAFILTRATION. It can be used to remove sugars from juice and ultimately results in the ALCOHOL

REDUCTION of the final wines. Furthermore, wine CONCENTRATION by nanofiltration can result in a wine with decreased ETHANOL and water content (see ALCOHOL REDUCTION). However, more smaller molecules that contribute to wine flavour can be lost using this technique than with REVERSE OSMOSIS, and it should be used with care.

Wollan, D., 'Membrane and other techniques for the management of wine composition', in A. G. Reynolds (ed.), *Managing Wine Quality 2: Oenology and Wine Quality* (2nd edn, 2021), 183–212.

Naoussa is the most well-known appellation of northern GREECE, on the south-eastern slopes of Mount Vermio at ELEVATIONS of 200–500 m/660–1,650 ft, where there is usually no lack of rain and winters are cool by Greek standards. The PDO applies only to red wines made from the XINOMAVRO grape, aged for at least a year in OAK. Traditionally, wine was matured in old wooden CASKS, but there has been considerable experimentation with new, small BARRIQUES. This may be the only appellation in Greece, with the possible exception being Nemea, where producers are working to identify the best subregions, akin to a CRU system in its genesis. SINGLE-VINEYARD bottlings are increasing, from vineyards such as Palaiokalias, Gastra, or Trilofos.

Naoussa reds can age well for several decades, maintaining an ethereal, BAROLO-like personality for a fraction of the price. Naoussa Xinomavro is also used for rosé wines and some impressive BLANC DE BLANC wines, some OAK AGED, but these all are allowed only under the PGI Imathia. PGI wines can contain other varieties as well, such as Merlot and Syrah, which are often used to soften the edges of Xinomavro, resulting in some popular red blends. K.L.

Napa, small city north of San Francisco in CALIFORNIA that gives its name to Napa County and, California's most famous wine region and an AVA, the Napa Valley. Though Napa Valley's modern history began,

arguably, in the 1960s, its wine industry can trace its roots back to the winter of 1838–9 when early settler George C. Yount planted the area's first VITIS VINIFERA vines. Yount, a homesteader, was brought to the region by the Mexican government, which awarded him a land grant in a bid to increase the population of California, which was under its control at the time. Yount's stake was a relatively lonely one until the Gold Rush of 1849 ushered in an era of mass migration to California. This was the mechanism by which many of Napa's first winemakers, generally of European origin, came to settle 'the Valley'.

Napa's wine industry boomed in the wake of the Gold Rush, and by the 1880s there were nearly 150 wineries and over 8,094 ha/20,000 acres of *vinifera* in the ground. Napa achieved a reputation for high quality early on, due to its genial climate, water resources that allow vines to be DRY-FARMED (Napa has a high and independent water table in many places), and the long band of ALLUVIAL fans that stretch along the valley's western foothills. The fact that the region was connected to San Francisco via water routes was also an early advantage; proximity to San Francisco remains a major economic boon still.

In the 1890s PHYLLOXERA devastated Napa's vineyards, and a national recession forestalled reinvestment, leaving many fields vacant. The increasingly vocal temperance movement also made replanting seem unwise, and PROHIBITION was indeed enacted in 1920. A handful of wineries remained in business by selling wine to the clergy, but most operations shuttered. However, the national enthusiasm for HOME WINEMAKING kept many vines in the ground, though the varieties planted shifted to favour the so-called 'shipper varieties'—grapes such as ZINFANDEL, PETITE SIRAH, CARIGNAN, and ALICANTE BOUSCHET that were sturdy enough to survive a cross-country journey via unrefrigerated rail car. Pockets of these gnarled old vines remain in less-fashionable appellations such as Calistoga and Oak Knoll, where now-popular Cabernet Sauvignon has not gained as much traction.

The few Napa wineries that reopened upon Repeal in the 1930s faced many challenges: the Great Depression, a fundamentally

altered national palate, and a poor understanding of cellar HYGIENE. It was this last point that sent Beaulieu Vineyards' owner Georges de Latour to France in search of a winemaker with scientific training. He returned in 1938 with André TCHELISTCHEFF, who would do much to elevate the baseline quality of wines at BV and in Napa at large. Tchelistcheff worked closely with many of Napa's winegrowers, including the MONDAVI brothers, who were then at Charles KRUG. In 1966, Robert Mondavi was kicked out of the family winery and started his own eponymous operation; many consider this to mark the birth of Napa's modern history.

Though Napa was slow to recover after Prohibition, the number of new wineries began to pick up speed in the 1960s. This was good news for the wine industry, but environmentalists were concerned that the region's proximity to San Francisco would encourage the kind of unchecked development that turned nearby Marin and Santa Clara counties from agricultural wonderlands into slopes of stacked houses. In 1968 the Agricultural Preserve was enacted. This forward-looking, controversial legislature has helped Napa maintain its agrarian status and preserve its wild lands. The 'Ag Preserve', coupled with restrictions regarding planting on slopes and in proximity to waterways, mean that Napa is effectively 'planted out' at around 18,616 ha/46,000 acres. All together, these vines produce around 4% of California's wine, but its value amounts to more than 25% of the state's wine revenue.

Growth in Napa Valley continued into the 1970s, spurred on by the 1976 JUDGMENT OF PARIS, which attracted a slew of increasingly wealthy investors. Many of these new winery owners were interested in an estate model of operation, where winemaking and grape-growing were farmed out to employees. Because of this, the need for skilled winemakers skyrocketed, and universities such as UC DAVIS began to establish or expand their VITICULTURE and OENOLOGY programmes. As many of Napa's top wineries produce relatively little wine, CONSULTANT winemakers have become more and more common. Today, a small handful of elite winemakers are responsible for a

sizable chunk of the area's top brands. This is especially true among the so-called CALIFORNIA CULT producers.

Napa Valley arcs gently to the north-west, with the San Pablo Bay in the south and Mount St Helena, the highest point in Napa County, in the north. Because of this positioning, the southern, bay-side section of Napa Valley is considerably cooler (average summer daytime high of 27 °C/80 °F) than the north (35 °C/95 °F). Nighttime temperatures drop significantly, to a valley-wide average of 12 °C/53 °F. This extreme DIURNAL TEMPERATURE RANGE, coupled with the fog that blankets the valley floor every morning during the growing season, help to slow ripening and retain acidity. Overall, the region enjoys a MEDITERRANEAN CLIMATE, with hot, rainless summers and cool, wet winters.

This has allowed many winegrowers to turn to SUSTAINABLE, ORGANIC, or BIODYNAMIC VITICULTURE, even as growers need to contend with pests such as the glassy-winged SHARPSHOOTER, vine and grape MEALYBUGS, and NEMATODES. In the 2000s, the region's main viticultural challenges have been DROUGHT and HEATWAVES, which in turn increase the potential for WILDFIRES.

Napa's magic is derived in no small part from a magnificent diversity of ASPECT, MESOCLIMATE, and soil. The valley itself is around 48 km/30 miles long and 5 miles across at its widest. ELEVATIONS range from sea level to 800 m/2,600 ft, and vineyards exist at all ASPECTS to the sun. It is important to note that only the eastern half of the Mayacamas mountain range belongs to Napa; as the county line traces the ridge, the western half resides in SONOMA. Across the valley, the Vaca Mountains are entirely contained within Napa County.

The diverse terrain contains soils from half of the world's 12 recognized soil orders and 33 different series. This variegation has informed the creation of 16 nested AVAs, though Napa's appellation system is still very much a work in progress. In general, they can be divided into two groups: those in middle of the valley (from south to north, Coombsville, Oak Knoll, Yountville, Stags Leap, Oakville, Rutherford, St Helena, and Calistoga); and those on hills and

mountains (Wild Horse Valley, Atlas Peak, Chiles Valley, and Howell Mountain in the Vaca Range, and Mount Veeder, Spring Mountain, and Diamond Mountain in the Mayacamas). Some appellations, such as Wild Horse Valley, contain very few vines, while other significant grape-growing areas such as Pritchard Hill, Conn Valley, and the slopes between St Helena and Howell Mountain possess no official designation. One of the biggest controversies of the appellation system is the Napa Valley AVA itself. Due to emphatic lobbying by big producers to allow the inclusion of fruit from far-flung areas such as the Pope and Chiles Valleys, the Napa Valley AVA extends far beyond the limits of what might reasonably be thought of as 'the valley' to include almost the entirety of Napa County. As with the rest of Napa Valley, the majority of the fruit grown here is Cabernet Sauvignon, but Zinfandel and Sauvignon Blanc are also high in quality.

The following are Napa's most significant subappellations.

Atlas Peak AVA

Located in Napa's southern reaches, Atlas Peak is one of its cooler mountain regions. It also boasts one of its taller peaks, cresting at 814 m/2,671 ft above sea level. It is a fairly arid region, and much of the land is tied up in cattle ranches. Viticulturally, it is an appellation of extremes, with massive vineyards such as Antica Gallo's Stagecoach and boutique properties such as Kongsgaard and Au Sommet. Cabernet Sauvignon and Chardonnay are the region's focus.

Calistoga AVA

Napa Valley's northernmost sub-AVA, Calistoga receives little of the cooling fog and winds that come up from the San Pablo Bay, though small cracks in Diamond Mountain allow some ingress. Except for St Helena to the south, the region is almost entirely ringed by mountains, which further act to trap in the heat. Summer temperatures can reach more than 38 °C/100 °F. Napa's volcanic past is on clear display here, both in the IRON-rich soils and the prolific hot springs. Red and black grape varieties dominate: Cabernet Sauvignon, of course, but pockets of OLD VINE Zinfandel, PETITE SIRAH, and CHARBONO also.

Coombsville AVA

Napa's newest AVA has been the backbone of big Napa Cabernet blends for many years, often adding STRUCTURE and freshness. These qualities are directly the result of the climate—being situated in the south-east of Napa Valley, Coombsville lies straight in the path of the daily fog and breezes that come up off the San Pablo Bay. The region is ampitheatre-shaped and carpeted with vines, which stretch from sea level to high up the Vacas, with very few wineries interspersed among the vineyards. Because the region is so relatively cool, it is also well-known for its Chardonnay and, to a lesser extent, Pinot Noir.

Diamond Mountain District AVA

This rugged appellation in the Mayacamas mountain range is only intermittently flat enough to cultivate a vineyard. VOLCANIC soil abounds; though the region is quite warm, the Diamond Creek DRAINAGE allows an influx of cooling Pacific influence to creep downslope. Mainly planted to Cabernets Sauvignon and Franc, the region tends to produce wines that are distinctly 'mountain' in tone, with intense structure and concentration.

Howell Mountain AVA

In the north-east of Napa Valley, Howell Mountain is the most widely cultivated of Napa's mountains (it is something of a plateau, which makes it easier to farm than other craggier mountains) as well as the most populous, being the only one to contain its own town, Angwin. It is arguably the most distinct appellation in that it is drawn entirely by ELEVATION. The AVA starts along the fog line, at 1,400 ft/427 m. Wines produced below the 1,400-ft elevation mark are eligible for the Napa Valley AVA only. Cabernet Sauvignon dominates, but Zinfandel and Merlot can be noteworthy.

Mount Veeder AVA

Mount Veeder, at the south-western end of the valley, just above Carneros, is the coolest of Napa's Mountain AVAs, as well as the least cultivated. It enjoys regular breezes off San Pablo Bay, and its steep hillsides are blanketed in giant redwoods and Douglas fir trees. Winemaking operations here tend to be small and characterful. Unlike the rest of Napa's mountains, very little VOLCANIC soil is found on Mount Veeder. Cabernet Sauvignon, the dominant grape variety, can produce wines with pronounced ageability in this cool mountain terrain.

Oakville AVA

In the centre of the valley, the Oakville appellation varies considerably from east to west. In the east, the AVA boundaries were extended upslope to include Dalla Valle Vineyards, which overlooks the appellation from its sun-kissed, rust-stained perch. Heading west the mountain dissolves into small hills where Rudd, Screaming Eagle, and Plumpjack are located. The centre of the appellation possesses deep, rich soils that turn into ALLUVIAL fans near the Mayacamas foothills. Here such historic vineyards as To Kalon and Martha's are located. The western hillsides are tree-shrouded and steep and contain such impressive properties as Harlan and Futo. This is the heartland for Napa Valley Cabernet Sauvignon, which roundly dominates.

Rutherford AVA

Rutherford is a rectangle-shaped appellation, right in the centre of Napa Valley and at its widest point. It is perhaps most famous for its BENCH—the long, snaky alluvial band that stretches along the valley's west side. Cabernet Sauvignon dominates here, although there is a surprising amount of Sauvignon Blanc, given the heat of the region. Several large landholders own big chunks of Rutherford, including those behind Round Pond, Frog's Leap, and Beckstoffer Vineyards.

Spring Mountain District AVA

Named for the abundant freshwater springs that trickle down or underneath the mountainside towards St Helena below, Spring Mountain District is a craggy, twisted terrain that, despite a few big players like Spring Mountain Vineyards, is home to mostly small family-run operations. Though Cabernet is dominant, less common varieties such as Riesling and Syrah can thrive in the dramatically ranging MESOCLIMATES.

Stags Leap District AVA

This small AVA is the only 'floor' appellation not to stretch across the entire valley. Instead, it is surrounded by Yountville on three sides, with its eastern edge formed by the dramatic bald rock cliffs known as 'the Palisades'. The Palisades not only divide Stags Leap from Atlas Peak to its east but also serve to reflect light and heat down on the vines, making this region warmer than surrounding Yountville. A series of high knolls in the west end of the appellation create a wind tunnel in conjunction with the Palisades that can be so strong that plant STOMATA will close, thereby stalling PHOTOSYNTHESIS. This slows ripening and makes for distinctively TEXTURED Cabernet Sauvignons that tend to be both supple and bright.

Yountville AVA

Yountville occupies the cooler southern end of the valley; because of this, Cabernet Sauvignon can be found next to broad swathes of white wine grapes, including many earmarked for sparkling wine. Although the region is perhaps best known for its culinary scene, anchored by Thomas Keller's French Laundry, it is responsible for some of Napa's most profound and underrated wines. The most viticulturally exciting band of Yountville is the western BENCH, where such luminary vineyards as Dominus's Napanook, Blankiet Estate, and Sleeping Lady are located. These deep, GRAVEL-rich soils are woven through with CLAY, and the gentle climate makes for elegant and understated wines.

Naples, large south Italian port and capital of the CAMPANIA region. The area around Naples had once produced all the greatest wines of ancient ROME, not only FALERNIAN but also CAECUBAN, MASSIC, and SURRENTINE, but in viticultural terms it was never to be that famous again. With the fall of the Roman Empire and the economic decline of Italy, the market for fine wines collapsed.

Its oriental trade, which dates from Naples's medieval period under Byzantine rule, included the strong sweet MALMSEY of Crete, but PUGLIA produced similar wines itself, mostly for consumption in southern Italy. Naples also traded in the VERNACCIA of Liguria, which it sold to Sicily, Majorca, and PARIS. These wines were known collectively as *vini grechi* because, like the wines imported from the Aegean, they were high-quality sweet wines, capable of surviving a long sea voyage. The wines of Campania, which were not in the Greek style but dry, were called *vini latini*. They were considered inferior and were not long-lived enough to be sent overseas to northern Europe. The highest-regarded of the *vini latini* were those of Mount Vesuvius, which were sold to other parts of Italy by the merchants of Naples and Salerno. In addition, Naples sold CALABRIAN wines to Aragón and the Balearic Islands.

All this made Naples the most important Mediterranean wine-trading port in the 14th century, yet, because of its many changes of regime and its severance from Sicily in 1282, Naples never became a political or economic power to match the northern city states. Geographically it was far better placed than VENICE and GENOA to conduct the lucrative trade in Aegean wines and other luxury goods with northern Europe, but by the late 13th century, when Genoa began to send its galleys to Southampton and Bruges, Naples was no longer in a position to compete.

Today the name 'Naples' is more readily associated by American wine lovers with an important charity AUCTION held in the city of the same name in Florida. H.M.W.

Nascetta, white wine grape recently revived in the LANGHE and increasingly appreciated as a savoury VARIETAL wine.

Nasco, ancient light-berried vine making soft white wines from fewer than 100 ha/247 acres around Cagliari on SARDINIA.

natamycin, an antiobiotic used to control the growth of yeasts and moulds in the food industry but not generally permitted as a wine ADDITIVE except in SOUTH AFRICA.

natural alcohol, defined in EU regulations as the total ALCOHOLIC STRENGTH of a wine before any ENRICHMENT.

natural wine, unregulated term, sometimes abbreviated to natty wine, used to describe wines made with ORGANIC grapes and no ADDITIVES other than minimal SULFITE additions.

A 2020 OIV presentation described the natural wine movement as more of a philosophy than a practice, stemming from a desire to have 'minimal intervention to achieve maximum purity'.

General guidelines for these minimalists' wines start with the notion that natural wine is made from one ingredient—hand-picked, organically grown grapes with nothing added: no YEAST, ENZYMES, or LACTIC ACID BACTERIA. The wine should be made with minimal intervention: no ENRICHMENT, ACIDIFICATION, CONCENTRATION, or REVERSE OSMOSIS, no cross-flow or tangential FILTRATION, and no extreme TEMPERATURE CONTROL. Nothing that affects the taste and flavour of the wine is allowed, although some more pragmatic practitioners allow a coarse filtration.

The current natural-wine sector, especially popular with younger wine drinkers, was seen as a response to the increased use of AGROCHEMICALS after the Second World War and the resulting need for AMELIORATION in the winery, such as reliance on cultured yeast,

excessive SULFUR DIOXIDE, and sugar and the many other approved additives such as enzymes, BACTERIA, TANNINS, and NUTRIENTS.

Marcel Lapierre of Morgon was a seminal figure in the history of natural wine. In the late 1970s the young Beaujolais vigneron became inspired by a neighbour: vigneron, négociant, and scientist Jules Chauvet (now often referred to as the grandfather of the natural-wine movement). As a scientist, Chauvet conducted studies on FERMENTATIONS with and without sulfite additions. As a vigneron he worked organically and used more traditional winemaking methods, including SPONTANEOUS FERMENTATION, and no additives. Lapierre followed Chauvet's minimalist approach, as did his friends Jean Foillard, Jean-Paul Thévenet, and Guy Breton, forming what is often referred to as the 'gang of four'. Jacques Néauport, who worked with Chauvet, became the pre-eminent CONSULTANT for the blossoming band of natural winemakers.

These new wines found their way to the Paris wine bars in the early 1980s and then influenced winemakers throughout France, most notably in the Loire. By 2015, this wine outlier had become widespread if not mainstream, especially but by no means exclusively in wine bars. Italy, Spain, and Georgia were early hot spots but by the second decade of the 21st century it was a global phenomenon, aided by a proliferation of natural wine fairs.

The movement has inspired both zealous followers and virulent critics. American wine writer Robert PARKER called natural wine advocates 'terroir jihadists'.

The category's existence has led in some quarters to a reconsideration of what had been considered FAULTS, with adherents tolerant of cloudiness and perceptible VOLATILE ACIDITY, for instance. Lower sulfite levels have also led to an increase in MOUSY wines.

The genre has encouraged a return to techniques such as SKIN-FERMENTED white wines and PET-NATS as well as a revival of PIQUETTE. The movement is also in tune with other more general trends such as much wider adoption of organic, BIODYNAMIC, and REGENERATIVE viticulture; lower sulfite and alcohol levels; chillable reds such as

those described as GLOU-GLOU; less OAKY wines; and experimentation with materials other than oak for fermentation and ageing such as CONCRETE, CLAY, and glass to decrease the impact of exogenic flavours on the wine.

Being often cloudy and reductive (see REDUCTION), natural wines rarely align with standardized tasting profiles and so have often been rejected in European CONTROLLED APPELLATION tastings with the result that many are now sold with no more geographical specificity than their country of origin. Hence VIN DE FRANCE, and several court cases.

There was an anarchic element to those originally involved in the movement who resisted definitions and regulations, but that is changing as the term has gained marketing power and less purist wines sold as 'natural' have emerged. As an attempt to give the consumer protection, at least one private certification, Vin Méthode Nature, was devised in the Loire in 2020 and is recognized by the INAO.

Nomenclature continues to be problematic. Many conventional winemakers resent the implication that their wines are 'unnatural'. The term 'low intervention' is preferred by some producers. See also ZERO-ZERO wines. A.F.

Feiring, A., *Naked Wine* (2011).

nature when applied to a French wine usually means 'still'. Nature, with a capital N, is viewed by wine producers as friend or enemy and everything in between, depending on whether they are, respectively, TRADITIONALISTS or technocrats. See NATURAL WINE.

Naturwein, German term for wine from MUSTS to which neither sugar nor water has been added. Once an important mark of quality, the term was abolished by the 1971 German wine law, which replaced it with the notion of wine with PRÄDIKAT. See GERMAN HISTORY.

Navarra, known in English as Navarre, autonomous region in north-east SPAIN which also lends its name to a DOP with 10,000 ha/24,711 acres of vineyard in 2021. The kingdom of Navarra once stretched from BORDEAUX to Barcelona, but today this extensive denomination is overshadowed by RIOJA, a small part of which extends into the province of Navarra (see map under SPAIN). The wines share a common history.

Pilgrims en route to Santiago de Compostela fuelled the demand for wine in the Middle Ages. Later, in the mid 19th century, both Rioja and Navarra benefited greatly from their proximity to France after it was invaded by PHYLLOXERA. Because northern Spain was affected considerably later than south-west France, vineyards here were expanded and large quantities of Navarran wine were sold to producers in France until phylloxera arrived in Navarra itself in 1892. The region recovered fairly quickly, but the area under vine in 1990 was less than one-third of that a century before.

The region splits into five subzones according to climate, from the cooler slopes of the Baja Montaña close to the Pyrenean foothills and the slightly warmer Valdizarbe and Tierra Estella districts in the north of Navarra to Ribera Alta in the centre of the region and Ribera Baja round the city of Tudela in the south. Rainfall totals range between 700 mm/28 in in the north and 400 mm in the south and east, while summer temperatures become correspondingly warmer. With over 30% of Navarra's vineyards, Ribera Baja has traditionally been the most important of the five subzones, although most of the planting in the late 1980s and early 1990s took place in the cooler north.

The GARNACHA grape used to dominate Navarra's vineyards but now makes up just 23% as plantings of TEMPRANILLO have increased since the 1990s, now making up 35% of the vineyards. Examples from Terra Estrella can bear a certain resemblance to those of Rioja, which is directly adjacent. For a long time, Garnacha was mainly relegated to good, dry rosé, which the region continues to make in large quantities, but producers such as Santa Cruz de Artazu, Viña Zorzal, Unsi, and Chivite, working with increased respect for the variety, have since proved Garnacha's ability to produce world-class red wines on

its own. Cabernet Sauvignon and Merlot are also widely grown, making up 16% and 14% respectively.

White wines are made principally from CHARDONNAY, which was brought to the region from BURGUNDY in the 1200s, and VIURA. Some distinctive sweet whites are made from Moscatel de Grano Menudo (MUSCAT BLANC À PETITS GRAINS) grown in the south.

Néac , small red BORDEAUX appellation to the immediate north-east of POMEROL.

Nebbiolo, great black grape variety responsible for some of the finest and longest-lived wines in the world. It has been known in the PIEMONTE region in the north-west of Italy since at least the 13th century and is that area's most distinctive and distinguished vine. The quality of wines such as BAROLO and BARBARESCO inspires hopeful planting of the variety all over the world.

Nebbiolo in Italy

Documents from the castle of Rivoli dating from 1266, when Conto Umberto de Balma is recorded as obtaining a wine named 'Nibiol', provide early evidence of Nebbiolo's existence. PETRUS DE CRESCENTIIS' *Liber ruralium commodorum* in 1304 made an unambiguous link between the 'Nubiola' grape, which he termed 'delightful', and 'excellent wine'. Some have postulated that the name derives from *nobile*, or 'noble', but a more likely derivation is from *nebbia*, or 'fog', a frequent phenomenon in Piemonte in October when the grape is harvested and also possibly a reference to the thick BLOOM on ripe Nebbiolo berries.

Modern Piemonte has shown its respect for Nebbiolo by restricting its planting to a few areas: of the 2020 total of 6,324 ha/15,627 acres (up from 4,476 ha in 2012), more than 80% were in the province of Cuneo, predominantly in Barolo, Barbaresco, and Roero.

Nebbiolo is always the first variety to bud and the last to ripen, with harvests that regularly last well past the middle of October, and the variety is accordingly granted the most favourable HILLSIDE exposures, generally south to south-west. Perhaps as important as the vineyard site, however, are the soils: Nebbiolo has shown itself to be extremely fussy and, with a few exceptions, notably VALTELLINA and ALTO PIEMONTE, has in the past century given best results only in the CALCAREOUS marls to the north and south of Alba on the right bank of the Tanaro in the DOCG zones of BARBARESCO and BAROLO respectively. Here Nebbiolo-based wines reach their maximum aromatic complexity and express a fullness of flavour which balances the relatively high ACIDITY and substantial TANNINS which are invariably present.

Historically, much more Nebbiolo was planted in Alto Piemonte, under the name SPANNA. Total vineyard area declined rapidly there during Italy's industrial revolution in the 1950s but, thanks to growing international interest in this area's elegant Nebbiolo-based wines, has expanded slowly to 630 ha/1,557 acres in 2019.

NEBBIOLO D'ALBA, an earlier-drinking version of the variety, suggests the heights which it can gain in more choice positions. The ROERO DOCG on the left bank of the Tanaro has predominantly sandy soils which produced better and better wine throughout the 1990s. Roero wines, made from at least 95% Nebbiolo, are notably lighter in style and generally age faster than Barbaresco and Barolo.

Nebbiolo, often called Picutener, also plays the leading role in the postage-stamp-size DOC of CAREMA on the border of the Valle d'Aosta, in the neighbouring and equally Lilliputian DOCs of Donnaz and Arnad-Montjovet in the Valle d'AOSTA itself. In Lombardy's VALTELLINA, Nebbiolo is known as Chiavennasca, with 850 ha/2,100 acres, the only sizeable zone where Nebbiolo is cultivated outside Piemonte. These four areas, subalpine in latitude and definitely cool during the growing season, produce a medium-bodied, fragrant style of Nebbiolo from south-facing vineyards on vertigo-inducing slopes which guarantee enough ripeness to mitigate the grape's tannic asperity and acidic sharpness, helped further by CLIMATE CHANGE. Ripeness can also be achieved by drying the grapes, for example Valtellina's full-bodied, complex dry red wine speciality SFORZATO, or Sfurzat.

These zones apart, Nebbiolo is rarely cultivated elsewhere in Italy, although it is an ingredient in the FRANCIACORTA cocktail. The purported plantings of the variety on the island of Sardinia are in all likelihood DOLCETTO.

Three principal CLONES of Nebbiolo are conventionally identified: Lampia (the most common), Michet, and Bolla. This last is declining because of the pale colour of its wines, while Michet is Lampia afflicted with a virus which causes the vine's canes to fork. Although Michet produces smaller bunches and YIELDS and particularly intense aromas and flavours, it does not adapt itself to all soils and is slowly being replaced by superior clonal material, which can achieve Lampia's intensity but without its viral defects. Quite a few producers continue to cherish virus-affected vines, notably Sandrone, who has propagated material from an unspecified, multi-virus-affected Nebbiolo clone giving 50% more PHENOLICS than Lampia. Most

producers prefer to rely on a careful MASS SELECTION in their vineyards rather than staking their future on a single clone. More systematic clonal research in the 1990s confirmed that Nebbiolo has serious problems with VIRUSES, perhaps the result of excessive inbreeding in an ancient variety so concentrated on a relatively small area.

The total area planted with Nebbiolo declined towards the turn of the century but seems to be increasing once more in the Langhe, with 6,324 ha/15,627 acres recorded in Piemonte in 2020. W.S.

Genetic relationships

Through DNA PROFILING, researchers in Anna Schneider's laboratory at Torino and José Vouillamoz at DAVIS found that Nebbiolo Rosé is not a clone of Nebbiolo but a distinct variety. Furthermore, Nebbiolo Rosé turned out to have a parent–offspring relationship with Nebbiolo. Several additional parent–offspring relationships were discovered between Nebbiolo and traditional varieties from Piemonte (FREISA, VESPOLINA, and Bubbierasco) and Valtellina (Negrera and Rossola). DNA profiling and sequencing has made it possible to classify 98 Nebbiolo clones into seven main genotypes, which generally coincided with the geographical origin of accessions, pointing to Piemonte (and not Valtellina) as its likely place of origin. It was also possible for the first time to discriminate some Nebbiolo clones from the others. J.V.

Gambino, G., et al., 'Whole-genome sequencing and SNV genotyping of "Nebbiolo" (*Vitis vinifera* L.) clones', *Scientific Reports*, 7/17294 (2017).

Robinson, J., et al., *Wine Grapes: A Complete Guide to 1,368 Vine Varieties, Including Their Origins and Flavours* (2012).

Outside Italy

Vine-growers all over the world are experimenting with Nebbiolo. The results often lack the haunting aromas that characterize the variety, but isolated examples in regions as far apart as Oregon, Washington State, and Australia's King Valley and the Yarra Valley in Victoria suggest the quest may not be fruitless. Nebbiolo has so far somewhat reluctantly accompanied Barbera to both North and South America (including Mexico). In California, Sangiovese has proved generally more successful, but there were just 57 ha/142 acres of Nebbiolo in the ground in 2020 compared with South Africa's 78 ha. High yields have tended to subsume the variety's quality in South America. But as the special charms of Barolo and Barbaresco are increasingly appreciated around the world, it is unlikely that growers will give up hope of making great Nebbiolo outside Italy.

Nebbiolo d'Alba is an Italian DOC red produced from NEBBIOLO grapes grown in 2020 on a growing total of 1,087 ha/2,686 acres of vineyard in 32 communes surrounding the city of ALBA in PIEMONTE. Seven of the communes are partially inside the Barolo DOCG zone, although the areas which can produce Nebbiolo d'Alba—the southern sections of Monforte d'Alba and Novello, the north-eastern tip of La Morra, all but a western slice of Diano d'Alba, the northern parts of Verduno, Grinzano Cavour, and Roddi—have been excluded from the Barolo zone. Most of the vineyard land is on the northern bank of the River Tanaro in the Roero hills (which, absurdly, does not belong under the administration of Alba as it lies outside the LANGHE), on sandier soils that yield wines that are softer, less intense, and faster maturing than a Barolo or a Barbaresco, more generically 'Nebbiolo' and less pointedly characterful. The demarcation of the DOC Nebbiolo d'Alba comprises the whole of the DOCG ROERO and therefore can be used by Roero producers for declassification of their wines, more frequently used than ever since Roero DOCG is much less famous than Nebbiolo d'Alba. W.S.

Nebbiolo delle Langhe, now Langhe Nebbiolo, See LANGHE.

W.S.

necrosis, a term used to describe death of tissue. For example, necrotic spots of leaf tissue caused by DOWNY MILDEW appear blackish-brown. For many vine foliar diseases and disorders, the yellowing of leaf sections, or CHLOROSIS, precedes necrosis.

négociant, French term for a MERCHANT and one used particularly of wine merchants who buy in grapes, MUST, or wine, blend different lots of wine within an AOC, and bottle the result under their own label. The role of the négociant is particularly worthwhile in BURGUNDY, where the oldest négociants, traditionally concentrated in Beaune, have been joined since the later 20th century by a new breed of smaller operators, often run alongside a grower's own DOMAINE. So many individual growers produce tiny quantities from each of a number of different appellations that it can make sense to make up commercially more significant quantities and bottle them together. Many of the larger Burgundy négociants have significant vineyard holdings of their own. BOUCHARD PÈRE ET FILS and BOISSET, for example, are two of the CÔTE D'OR's most substantial vineyard owners. Louis LATOUR, Louis JADOT, and Joseph DROUHIN are other important Burgundian négociants. The term négociant-éleveur implies that the négociant oversees the ÉLEVAGE of the wine it sells (not always the case).

Like all important French wine regions, Bordeaux also has a great concentration of négociants, many of which own CHÂTEAUX (while some of the CLASSED GROWTHS are run alongside a négociant business). For more details, see BORDEAUX TRADE.

Negoska, dark-skinned Greek vine variety producing deeply coloured and relatively tannic wines that are often blended with the

more acidic XINOMAVRO, particularly in Goumenissa PDO. An increasing number of successful VARIETAL wines are now also being made.

Negramoll, Iberian dark-skinned grape variety and by far the most commonly planted vine variety on the island of MADEIRA, where it is called TINTA NEGRA. As Negramoll or Negra Mole it is grown in the CANARY ISLANDS. DNA PROFILING has shown it to be identical to the Portuguese variety Molar. A distinct variety called Negra Mole in Portugal's ALENTEJO is the same as the Andalucian variety Mollar, or Mollar Cano, of which there were 38 ha/94 acres in 2020.

Negrara, name related to the colour of the berries (*negra* meaning 'black') and corresponding to a group of several distinct grape varieties in northern Italy. Negrara Trentina is the most common, and recent DNA PROFILING revealed a parent–offspring relationship with ENANTIO. J.V.

Négrette, black grape variety special to the vineyards north of Toulouse in SOUTH WEST FRANCE. In FRONTON, it must dominate the blend, and it is a more minor component in Vins de Lavilledieu. Wine made from Négrette is more supple, perfumed, and flirtatious than that produced from the more famous south-western black grape variety TANNAT, and it is best drunk young, with its fruit—sometimes described as having a slightly animal, or violet, flavour—unsuppressed by heavy OAK AGEING. The variety is inconveniently prone to POWDERY MILDEW and BOTRYTIS BUNCH ROT and is therefore better suited to the hot, dry climate of Toulouse than to many other wine regions. Total French plantings had fallen slightly to 1,086 ha/2,684 acres by 2019. A little is also planted in California, where it was once known as Pinot St George.

Negroamaro, sometimes written Negro Amaro, dark-skinned southern Italian grape variety that fell victim to the EU VINE-PULL SCHEMES with the total area planted falling from 31,000 ha/76,500 acres in 1990 to just 11,431 ha/28,247 acres by 2015. It is particularly associated with the eastern half of the Salento peninsula, in the provinces of Lecce and Brindisi, where it forms the base, blended with small proportions of Malvasia Nera and (not necessarily legally) the more structured PRIMITIVO, for DOCs such as Salice Salentino, Copertino, Brindisi, Leverano, and Squinzano. It is later ripening than Primitivo, with chunkier tannins. It is also used to produce some lively rosé. For more details, see PUGLIA. The name means 'dark, bitter', but the wines are sometimes a bit soft.

Neheleschol, extremely ancient Middle Eastern light-berried vine with enormous bunches, planted experimentally at Mas de Daumas Gassac in the Languedoc.

Nelson, (Whakatū in Māori) is a GEOGRAPHICAL INDICATION in the north-west of NEW ZEALAND's South Island. North of the Southern Alps, it enjoys mild winters and warm summers. Challenges lie in its vulnerability to north-westerly rain during harvest. Sauvignon Blanc dominates with over 600 ha/1,483 acres, while Pinot Noir, Pinot Gris, and Chardonnay shadow with sub-200 ha each. Nelson's two main subregions lie west of the city: the Waimea Plains has light, alluvial-derived soils, while the Moutere Hills are clay-based. S.P.T.

nematodes, microscopic roundworms generally found in soil which can seriously harm vines and other plants. Some feed on bacteria or fungi and are part of the normal vineyard ECOSYSTEM. Others, however, feed on grapevine roots and thus reduce both the size and efficiency of the root system. Although the vines do not necessarily die, they suffer WATER STRESS and deficiencies in VINE NUTRITION and grow weakly. Some species of nematodes are important because they

also transmit VIRUS DISEASES. The viruses spread by nematodes are called NEPOVIRUSES. They can be spread throughout the vineyard from just one infected plant by nematode feeding. Often they show up as a few yellow vines in the vineyard.

The fact that nematodes damage vines was first established in about 1930, in California. Because of characteristic and visually striking root damage, the root-knot nematode, *Meloidogyne* species, was considered most important. However, in 1958 it was discovered that FANLEAF DEGENERATION was spread by nematodes of the species *Xiphenema index*, the so-called dagger nematode. This milestone discovery in plant pathology was made by Hewitt and colleagues of the University of California at DAVIS. It had been established in France as long ago as 1883 that fanleaf degeneration spread through the soil, and some French authorities believed until the 1950s that the aphid-like PHYLLOXERA was responsible for the spread.

Root-knot nematodes occur mainly in SANDY soil. Their presence is visible to the naked eye since the knots (swollen tissue or galls) on the roots formed in response to their feeding resemble a string of beads. One female can lay up to 1,000 eggs, and with up to ten generations a year in warm climates they can spread rapidly. The root-lesion nematode *Pratylenchus* also damages vines by feeding on their roots. Virus particles can survive for many years in root fragments after an infected vineyard is removed. Replanting a new, 'virus-free' vineyard can lead to disappointment, as reinfection with nematode feeding can follow.

At one time vineyards in which nematodes were previously present were subjected to FUMIGATION with injected chemicals before planting, but the nematicides DBCP and methyl bromide have both been banned because of environmental considerations. Fumigation is becoming rare, and in California, for example, INTEGRATED PEST MANAGEMENT is suggested as an important alternative, using PESTICIDES such as spirotetramat. COVER CROPS such as daikon radish and mustard have been found to act as biofumigants that deter some types of nematodes.

Nematode diseases are often spread on infected planting material or by the movement of infected soil on cultivation implements or by irrigation water. Infected nursery plants can be freed of nematodes by HOT-WATER treatment. Biological control using ROOTSTOCKS is possible and generally preferred. Some VITIS species (*V. solonis*, *V. champini*, and *V. doaniana*) show resistance to nematodes. Among the most nematode-resistant rootstocks are Couderc 1613, Ramsey, Schwarzmann, Harmony, and Dog Ridge. New ones have been released in the US but have not been widely adopted; the rootstock breeding programme at CSIRO in Australia is developing rootstocks that are both nematode- and phylloxera-resistant. R.E.S.

Ferris, H., et al., 'Resistance of grape rootstocks to plant-parasitic nematodes', *Journal of Nematology*, 44/4 (2012), 377–86.

Nepal . Notwithstanding sweet wines produced from imported MUST and a variety of wines made from fruits other than grapes, this mountainous country in ASIA had only one winery producing grape wine commercially from own-grown fruit in 2020. Pataleban, started in 2007 with 500 Japanese vines, has four vineyards east of Kathmandu at ELEVATIONS of 800–1,550 m/2,625–5,085 ft. At these heights, the climate is relatively mild, with winter temperatures averaging 2–8 °C/36–46 °F and summer 24–36 °C/75–97 °F. However, annual rainfall averages 2,812 mm/111 in, most of it falling between June and August. Contending with contracted growing seasons due to these annual monsoon rains, Pataleban has planted

30 grape varieties, of which SOLARIS, CABERNET SAUVIGNON, CHARDONNAY, and PHOENIX have been most productive. T.H.

nepoviruses, group of 13 VIRUS DISEASES which are spread from plant to plant by the feeding of NEMATODES (microscopic worms) on roots. They also have in common a polyhedral structure, hence the name 'nepovirus': 'ne' for nematode and 'po' for polyhedral. Such diseases can be very destructive and almost impossible to control. This is because the virus can survive for years in nematodes and root fragments even after all infected vines have been removed. So, even if a new, supposedly virus-free, vineyard is planted, it will quickly become infected by the nematode feeding. Among the important virus diseases in this group are FANLEAF DEGENERATION, tomato ringspot, and tobacco ringspot. R.E.S.

Bettiga, L. J., (ed.), *Grape Pest Management* (3rd edn, 2013).

Nerello Cappuccio produces wines that are rather softer and earlier-maturing than those made from NERELLO MASCALESE. Recent DNA PROFILING has revealed that 70% of the vines on SICILY referred to as Nerello Cappuccio are in fact CARIGNAN. The remaining 30% were a mixture of other known or unknown varieties, including 125 ha/309 acres of Nerello Cappuccio. J.V.

Branzanti, E., et al., 'Analysis of genetic structure of twelve Sicilian grapevine cultivars', *Acta Horticulturae*, 1046 (2014), 677–80.

Nerello Mascalese. The most important and increasingly respected red grape on ETNA, Sicily, also known as Nerello Calabrese, makes fine, firm, pale, but long-lived wines. DNA PROFILING has shown it to be a cross of SANGIOVESE and Mantonico Bianco. Total plantings in 2020 were 3,080 ha/7,611 acres, many of the vines being extremely old. See also NERELLO CAPPUCCIO. J.V.

Nero d'Avola, the characteristic red grape variety of southern SICILY, also known as Calabrese, is a possible progeny of the local Mantonico Bianco, suggesting origins in Calabria on the mainland. It is the island's most planted red wine grape, with 14,749 ha/36,446 acres recorded there in 2020. Producers value the body, deep colour, and sweet-cherry fruit which Nero d'Avola can bring to a blend. VARIETAL Nero d'Avola responds well to BARREL AGEING. Like Syrah, Nero d'Avola requires a good site, warmth, and low VINE TRAINING to succeed. Avola itself is in the southern part of the province of Siracusa, and nearby Pachino, on the extreme south-eastern tip of the island, is particularly reputed for the quality of its Nero d'Avola grapes.

Nero di Troia, fine red wine grape speciality named after a village near Foggia making firm, savoury wines in Castel del Monte in PUGLIA that was recently renamed from Uva di Troia by locals mindful of the success of NERO D'AVOLA. DNA PROFILING has shown that it is a natural offspring of BOMBINO BIANCO and Quagliano from Piemonte. There were 2,512 ha/6,220 acres in Italy in 2015.

Netherlands , north European country more often referred to as Holland, whose inhabitants are known as the Dutch. In the 17th century particularly, they played a dominant role in the world's wine and spirit trade (see DUTCH WINE TRADE) and played a key role in draining the MÉDOC lowlands bordering the Gironde.

The country also has its own small wine industry with an impressive history, despite the coolness of the climate. There are records of wine-producing vines growing in Limburg in southern Holland in 1324, and vine-growing around Maastricht ceased only in the early 19th century, discouraged by a series of cold summers and the economic turbulence of the Napoleonic era. It was not until 1967 that the Netherlands became a wine producer once more when Frits Bosch created his Slavante vineyard of just 800 sq m.

Nowadays CLIMATE CHANGE is encouraging more winegrowing and improving wine quality. In 2021 there were about 200 active vine-growers, with an estimated total of 300 ha/740 acres of vines planted.

Vines are spread throughout the country, among 12 PGIs: Drenthe, Flevoland, Friesland, Gelderland, Groningen, Limburg, Noord-Brabant, Noord-Holland, Overijssel, Utrecht, Zeeland, and Zuid-Holland. In 2017 the country introduced its first PDO (called Beschermde Oorsprongsbenaming, or BOB, in Dutch), Limburg Maasvallei. This is also the first European cross-border appellation, with vineyards in BELGIUM as well in the Netherlands. Dutch producer Wijngoed Thorn worked closely with Aldeneyck in Belgium to achieve this recognition. By 2021, five more BOBs were registered: Achterhoek-Winterswijk along the border with Germany; Ambt Delden, in the province of Overijssel; Mergelland, in the hills of southern Limburg; Oolde in Gelderland; and Vijlen, the highest village in the Netherlands at 200 m/656 ft in ELEVATION.

The Netherland's best and largest producers tend to be found in the south, in the province of Limburg, where Apostelhoeve, the country's oldest commercial winery, was founded in the 1970s, although Gelderland, the province just north of Limburg, produces the most wine by volume, and Zeeland, in the sunny south-west, is home to one of the best Dutch producers: Kleine Schorre.

Vineyards in the south are planted mainly to VITIS VINIFERA varieties such as Riesling, Müller-Thurgau, Auxerrois, Chardonnay, Pinot Blanc, and Pinot Gris for white wines and Pinot Noir for light reds. In recent years, production of sparkling wines has grown considerably, with the advent of producers such as Wijngaard Raarberg focusing entirely on TRADITIONAL METHOD sparkling wines.

Winegrowing in more northerly and eastern parts of the country, notably Gelderland and Overijssel, depends largely on DISEASE-RESISTANT VARIETIES such as REGENT, RONDO, Pinotin, and Cabernet Cortis for reds and Cabernet Blanc, Johanniter, Merzling, Souvignier Gris, and SOLARIS for white wines. R.d.G.

nets can literally save a grape crop. See BIRDS and HAIL.

Neuburger, sometimes distinguished white grape variety grown almost exclusively on 260 ha/642 acres in AUSTRIA. DNA PROFILING in Austria showed it is a CROSS, possibly accidental, of ROTER VELTLINER × SYLVANER. It makes nutty wine that tastes like an even fuller-bodied WEISSBURGUNDER. It is also encountered in Czechia and Slovakia (as Neuburské), in Slovenia, and in Romania's Transylvania.

Neusiedlersee refers to both the 133-km/83-mile-long, notably shallow lake of mysterious origin that plays a critical role in the winegrowing MESOCLIMATES of the northern half of Austrian BURGENLAND and to an official wine region and DAC covering much of that lake's shore, with 6,240 ha/15,419 acres of vines in 2021 making up 14% of Austria's total.

A quick tour of this region highlights its geological, mesoclimatic, and vinous diversity. The villages of Winden and Jois in the region's north-west alternately feature slopes of mica SCHIST and LIMESTONE, and sites such as the Alter Berg and Junger Berg are gradually re-establishing reputations with BLAUFRÄNKISCH and Pinot Noir (Blauburgunder). Among white wines, the Pinot Blanc (WEISSBURGUNDER) in this sector—while not widely planted—also distinguishes itself. At the northern tip of the lake, the low range of hills between the Parndorfer Platte and the lake shore at Weiden and Gols features combinations of GRAVEL, SAND, and CLAY that support all the local red grape varieties—notably Blaufränkisch, ST-LAURENT, Pinot Noir, and ZWEIGELT—as well as Merlot, Cabernet, and even some Syrah. The wealth of white grapes in this sector includes Chardonnay, NEUBURGER, Weissburgunder, and Sauvignon Blanc. Few villages in Austria are more singularly devoted to viticulture nor so crowded with family wineries than Gols, among which Hans 'John' Nittnaus was the pioneer in the 1980s, champion of unblended Blaufränkisch. Josef 'Pepi' Umathum is notable for his rigorous Blaufränkisch vine

selection, part of a multifaceted local cultural preservation project. A wide diversity of vine varieties is perpetuated around Mönchhof, Halbturn, and Frauenkirchen further south and east—the so-called Heideboden sector—more dominated by the warmth of the Great Pannonian Plain and less by the lake, a dominance that reaches its Austrian apex at Andau on the Hungarian frontier, known for its rich, powerful Zweigelt.

Along the alternately SANDY and GRAVELLY eastern shore of the Neusiedlersee as it descends towards the Hungarian border and an expanse of reedy swampland east of SOPRON, the villages of Podersdorf, Illmitz, and Apetlon are home—like Rust on the opposite shore—to Austria's most renowned BOTRYTIZED sweet wines, along with occasionally remarkable dry whites. Fog and humidity from Lake Neusiedl and a mosaic of other small lakes engender frequent BOTRYTIS, while sunshine reflected off their surfaces and off the bright white expanses of sand and dried mineral salts serves to project light into the grape clusters and, conjoined with this sector's generally low rainfall, ensures that the rot remains NOBLE. In this so-called Seewinkel sector of the Neusiedlersee, grape varieties include Chardonnay, MUSKATELLER, Sauvignon Blanc, Traminer, Pinot Blanc, and WELSCHRIESLING plus significant amounts of BOUVIER, MUSCAT OTTONEL, Zweigelt, and SCHEUREBE (known locally as SÄMLING 88). Strohwein—STRAW WINE known locally as *Schilfwein*—contrasts with the region's far more prevalent botrytized AUSLESE, BEERENAUSLESE, and TROCKENBEERENAUSLESE wines, while EISWEIN is also made with relative regularity.

In 2011 Neusiedlersee became a DAC associated exclusively with Zweigelt or blends dominated by that grape, with a Reserve category specifying CASK AGEING, higher minimum alcohol, and later release. In 2020 the DAC was extended to encompass sweet wines labelled Spätlese, Auslese, Beerenauslese or Trockenbeerenauslese. D.S.

Neusiedlersee-Hügelland, former name of an Austrian wine region now known as LEITHABERG.

Nevers is the town that gives its name to the central French *département* of Nièvre, most famous in the wine world for the wines of POUILLY-FUMÉ and for its OAK.

New England Australia , inland region in the northern hilltops of NEW SOUTH WALES boasting Australia's highest vineyard at an ELEVATION of 1,320 m/4,330 ft. The elevation coupled with a CONTINENTAL CLIMATE and significant humidity make FROST, HAIL, thunderstorms, and disease pressure significant challenges, but winegrowers are increasingly drawn to the cool climate and TERRA ROSSA soils. Riesling, Chardonnay, and Shiraz dominate, but other varieties including Nebbiolo, Barbera, Sangiovese, Gewürztraminer, and Tempranillo also show promise. A.R.P.

New Jersey , state in the north-east United States with a history of winemaking dating to 1758, when Great Britain's Royal Society offered £100 to any colonist who would produce red or white wine 'of acceptable quality', meaning of the same calibre as that being purchased from France. By 1767, two residents of what is now New Jersey had succeeded, and the region's wine industry had begun.

New Jersey wine flourished in the late 19th and early 20th centuries, with the town of Egg Harbor City even earning the moniker 'Wine City' thanks to the success of the Renault Winery, run by an expat from Champagne. The winery became the largest distributor of 'American champagne' in the US and still sells it under that name thanks to a grandfather clause in federal labelling laws.

PROHIBITION took a toll on industry growth and produced a restrictive state law that allowed only one winery licence for every 1,000,000 state residents. This was repealed in 1981 with the New Jersey Farm Winery Act. By 2022 the state counted over 60 wineries, more than 1,124 ha/3,000 acres of vineyards, and four AVAs: Cape May Peninsula, Warren Hills, Central Delaware Valley (shared with PENNSYLVANIA), and the Outer Coastal Plain.

While the state is the fifth smallest in the nation, it offers a wide variety of MESOCLIMATES thanks to its varied GEOLOGY and the proximity of the Atlantic Ocean, with which it shares 225 km/140 miles of coastline. In the hilly north, soils are mainly CLAY and the climate is temperate, with 2429 growing degree days (GDD; see CLIMATE CLASSIFICATION); the south is warmer (3659 GDD), with mainly SANDY soils. Over 80 grape varieties are grown, with VITIS VINIFERA at 60%, HYBRIDS at 30%, and VITIS LABRUSCA at 10%. Leading white varieties are ALBARIÑO, CHARDONNAY, GRÜNER VELTLINER, PETIT MANSENG, and RIESLING. Leading red varieties include CABERNET FRANC, CABERNET SAUVIGNON, PINOT NOIR, MERLOT, PETIT VERDOT, and BLAUFRÄNKISCH. Major French-American hybrids that flourish in New Jersey include CHAMBOURCIN, VIDAL Blanc, and VIGNOLES.

The state receives on average 64 cm/25 in of rain during the growing season; thus controlling the major fungal diseases POWDERY MILDEW, DOWNY MILDEW, BLACK ROT, and BOTRYTIS is a constant challenge. Still, many winegrowers are making a concerted effort towards SUSTAINABLE VITICULTURE. In the past, WINTER FREEZE was a primary concern, but CLIMATE CHANGE has brought about milder winters. Deer and BIRDS remain a challenge, and control measures for the SPOTTED LANTERNFLY are still being researched.

New Jersey wines now regularly receive critical acclaim in major wine publications and wine competitions. Most wineries are small, selling direct to the consumer at the CELLAR DOOR, though state legislation allows the state's wines to be sold in BYO restaurants, an arrangement that has been very beneficial for wine sales. G.C.P.

New Latitude Wines, term used largely to refer to wines made in the TROPICAL fringes of the global wine map such as CAMBODIA, INDONESIA, MYANMAR, SRI LANKA, THAILAND, and VIETNAM, although it could equally well apply to those grown at high LATITUDE where

viticulture has recently been encouraged by CLIMATE CHANGE. See DENMARK, ESTONIA, FINLAND, LATVIA, LITHUANIA, NORWAY, and SWEDEN.

New Mexico , state in south-west United States where VITIS VINIFERA vineyards date to 1629. Spanish Europeans, using water sourced by indigenous Pueblo people near what is now Socorro, New Mexico, planted MISSION grapes to make wine for the EUCHARIST. In 2021, New Mexico had *c.*405 ha/1,000 acres of vineyard and 55 bonded wineries.

Although the territory (New Mexico gained statehood in 1912) produced nearly a million gallons of wine by the early 1900s, the industry was repeatedly wiped out by flooding of the Rio Grande River that bisects the state. PROHIBITION closed down the remaining industry.

The state underwent a renewal in the 1980s, led by European winegrowers, chief among them Paolo D'Andrea, from Friuli, Italy; Herve Lescombes from Algeria by way of France; and the Gruet family from France.

The state's CONTINENTAL CLIMATE is generally categorized as semi-arid and hot. However, New Mexico has 10 USDA climatic zones and a wide range of MESOCLIMATES, and growing DEGREE DAYS vary from 1800 in Taos to 5133 in Las Cruces. ELEVATION plays a crucial role, with vineyards ranging from 1,158 m/3,800 ft in the south to 2,134 m/7,000 ft in the north. Precipitation also varies widely, averaging 75–500 mm/3–20 in annually, with most occurring during July and August, known as the 'monsoon' season. New Mexico vineyards benefit from low humidity that minimizes FUNGAL DISEASE pressure, and the DIURNAL TEMPERATURE RANGE can be as much as 22–28 °C/40–50 °F. Alkaline desert soils are predominant, with a PH range of 6 to 9. (See SOIL ALKALINITY.) Soil SALINITY is problematic in many vineyards given mineral-laden (often sodium) IRRIGATION water, scarce rainfall, and high EVAPORATION rates. Other grape-growing challenges include high WINDS, dust storms, DROUGHT, FROST, and damaging cold events

post-harvest before the vine has had time to adapt to local conditions. Elevated temperatures during grape ripening can also result in juice with excessive sugar levels and high pH that must be addressed in the winery (see AMELIORATION and MANIPULATION).

Grapevine acreage is concentrated in the south-west and centre of the state where the climate is milder and there is access to irrigation water from the Rio Grande or wells. The state's three AVAs, Mesilla Valley, Mimbres Valley, and Middle Rio Grande Valley, are in these sections. However, many winegrowers are increasingly setting up wineries further north, closer to popular destinations such as Santa Fe and Taos, to take advantage of the TOURISM potential. Vine-growing can be risky at these higher elevations (especially north of Albuquerque) as vineyards can be regularly killed to the ground by winter cold. Growers there tend to grow UNGRAFTED VINES as this allows them to train a new shoot from the surviving root system rather than replanting.

The state supports an impressively diverse range of grape varieties, from Chardonnay, Pinot Noir, and Pinot Meunier dedicated to the TRADITIONAL METHOD sparkling wines of Gruet, New Mexico's largest producer, to Italian varieties such as Montepulciano, Aglianico, Negroamaro, Refosco, and Teroldego, and Austrian Grüner Veltliner and Zweigelt, not to mention the classic INTERNATIONAL VARIETIES Riesling, Cabernet Franc, Zinfandel, Chenin Blanc, and Malbec. Muscat, often bottled as 'Moscato' in an off-dry to semi-sweet style, pairs especially well with the state's traditionally spicy food.

HYBRIDS, ever popular with New Mexico's growers due to their hardiness, consistent yields, and quality, are gaining more attention due to the constant threat of PIERCE'S DISEASE and PHYLLOXERA in neighbouring states and CLIMATE CHANGE. Chambourcin, Regent, Baco Noir, and Norton are proven reds; in whites, Vidal, Seyval, and Traminette stand out. Frontenac, Marquette, and new releases from the University of Arkansas and CORNELL are also showing potential.

Today, MISSION, New Mexico's original heritage grape, is enjoying a resurgence. Several producers take advantage of its consistent

cropping ability and light colour to produce a refreshingly dry rosé.

G.G.

New South Wales , Australia's most populous state, situated on the continent's south-east coast, boasts the longest history of grape-growing in Australia.

The original grapevines from the First Fleet were planted at Sydney Cove in 1788, with subsequent vineyards planted around the fertile agricultural lands surrounding Sydney in the early 1800s. In 1833, James BUSBY's collection of vines arrived in Sydney; CUTTINGS from these vines were later taken to other parts of the state and across to Victoria and South Australia, helping to establish viticulture across a great swathe of the country.

Today, New South Wales has eight official wine zones that are further divided into 16 GEOGRAPHICAL INDICATIONS (GIs). Spread over approximately 810,000 square kilometres/312,742 square miles, the state features an incredibly diverse range of climates, from warm inland areas reliant on IRRIGATION and cool high-ELEVATION sites perched along the Great Dividing Range to coastal climates marked by significant HUMIDITY. The region is second only to South Australia in terms of volumes produced, contributing 29% of the national crush in 2022.

The state's best-known region is the **Hunter Valley**, 130 km/80 miles north of Sydney. Although the climate is subtropical, with high temperatures, humidity, and regular rainfall making it a less obvious choice for the production of quality wine, the region has become famed for its SÉMILLON, produced in a dry, unoaked style that develops astonishing COMPLEXITY with bottle age. The very best reach their peak at 15–25 years of age, developing toasty, honeyed, nutty, lemon-curd tertiary flavours. The grapes are picked early, resulting in ALCOHOLIC STRENGTH of just 10–11.5%. The region also excels in ripe, generous Chardonnay and has historically been known for a distinctive style of Shiraz with savoury 'sweaty-saddle' overtones, though more recent examples offer a more vibrant red-berry fruit profile.

Lying to the west and south of the Hunter Valley along the western slopes of the Great Dividing Range is the cooler Central Ranges Zone, with three subregions. **Mudgee** is the oldest, with a history of viticulture dating back to 1858; with a temperate CONTINENTAL CLIMATE and VOLCANIC and sandy LOAM soils, it is best known for bold, full-bodied, generous Shiraz and Cabernet Sauvignon, though it is also gaining traction for crisp, ageworthy Riesling. To its south, the cooler, higher ELEVATIONS of **Orange** have gained a reputation for crisp, elegant Chardonnay with bright peach notes, lively Sauvignon Blanc, peppery Shiraz, and mid-weight Cabernet Sauvignon blends. Both Pinot Noir and Riesling show promise, as does the production of TRADITIONAL METHOD sparkling wine. **Cowra** forms the southern end of the zone, a warm, flat, low-lying region producing generous Chardonnay and soft, fruity Shiraz, Cabernet Sauvignon, and Grenache.

The Southern New South Wales zone radiates out north and west from the capital city of Canberra, with four GIs. The **Canberra District** GI encompasses vineyards in both the Australian Capital Territory itself as well as the surrounding hills; with various elevations and a strongly continental climate, it produces everything from Riesling to Shiraz, with noteworthy examples of Chardonnay, Pinot Noir, and Rhône white varieties including Marsanne, Roussanne, and Viognier. To its north-west, the moderately cool-climate **Hilltops** GI, situated on the south-western slopes of the Great Dividing Range, excels with elegant, cool-climate styles of Shiraz and Cabernet Sauvignon. Plantings of Italian and Mediterranean varieties are also on the rise. **Gundagai** sits to its south, its warmer, lower elevations producing ripe Shiraz, Cabernet Sauvignon, and Chardonnay, while **Tumbarumba**, which climbs into the Australian Alps, focuses on cool-climate Chardonnay and Pinot Noir, producing impressive base wines for sparkling wine as well as elegant still wines.

The large catchment area of the Big Rivers Zone comprising the **Murray Darling**, **Perricoota**, **Riverina**, and **Swan Hill** regions is responsible for the vast majority of production in the state. Vineyards are reliant on IRRIGATION, allowing for high yields and substantial

production volumes. Much of it is destined for CASK and BULK WINE markets. Many wines produced here end up exported as wines of SOUTH EASTERN AUSTRALIA. Chardonnay is still the most planted variety, although with the rising cost of water required for irrigation, interest is increasing in less water-intensive Italian and Mediterranean varieties.

There are just two GIs north of Hunter: HASTINGS RIVER, up the coast from Sydney, and, further north, meeting the border with Queensland, NEW ENGLAND AUSTRALIA. A.R.P.

www.nswwine.com.au

new varieties, somewhat loose and relative term used to describe VINE VARIETIES that have been specifically and deliberately developed, which effectively means developed since the late 19th century.

There is interest in breeding new varieties which are resistant, for example, to environmental stresses, fungal and bacterial diseases, and nematodes and insects (see VINE BREEDING and DISEASE-RESISTANT VARIETIES). Of these, the major goals are varieties tolerant of the fungal diseases DOWNY MILDEW, POWDERY MILDEW, and BOTRYTIS BUNCH ROT or resistant to PIERCE'S DISEASE. Unfortunately, new varieties, especially HYBRIDS but even some CROSSES, suffer from the stigma of the poor wine quality of the early French hybrids. The uptake of newly developed grape varieties has been further hindered by consumer preference for traditional varieties, especially INDIGENOUS VARIETIES with a long history, and INTERNATIONAL VARIETIES.

The early French hybridizers mentioned in FRENCH HYBRIDS were not the only French vine breeders to have developed new varieties. Louis BOUSCHET and his son Henri used controlled pollination from 1824 to create a range of seedlings which after selection became known as the Bouschet CROSSES, the most important of which was the TEINTURIER variety ALICANTE BOUSCHET—the only one to be officially

recommended for planting in France. Another early and successful VITIS VINIFERA vine breeder was Hermann Müller, whose variety MÜLLER-THURGAU was once the most planted in Germany. A succession of new crosses followed, notably from research institutes at Alzey, Freiburg, Geilweilerhof, GEISENHEIM, Weinsburg, and Würzburg. For details of these, see GERMAN CROSSES.

Other newish varieties such as Zweigelt, Blauburger, and Neuburger were bred in Austria, the first two at KLOSTERNEUBURG. The emphasis in RUSSIA has been on breeding varieties with cold tolerance as well as disease tolerance, and there are substantial areas, not just in Russia but in other ex-Soviet republics, planted with varieties such as SAPERAVI Severny, Stepniak, Fioletovy Ranni, and CABERNET SEVERNY. In NEW YORK State and CANADA, the emphasis also has been on developing varieties with cold and disease tolerance, often relying on the French hybrids for resistant genes. Releases such as CAYUGA WHITE (1972), CHARDONEL (1990), and TRAMINETTE (1996), all bred at CORNELL, are being more widely planted. The names of the last two varieties, incorporating those of their respective *vinifera* parents, may make them more acceptable to consumers. There is particular enthusiasm for grapevine breeding in the American Midwest, where new varieties seem to be valued as much by consumers for their local origins as by growers for their cold hardiness and disease resistance (see, for example, LA CROSSE, MARQUETTE, and TRAMINETTE).

New varieties in France, most of them developed in association with the University of MONTPELLIER, have been *vinifera* crosses such as PORTAN, CALADOC, CHASAN, and Arriloba, as well as EGIODOLA and ARINARNOA developed by INRA at Bordeaux.

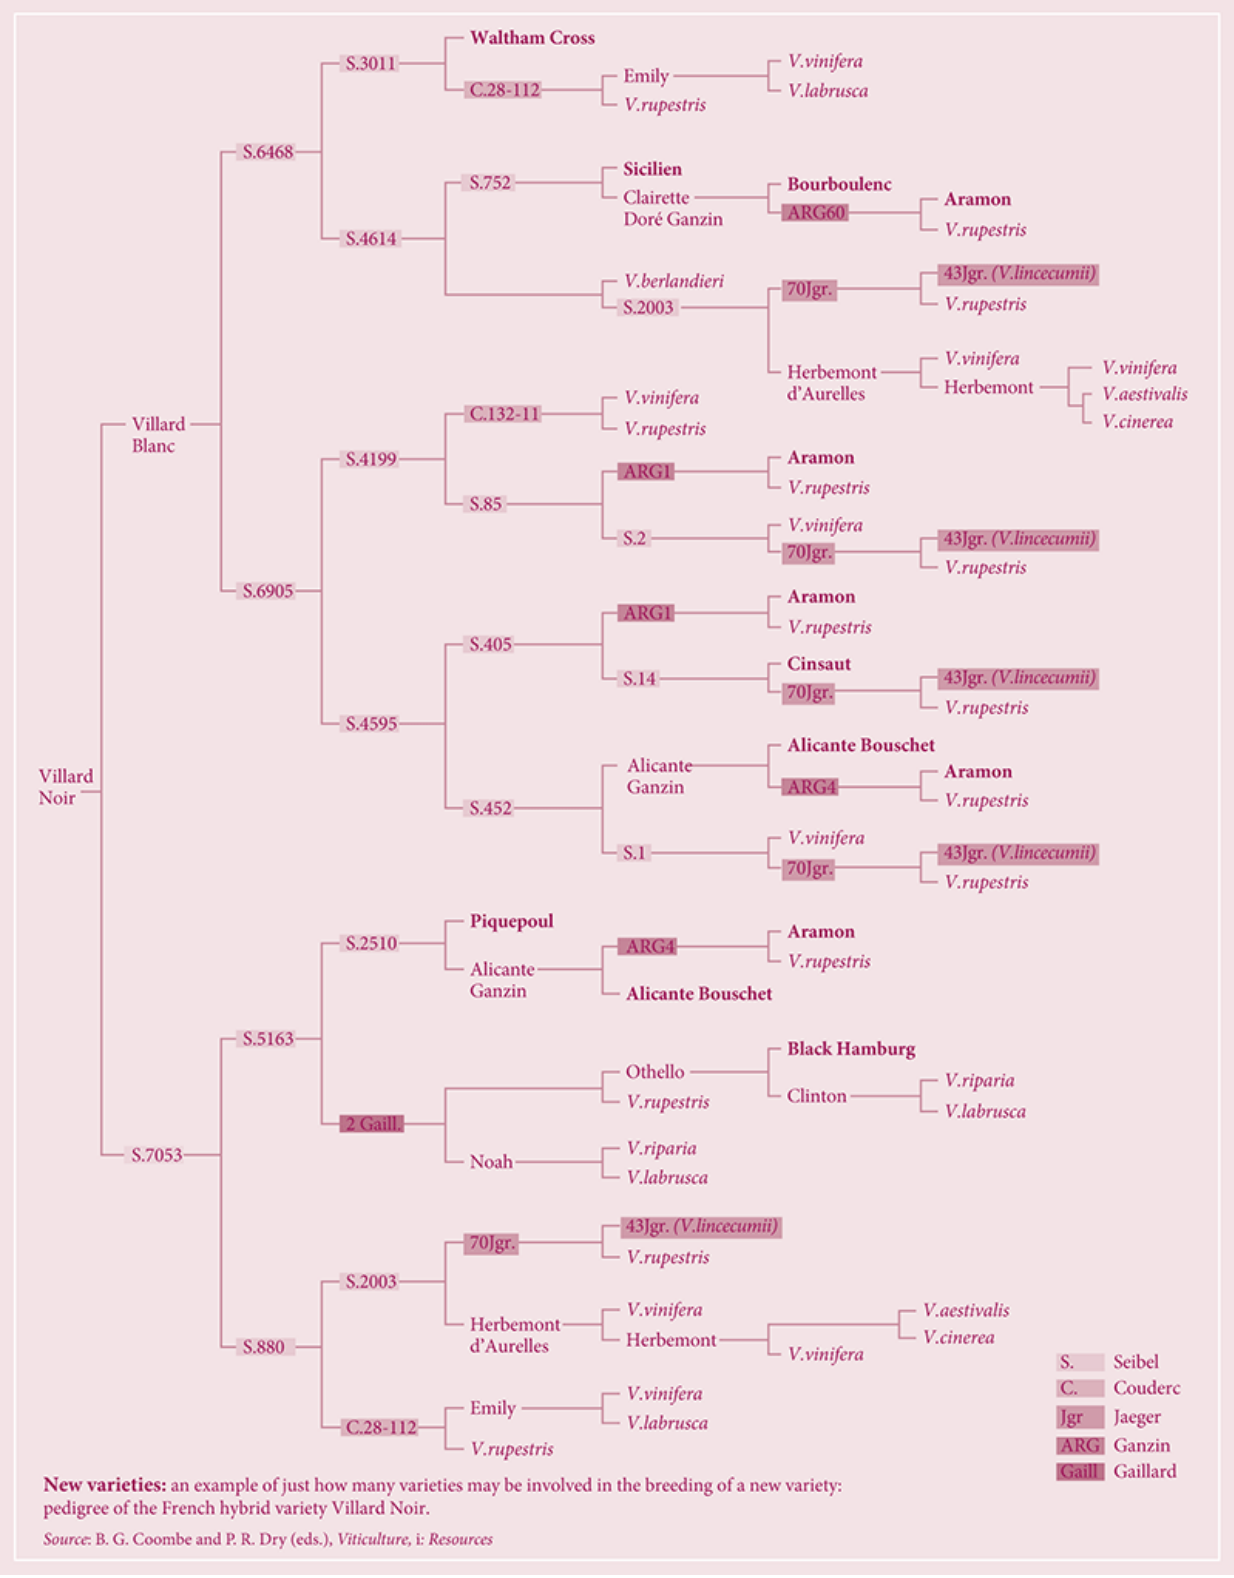
In France, new varieties must first be registered with the Comité Technique Permanent de la Sélection des Plantes Cultivées (CTPS) as a prelude to their recognition in the EU. Active breeding programmes are underway in many other parts of Europe, notably in CZECHIA and in SLOVAKIA.

Australia has a vine-breeding programme designed to produce varieties suitable for hot climates, and Goyura, TARRANGO, Tullilah, TAMINGA, TYRIAN, and CIENNA have all been released. In California such new varieties as CARNELIAN, RUBY CABERNET, EMERALD RIESLING, SYMPHONY, and FLORA have all enjoyed popularity at some point, while RUBIRED, unlike similarly red-fleshed ROYALTY, is widely planted to add colour to blends.

New varieties of particular interest offer natural disease resistance with much-reduced use of AGROCHEMICALS. These DISEASE-RESISTANT VARIETIES have complex genealogies which may include not just *vinifera* genes but also those of various AMERICAN VINE SPECIES, French hybrids, and even Asian vine species.

INRAE's ResDur (RÉSistance DURable) programme, for example, released its first four disease-resistant varieties for planting in 2018: the reds Artaban and Vidoc and whites Floréal and Voltis are classified as interspecific hybrids that incorporate genes that confer polygenic resistance to downy and powdery mildew. This has been done by traditional breeding techniques enhanced by the ability to identify genetic markers, not by GENETIC MODIFICATION. They have been included in the French official catalogue of varieties and authorized by the INAO for planting within strict limits as so-called *variétés d'intérêt à fin d'adaptation* (VIFA) in wine regions such as Bordeaux. Further disease-resistant varieties were included in the catalogue in 2021 and 2022: Coliris, Lilaro, Sirano, Selenor, and Opalor.

Such breeding programmes are being carried out in many parts of the world as CLIMATE CHANGE and increasing disease pressure threaten the quality and character of established combinations of variety and vineyard region.



New varieties: an example of just how many varieties may be involved in the breeding of a new variety: pedigree of the French hybrid variety Villard Noir.

New World, term once much used in the wine world, initially somewhat patronizingly, to distinguish the wine regions established in European colonies from the early 16th to the early 19th centuries, including MEXICO, PERU, CHILE, ARGENTINA, the UNITED STATES, SOUTH AFRICA, AUSTRALIA, and NEW ZEALAND. Colonists needed wine for religious reasons (see EUCHARIST), but vines were also planted on secular estates. In these historical terms, wine's New World contrasts with the OLD WORLD of Europe and the other Mediterranean countries where the vine was widely established by the 4th century. (See individual country entries for these histories.) A more appropriate term for countries with a relatively short history of wine production, for example FINLAND, ESTONIA, or THAILAND, might be 'emerging wine regions'. While the labels Old and New World have precise historical origins, in today's expanding world of wine they are more typically and loosely used to describe different approaches to VITICULTURE and WINEMAKING, as outlined below. What might once have been clear differences between the Old and New Worlds of wine have been steadily eroded by the exchange of ideas and technologies around the globe so that as a way of characterizing wine styles, the terms are little more than short-hand generalizations and far less useful than they once were.

Viticulture

While it is almost impossible to generalize about the viticultural practices of countries as diverse as the United States, Australia, New Zealand, South Africa, Chile, Argentina, and Mexico as opposed to those more usual in Europe, it is possible to outline the approaches and methods typically associated with the phrase 'New World viticulture'.

Planting distances, or VINE DENSITY: there is a particularly marked contrast between the 1 m by 1 m (3 ft by 3 ft) high-density planting of the MÉDOC and the 3.7 m by 2.5 m (12 ft by 8 ft) planting pattern that was long common in California and Australia. But no difference is absolute or constant. In some parts of the Old World, there is a trend towards wider spacings for reasons of economy and MECHANIZATION, while some growers in the New World have been planting more densely, sometimes to an extreme extent, in a search for higher quality.

VINE VARIETIES and ROOTSTOCKS: there is little difference in what is planted in the New and Old Worlds, usually because the New World has concentrated on the INTERNATIONAL VARIETIES made famous in the Old World. New World regions are less likely to have a rich heritage of INDIGENOUS VARIETIES (of VITIS VINIFERA), but some have become specifically associated with certain varieties, for example the PAÍS and CARMENÈRE of Chile, the PINOTAGE and almost extinct PONTAC of South Africa, or the ZINFANDEL of California.

Vineyards and MECHANIZATION: Old World methods are more traditional, and many aspects of modern viticultural technology, especially MECHANIZATION and PRECISION VITICULTURE, have been developed and first used in the New World. MECHANICAL HARVESTING and MECHANICAL PRUNING, for example, were first developed in America, but by the early 1990s there was a high degree of acceptance, of the former at least, in Europe. Technological advance is by no means the sole prerogative of the New World, however. The development and application of new technology in Europe is the

equal of anywhere in the world, as evidenced by work there on CLONAL SELECTION, VINE BREEDING, and CANOPY MANAGEMENT. Some vineyard sites in the Old World have been used for viticulture for hundreds of years, but there are probably more potential new vineyard regions to be discovered in the New World (see VINEYARD SITE SELECTION). R.E.S.

Winemaking

Old World winegrowers are far more likely to be restricted by local regulations governing CONTROLLED APPELLATIONS, whereas both viticulturists and winemakers in the New World are much more willing, and much freer, to experiment and may therefore be more subject to changes of direction and swings of FASHION. The belief in some quarters that the Old World, with its centuries of winemaking tradition, was ruled by Nature, the New World by the application of SCIENCE, has been well and truly turned on its head by the increasingly extreme events brought about by CLIMATE CHANGE. A scientific understanding of Nature and winemaking is now applied throughout the world to adapt to the changing climate and promote SUSTAINABILITY.

New World winemaking was once associated with PROTECTIVE WINEMAKING methods, attempting to shield grapes, juice, MUST, and wine from OXYGEN throughout the winemaking process, especially for white wines and light reds. However, as with so many New/Old World distinctions, this one has become more blurred as research into oxygen management in all parts of the wine world progresses, especially when it comes to BOTTLING and CLOSURES (see, for example, TOTAL PACKAGE OXYGEN and PREMATURE OXIDATION). Obsession with HYGIENE is generally more marked in the New World, with the consequence that WATER use is much higher, although water shortages and the need for water conservation and reuse are now global issues in just about every wine region.

Other winemaking practices that might once have differentiated producers in the New World from those in Old include cooler FERMENTATION temperatures, the use of cultured versus ambient YEASTS, shorter post-fermentation MACERATION time for red wines, and the use of ENZYMES, both for settling and for releasing flavours.

Style

Today 'New World' is just as likely to be used to refer to the style of a wine as to its origin. So-called New World wines are much more likely to be VARIETAL in both how they are described on the label and how they taste, although a growing proportion of these wines are now being made with the clear intention of expressing their geographical provenance (see REGIONALITY and TERROIR). A 'New World' wine is more likely to be immediately appealing on release with less capacity for extended bottle AGEING. FRUIT-DRIVEN was an essentially New World wine description, coined in the 1980s, although today it may be heard and appreciated everywhere.

While the terms 'Old World' and 'New World' have their origin in a historical context, they are perhaps more useful in describing the different approaches to winegrowing and wine styles than in locating a wine in a particular country or continent. J.E.H.

New York , north-eastern state of the United States between the Atlantic Ocean and the Great Lakes, historically an important source of wine and now third to CALIFORNIA and WASHINGTON in both vineyard hectarage and volume produced. History

Before European colonists arrived in the 17th century, the fertile lands of New York were home to many Native American communities who made ample use of the state's abundant wild grapes. (See AMERICAN VINE SPECIES.) The fruit was used as both food and medicine, fresh and dried. It was the Europeans, however, who attempted to make wine with it, but they found the FOXY flavour of the native VITIS LABRUSCA unpleasant. After several unsuccessful trials with imported VITIS VINIFERA around Manhattan Island, little more was heard of viticulture in New York until the early 19th century. By that time, many of the Lenape people downstate and the Haudenosaunee Confederacy to the north had been forced to flee west by land-hungry settlers and the disease and violence they spread.

Vine-growing slowly developed across the state. While *vinifera* plantings remained challenging, the native vines often hybridized by chance with other *labruscas*, other American vine species such as *Vitis aestivalis*, or even *vinifera* varieties, producing a second generation of native grapes such as CONCORD and ISABELLA. Propagated by vine-growers such as Long Island nurseryman William Robert Prince, who saw the value in their cold hardiness and disease resistance, these vines became the basis for the state's first successful commercial winery, Blooming Grove, founded in 1839 in Washingtonville, about 89 km/55 miles north of New York City, on the Hudson River.

By the 1850s, a fledgling wine industry had started up around the FINGER LAKES of north-central New York, growing to encompass 9,700 ha/24,000 acres of vines by 1890s. Meanwhile, the grape-growing industry that had started in OHIO spread northwards along the Lake Erie shore and into western New York. Some of the region's grapes went into wine, but the temperance movement leading up to PROHIBITION turned vine-growers increasingly towards growing Concord for GRAPE JUICE. This 'grape-belt' would become—and still is—

the world's largest Concord grape–growing region, with 6,542 ha/16,166 acres planted in 2021.

Vinifera vines didn't begin to catch on in New York until the 1950s, when viticulturist Dr Konstantin Frank was hired as a consultant at Gold Seal Winery in the Finger Lakes region. Having worked with *vinifera* in his native UKRAINE, he was convinced of their viability in the state's cool climate. Using PHYLLOXERA-resistant ROOTSTOCKS and implementing techniques such as burying the vines for WINTER PROTECTION, he established *vinifera* vineyards fast enough for Gold Seal to release its first commercial *vinifera* wines in 1960. By 1962 Frank was distributing *vinifera* CUTTINGS from his own nursery, where he had 60-some varieties on trial.

Still, winemaking was slow to take off until the Farm Winery Act of 1976, which made it economically feasible for grape-growers to own and operate a small winery by allowing direct sales to consumers. Prior to the act, there were only 20 licensed wineries. By 2019 there were 471, with 14,164 ha/35,000 acres of vineyards. The state continues to have more vinous diversity than any other major wine-producing state, as native American vines, AMERICAN HYBRIDS, and FRENCH HYBRIDS still account for 76% of its vineyards. Most of their produce, however, goes to grape juice, preserves, and TABLE GRAPES; 90% of NY wines are produced from *vinifera* varieties, although CLIMATE CHANGE concerns are inspiring some winegrowers to give hybrids another look.

Pinney, T., *A History of Wine in America, from the Beginnings to Prohibition* (1989).

Geography and climate

New York has 11 American Viticultural Areas (AVAs), with Lake Erie and Niagara Escarpment at the western end; the Finger Lakes (which includes Cayuga and Seneca Lake AVAs) in the centre; Hudson River, Upper Hudson, and Lake Champlain stretching north of New York City, and Long Island (including The Hamptons and North Fork AVAs) at its easternmost point.

As the state extends 705 km/438 miles east to west, from the Atlantic Ocean to Lake Erie, and from latitudes 40.7 to 44.9° N, it's hard to make any generalizations about its climate. While Long Island sits on the same parallel as Sardinia, the region's warm summers are modified by the cold Atlantic; likewise, the state's westernmost vineyards are spared from the harshest effects of the CONTINENTAL CLIMATE due to the moderating influence of Lake Erie (see LAKE EFFECT). An abundance of significant bodies of water (Lakes Ontario, Erie, and Champlain as well as the Finger Lakes and the Niagara and Hudson rivers) and the Catskills and Adirondack Mountain ranges further diversify the topography and range of climates. Average growing degree days (GDD; see CLIMATE CLASSIFICATION) range widely within the state, from 799 C° in northernmost Champlain Valley to 1925 C° in Long Island. Across the state, the greatest viticultural hazards are WINTER FREEZE and rainfall, which can lead to DOWNY MILDEW and ROT.

VINE DENSITY ranges from 1.5×2 m/5×7 ft to sometimes as close as 1×1.5 m/3×5 ft. The most common vine TRAINING SYSTEM for *vinifera* is vertical shoot positioning. In the warmer Long Island region, the open LYRE training system is gaining favour. Where growing seasons are shorter, trellises are managed to maximize SUNLIGHT.

Increasingly extreme weather events are making SUSTAINABILITY a hot topic. Producers have leaned on grape diversity to manage difficult growing seasons and, outside of Long Island, are increasingly embracing HYBRID and INDIGENOUS VARIETIES. The Long Island Sustainable Winegrowing programme was the first of its kind on the

east coast, and the New York Wine & Grape Foundation is developing the state's first sustainability certification, scheduled to launch in 2023.

Finger Lakes, also referred to as the FLX, is the state's oldest AVA, with 3,801 ha/9,393 acres of vineyards in 2021 responsible for 90% of the state's wine. The region sits in the middle of the state, defined by 11 narrow, deep lakes carved by Ice Age glaciers that left behind steep SHALE slopes with shallow topsoil. Those significant to the wine industry are Canandaigua, Keuka, Seneca, and Cayuga, which are large enough to temper the cold winters and warm summers while their banks allow for good AIR DRAINAGE and water DRAINAGE. Cayuga and Seneca each have their own AVAs; Seneca,which is the largest lake by volume at 188 m/618 ft deep, creates a 9-mile MESOCLIMATE affectionately referred to as the Banana Belt, where temperatures are 3–8 °C/5–15 °F warmer than its surroundings.

Riesling, the region's widest-planted *vinifera* variety, does exceptionally well here and is made in styles from bone-dry to ICE WINE–sweet, with STRUCTURE and COMPLEXITY that can echo Germany's best. Chardonnay is also popular, lending itself to balanced, often CHABLIS-style wines. Cabernet Franc is the most widely planted red-wine variety and shows up in many forms, from pink PET-NAT to BARREL FERMENTED reds and even APPASSIMENTO styles. Producers are also excited about the potential of SAPERAVI, GAMAY, BLAUFRÄNKISCH, PINOT GRIS, and RKATSITELI. Varieties such as GRÜNER VELTLINER, Pinot Gris, and Cabernet Sauvignon do well in the Banana Belt, while Pinot Noir can make fine reds in exceptional growing seasons; otherwise, it is utilized for rosés and sparkling wines, on its own or in combination with Chardonnay and PINOT MEUNIER.

Hybrid varieties remain important, many bred locally at Cornell AgriTech, the viticultural research arm of CORNELL UNIVERSITY. The most import for FLX wines include Aurora, the Cornell AgriTech-developed CAYUGA WHITE, as well as SEYVAL BLANC and BACO Noir. MARQUETTE and MARÉCHAL FOCH are also showing promise in the region. INDIGENOUS VARIETIES account for the remaining half of plantings and include CONCORD, NIAGARA, and CATAWBA.

A minimalist style in the cellar is trending in the Finger Lakes as winemakers are eager to show a sense of place (see TERROIR) through the wines. Many winegrowers have introduced SINGLE-VINEYARD WINES; some are also focused on increasing texture and complexity in their wines through SKIN CONTACT, LEES CONTACT, and BARREL FERMENTATION and BARREL AGEING in neutral OAK. PET-NATS from *vinifera*, indigenous, and hybrid varieties such as Seyval Blanc, Cayuga White, Catawba, and Delaware are becoming mainstream.

Though most FLX wine is sold locally, the region is the most well-known in the state, its 144 wineries an important draw for TOURISM and its wines featured on restaurant lists from Buffalo to NYC. They also enjoy robust European and Asian Pacific export markets.

Lake Erie is New York's largest AVA, spanning 16,200 ha/40,000 acres along the southern edge of Lake Erie before continuing into PENNSYLVANIA and OHIO. This area averages 1667 F° growing degree days (GDD; see CLIMATE CLASSIFICATION) and benefits from the moderating effect of the lake, which is the smallest, shallowest, and most southerly of the Great Lakes, distanced from the Arctic air masses that prevail over lakes Superior and Huron. In 2022, 7,561 ha/18,684 acres were planted, but the region has only 20 wineries since most of the vineyards are planted to Concord, used for GRAPE JUICE.

Hudson River Region is one of the oldest winemaking regions in the eastern US, its first commercial winery dating to 1837, now called Brotherhood Winery, the oldest continuously operated winery in the US. The region is defined by the Hudson River, framed by steep cliffs that act as a conduit for maritime air and weather generated by the Atlantic Ocean. Glaciers have deposited SHALE, SLATE, SCHIST, and LIMESTONE throughout the region. Growing degree days averaged 1762 from 2010 to 2019, an increase of 9% from the average ten years prior. The short growing season (180–195 days) and cold winters favour cold-hardy varieties such as SEYVAL BLANC. Some VINIFERA varieties, including Chardonnay, Cabernet Franc, Pinot Noir, and Gamay, are also grown. The region's proximity to NYC has led to a robust TOURISM industry supporting 59 wineries in 2022. With only 95 ha/235 acres of vines, many source grapes from other regions.

Upper Hudson is New York's youngest wine region, established in 2019. The AVA covers 427,348 ha/1,056,000 acres north and west of Albany, surrounded on three sides by mountains (Adirondack, Taconic, and Catskills), yet just 80 acres/32 ha were under vine in 2022. Humid summers and cold winters favour cold-hardy vines such as La Crescent, MARQUETTE, FRONTENAC, and St Croix. With an average of 1389 F° GDD and only 130–155 days in the growing season, producers focus on early-ripening varieties such as Itasca.

Winemakers will often employ MALOLACTIC CONVERSION to lessen acidity.

Champlain Valley of New York is the state's northernmost AVA, averaging only 141 growing-season days and 1439 F° GDD. Established in 2016, the AVA is also referred to as the Adirondack Coast and extends the length of Lake Champlain to the Canadian border. It is home to just seven wineries and 40 ha/100 acres of vineyards planted mainly to hybrids, particularly Marquette.

Long Island extends 190 km/118 miles into the Atlantic at the south-eastern tip of New York State. At only 37 km/23 miles at its widest, the climate is fully MARITIME, with ocean breezes moderating summer's heat and humidity. The region's modern-day history begins with Alex and Louisa Hargrave, who replanted potato fields to vines to start Hargrave Vineyard (now Castello di Borghese), the island's first commercial *vinifera* vineyard, in 1973. The island contains three AVAs: Long Island, the largest, with 826 ha/2,041 acres planted in 2022, comprises the western two-thirds of the island; North Fork of Long Island covers the island's north-eastern peninsula, sandwiched between Long Island Sound and Peconic Bay; while Hamptons Long Island covers the south-eastern peninsula (the 'South Fork'), open to the Atlantic Ocean. The North Fork soils, with less SILT and LOAM than those on the South Fork, require IRRIGATION because of their reduced water-holding capacity. In general, the growing season is at least three weeks longer than in other New York State wine regions, with 215–233 growing days and an average 1925 F° GDD. Only *vinifera* varieties are planted, and dark-skinned varieties thrive. Merlot is considered the region's flagship grape; Cabernets Franc and Sauvignon also excel, presented in VARIETAL or MERITAGE wines. Chardonnay is most widely planted, followed by Sauvignon Blanc and Riesling. Sparkling wines, many produced by the TRADITIONAL METHOD, are also produced. Eastern Long Island, a popular destination for weekend escapes from nearby New York City, enjoys strong sales of its wines to summer visitors.

Niagara Escarpment, in the north-western corner of the state, is defined by a LIMESTONE escarpment which runs some 700 miles from Rochester, NY, through southern Ontario, Canada, and into Michigan. Its 337 ha/883 acres of vines are grown on benchland (see BENCH) between the ridge and Lake Ontario's southern shoreline where air warmed by the lake settles over the vines, protecting them from drastic temperature swings in an otherwise cold climate. The area enjoys a 205-day growing season, the second longest in the state, which allows for *vinifera* such as Riesling, Chardonnay, Sauvignon Blanc, Pinot Noir, Cabernet Sauvignon, and even Syrah to ripen.

www.newyorkwines.org

New Zealand , known as Aotearoa in Māori, in the southern Pacific Ocean, may look small on a map next to the nearest land mass, AUSTRALIA, which is 1,600 km/1,000 miles away, but its own land area is greater than that of the United Kingdom. The country has a diverse agricultural economy, with dairy the top contributor, though wine is New Zealand's sixth biggest export and growing, reaching $2.01 billion in export revenue in 2020. Vines were first planted in 1819, but it took more than 150 years for New Zealanders to discover that their country's cool MARITIME CLIMATE was suitable for high-quality wine production. Although production was just 1% of world wine production in 2022, vines cover 41,603 ha/102,803 acres in 19 registered GEOGRAPHICAL INDICATIONS (GIs) spanning 1,200 km/720 miles, almost the full length of the country's North and South islands.

History

New Zealand's first vines were planted in 1819 at Kerikeri in NORTHLAND by the Reverend Samuel Marsden, an English MISSIONARY. Sadly the vines never bore fruit as they were ravaged by goats a few months later. James BUSBY, the first British Resident, produced the first New Zealand wine from his vineyard, planted at nearby Waitangi in 1833. He started selling the wine to British troops in the same year the country's founding document, the Treaty of Waitangi of 1840, was signed.

European settlers from France, Germany, Lebanon, Spain, and Croatia, with their strong traditions of winemaking and consumption, played a pivotal role in New Zealand's early history, though the Dalmatian immigrants who settled West Auckland were arguably the most influential in shaping the modern wine industry. A significant contributing factor was their fortune of settling in rural West Auckland. Land values quite rapidly increased here due to the 1958 opening of the North-Western Motorway and subsequent expansion of Auckland city. This newfound wealth drove the growth of the nascent wine industry.

Yet the early history of New Zealand wine was fraught with difficulties. PHYLLOXERA and POWDERY MILDEW in the late 1800s were major setbacks, while the damaging effects of an emphatic temperance movement threatened nationwide PROHIBITION several times during 1910–34. Rubbing salt in the wound was the post-war economic depression and a 50-year enforcement of six o'clock closing, requiring pubs to close at 6 pm every night, until 1967. Coupled with the working-class taste for beer and the upper-class preference for imported wines, domestic wine sales suffered (per capita consumption of wine was just 2 litres in 1950, while beer was a staggering 100 litres).

In 1960 New Zealand had just 388 ha/959 acres of vineyard, the majority in West Auckland and HAWKE'S BAY. Most of the vines were disease-resistant AMERICAN HYBRIDS, the most prominent being ISABELLA

(nicknamed 'Albany Surprise'), and 90% of the wines at this time were FORTIFIED in the style of SHERRY and PORT. A domestic wine renaissance began, catalysed by a progressive government legislating that 'light table wine' could be served in licensed restaurants alongside 'substantial meals'. The duty on wine, beer, and spirits was also raised and imports restricted. Eventually wine-sellers' licences were granted more liberally, though it wasn't until 1990 that supermarkets could sell wine.

The increasing popularity of dry TABLE WINE in the 1970s saw American hybrids giving way to VITIS VINIFERA crossings such as Müller-Thurgau, which were in turn replaced in the late 1970s and early 1980s by Sauvignon Blanc, Chardonnay, Cabernet Sauvignon, and Riesling. A government-sponsored VINE-PULL SCHEME in 1986 resulted in one-quarter of the nation's vines being uprooted, providing a relatively clean slate for the modern era. Much of the planting occurred on a trial-and-error basis; the first commercial Marlborough Sauvignon Blanc was produced in 1979 by Montana, and the first Central Otago Pinot Noir was made in 1987 by Alan Brady for Gibbston Valley Wines. The rest, as they say, is history.

Geography and climate

New Zealand has an incredibly diverse array of local climates, from warm subtropical conditions in the far north to extreme CONTINENTAL CLIMATES in the alpine areas in the south. Most of the country's winegrowing regions lie on its eastern coast, hiding in the rain shadow of the central mountain ranges. This is particularly important on the South Island, as the Southern Alps separate the country's wettest region (as much as 6,000 mm/236 in annually on the West Coast) from its driest (as low as 300 mm in Central Otago). A parallel is sometimes made between the southern LATITUDES of New Zealand's wine regions and those of famous European regions. If New Zealand were in the northern hemisphere, the country would stretch from North Africa to BEAUNE, but the moderating influence of the Gulf Stream on European vineyards results in hotter growing conditions than in the vineyards of equivalent southern latitudes.

Of the country's ten umbrella GIs (and nine subregional GIs), MARLBOROUGH at the north-eastern tip of the South Island looms largest, occupying nearly three-quarters of both total vineyard area and total production volume. Its cool maritime climate, DIURNAL TEMPERATURE RANGE, and diversity of soil types allows it to successfully grow many varieties, but it is almost synonymous with Sauvignon Blanc, which thrives in the rich, ALLUVIAL soils of the Wairau and Awatere Valleys. Sauvignon Blanc also dominates in the adjacent NELSON GI, where a more TEMPERATE but slightly wetter maritime climate exists.

CANTERBURY, including the North Canterbury GI, lies south of Marlborough. Its seaward range protects vineyards from the fierce easterly and southerly winds, and vines are found in either CLAY or LIMESTONE soils.

Further south, along the Waitaki River between the Pacific Coast and the Southern Alps, Waitaki Valley is New Zealand's coolest region, its limestone soils excelling with Pinot Noir. Pinot Noir also dominates in CENTRAL OTAGO, this deep-south region the only one in

New Zealand not to benefit from the moderating effect of the Pacific Ocean, some 120 km/75 miles away. The BANNOCKBURN GI in the Cromwell Basin is perhaps its most prestigious subregion, having Felton Road as its calling card. On the North Island, WAIRARAPA is the most southerly GI, an hour's drive north from the capital city, Wellington. Surrounded by ranges that create a rain shadow, Wairarapa and its subregions, including Martinborough, excel with Pinot Noir and smaller amounts of Sauvignon Blanc and Chardonnay.

Further north along the eastern coast lies HAWKE'S BAY, New Zealand's second-largest wine region, though it claims an equivalent of 15% of Marlborough's vineyard area. A multitude of soil types in a maritime setting allows for success with numerous varieties, though the region has a particular penchant for red blends, Syrah, and Chardonnay, with greater acclaim for those from the hallowed Gimblett Gravels subregion.

New Zealand recently lost its claim to the world's most southerly vineyards (to ARGENTINA) but, less significantly, it can still claim the world's most easterly, thanks to an adjacent dateline. This title belongs to GISBORNE, north-east of Hawke's Bay, which also means it is occasionally visited by cyclones from the tropics. Its warm maritime climate sees a preponderance of ripe and lush white wines produced at all quality levels. Further north, the climate continues to become milder and more subtropical. Both AUCKLAND and NORTHLAND are fiercely MARITIME, with fertile soils, frequently of VOLCANIC origin. They each host less than 1% of vineyard area, while the hinterland of Auckland, New Zealand's largest city, is increasingly under pressure from urban sprawl.

New Zealand has not been immune to the effects of CLIMATE CHANGE, and data shows the country saw its seventh-warmest year on record in 2020 and six vintages between 2012 and 2020 among the hottest ever recorded. The depleted ozone here and the little air pollution contribute to the exceptionally high ULTRAVIOLET RADIATION levels, which is an important driver in grape flavour development.

Viticulture

It was only when New Zealand moved away from American hybrids to higher quality *vinifera* varieties in the 1980s and, subsequently, better CLONES in the 1990s that it made sense to invest significantly in higher input and more detailed viticultural practices.

Since then, improved clonal material and more detailed CANOPY MANAGEMENT techniques have led to significant gains in quality. While many different TRAINING SYSTEMS were trialled in the 1990s, today the majority of Sauvignon Blanc in Marlborough is VSP-trained (see VERTICAL TRELLIS) with one or two fruiting wires. VSP with CANE PRUNING is the primary viticultural set-up in New Zealand though there are some CORDON-trained and SPUR-PRUNED vineyards, especially for red Bordeaux varieties.

New Zealanders' pioneering spirit is clear in the viticultural sector with the embrace of increased MECHANIZATION and ROBOTS. Interest in SUSTAINABILITY is also strong, with 96% of all vineyards participating in the certification programme offered by the national wine body New Zealand Winegrowers. The organization also offers members advice on pest, disease, and biosecurity concerns. PHYLLOXERA is a minor threat to New Zealand vineyards as the majority are planted to phylloxera-resistant ROOTSTOCKS. For all regions, POWDERY MILDEW remains a perennial challenge; DOWNY MILDEW is all but absent in Marlborough, and it could in fact be the absence of copper sulfate (see BORDEAUX MIXTURE) in the vineyards that allows Sauvignon Blanc's high THIOL expression. The number of vines succumbing to TRUNK DISEASES has increased. Controlling MEALYBUGS, the vector for LEAFROLL VIRUSES, is a significant challenge, and there is concern about the BROWN MARMORATED STINK BUG and LEAFHOPPERS reaching this remote location.

Vine varieties

SAUVIGNON BLANC, the variety for which New Zealand established an international reputation, is the country's most planted variety (25,326 ha/62,581 acres in 2021) and is responsible for 85% of the country's exports. PINOT NOIR, produced in both still and sparkling form, is a distant second with 5,779 ha/14,280 acres. Chardonnay is in third place with just over 3,000 ha, and Pinot Gris follows closely behind with 2,774 ha. Merlot and Riesling have declined in the 2010s as they fall out of favour with a largely domestic consumer, counting just over 1,000 ha and 600 ha respectively by 2021, while Syrah has been on the rise, claiming 434 ha. Other varieties planted on a total of more than 100 ha are, in declining order, Cabernet Sauvignon, Gewürztraminer (often spelt without the umlaut), Sauvignon Gris, and Malbec. All vine materials are screened for VIRUS DISEASES by a government-run agency.

Winemaking

Because New Zealand's prevalent wine style is fruit-driven Sauvignon Blanc, approximately 95% of its fruit is machine-harvested, then processed quickly to minimize SKIN CONTACT. On delivery, trucks generally tip the grapes straight into a hopper (receival bin) which feeds into the most common fixture in New Zealand wineries, the pneumatic PRESS. TEMPERATURE CONTROL systems are also important, as the MUST of Sauvignon Blanc and other aromatic varieties such as Riesling is typically fermented cool in STAINLESS STEEL tanks with a selected YEAST strain. These wines are released as early as May/June following a March/April harvest. Some producers make an alternative category of Sauvignon Blanc that involves hand-harvesting, WHOLE-BUNCH PRESSING, SPONTANEOUS FERMENTATION in barrel, and LEES CONTACT. Use of technology such as REVERSE OSMOSIS and SPINNING CONES in New Zealand is rare.

New Zealand produces an increasing array of premium red wines from Pinot Noir, Bordeaux varieties, and Syrah, which are typically hand-harvested, while premium Chardonnay is always hand-harvested. Hand-plunging reds in open-top fermenters is a common sight in many wineries, though bigger entities tend to rely on automated punch-down machines (see PUNCHING DOWN). For Bordeaux varieties and some Syrah wines, pump-overs and RACK AND RETURN cap management is used.

While 225- and 228-l OAK barrels still dominate in the maturation of these wines and the fermentation of premium Chardonnay, there has been a trend in the use of larger format barrels such as puncheons (500 l), particularly for white wines. Some producers are experimenting with vessels such as CONCRETE eggs and AMPHORAE.

All winery records are electronic, which makes traceability and auditing transparent.

Industry organization

Of New Zealand's 717 registered wineries, 88% are classified as small (annual sales fewer than 22,000 cases), yet most of the country's wine production is dominated by 20 wineries which sell more than 444,000 cases of wine per year. Several produce many multiples more than this.

Many large players in New Zealand's industry are owned completely or partly by offshore interests. US-based CONSTELLATION BRANDS, owner of the Kim Crawford BRAND, and French-based Pernod Ricard NZ, whose leading brand is Brancott Estate, claim the number one and two spots for New Zealand wine brands globally in volume terms. Australian-owned TREASURY WINE ESTATES own Matua, and US-based E. & J. GALLO moved into the high-volume section of NZ wine in 2020, having secured ownership of Nobilo from Constellation.

Some large wineries remain under New Zealand ownership, most notably Delegats (behind the Oyster Bay brand), the Villa Maria Group, and Yealands Wine Group, which is owned by the regional lines power network, which in turn is held in trust for the local community.

All wineries must legally belong to the national wine body, New Zealand Winegrowers, which is a levy-funded organization founded in 1975.

For details on specific appellations, see AUCKLAND, CANTERBURY, CENTRAL OTAGO, GISBORNE, HAWKE'S BAY, MARLBOROUGH, NELSON, NORTHLAND, WAIRARAPA, and WAITAKI. S.P.-T.

Neyret, Neret, or Neiret, rare, dark-berried vine, strictly Neret di Saint-Vincent, recently rescued from extinction in the Valle d'AOSTA and likely to be related to several transalpine varieties.

NFT ,or Non-Fungible Token, is a unique digital file that lives on a BLOCKCHAIN. The file can be in graphic, video or audio format, and its ownership is verifiable, programmable, divisible, and transferrable. NFTs can be coded to provide a stream of royalties to creators when pre-programmed conditions are met and gain value due to their scarcity. The NFT is a digital receipt that verifies the buyer's ownership and the AUTHENTICITY of the bottle. The market for NFTs, mainly digital art tokens, reached $22 billlion in 2021 and continues to grow. In May 2021, auctioneers Acker sold the first-ever NFTs from Burgundy, 2019s from Domaine du Comte Liger-Belair.

However, in line with a sharp drop in more traditional assets caused by the rising interest rate environment, the third quarter of 2022 saw $3.4 billion in NFT sales, down from $8.4 billion in the previous quarter.

Coupling NFTs with the physical twin is an opportunity for the fine-wine industry to create new products where the NFT is unique, and the physical wine has PROVENANCE because the supply chain is based on a blockchain. The NFT allows a wine producer to create new channels for its product, particularly in the fine-wine industry where digital twins can be created that can become as collectible as the physical bottle, due to their scarcity value and authenticity.

The combination of the NFT, together with its physical twin, and the immersive metaverse will offer wine producers the opportunity to create entirely new retail experiences. Just as fashionable sneaker brands are selling NFTs at higher prices than their physical counterparts, we may see NFTs of wine bottles becoming worth as much as their physical twins. M.K.

Niagara, AMERICAN HYBRID grown successfully in NEW YORK State. This VITIS LABRUSCA variety is vigorous, is productive, and withstands

low temperatures well. Known as the white answer to CONCORD, one of its parents, it makes wines with a particularly FOXY flavour. It was created in Niagara County, New York, in 1868 and is now also planted widely in Canada and Brazil. For details of the Niagara region, Canada, see ONTARIO.

Nieddera, promising Sardinian red wine grape.

Niederösterreich , or Lower AUSTRIA, is the state in which just over 60% of the country's vineyards are situated. This state's name figures prominently on labels of non-DAC wine grown in any of its eight regions covered by a DAC appellation: CARNUNTUM, KAMPTAL, KREMSTAL, THERMENREGION, TRAISENTAL, WACHAU, WAGRAM, and WEINVIERTEL. D.S.

Nielluccіu, also spelt Nielluccio, Corsica's name for SANGIOVESE, probably brought there by the GENOESE, who ruled the island until the late 18th century. Often blended with SCIACCARELLU (Mammolo), it constitutes an increasing proportion of the island's AOC reds and, particularly, rosés, for which it is especially suitable. It is the principal ingredient in Patrimonio, on whose CLAY and LIMESTONE soils it thrives. It buds early and ripens late and is therefore susceptible to late frosts in spring and rot during the harvest.

nitrogen, mineral element and inert colourless, odourless, tasteless gas that is extremely useful in both grape-growing and winemaking. Nitrogen gas is an inert constituent of the atmosphere, making up 78% by volume. It is also an essential element in AMINO ACIDS, PROTEINS, and ENZYMES, without which life could not exist. In soil, it is an important constituent of ORGANIC MATTER, from which it is released during decomposition in the form of ammonium ions. Although these ions are taken up by plant roots, much of the ammonium is oxidized

by specialist soil bacteria to nitrate ions, which are also absorbed by roots. Ammonium and nitrate compounds are important constituents of many FERTILIZERS.

Viticulture

Nitrogen has a major impact on vineyard VIGOUR and potentially on wine quality. It is essential for vine growth and is one of the three major elements, along with POTASSIUM and PHOSPHORUS, needed most for plant growth. It is an important component of proteins and also of chlorophyll. The most common symptoms of nitrogen deficiency, which can be expected on SANDY soils low in organic matter, are reduced vigour and uniformly pale green or yellow leaves. Soil and plant tests can be used as a guide to the use of nitrogen fertilizers.

Much more caution is needed with vines than with most other plants in applying nitrogen fertilizers, or large amounts of manure, or planting in soils naturally rich in nitrogen. The use of COVER CROPS containing clover and other LEGUMES should also be monitored carefully as they might add excessive nitrogen to the vineyard soil.

Whatever the origin, too much nitrogen in a vineyard results in excessive vegetative vine growth, termed 'high vigour'. Such vineyards typically show higher YIELDS than low-vigour vines and reduced quality owing to the SHADE effects. CANOPY MANAGEMENT procedures may be used to overcome some of these effects but will not eliminate them completely. Vineyards with excessive nitrogen supplies are also prone to poor FRUIT SET (COULURE, for example) and are more susceptible to BOTRYTIS BUNCH ROT. Excessive nitrogen is also considered to have a direct and negative effect on red-wine quality, reducing SUGARS, COLOUR, and PHENOLICS and increasing ACIDITY. High nitrogen levels in the soil also lead to increased wine levels of urea, ETHYL CARBAMATES, and HISTAMINES. In some parts of Europe such as Germany, excessive nitrogen fertilization of vineyards in the latter part of the 20th century led to pollution of water supplies with nitrates.

Vineyards producing high fruit quality typically have a restricted supply of nitrogen (although for Sauvignon Blanc, nitrogen is important in the production of THIOL precursors). Along with moderate WATER STRESS, this is one of two important checks on vine

growth which result in the vine BALANCE that is essential for premium wine quality. All grass or cereal cover crops can be grown to use up soil-rich supplies of nitrogen and so make it less available to vines.

On the other hand, severe nitrogen deficiency is equally disadvantageous to quality, especially for white wines. Fruit from nitrogen-deficient vineyards can be lower in fermentable SUGARS and may also result in STUCK FERMENTATIONS, with the concomitant risk of forming undesirable SULFIDES. See also ATYPICAL AGEING.

R.E.S. & R.E.W.

Winemaking

In combination with phosphorus and potassium, nitrogen can serve as a critical factor in YEAST growth and therefore FERMENTATION. Ammonium ions, primary amino acids, and small peptides, but not the secondary amino acids proline and hydroxyproline, are the principal forms of nitrogen present in grapes that can be used by yeast; these nitrogen components constitute what is often referred to as yeast assimilable nitrogen (YAN). Simple tests have only recently been developed for measuring YAN so that a deficiency of this essential yeast nutrient can now be easily determined. When a deficiency occurs, an ammonium salt, usually DIAMMONIUM PHOSPHATE (DAP), is often added. Nitrogen can also affect wine composition: in high concentrations it is associated with intensified AROMAS, while low concentrations favour the formation of HYDROGEN SULFIDE.

Obtained by fractional distillation of liquid air, nitrogen in both gaseous and liquid forms is a major commercial product used in a wide range of industrial activities. As ammonia, it is the starting material for most fertilizer mixtures. In liquid form, it has myriad uses in REFRIGERATION. In pure gas form, it is used to prevent a wide range of sensitive products from coming into contact with oxygen. Wine is just one of these.

Nitrogen as an INERT GAS is extremely useful to the winemaker in filling the HEAD SPACE in closed stainless-steel tanks and in bottles (see SPARGING and LEFTOVER WINE). Nitrogen is more expensive but more effective than an inert-gas mixture at preserving wine from potential harmful contact with oxygen. M.J.T.
